When distances are calculated with geodetic (angular) coordinates, as is the case with the default WGS84 (4326) SRID, you can set the spheroid keyword argument to decide if the calculation should be based on a simple sphere (less accurate, less resource-intensive) or on a spheroid (more accurate, more resource-intensive).

In the following example, the distance from the city of Hobart to every other PointField in the AustraliaCity queryset is calculated:
>>> from django.contrib.gis.db.models.functions import Distance
>>> pnt = AustraliaCity.objects.get(name='Hobart').point
>>> for city in AustraliaCity.objects.annotate(distance=Distance('point', pnt)):
...     print(city.name, city.distance)
Wollongong 990071.220408 m
Shellharbour 972804.613941 m
Thirroul 1002334.36351 m
...

Note: Because the distance attribute is a Distance object, you can easily express the value in the units of your choice. For example, city.distance.mi is the distance value in miles and city.distance.km is the distance value in kilometers. See Measurement Objects for usage details and the list of Supported units.

Envelope
class Envelope(expression, **extra)

Availability: MariaDB, MySQL, Oracle, PostGIS, SpatiaLite

Accepts a single geographic field or expression and returns the geometry representing the bounding box of the geometry.

ForcePolygonCW
class ForcePolygonCW(expression, **extra)

Availability: PostGIS, SpatiaLite

Accepts a single geographic field or expression and returns a modified version of the polygon/multipolygon in which all exterior rings are oriented clockwise and all interior rings are oriented counterclockwise. Non-polygonal geometries are returned unchanged.

GeoHash
class GeoHash(expression, precision=None, **extra)

Availability: MySQL (≥ 5.7.5), PostGIS, SpatiaLite (LWGEOM/RTTOPO)

Accepts a single geographic field or expression and returns a GeoHash representation of the geometry.

The precision keyword argument controls the number of characters in the result.
GeometryDistance

class GeometryDistance(expr1, expr2, **extra)

Availability: PostGIS

Accepts two geographic fields or expressions and returns the distance between them. When used in an order_by() clause, it provides index-assisted nearest-neighbor result sets.

Intersection

class Intersection(expr1, expr2, **extra)

Availability: MariaDB, MySQL, PostGIS, Oracle, SpatiaLite

Accepts two geographic fields or expressions and returns the geometric intersection between them.

IsValid

class IsValid(expr)

Availability: MySQL (≥ 5.7.5), PostGIS, Oracle, SpatiaLite

Accepts a geographic field or expression and tests if the value is well formed. Returns True if its value is a valid geometry and False otherwise.

Length

class Length(expression, spheroid=True, **extra)

Availability: MariaDB, MySQL, Oracle, PostGIS, SpatiaLite

Accepts a single geographic linestring or multilinestring field or expression and returns its length as a Distance measure.

On PostGIS and SpatiaLite, when the coordinates are geodetic (angular), you can specify if the calculation should be based on a simple sphere (less accurate, less resource-intensive) or on a spheroid (more accurate, more resource-intensive) with the spheroid keyword argument.

MySQL doesn’t support length calculations on geographic SRSes.
LineLocatePoint

**class LineLocatePoint***(linestring, point, **extra)***

Availability: PostGIS, SpatiaLite

Returns a float between 0 and 1 representing the location of the closest point on *linestring* to the given *point*, as a fraction of the 2D line length.

MakeValid

**class MakeValid**(expr)

Availability: PostGIS, SpatiaLite (LWGEOM/RTTOPO)

Accepts a geographic field or expression and attempts to convert the value into a valid geometry without losing any of the input vertices. Geometries that are already valid are returned without changes. Simple polygons might become a multipolygon and the result might be of lower dimension than the input.

MemSize

**class MemSize**(expression, **extra)***

Availability: PostGIS

Accepts a single geographic field or expression and returns the memory size (number of bytes) that the geometry field takes.

NumGeometries

**class NumGeometries**(expression, **extra)***

Availability: MariaDB, MySQL, PostGIS, Oracle, SpatiaLite

Accepts a single geographic field or expression and returns the number of geometries if the geometry field is a collection (e.g., a GEOMETRYCOLLECTION or MULTI* field). Returns 1 for single geometries.

On MySQL, returns None for single geometries.
NumPoints

class NumPoints(expression, **extra)

Availability: MariaDB, MySQL, PostGIS, Oracle, SpatiaLite

Accepts a single geographic field or expression and returns the number of points in a geometry.

On MySQL, returns None for any non-LINestring geometry.

Perimeter

class Perimeter(expression, **extra)

Availability: PostGIS, Oracle, SpatiaLite

Accepts a single geographic field or expression and returns the perimeter of the geometry field as a Distance object.

PointOnSurface

class PointOnSurface(expression, **extra)

Availability: PostGIS, MariaDB, Oracle, SpatiaLite

Accepts a single geographic field or expression and returns a Point geometry guaranteed to lie on the surface of the field; otherwise returns None.

Reverse

class Reverse(expression, **extra)

Availability: PostGIS, Oracle, SpatiaLite

Accepts a single geographic field or expression and returns a geometry with reversed coordinates.

Scale

class Scale(expression, x, y, z=0.0, **extra)

Availability: PostGIS, SpatiaLite

Accepts a single geographic field or expression and returns a geometry with scaled coordinates by multiplying them with the x, y, and optionally z parameters.
SnapToGrid

class SnapToGrid(expression, *args, **extra)

Availability: PostGIS, SpatiaLite

Accepts a single geographic field or expression and returns a geometry with all points snapped to the given grid. How the geometry is snapped to the grid depends on how many numeric (either float, integer, or long) arguments are given.

<table>
<thead>
<tr>
<th>Number of Arguments</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>A single size to snap both the X and Y grids to.</td>
</tr>
<tr>
<td>2</td>
<td>X and Y sizes to snap the grid to.</td>
</tr>
<tr>
<td>4</td>
<td>X, Y sizes and the corresponding X, Y origins.</td>
</tr>
</tbody>
</table>

SymDifference

class SymDifference(expr1, expr2, **extra)

Availability: MariaDB, MySQL, PostGIS, Oracle, SpatiaLite

Accepts two geographic fields or expressions and returns the geometric symmetric difference (union without the intersection) between the given parameters.

Transform

class Transform(expression, srid, **extra)

Availability: PostGIS, Oracle, SpatiaLite

Accepts a geographic field or expression and a SRID integer code, and returns the transformed geometry to the spatial reference system specified by the srid parameter.

Note: What spatial reference system an integer SRID corresponds to may depend on the spatial database used. In other words, the SRID numbers used for Oracle are not necessarily the same as those used by PostGIS.
Translate

class Translate(expression, x, y, z=0.0, **extra)

Availability: PostGIS, SpatiaLite

Accepts a single geographic field or expression and returns a geometry with its coordinates offset by the x, y, and optionally z numeric parameters.

Union

class Union(expr1, expr2, **extra)

Availability: MariaDB, MySQL, PostGIS, Oracle, SpatiaLite

Accepts two geographic fields or expressions and returns the union of both geometries.

Measurement Objects

The `django.contrib.gis.measure` module contains objects that allow for convenient representation of distance and area units of measure. Specifically, it implements two objects, `Distance` and `Area`—both of which may be accessed via the `D` and `A` convenience aliases, respectively.

Example

`Distance` objects may be instantiated using a keyword argument indicating the context of the units. In the example below, two different distance objects are instantiated in units of kilometers (km) and miles (mi):

```python
>>> from django.contrib.gis.measure import D, Distance
>>> d1 = Distance(km=5)
>>> print(d1)
5.0 km
>>> d2 = D(mi=5)  # `D` is an alias for `Distance`
>>> print(d2)
5.0 mi
```

For conversions, access the preferred unit attribute to get a converted distance quantity:

```python
>>> print(d1.mi)  # Converting 5 kilometers to miles
3.0685596119
>>> print(d2.km)  # Converting 5 miles to kilometers
8.04672
```

---

1 Robert Coup is the initial author of the measure objects, and was inspired by Brian Beck’s work in geopy and Geoff Biggs’ PhD work on dimensioned units for robotics.
Moreover, arithmetic operations may be performed between the distance objects:

```python
>>> print(d1 + d2)  # Adding 5 miles to 5 kilometers
13.04672 km

>>> print(d2 - d1)  # Subtracting 5 kilometers from 5 miles
1.89314403881 mi
```

Two `Distance` objects multiplied together will yield an `Area` object, which uses squared units of measure:

```python
>>> a = d1 * d2  # Returns an Area object.

>>> print(a)
40.2336 sq_km
```

To determine what the attribute abbreviation of a unit is, the `unit_attname` class method may be used:

```python
>>> print(Distance.unit_attname('US Survey Foot'))
survey_ft

>>> print(Distance.unit_attname('centimeter'))
cm
```

### Supported units

Note: *Area* attributes are the same as *Distance* attributes, except they are prefixed with `sq_` (area units are square in nature). For example, *Area*(sq_m=2) creates an *Area* object representing two square meters.

Measurement API

Distance

**class Distance(**

To initialize a distance object, pass in a keyword corresponding to the desired unit attribute name set with desired value. For example, the following creates a distance object representing 5 miles:

```python
>>> dist = Distance(mi=5)
```

`__getattr__`(unit_att)

Returns the distance value in units corresponding to the given unit attribute. For example:

```python
>>> print(dist.km)
8.04672
```

`classmethod unit_attname`(unit_name)

Returns the distance unit attribute name for the given full unit name. For example:
>>> Distance.unit_attname('Mile')
'mi'

class D

    Alias for *Distance* class.

**Area**

class Area(**kwargs)

    To initialize an area object, pass in a keyword corresponding to the desired *unit attribute name* set with desired value. For example, the following creates an area object representing 5 square miles:

    >>> a = Area(sq_mi=5)

    __getattr__(unit_att)

    Returns the area value in units corresponding to the given unit attribute. For example:

    >>> print(a sq_km)
    12.949940551680001

    classmethod unit_attname(unit_name)

    Returns the area unit attribute name for the given full unit name. For example:

    >>> Area.unit_attname('Kilometer')
    'sq_km'

class A

    Alias for *Area* class.

**GEOS API**

**Background**

**What is GEOS?**

*GEOS* stands for Geometry Engine - Open Source, and is a C++ library, ported from the *Java Topology Suite*. GEOS implements the *OpenGIS Simple Features for SQL* spatial predicate functions and spatial operators. GEOS, now an OSGeo project, was initially developed and maintained by *Refractions Research* of Victoria, Canada.
Django Documentation, Release 4.2.dev20220706084552

Features
GeoDjango implements a high-level Python wrapper for the GEOS library, its features include:
• A BSD-licensed interface to the GEOS geometry routines, implemented purely in Python using ctypes.
• Loosely-coupled to GeoDjango. For example, GEOSGeometry objects may be used outside of a Django
project/application. In other words, no need to have DJANGO_SETTINGS_MODULE set or use a database,
etc.
• Mutability: GEOSGeometry objects may be modified.
• Cross-platform and tested; compatible with Windows, Linux, Solaris, and macOS platforms.
Tutorial
This section contains a brief introduction and tutorial to using GEOSGeometry objects.
Creating a Geometry
GEOSGeometry objects may be created in a few ways. The first is to simply instantiate the object on some
spatial input –the following are examples of creating the same geometry from WKT, HEX, WKB, and GeoJSON:
>>> from django.contrib.gis.geos import GEOSGeometry
>>> pnt = GEOSGeometry('POINT(5 23)') # WKT
>>> pnt = GEOSGeometry('010100000000000000000014400000000000003740') # HEX
>>> pnt = GEOSGeometry(buffer('\x01\x01\x00\x00\x00\x00\x00\x00\x00\x00\x00\x14@\x00\x00\x00\x00\
,→

x00\x007@'))

>>> pnt = GEOSGeometry('{ "type": "Point", "coordinates": [ 5.000000, 23.000000 ] }') # GeoJSON

Another option is to use the constructor for the specific geometry type that you wish to create. For example,
a Point object may be created by passing in the X and Y coordinates into its constructor:
>>> from django.contrib.gis.geos import Point
>>> pnt = Point(5, 23)

All these constructors take the keyword argument srid. For example:
>>> from django.contrib.gis.geos import GEOSGeometry, LineString, Point
>>> print(GEOSGeometry('POINT (0 0)', srid=4326))
SRID=4326;POINT (0 0)
>>> print(LineString((0, 0), (1, 1), srid=4326))
SRID=4326;LINESTRING (0 0, 1 1)
(continues on next page)

1148

Chapter 6. API Reference


Finally, there is the `fromfile()` factory method which returns a `GEOSGeometry` object from a file:

```
>>> from django.contrib.gis.geos import fromfile
>>> pnt = fromfile('/path/to/pnt.wkt')
>>> pnt = fromfile(open('/path/to/pnt.wkt'))
```

My logs are filled with GEOS-related errors

You find many `TypeError` or `AttributeError` exceptions filling your web server’s log files. This generally means that you are creating GEOS objects at the top level of some of your Python modules. Then, due to a race condition in the garbage collector, your module is garbage collected before the GEOS object. To prevent this, create `GEOSGeometry` objects inside the local scope of your functions/methods.

**Geometries are Pythonic**

`GEOSGeometry` objects are ‘Pythonic’, in other words components may be accessed, modified, and iterated over using standard Python conventions. For example, you can iterate over the coordinates in a `Point`:

```
>>> pnt = Point(5, 23)
>>> [coord for coord in pnt]
[5.0, 23.0]
```

With any geometry object, the `GEOSGeometry.coords` property may be used to get the geometry coordinates as a Python tuple:

```
>>> pnt.coords
(5.0, 23.0)
```

You can get/set geometry components using standard Python indexing techniques. However, what is returned depends on the geometry type of the object. For example, indexing on a `LineString` returns a coordinate tuple:

```
>>> from django.contrib.gis.geos import LineString
>>> line = LineString((0, 0), (0, 50), (50, 50), (50, 0), (0, 0))
>>> line[0]
(0.0, 0.0)
>>> line[-2]
(50.0, 0.0)
```
Whereas indexing on a \textit{Polygon} will return the ring (a \textit{LinearRing} object) corresponding to the index:

```python
>>> from django.contrib.gis.geos import Polygon
>>> poly = Polygon((0.0, 0.0), (0.0, 50.0), (50.0, 50.0), (50.0, 0.0), (0.0, 0.0))
>>> poly[0]
<LinearRing object at 0x1044395b0>
>>> poly[0][-2] # second-to-last coordinate of external ring
(50.0, 0.0)
```

In addition, coordinates/components of the geometry may be added or modified, just like a Python list:

```python
>>> line[0] = (1.0, 1.0)
>>> line.pop()
(0.0, 0.0)
>>> line.append((1.0, 1.0))
>>> line.coords
((1.0, 1.0), (0.0, 50.0), (50.0, 50.0), (50.0, 0.0), (1.0, 1.0))
```

Geometries support set-like operators:

```python
>>> from django.contrib.gis.geos import LineString
>>> ls1 = LineString((0, 0), (2, 2))
>>> ls2 = LineString((1, 1), (3, 3))
>>> print(ls1 | ls2)  # equivalent to \texttt{\texttt{ls1.union(ls2)}}
MULTILINESTRING ((0 0, 1 1), (1 1, 2 2), (2 2, 3 3))
>>> print(ls1 & ls2)  # equivalent to \texttt{\texttt{ls1.intersection(ls2)}}
LINESTRING (1 1, 2 2)
>>> print(ls1 - ls2)  # equivalent to \texttt{\texttt{ls1.difference(ls2)}}
LINESTRING (0 0, 1 1)
>>> print(ls1 ^ ls2)  # equivalent to \texttt{\texttt{ls1.sym_difference(ls2)}}
MULTILINESTRING ((0 0, 1 1), (2 2, 3 3))
```

Equality operator doesn’t check spatial equality

The \textit{GEOSGeometry} equality operator uses \texttt{equals\_exact()}, not \texttt{equals()}, i.e. it requires the compared geometries to have the same coordinates in the same positions with the same SRIDs:

```python
>>> from django.contrib.gis.geos import LineString
>>> ls1 = LineString((0, 0), (1, 1))
>>> ls2 = LineString((1, 1), (0, 0))
>>> ls3 = LineString((1, 1), (0, 0), srid=4326)
>>> ls1.equals(ls2)
True
>>> ls1 == ls2
False
```
Geometry Objects

GEOSGeometry

class GEOSGeometry(geo_input, srid=None)

Parameters

- **geo_input** – Geometry input value (string or buffer)
- **srid** (`int`) – spatial reference identifier

This is the base class for all GEOS geometry objects. It initializes on the given `geo_input` argument, and then assumes the proper geometry subclass (e.g., `GEOSGeometry('POINT(1 1)')` will create a `Point` object).

The `srid` parameter, if given, is set as the SRID of the created geometry if `geo_input` doesn’t have an SRID. If different SRIDs are provided through the `geo_input` and `srid` parameters, `ValueError` is raised:

```python
>>> from django.contrib.gis.geos import GEOSGeometry
>>> GEOSGeometry('POINT EMPTY', srid=4326).ewkt
'SRID=4326;POINT EMPTY'
>>> GEOSGeometry('SRID=4326;POINT EMPTY', srid=4326).ewkt
'SRID=4326;POINT EMPTY'
>>> GEOSGeometry('SRID=1;POINT EMPTY', srid=4326)
Traceback (most recent call last):
...  ValueError: Input geometry already has SRID: 1.
```

The following input formats, along with their corresponding Python types, are accepted:

<table>
<thead>
<tr>
<th>Format</th>
<th>Input Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>WKT / EWKT</td>
<td>str</td>
</tr>
<tr>
<td>HEX / HEXEWKB</td>
<td>str</td>
</tr>
<tr>
<td>WKB / EWKB</td>
<td>buffer</td>
</tr>
<tr>
<td>GeoJSON</td>
<td>str</td>
</tr>
</tbody>
</table>

For the GeoJSON format, the SRID is set based on the `crs` member. If `crs` isn’t provided, the SRID defaults to 4326.
classmethod GEOSGeometry.from_gml(gml_string)

Constructs a GEOSGeometry from the given GML string.

Properties

GEOSGeometry.coords

Returns the coordinates of the geometry as a tuple.

GEOSGeometry.dims

Returns the dimension of the geometry:

- 0 for Points and MultiPoints
- 1 for LineStrings and MultiLineStrings
- 2 for Polygons and MultiPolygons
- -1 for empty GeometryCollections
- the maximum dimension of its elements for non-empty GeometryCollections

GEOSGeometry.empty

Returns whether or not the set of points in the geometry is empty.

GEOSGeometry.geom_type

Returns a string corresponding to the type of geometry. For example:

```python
>>> pnt = GEOSGeometry('POINT(5 23)')
>>> pnt.geom_type
'Point'
```

GEOSGeometry.geom_typeid

Returns the GEOS geometry type identification number. The following table shows the value for each geometry type:

<table>
<thead>
<tr>
<th>Geometry</th>
<th>ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>0</td>
</tr>
<tr>
<td>LineString</td>
<td>1</td>
</tr>
<tr>
<td>LinearRing</td>
<td>2</td>
</tr>
<tr>
<td>Polygon</td>
<td>3</td>
</tr>
<tr>
<td>MultiPoint</td>
<td>4</td>
</tr>
<tr>
<td>MultiLineString</td>
<td>5</td>
</tr>
<tr>
<td>MultiPolygon</td>
<td>6</td>
</tr>
<tr>
<td>GeometryCollection</td>
<td>7</td>
</tr>
</tbody>
</table>
GEOSGeometry.num_coords

Returns the number of coordinates in the geometry.

GEOSGeometry.num_geom

Returns the number of geometries in this geometry. In other words, will return 1 on anything but geometry collections.

GEOSGeometry.hasz

Returns a boolean indicating whether the geometry is three-dimensional.

GEOSGeometry.ring

Returns a boolean indicating whether the geometry is a LinearRing.

GEOSGeometry.simple

Returns a boolean indicating whether the geometry is ‘simple’. A geometry is simple if and only if it does not intersect itself (except at boundary points). For example, a LineString object is not simple if it intersects itself. Thus, LinearRing and Polygon objects are always simple because they do cannot intersect themselves, by definition.

GEOSGeometry.valid

Returns a boolean indicating whether the geometry is valid.

GEOSGeometry.valid_reason

Returns a string describing the reason why a geometry is invalid.

GEOSGeometry.srid

Property that may be used to retrieve or set the SRID associated with the geometry. For example:

```python
>>> pnt = Point(5, 23)
>>> print(pnt.srid)
None
>>> pnt.srid = 4326
>>> pnt.srid
4326
```

Output Properties

The properties in this section export the GEOSGeometry object into a different. This output may be in the form of a string, buffer, or even another object.

GEOSGeometry.ewkt

Returns the “extended” Well-Known Text of the geometry. This representation is specific to PostGIS and is a superset of the OGC WKT standard.\(^1\) Essentially the SRID is prepended to the WKT representation, for example SRID=4326;POINT(5 23).

\(^1\) See PostGIS EWKB, EWKT and Canonical Forms, PostGIS documentation at Ch. 4.1.2.
Note: The output from this property does not include the 3dm, 3dz, and 4d information that PostGIS supports in its EWKT representations.

GEOSGeometry.hex

Returns the WKB of this Geometry in hexadecimal form. Please note that the SRID value is not included in this representation because it is not a part of the OGC specification (use the GEOSGeometry.hexewkb property instead).

GEOSGeometry.hexewkb

Returns the EWKB of this Geometry in hexadecimal form. This is an extension of the WKB specification that includes the SRID value that are a part of this geometry.

GEOSGeometry.json

Returns the GeoJSON representation of the geometry. Note that the result is not a complete GeoJSON structure but only the geometry key content of a GeoJSON structure. See also GeoJSON Serializer.

GEOSGeometry.geojson

Alias for GEOSGeometry.json.

GEOSGeometry.kml

Returns a KML (Keyhole Markup Language) representation of the geometry. This should only be used for geometries with an SRID of 4326 (WGS84), but this restriction is not enforced.

GEOSGeometry.ogr

Returns an OGRGeometry object corresponding to the GEOS geometry.

GEOSGeometry.wkb

Returns the WKB (Well-Known Binary) representation of this Geometry as a Python buffer. SRID value is not included, use the GEOSGeometry.ewkb property instead.

GEOSGeometry.ewkb

Return the EWKB representation of this Geometry as a Python buffer. This is an extension of the WKB specification that includes any SRID value that are a part of this geometry.

GEOSGeometry.wkt

Returns the Well-Known Text of the geometry (an OGC standard).
Spatial Predicate Methods

All of the following spatial predicate methods take another `GEOSGeometry` instance (other) as a parameter, and return a boolean.

`GEOSGeometry.contains(other)`

Returns True if `other.within(this)` returns True.

`GEOSGeometry.covers(other)`

Returns True if this geometry covers the specified geometry.

The covers predicate has the following equivalent definitions:

- Every point of the other geometry is a point of this geometry.
- The DE-9IM Intersection Matrix for the two geometries is T*****FF*, *T*****FF*, ***T**FF*, or ****T*FF*.

If either geometry is empty, returns False.

This predicate is similar to `GEOSGeometry.contains()`, but is more inclusive (i.e. returns True for more cases). In particular, unlike contains() it does not distinguish between points in the boundary and in the interior of geometries. For most situations, covers() should be preferred to contains(). As an added benefit, covers() is more amenable to optimization and hence should outperform contains().

`GEOSGeometry.crosses(other)`

Returns True if the DE-9IM intersection matrix for the two Geometries is T*T****** (for a point and a curve, a point and an area or a line and an area) 0******** (for two curves).

`GEOSGeometry.disjoint(other)`

Returns True if the DE-9IM intersection matrix for the two geometries is FF*FF****.

`GEOSGeometry.equals(other)`

Returns True if the DE-9IM intersection matrix for the two geometries is T*F**FFF*.

`GEOSGeometry.equals_exact(other, tolerance=0)`

Returns true if the two geometries are exactly equal, up to a specified tolerance. The tolerance value should be a floating point number representing the error tolerance in the comparison, e.g., poly1.equals_exact(poly2, 0.001) will compare equality to within one thousandth of a unit.

`GEOSGeometry.intersects(other)`

Returns True if `GEOSGeometry.disjoint()` is False.

`GEOSGeometry.overlaps(disjoint())`

Returns true if the DE-9IM intersection matrix for the two geometries is T*T***T** (for two points or two surfaces) 1*T***T** (for two curves).
GEOSGeometry.relate_pattern(other, pattern)

Returns True if the elements in the DE-9IM intersection matrix for this geometry and the other matches the given pattern—a string of nine characters from the alphabet: {T, F, *, 0}.

GEOSGeometry.touches(other)

Returns True if the DE-9IM intersection matrix for the two geometries is FT******, F**T***** or F***T****.

GEOSGeometry.within(other)

Returns True if the DE-9IM intersection matrix for the two geometries is T*F**F***.

Topological Methods

GEOSGeometry.buffer(width, quadsegs=8)

Returns a GEOSGeometry that represents all points whose distance from this geometry is less than or equal to the given width. The optional quadsegs keyword sets the number of segments used to approximate a quarter circle (default is 8).

GEOSGeometry.buffer_with_style(width, quadsegs=8, end_cap_style=1, join_style=1, mitre_limit=5.0)

Same as buffer(), but allows customizing the style of the buffer.

- end_cap_style can be round (1), flat (2), or square (3).
- join_style can be round (1), mitre (2), or bevel (3).
- Mitre ratio limit (mitre_limit) only affects mitered join style.

GEOSGeometry.difference(other)

Returns a GEOSGeometry representing the points making up this geometry that do not make up other.

GEOSGeometry.interpolate(distance)

GEOSGeometry.interpolate_normalized(distance)

Given a distance (float), returns the point (or closest point) within the geometry (LineString or MultiLineString) at that distance. The normalized version takes the distance as a float between 0 (origin) and 1 (endpoint).

Reverse of GEOSGeometry.project().

GEOSGeometry.intersection(other)

Returns a GEOSGeometry representing the points shared by this geometry and other.

GEOSGeometry.project(point)

GEOSGeometry.project_normalized(point)

Returns the distance (float) from the origin of the geometry (LineString or MultiLineString) to the
point projected on the geometry (that is to a point of the line the closest to the given point). The normalized version returns the distance as a float between 0 (origin) and 1 (endpoint).

Reverse of `GEOSGeometry.interpolate()`.

`GEOSGeometry.relate(other)`

Returns the DE-9IM intersection matrix (a string) representing the topological relationship between this geometry and the other.

`GEOSGeometry.simplify(tolerance=0.0, preserve_topology=False)`

Returns a new `GEOSGeometry`, simplified to the specified tolerance using the Douglas-Peucker algorithm. A higher tolerance value implies fewer points in the output. If no tolerance is provided, it defaults to 0.

By default, this function does not preserve topology. For example, `Polygon` objects can be split, be collapsed into lines, or disappear. `Polygon` holes can be created or disappear, and lines may cross. By specifying `preserve_topology=True`, the result will have the same dimension and number of components as the input; this is significantly slower, however.

`GEOSGeometry.sym_difference(other)`

Returns a `GEOSGeometry` combining the points in this geometry not in other, and the points in other not in this geometry.

`GEOSGeometry.union(other)`

Returns a `GEOSGeometry` representing all the points in this geometry and the other.

**Topological Properties**

`GEOSGeometry.boundary`

Returns the boundary as a newly allocated Geometry object.

`GEOSGeometry.centroid`

Returns a `Point` object representing the geometric center of the geometry. The point is not guaranteed to be on the interior of the geometry.

`GEOSGeometry.convex_hull`

Returns the smallest `Polygon` that contains all the points in the geometry.

`GEOSGeometry.envelope`

Returns a `Polygon` that represents the bounding envelope of this geometry. Note that it can also return a `Point` if the input geometry is a point.

`GEOSGeometry.point_on_surface`

Computes and returns a `Point` guaranteed to be on the interior of this geometry.
GEOSGeometry.unary_union

Computes the union of all the elements of this geometry.

The result obeys the following contract:

- Unioning a set of LineStrings has the effect of fully noding and dissolving the linework.
- Unioning a set of Polygons will always return a Polygon or MultiPolygon geometry (unlike GEOSGeometry.union(), which may return geometries of lower dimension if a topology collapse occurs).

Other Properties & Methods

GEOSGeometry.area

This property returns the area of the Geometry.

GEOSGeometry.extent

This property returns the extent of this geometry as a 4-tuple, consisting of (xmin, ymin, xmax, ymax).

GEOSGeometry.clone()

This method returns a GEOSGeometry that is a clone of the original.

GEOSGeometry.distance(geom)

Returns the distance between the closest points on this geometry and the given geom (another GEOSGeometry object).

Note: GEOS distance calculations are linear – in other words, GEOS does not perform a spherical calculation even if the SRID specifies a geographic coordinate system.

GEOSGeometry.length

Returns the length of this geometry (e.g., 0 for a Point, the length of a LineString, or the circumference of a Polygon).

GEOSGeometry.prepared

Returns a GEOS PreparedGeometry for the contents of this geometry. PreparedGeometry objects are optimized for the contains, intersects, covers, crosses, disjoint, overlaps, touches and within operations. Refer to the Prepared Geometries documentation for more information.

GEOSGeometry.srs

Returns a SpatialReference object corresponding to the SRID of the geometry or None.

GEOSGeometry.transform(ct, clone=False)

Transforms the geometry according to the given coordinate transformation parameter (ct), which may
be an integer SRID, spatial reference WKT string, a PROJ string, a SpatialReference object, or a CoordTransform object. By default, the geometry is transformed in-place and nothing is returned. However if the clone keyword is set, then the geometry is not modified and a transformed clone of the geometry is returned instead.

Note: Raises GEOSException if GDAL is not available or if the geometry’s SRID is None or less than 0. It doesn’t impose any constraints on the geometry’s SRID if called with a CoordTransform object.

GEOSGeometry.make_valid()

Returns a valid GEOSGeometry equivalent, trying not to lose any of the input vertices. If the geometry is already valid, it is returned untouched. This is similar to the MakeValid database function. Requires GEOS 3.8.

GEOSGeometry.normalize(clone=False)

Converts this geometry to canonical form. If the clone keyword is set, then the geometry is not modified and a normalized clone of the geometry is returned instead:

```python
>>> g = MultiPoint(Point(0, 0), Point(2, 2), Point(1, 1))
>>> print(g)
MULTIPOINT (0 0, 2 2, 1 1)
>>> g.normalize()
>>> print(g)
MULTIPOINT (2 2, 1 1, 0 0)
```

The clone argument was added.

Point

class Point(x=None, y=None, z=None, srid=None)

Point objects are instantiated using arguments that represent the component coordinates of the point or with a single sequence coordinates. For example, the following are equivalent:

```python
>>> pnt = Point(5, 23)
>>> pnt = Point([5, 23])
```

Empty Point objects may be instantiated by passing no arguments or an empty sequence. The following are equivalent:

```python
>>> pnt = Point()
>>> pnt = Point([])
```
**LineString**

```python
class LineString(*args, **kwargs)
```

`LineString` objects are instantiated using arguments that are either a sequence of coordinates or `Point` objects. For example, the following are equivalent:

```python
>>> ls = LineString(((0, 0), (1, 1)))
>>> ls = LineString(Point(0, 0), Point(1, 1))
```

In addition, `LineString` objects may also be created by passing in a single sequence of coordinate or `Point` objects:

```python
>>> ls = LineString(((0, 0), (1, 1)))
>>> ls = LineString([Point(0, 0), Point(1, 1)])
```

Empty `LineString` objects may be instantiated by passing no arguments or an empty sequence. The following are equivalent:

```python
>>> ls = LineString()
>>> ls = LineString([])
```

**closed**

Returns whether or not this `LineString` is closed.

**LinearRing**

```python
class LinearRing(*args, **kwargs)
```

`LinearRing` objects are constructed in the exact same way as `LineString` objects, however the coordinates must be closed, in other words, the first coordinates must be the same as the last coordinates. For example:

```python
>>> ls = LinearRing(((0, 0), (0, 1), (1, 1), (0, 0)))
```

Notice that (0, 0) is the first and last coordinate – if they were not equal, an error would be raised.

**is_counterclockwise**

Returns whether this `LinearRing` is counterclockwise.
Polygon

```python
class Polygon(*args, **kwargs)
```

Polygon objects may be instantiated by passing in parameters that represent the rings of the polygon. The parameters must either be `LinearRing` instances, or a sequence that may be used to construct a `LinearRing`:

```python
>>> ext_coords = ((0, 0), (0, 1), (1, 1), (1, 0), (0, 0))
>>> int_coords = ((0.4, 0.4), (0.4, 0.6), (0.6, 0.6), (0.6, 0.4), (0.4, 0.4))
>>> poly = Polygon(ext_coords, int_coords)
>>> poly = Polygon(LinearRing(ext_coords), LinearRing(int_coords))
```

```python
classmethod from_bbox(bbox)
```

Returns a polygon object from the given bounding-box, a 4-tuple comprising (xmin, ymin, xmax, ymax).

```python
num_interior_rings
```

Returns the number of interior rings in this geometry.

---

Comparing Polygons

Note that it is possible to compare `Polygon` objects directly with `<` or `>`, but as the comparison is made through `Polygon`’s `LineString`, it does not mean much (but is consistent and quick). You can always force the comparison with the `area` property:

```python
>>> if poly_1.area > poly_2.area:
...    pass
```

---

Geometry Collections

MultiPoint

```python
class MultiPoint(*args, **kwargs)
```

MultiPoint objects may be instantiated by passing in `Point` objects as arguments, or a single sequence of `Point` objects:

```python
>>> mp = MultiPoint(Point(0, 0), Point(1, 1))
>>> mp = MultiPoint( (Point(0, 0), Point(1, 1)) )
```
MultiLineString

class MultiLineString(*args, **kwargs)

MultiLineString objects may be instantiated by passing in LineString objects as arguments, or a single sequence of LineString objects:

```
>>> ls1 = LineString((0, 0), (1, 1))
>>> ls2 = LineString((2, 2), (3, 3))
>>> mls = MultiLineString(ls1, ls2)
>>> mls = MultiLineString([ls1, ls2])
```

merged

Returns a LineString representing the line merge of all the components in this MultiLineString.

closed

Returns True if and only if all elements are closed.

MultiPolygon

class MultiPolygon(*args, **kwargs)

MultiPolygon objects may be instantiated by passing Polygon objects as arguments, or a single sequence of Polygon objects:

```
>>> p1 = Polygon( ((0, 0), (0, 1), (1, 1), (0, 0)) )
>>> p2 = Polygon( ((1, 1), (1, 2), (2, 2), (1, 1)) )
>>> mp = MultiPolygon(p1, p2)
>>> mp = MultiPolygon([p1, p2])
```

GeometryCollection

class GeometryCollection(*args, **kwargs)

GeometryCollection objects may be instantiated by passing in other GEOSGeometry as arguments, or a single sequence of GEOSGeometry objects:

```
>>> poly = Polygon( ((0, 0), (0, 1), (1, 1), (0, 0)) )
>>> gc = GeometryCollection(Point(0, 0), MultiPoint(Point(0, 0), Point(1, 1)), poly)
>>> gc = GeometryCollection((Point(0, 0), MultiPoint(Point(0, 0), Point(1, 1)), poly))
```
Prepared Geometries

In order to obtain a prepared geometry, access the `GEOSGeometry.prepared` property. Once you have a PreparedGeometry instance its spatial predicate methods, listed below, may be used with other GEOSGeometry objects. An operation with a prepared geometry can be orders of magnitude faster—the more complex the geometry that is prepared, the larger the speedup in the operation. For more information, please consult the GEOS wiki page on prepared geometries.

For example:

```python
>>> from django.contrib.gis.geos import Point, Polygon
>>> poly = Polygon.from_bbox((0, 0, 5, 5))
>>> prep_poly = poly.prepared
>>> prep_poly.contains(Point(2.5, 2.5))
True
```

**PreparedGeometry**

```python
class PreparedGeometry
```

All methods on PreparedGeometry take an `other` argument, which must be a `GEOSGeometry` instance.

- `contains(other)`
- `contains_properly(other)`
- `covers(other)`
- `crosses(other)`
- `disjoint(other)`
- `intersects(other)`
- `overlaps(other)`
- `touches(other)`
- `within(other)`
Geometry Factories

fromfile(file_h)

Parameters

file_h (a Python file object or a string path to the file) – input file that contains spatial data

Return type

a GEOSGeometry corresponding to the spatial data in the file

Example:

```python
>>> from django.contrib.gis.geos import fromfile
>>> g = fromfile('/home/bob/geom.wkt')
```

cfromstr(string, srid=None)

Parameters

- string (str) – string that contains spatial data
- srid (int) – spatial reference identifier

Return type

a GEOSGeometry corresponding to the spatial data in the string

cfromstr(string, srid) is equivalent to GEOSGeometry(string, srid).

Example:

```python
>>> from django.contrib.gis.geos import fromstr
>>> pnt = fromstr('POINT(-90.5 29.5)', srid=4326)
```

I/O Objects

Reader Objects

The reader I/O classes return a GEOSGeometry instance from the WKB and/or WKT input given to their read(geom) method.

class WKBReader

Example:

```python
>>> from django.contrib.gis.geos import WKBReader
>>> wkb_r = WKBReader()
>>> wkb_r.read('0101000000000000000000F03F0000000000000F03F')
<Point object at 0x103a88910>
```
class WKTReader

Example:

```python
>>> from django.contrib.gis.geos import WKTReader
>>> wkt_r = WKTReader()
>>> wkt_r.read('POINT(1 1)')
<Point object at 0x103a88b50>
```

**Writer Objects**

All writer objects have a `write(geom)` method that returns either the WKB or WKT of the given geometry. In addition, `WKBWriter` objects also have properties that may be used to change the byte order, and or include the SRID value (in other words, EWKB).

```python
class WKBWriter(dim=2)

WKBWriter provides the most control over its output. By default it returns OGC-compliant WKB when its `write` method is called. However, it has properties that allow for the creation of EWKB, a superset of the WKB standard that includes additional information. See the `WKBWriter.outdim` documentation for more details about the `dim` argument.

write(geom)

Returns the WKB of the given geometry as a Python `buffer` object. Example:

```python
>>> from django.contrib.gis.geos import Point, WKBWriter
>>> pnt = Point(1, 1)
>>> wkb_w = WKBWriter()
>>> wkb_w.write(pnt)
<read-only buffer for 0x103a898f0, size -1, offset 0 at 0x103a89930>
```

write_hex(geom)

Returns WKB of the geometry in hexadecimal. Example:

```python
>>> from django.contrib.gis.geos import Point, WKBWriter
>>> pnt = Point(1, 1)
>>> wkb_w = WKBWriter()
>>> wkb_w.write_hex(pnt)
'0101000000000000000000F03F0000000000000F03F'
```

byteorder

This property may be set to change the byte-order of the geometry representation.
<table>
<thead>
<tr>
<th>Byteorder Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Big Endian (e.g., compatible with RISC systems)</td>
</tr>
<tr>
<td>1</td>
<td>Little Endian (e.g., compatible with x86 systems)</td>
</tr>
</tbody>
</table>

Example:

```python
>>> from django.contrib.gis.geos import Point, WKBWriter
>>> wkb_w = WKBWriter()
>>> pnt = Point(1, 1)
>>> wkb_w.write_hex(pnt)
'0101000000000000000000F03F00000000000003F'
>>> wkb_w.byteorder = 0
'00000000013FF00000000000003FF000000000000'
```

**outdim**

This property may be set to change the output dimension of the geometry representation. In other words, if you have a 3D geometry then set to 3 so that the Z value is included in the WKB.

<table>
<thead>
<tr>
<th>Outdim Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>The default, output 2D WKB.</td>
</tr>
<tr>
<td>3</td>
<td>Output 3D WKB.</td>
</tr>
</tbody>
</table>

Example:

```python
>>> from django.contrib.gis.geos import Point, WKBWriter
>>> wkb_w = WKBWriter()
>>> wkb_w.outdim = 2
>>> pnt = Point(1, 1, 1)
>>> wkb_w.write_hex(pnt)  # By default, no Z value included:
'0101000000000000000000F03F00000000000003F'
>>> wkb_w.outdim = 3  # Tell writer to include Z values
>>> wkb_w.write_hex(pnt)
'0101000000000000000000F03F00000000000003F00000000000003F'
```

**srid**

Set this property with a boolean to indicate whether the SRID of the geometry should be included with the WKB representation. Example:

```python
>>> from django.contrib.gis.geos import Point, WKBWriter
>>> wkb_w = WKBWriter()
```
```
>>> pnt = Point(1, 1, srid=4326)
>>> wkb_w.write_hex(pnt) # By default, no SRID included:
'0101000000000000000000F03F000000000000F03F'
>>> wkb_w.srid = True # Tell writer to include SRID
>>> wkb_w.write_hex(pnt)
'0101000020E61000000000000000000F03F000000000000F03F'
```

```python
class WKTWriter(dim=2, trim=False, precision=None)

This class allows outputting the WKT representation of a geometry. See the `WKBWriter.outdim`, `trim`, and `precision` attributes for details about the constructor arguments.

```
write(geom)
```

Returns the WKT of the given geometry. Example:
```
>>> from django.contrib.gis.geos import Point, WKTWriter
>>> pnt = Point(1, 1)
>>> wkt_w = WKTWriter()
>>> wkt_w.write(pnt)
'POINT (1.0000000000000000 1.0000000000000000)'
```

```
outdim

See `WKBWriter.outdim`.
```

```
trim

This property is used to enable or disable trimming of unnecessary decimals.
```
```
>>> from django.contrib.gis.geos import Point, WKTWriter
>>> pnt = Point(1.44, 1.66)
>>> wkt_w = WKTWriter()
>>> wkt_w.trim
False
>>> wkt_w.write(pnt)
'POINT (1.0000000000000000 1.0000000000000000)'
>>> wkt_w.trim = True
>>> wkt_w.write(pnt)
'POINT (1 1)'
```

```
precision

This property controls the rounding precision of coordinates; if set to `None` rounding is disabled.
```
```
>>> from django.contrib.gis.geos import Point, WKTWriter
>>> pnt = Point(1.44, 1.66)
```
```
```python
>>> wkt_w = WKTWriter()
>>> print(wkt_w.precision)
None
>>> wkt_w.write(pnt)
'POINT (1.4399999999999999 1.6599999999999999)
>>> wkt_w.precision = 0
>>> wkt_w.write(pnt)
'POINT (1 2)
>>> wkt_w.precision = 1
>>> wkt_w.write(pnt)
'POINT (1.4 1.7)
```

### Settings

**GEOS_LIBRARY_PATH**

A string specifying the location of the GEOS C library. Typically, this setting is only used if the GEOS C library is in a non-standard location (e.g., `/home/bob/lib/libgeos_c.so`).

Note: The setting must be the full path to the C shared library; in other words you want to use `libgeos_c.so`, not `libgeos.so`.

### Exceptions

**exception GEOSException**

The base GEOS exception, indicates a GEOS-related error.

### GDAL API

**GDAL** stands for Geospatial Data Abstraction Library, and is a veritable “Swiss army knife” of GIS data functionality. A subset of GDAL is the **OGR** Simple Features Library, which specializes in reading and writing vector geographic data in a variety of standard formats.

GeoDjango provides a high-level Python interface for some of the capabilities of OGR, including the reading and coordinate transformation of vector spatial data and minimal support for GDAL’s features with respect to raster (image) data.

Note: Although the module is named `gdal`, GeoDjango only supports some of the capabilities of OGR and
GDAL’s raster features at this time.

## Overview

### Sample Data

The GDAL/OGR tools described here are designed to help you read in your geospatial data, in order for most of them to be useful you have to have some data to work with. If you’re starting out and don’t yet have any data of your own to use, GeoDjango tests contain a number of data sets that you can use for testing. You can download them here:

```
$ wget https://raw.githubusercontent.com/django/django/main/tests/gis_tests/data/cities/cities.{shp,prj,shx,dbf}
$ wget https://raw.githubusercontent.com/django/django/main/tests/gis_tests/data/rasters/raster.tif
```

### Vector Data Source Objects

**DataSource**

*DataSource* is a wrapper for the OGR data source object that supports reading data from a variety of OGR-supported geospatial file formats and data sources using a consistent interface. Each data source is represented by a *DataSource* object which contains one or more layers of data. Each layer, represented by a *Layer* object, contains some number of geographic features (*Feature*), information about the type of features contained in that layer (e.g. points, polygons, etc.), as well as the names and types of any additional fields (*Field*) of data that may be associated with each feature in that layer.

**class DataSource**(ds_input, encoding='utf-8')

The constructor for *DataSource* only requires one parameter: the path of the file you want to read. However, OGR also supports a variety of more complex data sources, including databases, that may be accessed by passing a special name string instead of a path. For more information, see the OGR Vector Formats documentation. The `name` property of a *DataSource* instance gives the OGR name of the underlying data source that it is using.

The optional `encoding` parameter allows you to specify a non-standard encoding of the strings in the source. This is typically useful when you obtain *DjangoUnicodeDecodeError* exceptions while reading field values.

Once you’ve created your *DataSource*, you can find out how many layers of data it contains by accessing the `layer_count` property, or (equivalently) by using the `len()` function. For information on accessing the layers of data themselves, see the next section:
from django.contrib.gis.gdal import DataSource

ds = DataSource('/path/to/your/cities.shp')

ds.name  # This file only contains one layer

layer_count

Returns the number of layers in the data source.

name

Returns the name of the data source.

Layer

class Layer

Layer is a wrapper for a layer of data in a DataSource object. You never create a Layer object directly. Instead, you retrieve them from a DataSource object, which is essentially a standard Python container of Layer objects. For example, you can access a specific layer by its index (e.g. ds[0] to access the first layer), or you can iterate over all the layers in the container in a for loop. The Layer itself acts as a container for geometric features.

Typically, all the features in a given layer have the same geometry type. The geom_type property of a layer is an OGRGeomType that identifies the feature type. We can use it to print out some basic information about each layer in a DataSource:

```python
>>> for layer in ds:
...     print('Layer "%s": %i %ss' % (layer.name, len(layer), layer.geom_type.name))
... Layer "cities": 3 Points
```

The example output is from the cities data source, loaded above, which evidently contains one layer, called "cities", which contains three point features. For simplicity, the examples below assume that you’ve stored that layer in the variable layer:

```python
>>> layer = ds[0]
```

name

Returns the name of this layer in the data source.

```python
>>> layer.name
'cities'
```
num_feat

Returns the number of features in the layer. Same as `len(layer):

```python
>>> layer.num_feat
3
```

geom_type

Returns the geometry type of the layer, as an `OGRGeomType` object:

```python
>>> layer.geom_type.name
'Point'
```

num_fields

Returns the number of fields in the layer, i.e the number of fields of data associated with each feature in the layer:

```python
>>> layer.num_fields
4
```

fields

Returns a list of the names of each of the fields in this layer:

```python
>>> layer.fields
['Name', 'Population', 'Density', 'Created']
```

Returns a list of the data types of each of the fields in this layer. These are subclasses of Field, discussed below:

```python
>>> [ft.__name__ for ft in layer.field_types]
['OFTString', 'OFTReal', 'OFTReal', 'OFTDate']
```

field_widths

Returns a list of the maximum field widths for each of the fields in this layer:

```python
>>> layer.field_widths
[80, 11, 24, 10]
```

field_precisions

Returns a list of the numeric precisions for each of the fields in this layer. This is meaningless (and set to zero) for non-numeric fields:
Returns the spatial extent of this layer, as an \texttt{Envelope} object:

```python
>>> layer.extent.tuple
(-104.609252, 29.763374, -95.23506, 38.971823)
```

Property that returns the \texttt{SpatialReference} associated with this layer:

```python
>>> print(layer.srs)
GEOGCS["GCS_WGS_1984",
    DATUM["WGS_1984",
        SPHEROID["WGS_1984",6378137,298.257223563]],
    PRIMEM["Greenwich",0],
    UNIT["Degree",0.017453292519943295]]
```

If the \texttt{Layer} has no spatial reference information associated with it, \texttt{None} is returned.

Property that may be used to retrieve or set a spatial filter for this layer. A spatial filter can only be set with an \texttt{OGRGeometry} instance, a 4-tuple extent, or \texttt{None}. When set with something other than \texttt{None}, only features that intersect the filter will be returned when iterating over the layer:

```python
>>> print(layer.spatial_filter)
None
>>> print(len(layer))
3
>>> [feat.get('Name') for feat in layer]
['Pueblo', 'Lawrence', 'Houston']
>>> ks_extent = (-102.051, 36.99, -94.59, 40.00) # Extent for state of Kansas
>>> layer.spatial_filter = ks_extent
>>> len(layer)
1
>>> [feat.get('Name') for feat in layer]
['Lawrence']
>>> layer.spatial_filter = None
>>> len(layer)
3
```

\texttt{get_fields()}
A method that returns a list of the values of a given field for each feature in the layer:

```python
def layer.get_fields(field):
    return [field.name for field in layer.fields]
```

```python
>>> layer.get_fields('Name')
['Pueblo', 'Lawrence', 'Houston']
```

`get_geoms(geos=False)`

A method that returns a list containing the geometry of each feature in the layer. If the optional argument `geos` is set to `True` then the geometries are converted to `GEOSGeometry` objects. Otherwise, they are returned as `OGRGeometry` objects:

```python
>>> [pt.tuple for pt in layer.get_geoms()]
[(-104.609252, 38.255001), (-95.23506, 38.971823), (-95.363151, 29.763374)]
```

test_capability(capability)

Returns a boolean indicating whether this layer supports the given capability (a string). Examples of valid capability strings include: 'RandomRead', 'SequentialWrite', 'RandomWrite', 'FastSpatialFilter', 'FastFeatureCount', 'FastGetExtent', 'CreateField', 'Transactions', 'DeleteFeature', and 'FastSetNextByIndex'.

Feature

class Feature

Feature wraps an OGR feature. You never create a Feature object directly. Instead, you retrieve them from a Layer object. Each feature consists of a geometry and a set of fields containing additional properties. The geometry of a field is accessible via its `geom` property, which returns an `OGRGeometry` object. A Feature behaves like a standard Python container for its fields, which it returns as Field objects: you can access a field directly by its index or name, or you can iterate over a feature’s fields, e.g. in a for loop.

`geom`

Returns the geometry for this feature, as an `OGRGeometry` object:

```python
>>> city.geom.tuple
(-104.609252, 38.255001)
```

`get`

A method that returns the value of the given field (specified by name) for this feature, not a Field wrapper object:

```python
>>> city.get('Population')
102121
```
**geom_type**

Returns the type of geometry for this feature, as an `OGRGeomType` object. This will be the same for all features in a given layer and is equivalent to the `Layer.geom_type` property of the `Layer` object the feature came from.

**num_fields**

Returns the number of fields of data associated with the feature. This will be the same for all features in a given layer and is equivalent to the `Layer.num_fields` property of the `Layer` object the feature came from.

**fields**

Returns a list of the names of the fields of data associated with the feature. This will be the same for all features in a given layer and is equivalent to the `Layer.fields` property of the `Layer` object the feature came from.

**fid**

Returns the feature identifier within the layer:

```python
>>> city.fid
0
```

**layer_name**

Returns the name of the `Layer` that the feature came from. This will be the same for all features in a given layer:

```python
>>> city.layer_name
'cities'
```

**index**

A method that returns the index of the given field name. This will be the same for all features in a given layer:

```python
>>> city.index('Population')
1
```
Field

class Field

    name

    Returns the name of this field:

    >>> city['Name'].name
    'Name'

    type

    Returns the OGR type of this field, as an integer. The FIELD_CLASSES dictionary maps these values onto subclasses of Field:

    >>> city['Density'].type
    2

    type_name

    Returns a string with the name of the data type of this field:

    >>> city['Name'].type_name
    'String'

    value

    Returns the value of this field. The Field class itself returns the value as a string, but each subclass returns the value in the most appropriate form:

    >>> city['Population'].value
    102121

    width

    Returns the width of this field:

    >>> city['Name'].width
    80

    precision

    Returns the numeric precision of this field. This is meaningless (and set to zero) for non-numeric fields:

    >>> city['Density'].precision
    15
as_double()

Returns the value of the field as a double (float):

```python
>>> city['Density'].as_double()
874.7
```

as_int()

Returns the value of the field as an integer:

```python
>>> city['Population'].as_int()
102121
```

as_string()

Returns the value of the field as a string:

```python
>>> city['Name'].as_string()
'Pueblo'
```

as_datetime()

Returns the value of the field as a tuple of date and time components:

```python
>>> city['Created'].as_datetime()
(c_long(1999), c_long(5), c_long(23), c_long(0), c_long(0), c_long(0), c_long(0))
```

Driver

class Driver(dr_input)

The Driver class is used internally to wrap an OGR DataSource driver.

driver_count

Returns the number of OGR vector drivers currently registered.

OGR Geometries

OGRGeometry

OGRGeometry objects share similar functionality with GEOSGeometry objects and are thin wrappers around OGR’s internal geometry representation. Thus, they allow for more efficient access to data when using DataSource. Unlike its GEOS counterpart, OGRGeometry supports spatial reference systems and coordinate transformation:
from django.contrib.gis.gdal import OGRGeometry

polygon = OGRGeometry('POLYGON((0 0, 5 0, 5 5, 0 5))')

class OGRGeometry(geom_input, srs=None):
    This object is a wrapper for the OGR Geometry class. These objects are instantiated directly from the given geom_input parameter, which may be a string containing WKT, HEX, GeoJSON, a buffer containing WKB data, or an OGRGeomType object. These objects are also returned from the Feature. geom attribute, when reading vector data from Layer (which is in turn a part of a DataSource).

classmethod from_gml(gml_string)
    Constructs an OGRGeometry from the given GML string.

classmethod from_bbox(bbox)
    Constructs a Polygon from the given bounding-box (a 4-tuple).

__len__()
    Returns the number of points in a LineString, the number of rings in a Polygon, or the number of geometries in a GeometryCollection. Not applicable to other geometry types.

__iter__()
    Iterates over the points in a LineString, the rings in a Polygon, or the geometries in a GeometryCollection. Not applicable to other geometry types.

__getitem__()
    Returns the point at the specified index for a LineString, the interior ring at the specified index for a Polygon, or the geometry at the specified index in a GeometryCollection. Not applicable to other geometry types.

dimension
    Returns the number of coordinated dimensions of the geometry, i.e. 0 for points, 1 for lines, and so forth:

    >> polygon.dimension
    2

coord_dim
    Returns or sets the coordinate dimension of this geometry. For example, the value would be 2 for two-dimensional geometries.

geom_count
    Returns the number of elements in this geometry:
>>> polygon.geom_count
1

**point_count**

Returns the number of points used to describe this geometry:

>>> polygon.point_count
4

**num_points**

Alias for *point_count*.

**num_coords**

Alias for *point_count*.

**geom_type**

Returns the type of this geometry, as an `OGRGeomType` object.

**geom_name**

Returns the name of the type of this geometry:

>>> polygon.geom_name
'POLYGON'

**area**

Returns the area of this geometry, or 0 for geometries that do not contain an area:

>>> polygon.area
25.0

**envelope**

Returns the envelope of this geometry, as an `Envelope` object.

**extent**

Returns the envelope of this geometry as a 4-tuple, instead of as an `Envelope` object:

>>> point.extent
(0.0, 0.0, 5.0, 5.0)

**srs**
This property controls the spatial reference for this geometry, or `None` if no spatial reference system has been assigned to it. If assigned, accessing this property returns a `SpatialReference` object. It may be set with another `SpatialReference` object, or any input that `SpatialReference` accepts. Example:

```python
>>> city.geom.srs.name
'GCS_WGS_1984'
```

**srid**

Returns or sets the spatial reference identifier corresponding to `SpatialReference` of this geometry. Returns `None` if there is no spatial reference information associated with this geometry, or if an SRID cannot be determined.

**geos**

Returns a `GEOSGeometry` object corresponding to this geometry.

**gml**

Returns a string representation of this geometry in GML format:

```python
>>> OGRGeometry('POINT(1 2)').gml
'<gml:Point><gml:coordinates>1,2</gml:coordinates></gml:Point>'
```

**hex**

Returns a string representation of this geometry in HEX WKB format:

```python
>>> OGRGeometry('POINT(1 2)').hex
'01010000000000000000F03F0000000000000040'
```

**json**

Returns a string representation of this geometry in JSON format:

```python
>>> OGRGeometry('POINT(1 2)').json
'{ "type": "Point", "coordinates": [ 1.000000, 2.000000 ] }'
```

**kml**

Returns a string representation of this geometry in KML format.

**wkb_size**

Returns the size of the WKB buffer needed to hold a WKB representation of this geometry:

```python
>>> OGRGeometry('POINT(1 2)').wkb_size
21
```
wkb
Returns a buffer containing a WKB representation of this geometry.

wkt
Returns a string representation of this geometry in WKT format.

ewkt
Returns the EWKT representation of this geometry.

clone()
Returns a new `OGRGeometry` clone of this geometry object.

close_rings()
If there are any rings within this geometry that have not been closed, this routine will do so by adding the starting point to the end:

```python
>>> triangle = OGRGeometry('LINEARRING (0 0,0 1,1 0)')
>>> triangle.close_rings()
>>> triangle.wkt
'LINEARRING (0 0 1 0 0 1 0 0 0 0 0)
```

transform(coord_trans, clone=False)
Transforms this geometry to a different spatial reference system. May take a `CoordTransform` object, a `SpatialReference` object, or any other input accepted by `SpatialReference` (including spatial reference WKT and PROJ strings, or an integer SRID).

By default nothing is returned and the geometry is transformed in-place. However, if the `clone` keyword is set to `True` then a transformed clone of this geometry is returned instead.

intersects(other)
Returns `True` if this geometry intersects the other, otherwise returns `False`.

equals(other)
Returns `True` if this geometry is equivalent to the other, otherwise returns `False`.

disjoint(other)
Returns `True` if this geometry is spatially disjoint to (i.e. does not intersect) the other, otherwise returns `False`.

touches(other)
Returns `True` if this geometry touches the other, otherwise returns `False`.
crosses(other)
Returns True if this geometry crosses the other, otherwise returns False.

within(other)
Returns True if this geometry is contained within the other, otherwise returns False.

contains(other)
Returns True if this geometry contains the other, otherwise returns False.

overlaps(other)
Returns True if this geometry overlaps the other, otherwise returns False.

boundary()
The boundary of this geometry, as a new OGRGeometry object.

convex_hull
The smallest convex polygon that contains this geometry, as a new OGRGeometry object.

difference()
Returns the region consisting of the difference of this geometry and the other, as a new OGRGeometry object.

intersection()
Returns the region consisting of the intersection of this geometry and the other, as a new OGRGeometry object.

sym_difference()
Returns the region consisting of the symmetric difference of this geometry and the other, as a new OGRGeometry object.

union()
Returns the region consisting of the union of this geometry and the other, as a new OGRGeometry object.

tuple
Returns the coordinates of a point geometry as a tuple, the coordinates of a line geometry as a tuple of tuples, and so forth:

```
>>> OGRGeometry('POINT (1 2)').tuple
(1.0, 2.0)
>>> OGRGeometry('LINESTRING (1 2,3 4)').tuple
((1.0, 2.0), (3.0, 4.0))
```
coords

An alias for tuple.

class Point

x

Returns the X coordinate of this point:

```python
>>> OGRGeometry('POINT (1 2)').x
1.0
```

y

Returns the Y coordinate of this point:

```python
>>> OGRGeometry('POINT (1 2)').y
2.0
```

z

Returns the Z coordinate of this point, or None if the point does not have a Z coordinate:

```python
>>> OGRGeometry('POINT (1 2 3)').z
3.0
```

class LineString

x

Returns a list of X coordinates in this line:

```python
>>> OGRGeometry('LINESTRING (1 2,3 4)').x
[1.0, 3.0]
```

y

Returns a list of Y coordinates in this line:

```python
>>> OGRGeometry('LINESTRING (1 2,3 4)').y
[2.0, 4.0]
```

z

Returns a list of Z coordinates in this line, or None if the line does not have Z coordinates:

```python
>>> OGRGeometry('LINESTRING (1 2,3 4)').z
[3.0, 6.0]
```
class Polygon

    shell

    Returns the shell or exterior ring of this polygon, as a LinearRing geometry.

    exterior_ring

    An alias for shell.

    centroid

    Returns a Point representing the centroid of this polygon.

class GeometryCollection

    add(geom)

    Adds a geometry to this geometry collection. Not applicable to other geometry types.

OGRGeomType

class OGRGeomType(type_input)

    This class allows for the representation of an OGR geometry type in any of several ways:

    >>> from django.contrib.gis.gdal import OGRGeomType
    >>> gt1 = OGRGeomType(3)  # Using an integer for the type
    >>> gt2 = OGRGeomType('Polygon')  # Using a string
    >>> gt3 = OGRGeomType('POLYGON')  # It's case-insensitive
    >>> print(gt1 == 3, gt1 == 'Polygon')  # Equivalence works w/non-OGRGeomType objects
       True True

    name

    Returns a short-hand string form of the OGR Geometry type:

    >>> gt1.name
    'Polygon'

    num

    Returns the number corresponding to the OGR geometry type:

    >>> gt1.num
    3
Returns the Django field type (a subclass of GeometryField) to use for storing this OGR type, or `None` if there is no appropriate Django type:

```python
>>> gtl.django
'PolygonField'
```

**Envelope**

class Envelope(*args)

 Represents an OGR Envelope structure that contains the minimum and maximum X, Y coordinates for a rectangle bounding box. The naming of the variables is compatible with the OGR Envelope C structure.

min_x

The value of the minimum X coordinate.

min_y

The value of the maximum X coordinate.

max_x

The value of the minimum Y coordinate.

max_y

The value of the maximum Y coordinate.

ur

The upper-right coordinate, as a tuple.

ll

The lower-left coordinate, as a tuple.

tuple

A tuple representing the envelope.

wkt

A string representing this envelope as a polygon in WKT format.

expand_to_include(*args)
Coordinate System Objects

SpatialReference

class SpatialReference(srs_input)

Spatial reference objects are initialized on the given srs_input, which may be one of the following:

- OGC Well Known Text (WKT) (a string)
- EPSG code (integer or string)
- PROJ string
- A shorthand string for well-known standards ('WGS84', 'WGS72', 'NAD27', 'NAD83')

Example:

```python
>>> wgs84 = SpatialReference('WGS84')  # shorthand string
>>> wgs84 = SpatialReference(4326)  # EPSG code
>>> wgs84 = SpatialReference('EPSG:4326')  # EPSG string
>>> proj = '+proj=longlat +ellps=WGS84 +datum=WGS84 +no_defs'
>>> wgs84 = SpatialReference(proj)  # PROJ string
>>> wgs84 = SpatialReference("GEOGCS["WGS 84", DATUM["WGS_1984", Spheroid["WGS 84", 6378137.0, 298.257223563, AUTHORITY["EPSG","7030"], AUTHORITY["EPSG","6326"], PRIMEM["Greenwich",0, AUTHORITY["EPSG","8901"], UNIT["degree",0.01745329251994328, AUTHORITY["EPSG","9122"], AUTHORITY["EPSG","4326"]]]]" ]")  # OGC WKT
```

__getitem__(target)

Returns the value of the given string attribute node, None if the node doesn’t exist. Can also take a tuple as a parameter, (target, child), where child is the index of the attribute in the WKT. For example:

```python
>>> wkt = 'GEOGCS["WGS 84", DATUM["WGS_1984", ... AUTHORITY["EPSG","4326"]]]'
>>> srs = SpatialReference(wkt)  # could also use 'WGS84', or 4326
>>> print(srs["GEOGCS"])
WGS 84
>>> print(srs["DATUM"])
WGS_1984
>>> print(srs["AUTHORITY"])  # The authority value
EPSG
>>> print(srs["AUTHORITY", 1])
```

(continues on next page)
4326
>>> print(srs['TOWGS84', 4]) # the fourth value in this wkt
0
>>> print(srs['UNIT\|AUTHORITY']) # For the units authority, have to use the pipe symbol.
EPSG
>>> print(srs['UNIT\|AUTHORITY', 1]) # The authority value for the units
9122

attr_value(target, index=0)

The attribute value for the given target node (e.g. 'PROJCS'). The index keyword specifies an index of the child node to return.

auth_name(target)

Returns the authority name for the given string target node.

auth_code(target)

Returns the authority code for the given string target node.

clone()

Returns a clone of this spatial reference object.

identify_epsg()

This method inspect the WKT of this SpatialReference and will add EPSG authority nodes where an EPSG identifier is applicable.

from_esri()

Morphs this SpatialReference from ESRI’s format to EPSG

to_esri()

Morphs this SpatialReference to ESRI’s format.

validate()

Checks to see if the given spatial reference is valid, if not an exception will be raised.

import_epsg(epsg)

Import spatial reference from EPSG code.

import_proj(proj)

Import spatial reference from PROJ string.

import_user_input(user_input)
import_wkt(wkt)

Import spatial reference from WKT.

import_xml(xml)

Import spatial reference from XML.

name

Returns the name of this Spatial Reference.

sridd

Returns the SRID of top-level authority, or None if undefined.

linear_name

Returns the name of the linear units.

linear_units

Returns the value of the linear units.

angular_name

Returns the name of the angular units."

angular_units

Returns the value of the angular units.

units

Returns a 2-tuple of the units value and the units name and will automatically determines whether to return the linear or angular units.

ellipsoid

Returns a tuple of the ellipsoid parameters for this spatial reference: (semimajor axis, semiminor axis, and inverse flattening).

semi_major

Returns the semi major axis of the ellipsoid for this spatial reference.

semi_minor

Returns the semi minor axis of the ellipsoid for this spatial reference.

inverse_flattening

Returns the inverse flattening of the ellipsoid for this spatial reference.
geographic
Returns True if this spatial reference is geographic (root node is GEOGCS).

local
Returns True if this spatial reference is local (root node is LOCAL_CS).

projected
Returns True if this spatial reference is a projected coordinate system (root node is PROJCS).

wkt
Returns the WKT representation of this spatial reference.

pretty_wkt
Returns the ‘pretty’ representation of the WKT.

proj
Returns the PROJ representation for this spatial reference.

proj4
Alias for SpatialReference.proj.

xml
Returns the XML representation of this spatial reference.

CoordTransform

class CoordTransform(source, target)

Represents a coordinate system transform. It is initialized with two SpatialReference, representing the source and target coordinate systems, respectively. These objects should be used when performing the same coordinate transformation repeatedly on different geometries:

```python
>>> ct = CoordTransform(SpatialReference('WGS84'), SpatialReference('NAD83'))
>>> for feat in layer:
...    geom = feat.geom # getting clone of feature geometry
...    geom.transform(ct) # transforming
```
**Raster Data Objects**

**GDALRaster**

*GDALRaster* is a wrapper for the GDAL raster source object that supports reading data from a variety of GDAL-supported geospatial file formats and data sources using a consistent interface. Each data source is represented by a *GDALRaster* object which contains one or more layers of data named bands. Each band, represented by a *GDALBand* object, contains georeferenced image data. For example, an RGB image is represented as three bands: one for red, one for green, and one for blue.

---

Note: For raster data there is no difference between a raster instance and its data source. Unlike for the Geometry objects, *GDALRaster* objects are always a data source. Temporary rasters can be instantiated in memory using the corresponding driver, but they will be of the same class as file-based raster sources.

---

**class GDALRaster**(ds_input, write=False)

The constructor for *GDALRaster* accepts two parameters. The first parameter defines the raster source, and the second parameter defines if a raster should be opened in write mode. For newly-created rasters, the second parameter is ignored and the new raster is always created in write mode.

The first parameter can take three forms: a string representing a file path (filesystem or GDAL virtual filesystem), a dictionary with values defining a new raster, or a bytes object representing a raster file.

If the input is a file path, the raster is opened from there. If the input is raw data in a dictionary, the parameters *width*, *height*, and *srid* are required. If the input is a bytes object, it will be opened using a GDAL virtual filesystem.

For a detailed description of how to create rasters using dictionary input, see Creating rasters from data. For a detailed description of how to create rasters in the virtual filesystem, see Using GDAL’s Virtual Filesystem.

The following example shows how rasters can be created from different input sources (using the sample data from the GeoDjango tests; see also the Sample Data section).

```python
>>> from django.contrib.gis.gdal import GDALRaster
>>> rst = GDALRaster('/path/to/your/raster.tif', write=False)
>>> rst.name
'/path/to/your/raster.tif'
>>> rst.width, rst.height  # This file has 163 x 174 pixels
(163, 174)
>>> rst = GDALRaster({  # Creates an in-memory raster
...   'srid': 4326,
...   'width': 4,
...   'height': 4,
})
(continues on next page)```
'datatype': 1,
'bands': [{
'data': (2, 3),
'offset': (1, 1),
'size': (2, 2),
'shape': (2, 1),
'nodata_value': 5,
}]}

>>> rst.srs.srid
4326

>>> rst.width, rst.height
(4, 4)

>>> rst.bands[0].data()
array([[5, 5, 5, 5],
       [5, 2, 3, 5],
       [5, 2, 3, 5],
       [5, 5, 5, 5]], dtype=uint8)

name

The name of the source which is equivalent to the input file path or the name provided upon instantiation.

>>> GDALRaster({'width': 10, 'height': 10, 'name': 'myraster', 'srid': 4326}).name
'myraster'

driver

The name of the GDAL driver used to handle the input file. For GDALRasters created from a file, the driver type is detected automatically. The creation of rasters from scratch is an in-memory raster by default ('MEM'), but can be altered as needed. For instance, use GTiff for a GeoTiff file. For a list of file types, see also the GDAL Raster Formats list.

An in-memory raster is created through the following example:

>>> GDALRaster({'width': 10, 'height': 10, 'srid': 4326}).driver.name
'MEM'
A file based GeoTiff raster is created through the following example:

```python
>>> import tempfile
>>> rstfile = tempfile.NamedTemporaryFile(suffix='.tif')
>>> rst = GDALRaster({'driver': 'GTiff', 'name': rstfile.name, 'srid': 4326,
...                   'width': 255, 'height': 255, 'nr_of_bands': 1})
>>> rst.name
'/tmp/tmp7x9H4J.tif' # The exact filename will be different on your computer
>>> rst.driver.name
'GTiff'
```

**width**

The width of the source in pixels (X-axis).

```python
>>> GDALRaster({'width': 10, 'height': 20, 'srid': 4326}).width
10
```

**height**

The height of the source in pixels (Y-axis).

```python
>>> GDALRaster({'width': 10, 'height': 20, 'srid': 4326}).height
20
```

**srs**

The spatial reference system of the raster, as a `SpatialReference` instance. The SRS can be changed by setting it to an other `SpatialReference` or providing any input that is accepted by the `SpatialReference` constructor.

```python
>>> rst = GDALRaster({'width': 10, 'height': 20, 'srid': 4326})
>>> rst.srs.srid
4326
>>> rst.srs = 3086
>>> rst.srs.srid
3086
```

**srid**

The Spatial Reference System Identifier (SRID) of the raster. This property is a shortcut to getting or setting the SRID through the `srs` attribute.

```python
>>> rst = GDALRaster({'width': 10, 'height': 20, 'srid': 4326})
>>> rst.srid
4326
>>> rst.srid = 3086
>>> rst.srid
3086
```
`geotransform`

The affine transformation matrix used to georeference the source, as a tuple of six coefficients which map pixel/line coordinates into georeferenced space using the following relationship:

\[
\begin{align*}
X_{geo} &= GT(0) + X_{pixel}GT(1) + Y_{line}GT(2) \\
Y_{geo} &= GT(3) + X_{pixel}GT(4) + Y_{line}GT(5)
\end{align*}
\]

The same values can be retrieved by accessing the `origin` (indices 0 and 3), `scale` (indices 1 and 5) and `skew` (indices 2 and 4) properties.

The default is `[0.0, 1.0, 0.0, 0.0, 0.0, -1.0]`.

```python
>>> rst = GDALRaster({'width': 10, 'height': 20, 'srid': 4326})
>>> rst.geotransform
[0.0, 1.0, 0.0, 0.0, 0.0, -1.0]
```

`origin`

Coordinates of the top left origin of the raster in the spatial reference system of the source, as a point object with `x` and `y` members.

```python
>>> rst = GDALRaster({'width': 10, 'height': 20, 'srid': 4326})
>>> rst.origin
[0.0, 0.0]
>>> rst.origin.x = 1
>>> rst.origin
[1.0, 0.0]
```

`scale`

Pixel width and height used for georeferencing the raster, as a point object with `x` and `y` members. See `geotransform` for more information.

```python
>>> rst = GDALRaster({'width': 10, 'height': 20, 'srid': 4326})
>>> rst.scale
[1.0, -1.0]
>>> rst.scale.x = 2
>>> rst.scale
[2.0, -1.0]
```

`skew`

Skew coefficients used to georeference the raster, as a point object with `x` and `y` members. In case
of north up images, these coefficients are both 0.

```python
>>> rst = GDALRaster({
    'width': 10, 'height': 20, 'srid': 4326
})
>>> rst.skew
[0.0, 0.0]
>>> rst.skew.x = 3
>>> rst.skew
[3.0, 0.0]
```

**extent**

Extent (boundary values) of the raster source, as a 4-tuple (xmin, ymin, xmax, ymax) in the spatial reference system of the source.

```python
>>> rst = GDALRaster({
    'width': 10, 'height': 20, 'srid': 4326
})
>>> rst.extent
(0.0, -20.0, 10.0, 0.0)
>>> rst.origin.x = 100
>>> rst.extent
(100.0, -20.0, 110.0, 0.0)
```

**bands**

List of all bands of the source, as GDALBand instances.

```python
>>> rst = GDALRaster({
    "width": 1, "height": 2, "srid": 4326,
    ...
    "bands": [{"data": [0, 1]}, {"data": [2, 3]}])
>>> len(rst.bands)
2
>>> rst.bands[1].data()
array([[ 2.,  3.]], dtype=float32)
```

**warp** (ds_input, resampling='NearestNeighbour', max_error=0.0)

Returns a warped version of this raster.

The warping parameters can be specified through the `ds_input` argument. The use of `ds_input` is analogous to the corresponding argument of the class constructor. It is a dictionary with the characteristics of the target raster. Allowed dictionary key values are width, height, SRID, origin, scale, skew, datatype, driver, and name (filename).

By default, the warp functions keeps most parameters equal to the values of the original source raster, so only parameters that should be changed need to be specified. Note that this includes the driver, so for file-based rasters the warp function will create a new raster on disk.

The only parameter that is set differently from the source raster is the name. The default value of the raster name is the name of the source raster appended with `_copy` + source_driver_name. For file-based rasters it is recommended to provide the file path of the target raster.

6.5. contrib packages 1193
The resampling algorithm used for warping can be specified with the `resampling` argument. The default is `NearestNeighbor`, and the other allowed values are `Bilinear`, `Cubic`, `CubicSpline`, `Lanczos`, `Average`, and `Mode`.

The `max_error` argument can be used to specify the maximum error measured in input pixels that is allowed in approximating the transformation. The default is 0.0 for exact calculations.

For users familiar with GDAL, this function has a similar functionality to the `gdalwarp` command-line utility.

For example, the warp function can be used for aggregating a raster to the double of its original pixel scale:

```python
>>> rst = GDALRaster({
    ...    "width": 6, "height": 6, "srid": 3086,
    ...    "origin": [500000, 400000],
    ...    "scale": [100, -100],
    ...    "bands": [{"data": range(36), "nodata_value": 99}]
    ...
})
>>> target = rst.warp({
    "scale": [200, -200], "width": 3, "height": 3
})
>>> target.bands[0].data()
array([[ 7.,  9., 11.],
       [19., 21., 23.],
       [31., 33., 35.]], dtype=float32)
```

---

```
transform(srs, driver=None, name=None, resampling='NearestNeighbour', max_error=0.0)
```

Transforms this raster to a different spatial reference system (`srs`), which may be a `SpatialReference` object, or any other input accepted by `SpatialReference` (including spatial reference WKT and PROJ strings, or an integer SRID).

It calculates the bounds and scale of the current raster in the new spatial reference system and warps the raster using the `warp` function.

By default, the driver of the source raster is used and the name of the raster is the original name appended with ' _copy' + source_driver_name. A different driver or name can be specified with the `driver` and `name` arguments.

The default resampling algorithm is `NearestNeighbour` but can be changed using the `resampling` argument. The default maximum allowed error for resampling is 0.0 and can be changed using the `max_error` argument. Consult the `warp` documentation for detail on those arguments.

```python
>>> rst = GDALRaster({
    ...    "width": 6, "height": 6, "srid": 3086,
    ...    "origin": [500000, 400000],
    ...    "scale": [100, -100],
    ...    "bands": [{"data": range(36), "nodata_value": 99}]
    ...
})
```
>>> target_srs = SpatialReference(4326)
>>> target = rst.transform(target_srs)
>>> target.origin
[-82.98492744885776, 27.601924753080144]

info

Returns a string with a summary of the raster. This is equivalent to the gdalinfo command line utility.

metadata

The metadata of this raster, represented as a nested dictionary. The first-level key is the metadata domain. The second-level contains the metadata item names and values from each domain.

To set or update a metadata item, pass the corresponding metadata item to the method using the nested structure described above. Only keys that are in the specified dictionary are updated; the rest of the metadata remains unchanged.

To remove a metadata item, use None as the metadata value.

>>> rst = GDALRaster({'width': 10, 'height': 20, 'srid': 4326})
>>> rst.metadata
{}
>>> rst.metadata = {'DEFAULT': {'OWNER': 'Django', 'VERSION': '1.0'}}
>>> rst.metadata
{'DEFAULT': {'OWNER': 'Django', 'VERSION': '1.0'}}
>>> rst.metadata = {'DEFAULT': {'OWNER': None, 'VERSION': '2.0'}}
>>> rst.metadata
{'DEFAULT': {'VERSION': '2.0'}}

vsi_buffer

A bytes representation of this raster. Returns None for rasters that are not stored in GDAL’s virtual filesystem.

is_vsi_based

A boolean indicating if this raster is stored in GDAL’s virtual filesystem.
**GDALBand**

**class GDALBand**

GDALBand instances are not created explicitly, but rather obtained from a GDALRaster object, through its bands attribute. The GDALBands contain the actual pixel values of the raster.

**description**

The name or description of the band, if any.

**width**

The width of the band in pixels (X-axis).

**height**

The height of the band in pixels (Y-axis).

**pixel_count**

The total number of pixels in this band. Is equal to width * height.

**statistics(refresh=False, approximate=False)**

Compute statistics on the pixel values of this band. The return value is a tuple with the following structure: (minimum, maximum, mean, standard deviation).

If the approximate argument is set to True, the statistics may be computed based on overviews or a subset of image tiles.

If the refresh argument is set to True, the statistics will be computed from the data directly, and the cache will be updated with the result.

If a persistent cache value is found, that value is returned. For raster formats using Persistent Auxiliary Metadata (PAM) services, the statistics might be cached in an auxiliary file. In some cases this metadata might be out of sync with the pixel values or cause values from a previous call to be returned which don’t reflect the value of the approximate argument. In such cases, use the refresh argument to get updated values and store them in the cache.

For empty bands (where all pixel values are “no data”), all statistics are returned as None.

The statistics can also be retrieved directly by accessing the min, max, mean, and std properties.

**min**

The minimum pixel value of the band (excluding the “no data” value).

**max**

The maximum pixel value of the band (excluding the “no data” value).

**mean**

The mean of all pixel values of the band (excluding the “no data” value).
std

The standard deviation of all pixel values of the band (excluding the “no data” value).

nodata_value

The “no data” value for a band is generally a special marker value used to mark pixels that are not valid data. Such pixels should generally not be displayed, nor contribute to analysis operations.

To delete an existing “no data” value, set this property to None.

datatype(as_string=False)

The data type contained in the band, as an integer constant between 0 (Unknown) and 11. If as_string is True, the data type is returned as a string with the following possible values: GDT_Unknown, GDT_Byte, GDT_UInt16, GDT_Int16, GDT_UInt32, GDT_Int32, GDT_Float32, GDT_Float64, GDT_CInt16, GDT_CInt32, GDT_CFloat32, and GDT_CFloat64.

color_interp(as_string=False)

The color interpretation for the band, as an integer between 0 and 16. If as_string is True, the data type is returned as a string with the following possible values: GCI_Undefined, GCI_GrayIndex, GCI_PaletteIndex, GCI_RedBand, GCI_GreenBand, GCI_BlueBand, GCI_AlphaBand, GCI_HueBand, GCI_SaturationBand, GCI_LightnessBand, GCI_CyanBand, GCI.MagentaBand, GCI_YellowBand, GCI_BlackBand, GCI_YCbCr_YBand, GCI_YCbCr_CbBand, and GCI_YCbCr_CrBand. GCI_YCbCr_CrBand also represents GCI_Max because both correspond to the integer 16, but only GCI_YCbCr_CrBand is returned as a string.

data(data=None, offset=None, size=None, shape=None)

The accessor to the pixel values of the GDALBand. Returns the complete data array if no parameters are provided. A subset of the pixel array can be requested by specifying an offset and block size as tuples.

If NumPy is available, the data is returned as NumPy array. For performance reasons, it is highly recommended to use NumPy.

Data is written to the GDALBand if the data parameter is provided. The input can be of one of the following types - packed string, buffer, list, array, and NumPy array. The number of items in the input should normally correspond to the total number of pixels in the band, or to the number of pixels for a specific block of pixel values if the offset and size parameters are provided.

If the number of items in the input is different from the target pixel block, the shape parameter must be specified. The shape is a tuple that specifies the width and height of the input data in pixels. The data is then replicated to update the pixel values of the selected block. This is useful to fill an entire band with a single value, for instance.

For example:
metadata

The metadata of this band. The functionality is identical to `GDALRaster.metadata`.
Creating rasters from data

This section describes how to create rasters from scratch using the `ds_input` parameter.

A new raster is created when a `dict` is passed to the `GDALRaster` constructor. The dictionary contains defining parameters of the new raster, such as the origin, size, or spatial reference system. The dictionary can also contain pixel data and information about the format of the new raster. The resulting raster can therefore be file-based or memory-based, depending on the driver specified.

There’s no standard for describing raster data in a dictionary or JSON flavor. The definition of the dictionary input to the `GDALRaster` class is therefore specific to Django. It’s inspired by the `geojson` format, but the `geojson` standard is currently limited to vector formats.

Examples of using the different keys when creating rasters can be found in the documentation of the corresponding attributes and methods of the `GDALRaster` and `GDALBand` classes.

The `ds_input` dictionary

Only a few keys are required in the `ds_input` dictionary to create a raster: `width`, `height`, and `srid`. All other parameters have default values (see the table below). The list of keys that can be passed in the `ds_input` dictionary is closely related but not identical to the `GDALRaster` properties. Many of the parameters are mapped directly to those properties; the others are described below.

The following table describes all keys that can be set in the `ds_input` dictionary.

<table>
<thead>
<tr>
<th>Key</th>
<th>Default</th>
<th>Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>srid</code></td>
<td>required</td>
<td>Mapped to the <code>srid</code> attribute</td>
</tr>
<tr>
<td><code>width</code></td>
<td>required</td>
<td>Mapped to the <code>width</code> attribute</td>
</tr>
<tr>
<td><code>height</code></td>
<td>required</td>
<td>Mapped to the <code>height</code> attribute</td>
</tr>
<tr>
<td><code>driver</code></td>
<td>MEM</td>
<td>Mapped to the <code>driver</code> attribute</td>
</tr>
<tr>
<td><code>name</code></td>
<td>''</td>
<td>See below</td>
</tr>
<tr>
<td><code>origin</code></td>
<td>0</td>
<td>Mapped to the <code>origin</code> attribute</td>
</tr>
<tr>
<td><code>scale</code></td>
<td>0</td>
<td>Mapped to the <code>scale</code> attribute</td>
</tr>
<tr>
<td><code>skew</code></td>
<td>0</td>
<td>Mapped to the <code>width</code> attribute</td>
</tr>
<tr>
<td><code>bands</code></td>
<td>[]</td>
<td>See below</td>
</tr>
<tr>
<td><code>nr_of_bands</code></td>
<td>0</td>
<td>See below</td>
</tr>
<tr>
<td><code>datatype</code></td>
<td>6</td>
<td>See below</td>
</tr>
<tr>
<td><code>papsz_options</code></td>
<td>{}</td>
<td>See below</td>
</tr>
</tbody>
</table>

**name**

String representing the name of the raster. When creating a file-based raster, this parameter must be the file path for the new raster. If the name starts with `/vsimem/`, the raster is created in GDAL’s virtual filesystem.
**datatype**

Integer representing the data type for all the bands. Defaults to 6 (Float32). All bands of a new raster are required to have the same datatype. The value mapping is:

<table>
<thead>
<tr>
<th>Value</th>
<th>GDAL Pixel Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>GDT_Byte</td>
<td>Eight bit unsigned integer</td>
</tr>
<tr>
<td>2</td>
<td>GDT_UInt16</td>
<td>Sixteen bit unsigned integer</td>
</tr>
<tr>
<td>3</td>
<td>GDT_Int16</td>
<td>Sixteen bit signed integer</td>
</tr>
<tr>
<td>4</td>
<td>GDT_UInt32</td>
<td>Thirty-two bit unsigned integer</td>
</tr>
<tr>
<td>5</td>
<td>GDT_Int32</td>
<td>Thirty-two bit signed integer</td>
</tr>
<tr>
<td>6</td>
<td>GDT_Float32</td>
<td>Thirty-two bit floating point</td>
</tr>
<tr>
<td>7</td>
<td>GDT_Float64</td>
<td>Sixty-four bit floating point</td>
</tr>
</tbody>
</table>

**nr_of_bands**

Integer representing the number of bands of the raster. A raster can be created without passing band data upon creation. If the number of bands isn’t specified, it’s automatically calculated from the length of the bands input. The number of bands can’t be changed after creation.

**bands**

A list of band_input dictionaries with band input data. The resulting band indices are the same as in the list provided. The definition of the band input dictionary is given below. If band data isn’t provided, the raster bands values are instantiated as an array of zeros and the “no data” value is set to None.

**papsz_options**

A dictionary with raster creation options. The key-value pairs of the input dictionary are passed to the driver on creation of the raster.

The available options are driver-specific and are described in the documentation of each driver.

The values in the dictionary are not case-sensitive and are automatically converted to the correct string format upon creation.

The following example uses some of the options available for the GTiff driver. The result is a compressed signed byte raster with an internal tiling scheme. The internal tiles have a block size of 23 by 23:

```python
>>> GDALRaster({
...   'driver': 'GTiff',
...   'name': '/path/to/new/file.tif',
...   'srid': 4326,
...   'width': 255,
...   'height': 255,
...   'nr_of_bands': 1,
... })
```
...  'papsz_options': {  ...
...        'compress': 'packbits',  ...
...        'pixeltype': 'signedbyte',  ...
...        'tiled': 'yes',  ...
...        'blockxsize': 23,  ...
...        'blocksize': 23,  ...
...    }  ...
...})

The band_input dictionary

The bands key in the ds_input dictionary is a list of band_input dictionaries. Each band_input dictionary can contain pixel values and the “no data” value to be set on the bands of the new raster. The data array can have the full size of the new raster or be smaller. For arrays that are smaller than the full raster, the size, shape, and offset keys control the pixel values. The corresponding keys are passed to the data() method. Their functionality is the same as setting the band data with that method. The following table describes the keys that can be used.

<table>
<thead>
<tr>
<th>Key</th>
<th>Default</th>
<th>Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>nodata_value</td>
<td>None</td>
<td>Mapped to the nodata_value attribute</td>
</tr>
<tr>
<td>data</td>
<td>Same as nodata_value or 0</td>
<td>Passed to the data() method</td>
</tr>
<tr>
<td>size</td>
<td>(with, height) of raster</td>
<td>Passed to the data() method</td>
</tr>
<tr>
<td>shape</td>
<td>Same as size</td>
<td>Passed to the data() method</td>
</tr>
<tr>
<td>offset</td>
<td>(0, 0)</td>
<td>Passed to the data() method</td>
</tr>
</tbody>
</table>

Using GDAL’s Virtual Filesystem

GDAL can access files stored in the filesystem, but also supports virtual filesystems to abstract accessing other kind of files, such as compressed, encrypted, or remote files.

Using memory-based Virtual Filesystem

GDAL has an internal memory-based filesystem, which allows treating blocks of memory as files. It can be used to read and write GDALRaster objects to and from binary file buffers.

This is useful in web contexts where rasters might be obtained as a buffer from a remote storage or returned from a view without being written to disk.

GDALRaster objects are created in the virtual filesystem when a bytes object is provided as input, or when the file path starts with /vsimem/.

6.5. contrib packages
Input provided as `bytes` has to be a full binary representation of a file. For instance:

```python
# Read a raster as a file object from a remote source.
>>> from urllib.request import urlopen
>>> dat = urlopen('http://example.com/raster.tif').read()
# Instantiate a raster from the bytes object.
>>> rst = GDALRaster(dat)
# The name starts with /vsimem/, indicating that the raster lives in the
# virtual filesystem.
>>> rst.name
'/vsimem/da300bdb-129d-49a8-b336-e410a9428dad'
```

To create a new virtual file-based raster from scratch, use the `ds_input` dictionary representation and provide a `name` argument that starts with `/vsimem/` (for detail of the dictionary representation, see Creating rasters from data). For virtual file-based rasters, the `vsi_buffer` attribute returns the `bytes` representation of the raster.

Here’s how to create a raster and return it as a file in an `HttpResponse`:

```python
>>> from django.http import HttpResponse
>>> rst = GDALRaster(
...     'name': '/vsimem/temporarymemfile',
...     'driver': 'tif',
...     'width': 6, 'height': 6, 'srid': 3086,
...     'origin': [500000, 400000],
...     'scale': [100, -100],
...     'bands': [{'data': range(36), 'nodata_value': 99}]
... )
>>> HttpResponse(rst.vsi_buffer, 'image/tiff')
```

**Using other Virtual Filesystems**

Depending on the local build of GDAL other virtual filesystems may be supported. You can use them by prepending the provided path with the appropriate `/vsi*` prefix. See the GDAL Virtual Filesystems documentation for more details.
Compressed rasters

Instead decompressing the file and instantiating the resulting raster, GDAL can directly access compressed files using the /vsizip/, /vsigzip/, or /vsitar/ virtual filesystems:

```python
from django.contrib.gis.gdal import GDALRaster
dev = GDALRaster('/vsizip/path/to/your/file.zip/path/to/raster.tif')
dev = GDALRaster('/vsigzip/path/to/your/file.gz')
dev = GDALRaster('/vsitar/path/to/your/file.tar/path/to/raster.tif')
```

Network rasters

GDAL can support online resources and storage providers transparently. As long as it’s built with such capabilities.

To access a public raster file with no authentication, you can use /vsicurl/:

```python
from django.contrib.gis.gdal import GDALRaster
dev = GDALRaster('/vsicurl/https://example.com/raster.tif')
print(dev.name)  # /vsicurl/https://example.com/raster.tif
```

For commercial storage providers (e.g. /vsis3/) the system should be previously configured for authentication and possibly other settings (see the GDAL Virtual Filesystems documentation for available options).

**Settings**

**GDAL_LIBRARY_PATH**

A string specifying the location of the GDAL library. Typically, this setting is only used if the GDAL library is in a non-standard location (e.g., /home/john/lib/libgdal.so).

**Exceptions**

**exception GDALException**

The base GDAL exception, indicating a GDAL-related error.

**exception SRSException**

An exception raised when an error occurs when constructing or using a spatial reference system object.
Geolocation with GeoIP2

The GeoIP2 object is a wrapper for the MaxMind geoip2 Python library.¹

In order to perform IP-based geolocation, the GeoIP2 object requires the geoip2 Python library and the GeoIP Country and/or City datasets in binary format (the CSV files will not work!). Grab the GeoLite2-Country.mmdb.gz and GeoLite2-City.mmdb.gz files and unzip them in a directory corresponding to the GEOIP_PATH setting.

Additionally, it is recommended to install the libmaxminddb C library, so that geoip2 can leverage the C library’s faster speed.

Example

Here is an example of its usage:

```
>>> from django.contrib.gis.geop2 import GeoIP2
>>> g = GeoIP2()
>>> g.country('google.com')
{'country_code': 'US', 'country_name': 'United States'}
>>> g.city('72.14.207.99')
{'city': 'Mountain View',
 'continent_code': 'NA',
 'continent_name': 'North America',
 'country_code': 'US',
 'country_name': 'United States',
 'dma_code': 807,
 'is_in_european_union': False,
 'latitude': 37.419200897216797,
 'longitude': -122.05740356445312,
 'postal_code': '94043',
 'region': 'CA',
 'time_zone': 'America/Los_Angeles'}
>>> g.lat_long('salon.com')
(39.0437, -77.4875)
>>> g.lon_lat('uh.edu')
(-95.4342, 29.834)
>>> g.geos('24.124.1.80').wkt
'POINT (-97 38)'
```

¹ GeoIP(R) is a registered trademark of MaxMind, Inc.
API Reference

class GeoIP2(path=None, cache=0, country=None, city=None)

The GeoIP object does not require any parameters to use the default settings. However, at the very least the *GEOIP_PATH* setting should be set with the path of the location of your GeoIP datasets. The following initialization keywords may be used to customize any of the defaults.

<table>
<thead>
<tr>
<th>Keyword Arguments</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>path</td>
<td>Base directory to where GeoIP data is located or the full path to where the city or country data files (.mmdb) are located. Assumes that both the city and country datasets are located in this directory; overrides the <em>GEOIP_PATH</em> setting.</td>
</tr>
<tr>
<td>cache</td>
<td>The cache settings when opening up the GeoIP datasets. May be an integer in (0, 1, 2, 4, 8) corresponding to the MODE_AUTO, MODE_MMAP_EXT, MODE_MMAP, and GEOIP_INDEX_CACHE MODE_MEMORY C API settings, respectively. Defaults to 0 (MODE_AUTO).</td>
</tr>
<tr>
<td>country</td>
<td>The name of the GeoIP country data file. Defaults to GeoLite2-Country.mmdb. Setting this keyword overrides the <em>GEOIP_COUNTRY</em> setting.</td>
</tr>
<tr>
<td>city</td>
<td>The name of the GeoIP city data file. Defaults to GeoLite2-City.mmdb. Setting this keyword overrides the <em>GEOIP_CITY</em> setting.</td>
</tr>
</tbody>
</table>

Methods

Instantiating

classmethod GeoIP2.open(path, cache)

This classmethod instantiates the GeoIP object from the given database path and given cache setting.

Querying

All the following querying routines may take either a string IP address or a fully qualified domain name (FQDN). For example, both '205.186.163.125' and 'djangoproject.com' would be valid query parameters.

GeoIP2.city(query)

Returns a dictionary of city information for the given query. Some of the values in the dictionary may be undefined (None).
GeoIP2.country(query)

Returns a dictionary with the country code and country for the given query.

GeoIP2.country_code(query)

Returns the country code corresponding to the query.

GeoIP2.country_name(query)

Returns the country name corresponding to the query.

**Coordinate Retrieval**

GeoIP2.coords(query)

Returns a coordinate tuple of (longitude, latitude).

GeoIP2.lon_lat(query)

Returns a coordinate tuple of (longitude, latitude).

GeoIP2.lat_lon(query)

Returns a coordinate tuple of (latitude, longitude).

GeoIP2.geos(query)

Returns a *Point* object corresponding to the query.

**Settings**

**GEOIP_PATH**

A string or *pathlib.Path* specifying the directory where the GeoIP data files are located. This setting is required unless manually specified with *path* keyword when initializing the *GeoIP2* object.

**GEOIP_COUNTRY**

The basename to use for the GeoIP country data file. Defaults to 'GeoLite2-Country.mmdb'.
GEOIP_CITY

The basename to use for the GeoIP city data file. Defaults to 'GeoLite2-City.mmdb'.

Exceptions

exception GeoIP2Exception

The exception raised when an error occurs in a call to the underlying geoip2 library.

GeoDjango Utilities

The django.contrib.gis.utils module contains various utilities that are useful in creating geospatial web applications.

LayerMapping data import utility

The LayerMapping class provides a way to map the contents of vector spatial data files (e.g. shapefiles) into GeoDjango models.

This utility grew out of the author’s personal needs to eliminate the code repetition that went into pulling geometries and fields out of a vector layer, converting to another coordinate system (e.g. WGS84), and then inserting into a GeoDjango model.

Note: Use of LayerMapping requires GDAL.

Warning: GIS data sources, like shapefiles, may be very large. If you find that LayerMapping is using too much memory, set DEBUG to False in your settings. When DEBUG is set to True, Django automatically logs every SQL query—and when SQL statements contain geometries, this may consume more memory than is typical.

Example

1. You need a GDAL-supported data source, like a shapefile (here we’re using a simple polygon shapefile, test_poly.shp, with three features):

   ```python
   >>> from django.contrib.gis.gdal import DataSource
   >>> ds = DataSource('test_poly.shp')
   >>> layer = ds[0]
   ```

   (continues on next page)
Now we define our corresponding Django model (make sure to use `migrate`):

```python
from django.contrib.gis.db import models

class TestGeo(models.Model):
    name = models.CharField(max_length=25)  # corresponds to the 'str' field
    poly = models.PolygonField(srid=4269)  # we want our model in a different SRID

    def __str__(self):
        return 'Name: %s' % self.name
```

3. Use `LayerMapping` to extract all the features and place them in the database:

```python
>>> from django.contrib.gis.utils import LayerMapping
>>> from geoapp.models import TestGeo

>>> mapping = {'name': 'str',  # The 'name' model field maps to the 'str' layer field.
             'poly': 'POLYGON',  # For geometry fields use OGC name.
             }  # The mapping is a dictionary

>>> lm = LayerMapping(TestGeo, 'test_poly.shp', mapping)

>>> lm.save(verbosity=True)  # Save the layermap, imports the data.
Saved: Name: 1
Saved: Name: 2
Saved: Name: 3
```

Here, `LayerMapping` transformed the three geometries from the shapefile in their original spatial reference system (WGS84) to the spatial reference system of the GeoDjango model (NAD83). If no spatial reference system is defined for the layer, use the `source_srs` keyword with a `SpatialReference` object to specify one.
LayerMapping API

```python
class LayerMapping(model, data_source, mapping, layer=0, source_srs=None, encoding=None, 
                    transaction_mode='commit_on_success', transform=True, unique=True, 
                    using='default')
```

The following are the arguments and keywords that may be used during instantiation of `LayerMapping` objects.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>model</code></td>
<td>The geographic model, not an instance.</td>
</tr>
<tr>
<td><code>data_source</code></td>
<td>The path to the OGR-supported data source file (e.g., a shapefile). Also accepts <code>django.contrib.gis.gdal.DataSource</code> instances.</td>
</tr>
<tr>
<td><code>mapping</code></td>
<td>A dictionary: keys are strings corresponding to the model field, and values correspond to string field names for the OGR feature, or if the model field is a geographic then it should correspond to the OGR geometry type, e.g., 'POINT', 'LINESTRING', 'POLYGON'.</td>
</tr>
<tr>
<td><code>layer</code></td>
<td>The index of the layer to use from the DataSource (defaults to 0)</td>
</tr>
<tr>
<td><code>source_srs</code></td>
<td>Use this to specify the source SRS manually (for example, some shapefiles don't come with a '.prj' file). An integer SRID, WKT or PROJ strings, and <code>django.contrib.gis.gdal.SpatialReference</code> objects are accepted.</td>
</tr>
<tr>
<td><code>encoding</code></td>
<td>Specifies the character set encoding of the strings in the OGR data source. For example, 'latin-1', 'utf-8', and 'cp437' are all valid encoding parameters.</td>
</tr>
<tr>
<td><code>transaction_mode</code></td>
<td>Maybe 'commit_on_success' (default) or 'autocommit'.</td>
</tr>
<tr>
<td><code>transform</code></td>
<td>Setting this to False will disable coordinate transformations. In other words, geometries will be inserted into the database unmodified from their original state in the data source.</td>
</tr>
<tr>
<td><code>unique</code></td>
<td>Setting this to the name, or a tuple of names, from the given model will create models unique only to the given name(s). Geometries from each feature will be added into the collection associated with the unique model. Forces the transaction mode to be 'autocommit'.</td>
</tr>
<tr>
<td><code>using</code></td>
<td>Sets the database to use when importing spatial data. Default is 'default'.</td>
</tr>
</tbody>
</table>
**save() Keyword Arguments**

LayerMapping.save(\[verbose=False, fid_range=False, step=False, progress=False, silent=False, stream=sys.stdout, strict=False\])

The `save()` method also accepts keywords. These keywords are used for controlling output logging, error handling, and for importing specific feature ranges.

<table>
<thead>
<tr>
<th>Save Keyword Arguments</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>fid_range</strong></td>
<td>May be set with a slice or tuple of (begin, end) feature ID’s to map from the data source. In other words, this keyword enables the user to selectively import a subset range of features in the geographic data source.</td>
</tr>
<tr>
<td><strong>progress</strong></td>
<td>When this keyword is set, status information will be printed giving the number of features processed and successfully saved. By default, progress information will be printed every 1000 features processed, however, this default may be overridden by setting this keyword with an integer for the desired interval.</td>
</tr>
<tr>
<td><strong>silent</strong></td>
<td>By default, non-fatal error notifications are printed to <code>sys.stdout</code>, but this keyword may be set to disable these notifications.</td>
</tr>
<tr>
<td><strong>step</strong></td>
<td>If set with an integer, transactions will occur at every step interval. For example, if <code>step=1000</code>, a commit would occur after the 1,000th feature, the 2,000th feature etc.</td>
</tr>
<tr>
<td><strong>stream</strong></td>
<td>Status information will be written to this file handle. Defaults to using <code>sys.stdout</code>, but any object with a <code>write</code> method is supported.</td>
</tr>
<tr>
<td><strong>strict</strong></td>
<td>Execution of the model mapping will cease upon the first error encountered. The default value (False) behavior is to attempt to continue.</td>
</tr>
<tr>
<td><strong>verbose</strong></td>
<td>If set, information will be printed subsequent to each model save executed on the database.</td>
</tr>
</tbody>
</table>

**Troubleshooting**

**Running out of memory**

As noted in the warning at the top of this section, Django stores all SQL queries when `DEBUG=True`. Set `DEBUG=False` in your settings, and this should stop excessive memory use when running `LayerMapping` scripts.
**MySQL: max_allowed_packet error**

If you encounter the following error when using `LayerMapping` and MySQL:

```
OperationalError: (1153, "Got a packet bigger than 'max_allowed_packet' bytes")
```

Then the solution is to increase the value of the `max_allowed_packet` setting in your MySQL configuration. For example, the default value may be something low like one megabyte – the setting may be modified in MySQL’s configuration file (`my.cnf`) in the `[mysqld]` section:

```
max_allowed_packet = 10M
```

**OGR Inspection**

`ogrinspect`

`ogrinspect(data_source, model_name, **kwargs)`

`mapping`

`mapping(data_source, geom_name='geom', layer_key=0, multi_geom=False)`

**GeoJSON Serializer**

GeoDjango provides a specific serializer for the GeoJSON format. See [Serializing Django objects](#) for more information on serialization.

The `geojson` serializer is not meant for round-tripping data, as it has no deserializer equivalent. For example, you cannot use `loaddata` to reload the output produced by this serializer. If you plan to reload the outputted data, use the plain `json serializer` instead.

In addition to the options of the `json serializer`, the `geojson` serializer accepts the following additional option when it is called by `serializers.serialize()`:

- `geometry_field`: A string containing the name of a geometry field to use for the `geometry` key of the GeoJSON feature. This is only needed when you have a model with more than one geometry field and you don’t want to use the first defined geometry field (by default, the first geometry field is picked).
- `id_field`: A string containing the name of a field to use for the `id` key of the GeoJSON feature. By default, the primary key of objects is used.
- `srid`: The SRID to use for the `geometry` content. Defaults to 4326 (WGS 84).
The *fields* option can be used to limit fields that will be present in the *properties* key, as it works with all other serializers.

Example:

```python
from django.core.serializers import serialize
from my_app.models import City

serialize('geojson', City.objects.all(),
          geometry_field='point',
          fields=('name',))
```

Would output:

```json
{
    'type': 'FeatureCollection',
    'crs': {
        'type': 'name',
        'properties': {'name': 'EPSG:4326'}
    },
    'features': [
        {
            'type': 'Feature',
            'id': 1,
            'geometry': {
                'type': 'Point',
                'coordinates': [-87.650175, 41.850385]
            },
            'properties': {
                'name': 'Chicago'
            }
        }
    ]
}
```

When the *fields* parameter is not specified, the *geojson* serializer adds a *pk* key to the *properties* dictionary with the primary key of the object as the value.

The *id* key for serialized features was added. Also, the *id_field* option was added to the *geojson* serializer.
GeoDjango Management Commands

inspectdb

django-admin inspectdb

When `django.contrib.gis` is in your `INSTALLED_APPS`, the `inspectdb` management command is overridden with one from GeoDjango. The overridden command is spatially-aware, and places geometry fields in the auto-generated model definition, where appropriate.

ogrinspect

django-admin ogrinspect data_source model_name

The `ogrinspect` management command will inspect the given OGR-compatible `DataSource` (e.g., a shapefile) and will output a GeoDjango model with the given model name. There’s a detailed example of using `ogrinspect` in the tutorial.

--blank BLANK

Use a comma separated list of OGR field names to add the `blank=True` keyword option to the field definition. Set with `true` to apply to all applicable fields.

--decimal DECIMAL

Use a comma separated list of OGR float fields to generate `DecimalField` instead of the default `FloatField`. Set to `true` to apply to all OGR float fields.

--geom-name GEOM_NAME

Specifies the model attribute name to use for the geometry field. Defaults to 'geom'.

--layer LAYER_KEY

The key for specifying which layer in the OGR `DataSource` source to use. Defaults to 0 (the first layer). May be an integer or a string identifier for the `Layer`. When inspecting databases, `layer` is generally the table name you want to inspect.

--mapping

Automatically generate a mapping dictionary for use with `LayerMapping`.

--multi-geom

When generating the geometry field, treat it as a geometry collection. For example, if this setting is enabled then a `MultiPolygonField` will be placed in the generated model rather than `PolygonField`.

--name-field NAME_FIELD

Generates a `__str__()` method on the model that returns the given field name.

--no-imports

Suppresses the `from django.contrib.gis.db import models` import statement.
--null NULL

Use a comma separated list of OGR field names to add the null=True keyword option to the field definition. Set with true to apply to all applicable fields.

--srid SRID

The SRID to use for the geometry field. If not set, ogrinspect attempts to automatically determine of the SRID of the data source.

GeoDjango’s admin site

GISModelAdmin

class GISModelAdmin

    gis_widget

    The widget class to be used for GeometryField. Defaults to OSMWidget.

    gis_widget_kwargs

    The keyword arguments that would be passed to the gis_widget. Defaults to an empty dictionary.

GeoModelAdmin

class GeoModelAdmin

    default_lon

    The default center longitude.

    default_lat

    The default center latitude.

    default_zoom

    The default zoom level to use. Defaults to 4.

    extra_js

    Sequence of URLs to any extra JavaScript to include.

    map_template

    Override the template used to generate the JavaScript slippy map. Default is 'gis/admin/openlayers.html'.
map_width

Width of the map, in pixels. Defaults to 600.

map_height

Height of the map, in pixels. Defaults to 400.

openlayers_url

modifiable

Defaults to True. When set to False, disables editing of existing geometry fields in the admin.

Note: This is different from adding the geometry field to readonly_fields, which will only display the WKT of the geometry. Setting modifiable=False, actually displays the geometry in a map, but disables the ability to edit its vertices.

Deprecated since version 4.0: This class is deprecated. Use ModelAdmin instead.

OSMGeoAdmin

class OSMGeoAdmin

A subclass of GeoModelAdmin that uses a Spherical Mercator projection with OpenStreetMap street data tiles.

Deprecated since version 4.0: This class is deprecated. Use GISModelAdmin instead.

Geographic Feeds

GeoDjango has its own Feed subclass that may embed location information in RSS/Atom feeds formatted according to either the Simple GeoRSS or W3C Geo standards. Because GeoDjango’s syndication API is a superset of Django’s, please consult Django’s syndication documentation for details on general usage.
Example

API Reference

Feed Subclass

class Feed

In addition to methods provided by the `django.contrib.syndication.views.Feed` base class, GeoDjango’s `Feed` class provides the following overrides. Note that these overrides may be done in multiple ways:

```python
from django.contrib.gis.feeds import Feed

class MyFeed(Feed):
    # First, as a class attribute.
    geometry = ...
    item_geometry = ...

    # Also a function with no arguments
    def geometry(self):
        ...

    def item_geometry(self):
        ...

    # And as a function with a single argument
    def geometry(self, obj):
        ...

    def item_geometry(self, item):
        ...

geometry(obj)
```
Takes the object returned by `get_object()` and returns the feed’s geometry. Typically this is a GEOSGeometry instance, or can be a tuple to represent a point or a box. For example:

```python
class ZipcodeFeed(Feed):

    def geometry(self, obj):
        # Can also return: `obj.poly`, and `obj.poly.centroid`.
        return obj.poly.extent # tuple like: (X0, Y0, X1, Y1).

    item_geometry(item)
```
Set this to return the geometry for each item in the feed. This can be a `GEOSGeometry` instance, or a tuple that represents a point coordinate or bounding box. For example:

```python
class ZipcodeFeed(Feed):
    def item_geometry(self, obj):
        # Returns the polygon.
        return obj.poly
```

**SyndicationFeed Subclasses**

The following `django.utils.feedgenerator.SyndicationFeed` subclasses are available:

```python
class GeoRSSFeed
class GeoAtom1Feed
class W3CGeoFeed
```

**Note:** W3C Geo formatted feeds only support `PointField` geometries.

**Geographic Sitemaps**

KML is an XML language focused on geographic visualization\(^1\). `KMLSitemap` and its compressed counterpart `KMZSitemap` allow you to present geolocated data in a machine-readable format.

**Example**

**Reference**

`KMLSitemap`

`KMZSitemap`

**Testing GeoDjango apps**

Included in this documentation are some additional notes and settings for PostGIS users.

\(^1\) [https://www.ogc.org/standards/kml](https://www.ogc.org/standards/kml)
PostGIS

Settings

Note: The settings below have sensible defaults, and shouldn’t require manual setting.

POSTGIS_VERSION

When GeoDjango’s spatial backend initializes on PostGIS, it has to perform an SQL query to determine the version in order to figure out what features are available. Advanced users wishing to prevent this additional query may set the version manually using a 3-tuple of integers specifying the major, minor, and micro version numbers for PostGIS. For example, to configure for PostGIS X.Y.Z you would use:

```
POSTGIS_VERSION = (X, Y, Z)
```

Obtaining sufficient privileges

Depending on your configuration, this section describes several methods to configure a database user with sufficient privileges to run tests for GeoDjango applications on PostgreSQL. If your spatial database template was created like in the instructions, then your testing database user only needs to have the ability to create databases. In other configurations, you may be required to use a database superuser.

Create database user

To make a database user with the ability to create databases, use the following command:

```
$ createuser --createdb -R -S <user_name>
```

The -R -S flags indicate that we do not want the user to have the ability to create additional users (roles) or to be a superuser, respectively.

Alternatively, you may alter an existing user’s role from the SQL shell (assuming this is done from an existing superuser account):

```
postgres# ALTER ROLE <user_name> CREATEDB NOSUPERUSER NOCREATEROLE;
```
Create database superuser

This may be done at the time the user is created, for example:

```
$ createuser --superuser <user_name>
```

Or you may alter the user’s role from the SQL shell (assuming this is done from an existing superuser account):

```
postgres# ALTER ROLE <user_name> SUPERUSER;
```

Windows

On Windows platforms you can use the pgAdmin III utility to add superuser privileges to your database user. By default, the PostGIS installer on Windows includes a template spatial database entitled `template_postgis`.

GeoDjango tests

To have the GeoDjango tests executed when running the Django test suite with `runtests.py` all of the databases in the settings file must be using one of the spatial database backends.

Example

The following is an example bare-bones settings file with spatial backends that can be used to run the entire Django test suite, including those in `django.contrib.gis`:

```python
DATABASES = {
    'default': {
        'ENGINE': 'django.contrib.gis.db.backends.postgis',
        'NAME': 'geodjango',
        'USER': 'geodjango',
    },
    'other': {
        'ENGINE': 'django.contrib.gis.db.backends.postgis',
        'NAME': 'other',
        'USER': 'geodjango',
    },
}
SECRET_KEY = 'django_tests_secret_key'
```
Assuming the settings above were in a `postgis.py` file in the same directory as `runtests.py`, then all Django and GeoDjango tests would be performed when executing the command:

```
$ ./runtests.py --settings=postgis
```

To run only the GeoDjango test suite, specify `gis_tests`:

```
$ ./runtests.py --settings=postgis gis_tests
```

### Deploying GeoDjango

Basically, the deployment of a GeoDjango application is not different from the deployment of a normal Django application. Please consult Django’s deployment documentation.

---

Warning: GeoDjango uses the GDAL geospatial library which is not thread safe at this time. Thus, it is highly recommended to not use threading when deploying—in other words, use an appropriate configuration of Apache.

For example, when configuring your application with `mod_wsgi`, set the `WSGIDaemonProcess` attribute `threads` to 1, unless Apache may crash when running your GeoDjango application. Increase the number of `processes` instead.

---

#### 6.5.6 `django.contrib.humanize`

A set of Django template filters useful for adding a “human touch” to data.

To activate these filters, add `'django.contrib.humanize'` to your `INSTALLED_APPS` setting. Once you’ve done that, use `{% load humanize %}` in a template, and you’ll have access to the following filters.

**apnumber**

For numbers 1-9, returns the number spelled out. Otherwise, returns the number. This follows Associated Press style.

Examples:

- 1 becomes `one`.
- 2 becomes `two`.
- 10 becomes `10`.

You can pass in either an integer or a string representation of an integer.
**intcomma**

Converts an integer or float (or a string representation of either) to a string containing commas every three digits.

Examples:
- 4500 becomes 4,500.
- 4500.2 becomes 4,500.2.
- 45000 becomes 45,000.
- 450000 becomes 450,000.
- 4500000 becomes 4,500,000.

Format localization will be respected if enabled, e.g. with the 'de' language:
- 4500 becomes '45.000'.
- 450000 becomes '450.000'.

**intword**

Converts a large integer (or a string representation of an integer) to a friendly text representation. Translates 1.0 as a singular phrase and all other numeric values as plural, this may be incorrect for some languages. Works best for numbers over 1 million.

Examples:
- 1000000 becomes 1.0 million.
- 1200000 becomes 1.2 million.
- 1200000000 becomes 1.2 billion.
- -1200000000 becomes -1.2 billion.

Values up to $10^{100}$ (Googol) are supported.

Format localization will be respected if enabled, e.g. with the 'de' language:
- 1000000 becomes '1,0 Million'.
- 1200000 becomes '1,2 Millionen'.
- 1200000000 becomes '1,2 Milliarden'.
- -1200000000 becomes '-1,2 Milliarden'.
naturalday

For dates that are the current day or within one day, return “today”, “tomorrow” or “yesterday”, as appropriate. Otherwise, format the date using the passed in format string.

Argument: Date formatting string as described in the date tag.

Examples (when ‘today’ is 17 Feb 2007):

- 16 Feb 2007 becomes yesterday.
- 17 Feb 2007 becomes today.
- 18 Feb 2007 becomes tomorrow.
- Any other day is formatted according to given argument or the DATE_FORMAT setting if no argument is given.

naturaltime

For datetime values, returns a string representing how many seconds, minutes or hours ago it was –falling back to the timesince format if the value is more than a day old. In case the datetime value is in the future the return value will automatically use an appropriate phrase.

Examples (when ‘now’ is 17 Feb 2007 16:30:00):

- 17 Feb 2007 16:30:00 becomes now.
- 17 Feb 2007 16:29:31 becomes 29 seconds ago.
- 17 Feb 2007 16:29:00 becomes a minute ago.
- 17 Feb 2007 16:25:35 becomes 4 minutes ago.
- 17 Feb 2007 15:30:29 becomes 59 minutes ago.
- 17 Feb 2007 15:30:01 becomes 59 minutes ago.
- 17 Feb 2007 15:30:00 becomes an hour ago.
- 17 Feb 2007 13:31:29 becomes 2 hours ago.
- 16 Feb 2007 13:31:29 becomes 1 day, 2 hours ago.
- 16 Feb 2007 13:30:01 becomes 1 day, 2 hours ago.
- 16 Feb 2007 13:30:00 becomes 1 day, 3 hours ago.
- 17 Feb 2007 16:30:30 becomes 30 seconds from now.
- 17 Feb 2007 16:30:29 becomes 29 seconds from now.
- 17 Feb 2007 16:31:00 becomes a minute from now.
- 17 Feb 2007 16:34:35 becomes 4 minutes from now.
• 17 Feb 2007 17:30:29 becomes an hour from now.
• 17 Feb 2007 18:31:29 becomes 2 hours from now.
• 18 Feb 2007 16:31:29 becomes 1 day from now.
• 26 Feb 2007 18:31:29 becomes 1 week, 2 days from now.

**ordinal**

Converts an integer to its ordinal as a string.

Examples:

• 1 becomes *1st*.
• 2 becomes *2nd*.
• 3 becomes *3rd*.

You can pass in either an integer or a string representation of an integer.

### 6.5.7 The messages framework

Quite commonly in web applications, you need to display a one-time notification message (also known as “flash message”) to the user after processing a form or some other types of user input.

For this, Django provides full support for cookie- and session-based messaging, for both anonymous and authenticated users. The messages framework allows you to temporarily store messages in one request and retrieve them for display in a subsequent request (usually the next one). Every message is tagged with a specific *level* that determines its priority (e.g., *info*, *warning*, or *error*).

**Enabling messages**

Messages are implemented through a *middleware* class and corresponding *context processor*.

The default *settings.py* created by *django-admin startproject* already contains all the settings required to enable message functionality:

• `'django.contrib.messages' is in `*INSTALLED_APPS*.

• `MIDDLEWARE` contains `'django.contrib.sessions.middleware.SessionMiddleware` and `'django.contrib.messages.middleware.MessageMiddleware`.

The default *storage backend* relies on *sessions*. That’s why *SessionMiddleware* must be enabled and appear before *MessageMiddleware* in `MIDDLEWARE`.

• The `'context_processors' option of the DjangoTemplates backend defined in your `*TEMPLATES` setting contains `'django.contrib.messages.context_processors.messages'`. 

6.5. **contrib packages**
If you don’t want to use messages, you can remove `django.contrib.messages` from your `INSTALLED_APPS`, the `MessageMiddleware` line from `MIDDLEWARE`, and the `messages` context processor from `TEMPLATES`.

**Configuring the message engine**

**Storage backends**

The messages framework can use different backends to store temporary messages.

Django provides three built-in storage classes in `django.contrib.messages`:

- **class storage.session.SessionStorage**
  
  This class stores all messages inside of the request’s session. Therefore it requires Django’s contrib.sessions application.

- **class storage.cookie.CookieStorage**
  
  This class stores the message data in a cookie (signed with a secret hash to prevent manipulation) to persist notifications across requests. Old messages are dropped if the cookie data size would exceed 2048 bytes.

- **class storage.fallback.FallbackStorage**
  
  This class first uses CookieStorage, and falls back to using SessionStorage for the messages that could not fit in a single cookie. It also requires Django’s contrib.sessions application.

  This behavior avoids writing to the session whenever possible. It should provide the best performance in the general case.

`FallbackStorage` is the default storage class. If it isn’t suitable to your needs, you can select another storage class by setting `MESSAGE_STORAGE` to its full import path, for example:

```python
MESSAGE_STORAGE = 'django.contrib.messages.storage.cookie.CookieStorage'
```

- **class storage.base.BaseStorage**

  To write your own storage class, subclass the BaseStorage class in `django.contrib.messages.storage.base` and implement the _get and _store methods.
**Message levels**

The messages framework is based on a configurable level architecture similar to that of the Python logging module. Message levels allow you to group messages by type so they can be filtered or displayed differently in views and templates.

The built-in levels, which can be imported from `django.contrib.messages` directly, are:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEBUG</td>
<td>Development-related messages that will be ignored (or removed) in a production deployment</td>
</tr>
<tr>
<td>INFO</td>
<td>Informational messages for the user</td>
</tr>
<tr>
<td>SUCCESS</td>
<td>An action was successful, e.g. “Your profile was updated successfully”</td>
</tr>
<tr>
<td>WARNING</td>
<td>A failure did not occur but may be imminent</td>
</tr>
<tr>
<td>ERROR</td>
<td>An action was not successful or some other failure occurred</td>
</tr>
</tbody>
</table>

The `MESSAGE_LEVEL` setting can be used to change the minimum recorded level (or it can be changed per request). Attempts to add messages of a level less than this will be ignored.

**Message tags**

Message tags are a string representation of the message level plus any extra tags that were added directly in the view (see Adding extra message tags below for more details). Tags are stored in a string and are separated by spaces. Typically, message tags are used as CSS classes to customize message style based on message type.

By default, each level has a single tag that’s a lowercase version of its own constant:

<table>
<thead>
<tr>
<th>Level Constant</th>
<th>Tag</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEBUG</td>
<td>debug</td>
</tr>
<tr>
<td>INFO</td>
<td>info</td>
</tr>
<tr>
<td>SUCCESS</td>
<td>success</td>
</tr>
<tr>
<td>WARNING</td>
<td>warning</td>
</tr>
<tr>
<td>ERROR</td>
<td>error</td>
</tr>
</tbody>
</table>

To change the default tags for a message level (either built-in or custom), set the `MESSAGE_TAGS` setting to a dictionary containing the levels you wish to change. As this extends the default tags, you only need to provide tags for the levels you wish to override:

```python
from django.contrib.messages import constants as messages
MESSAGE_TAGS = {
    messages.INFO: 'info',
    50: 'critical',
}
```
Using messages in views and templates

**add_message** *(request, level, message, extra_tags='', fail_silently=False)*

Adding a message

To add a message, call:

```python
from django.contrib import messages
messages.add_message(request, messages.INFO, 'Hello world.')
```

Some shortcut methods provide a standard way to add messages with commonly used tags (which are usually represented as HTML classes for the message):

```python
messages.debug(request, '%s SQL statements were executed.' % count)
messages.info(request, 'Three credits remain in your account.')
messages.success(request, 'Profile details updated.')
messages.warning(request, 'Your account expires in three days.')
messages.error(request, 'Document deleted.')
```

Displaying messages

**get_messages** *(request)*

In your template, use something like:

```html
{% if messages %}
<ul class="messages">
    {% for message in messages %}
        <li{% if message.tags %} class="{{ message.tags }}"{% endif %}>{{ message }}</li>
    {% endfor %}
</ul>
{% endif %}
```

If you’re using the context processor, your template should be rendered with a *RequestContext*. Otherwise, ensure *messages* is available to the template context.

Even if you know there is only one message, you should still iterate over the *messages* sequence, because otherwise the message storage will not be cleared for the next request.

The context processor also provides a *DEFAULT_MESSAGE_LEVELS* variable which is a mapping of the message level names to their numeric value:
Outside of templates, you can use `get_messages()`:

```python
from django.contrib.messages import get_messages

storage = get_messages(request)
for message in storage:
    do_something_with_the_message(message)
```

For instance, you can fetch all the messages to return them in a `JSONResponseMixin` instead of a `TemplateResponseMixin`.

`get_messages()` will return an instance of the configured storage backend.

**The Message class**

```python
class storage.base.Message
```

When you loop over the list of messages in a template, what you get are instances of the `Message` class. They have only a few attributes:

- `message`: The actual text of the message.
- `level`: An integer describing the type of the message (see the `message levels` section above).
- `tags`: A string combining all the message’s tags (`extra_tags` and `level_tag`) separated by spaces.
- `extra_tags`: A string containing custom tags for this message, separated by spaces. It’s empty by default.
- `level_tag`: The string representation of the level. By default, it’s the lowercase version of the name of the associated constant, but this can be changed if you need by using the `MESSAGE_TAGS` setting.
Creating custom message levels

Messages levels are nothing more than integers, so you can define your own level constants and use them to create more customized user feedback, e.g.:

```python
CRITICAL = 50

def my_view(request):
    messages.add_message(request, CRITICAL, 'A serious error occurred."
```

When creating custom message levels you should be careful to avoid overloading existing levels. The values for the built-in levels are:

<table>
<thead>
<tr>
<th>Level Constant</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEBUG</td>
<td>10</td>
</tr>
<tr>
<td>INFO</td>
<td>20</td>
</tr>
<tr>
<td>SUCCESS</td>
<td>25</td>
</tr>
<tr>
<td>WARNING</td>
<td>30</td>
</tr>
<tr>
<td>ERROR</td>
<td>40</td>
</tr>
</tbody>
</table>

If you need to identify the custom levels in your HTML or CSS, you need to provide a mapping via the `MESSAGE_TAGS` setting.

Note: If you are creating a reusable application, it is recommended to use only the built-in message levels and not rely on any custom levels.

Changing the minimum recorded level per-request

The minimum recorded level can be set per request via the `set_level` method:

```python
from django.contrib import messages

# Change the messages level to ensure the debug message is added.
messages.set_level(request, messages.DEBUG)
messages.debug(request, 'Test message..."

# In another request, record only messages with a level of WARNING and higher
messages.set_level(request, messages.WARNING)
messages.success(request, 'Your profile was updated.' # ignored
messages.warning(request, 'Your account is about to expire.' # recorded
```
# Set the messages level back to default.

```python
messages.set_level(request, None)
```

Similarly, the current effective level can be retrieved with `get_level`:

```python
from django.contrib import messages
current_level = messages.get_level(request)
```

For more information on how the minimum recorded level functions, see `Message levels` above.

**Adding extra message tags**

For more direct control over message tags, you can optionally provide a string containing extra tags to any of the add methods:

```python
messages.add_message(request, messages.INFO, 'Over 9000!', extra_tags='dragonball')
messages.error(request, 'Email box full', extra_tags='email')
```

Extra tags are added before the default tag for that level and are space separated.

**Failing silently when the message framework is disabled**

If you’re writing a reusable app (or other piece of code) and want to include messaging functionality, but don’t want to require your users to enable it if they don’t want to, you may pass an additional keyword argument `fail_silently=True` to any of the `add_message` family of methods. For example:

```python
messages.add_message(
    request, messages.SUCCESS, 'Profile details updated.',
    fail_silently=True,
)
messages.info(request, 'Hello world.', fail_silently=True)
```

Note: Setting `fail_silently=True` only hides the `MessageFailure` that would otherwise occur when the messages framework disabled and one attempts to use one of the `add_message` family of methods. It does not hide failures that may occur for other reasons.
Adding messages in class-based views

class views.SuccessMessageMixin

    Adds a success message attribute to FormView based classes

    get_success_message(cleaned_data)

        cleaned_data is the cleaned data from the form which is used for string formatting

Example views.py:

```python
from django.contrib.messages.views import SuccessMessageMixin
from django.views.generic.edit import CreateView
from myapp.models import Author

class AuthorCreateView(SuccessMessageMixin, CreateView):
    model = Author
    success_url = '/success/
    success_message = "%(name)s was created successfully"
```

The cleaned data from the form is available for string interpolation using the `%(field_name)s` syntax. For ModelForms, if you need access to fields from the saved object override the `get_success_message()` method.

Example views.py for ModelForms:

```python
from django.contrib.messages.views import SuccessMessageMixin
from django.views.generic.edit import CreateView
from myapp.models import ComplicatedModel

class ComplicatedCreateView(SuccessMessageMixin, CreateView):
    model = ComplicatedModel
    success_url = '/success/
    success_message = "%(calculated_field)s was created successfully"

    def get_success_message(self, cleaned_data):
        return self.success_message % dict(
            cleaned_data,
            calculated_field=self.object.calculated_field,
        )
```
Expiration of messages

The messages are marked to be cleared when the storage instance is iterated (and cleared when the response is processed).

To avoid the messages being cleared, you can set the messages storage to `False` after iterating:

```python
storage = messages.get_messages(request)
for message in storage:
    do_something_with(message)
storage.used = False
```

Behavior of parallel requests

Due to the way cookies (and hence sessions) work, the behavior of any backends that make use of cookies or sessions is undefined when the same client makes multiple requests that set or get messages in parallel. For example, if a client initiates a request that creates a message in one window (or tab) and then another that fetches any uniterated messages in another window, before the first window redirects, the message may appear in the second window instead of the first window where it may be expected.

In short, when multiple simultaneous requests from the same client are involved, messages are not guaranteed to be delivered to the same window that created them nor, in some cases, at all. Note that this is typically not a problem in most applications and will become a non-issue in HTML5, where each window/tab will have its own browsing context.

Settings

A few settings give you control over message behavior:

- `MESSAGE_LEVEL`
- `MESSAGE_STORAGE`
- `MESSAGE_TAGS`

For backends that use cookies, the settings for the cookie are taken from the session cookie settings:

- `SESSION_COOKIE_DOMAIN`
- `SESSION_COOKIE_SECURE`
- `SESSION_COOKIE_HTTPONLY`
6.5.8 django.contrib.postgres

PostgreSQL has a number of features which are not shared by the other databases Django supports. This optional module contains model fields and form fields for a number of PostgreSQL specific data types.

Note: Django is, and will continue to be, a database-agnostic web framework. We would encourage those writing reusable applications for the Django community to write database-agnostic code where practical. However, we recognize that real world projects written using Django need not be database-agnostic. In fact, once a project reaches a given size changing the underlying data store is already a significant challenge and is likely to require changing the code base in some ways to handle differences between the data stores.

Django provides support for a number of data types which will only work with PostgreSQL. There is no fundamental reason why (for example) a contrib.mysql module does not exist, except that PostgreSQL has the richest feature set of the supported databases so its users have the most to gain.

**PostgreSQL specific aggregation functions**

These functions are available from the django.contrib.postgres.aggregates module. They are described in more detail in the PostgreSQL docs.

Note: All functions come without default aliases, so you must explicitly provide one. For example:

```python
>>> SomeModel.objects.aggregate(arr=ArrayAgg('somefield'))
{'arr': [0, 1, 2]}
```

**Common aggregate options**

All aggregates have the filter keyword argument and most also have the default keyword argument.

**General-purpose aggregation functions**

ArrayAgg

```python
class ArrayAgg(expression, distinct=False, filter=None, default=None, ordering=(), **extra)
```

Returns a list of values, including nulls, concatenated into an array, or default if there are no values.

**distinct**

An optional boolean argument that determines if array values will be distinct. Defaults to False.
ordering

An optional string of a field name (with an optional "-" prefix which indicates descending order) or an expression (or a tuple or list of strings and/or expressions) that specifies the ordering of the elements in the result list.

Examples:

```python
'some_field'
'~some_field'
from django.db.models import F
F('some_field').desc()
```

Deprecated since version 4.0: If there are no rows and default is not provided, ArrayAgg returns an empty list instead of None. This behavior is deprecated and will be removed in Django 5.0. If you need it, explicitly set default to Value([]).

BitAnd

class BitAnd(expression, filter=None, default=None, **extra)

Returns an int of the bitwise AND of all non-null input values, or default if all values are null.

BitOr

class BitOr(expression, filter=None, default=None, **extra)

Returns an int of the bitwise OR of all non-null input values, or default if all values are null.

BitXor

class BitXor(expression, filter=None, default=None, **extra)

Returns an int of the bitwise XOR of all non-null input values, or default if all values are null. It requires PostgreSQL 14+.

BoolAnd

class BoolAnd(expression, filter=None, default=None, **extra)

Returns True, if all input values are true, default if all values are null or if there are no values, otherwise False.

Usage example:
class Comment(models.Model):
    body = models.TextField()
    published = models.BooleanField()
    rank = models.IntegerField()

>>> from django.db.models import Q
>>> from django.contrib.postgres.aggregates import BoolAnd
>>> Comment.objects.aggregate(booland=BoolAnd('published'))
{'booland': False}
>>> Comment.objects.aggregate(booland=BoolAnd(Q(rank__lt=100)))
{'booland': True}

BoolOr

class BoolOr(expression, filter=None, default=None, **extra)

Returns True if at least one input value is true, default if all values are null or if there are no values, otherwise False.

Usage example:

class Comment(models.Model):
    body = models.TextField()
    published = models.BooleanField()
    rank = models.IntegerField()

>>> from django.db.models import Q
>>> from django.contrib.postgres.aggregates import BoolOr
>>> Comment.objects.aggregate(boolor=BoolOr('published'))
{'boolor': True}
>>> Comment.objects.aggregate(boolor=BoolOr(Q(rank__gt=2)))
{'boolor': False}

JSONBAgg

class JSONBAgg(expressions, distinct=False, filter=None, default=None, ordering=(), **extra)

Returns the input values as a JSON array, or default if there are no values. You can query the result using key and index lookups.

distinct

An optional boolean argument that determines if array values will be distinct. Defaults to False.

ordering

An optional string of a field name (with an optional "-" prefix which indicates descending order)
or an expression (or a tuple or list of strings and/or expressions) that specifies the ordering of the elements in the result list.

Examples are the same as for `ArrayAgg.ordering`.

Usage example:

```python
from django.contrib.postgres.aggregates import JSONBAgg

Room.objects.annotate(
    requirements=JSONBAgg(
        'hotelreservation__requirements',
        ordering='-hotelreservation__start',
    )
).filter(requirements__0__sea_view=True).values('number', 'requirements')
```

Deprecation since version 4.0: If there are no rows and `default` is not provided, `JSONBAgg` returns an empty list instead of `None`. This behavior is deprecated and will be removed in Django 5.0. If you need it, explicitly set `default` to `Value('[]')`.

**StringAgg**

class StringAgg(expression, delimiter, distinct=False, filter=None, default=None, ordering=())

Returns the input values concatenated into a string, separated by the `delimiter` string, or `default` if there are no values.

- **delimiter**
  
  Required argument. Needs to be a string.

- **distinct**
  
  An optional boolean argument that determines if concatenated values will be distinct. Defaults to `False`. 
ordering

An optional string of a field name (with an optional "-" prefix which indicates descending order) or an expression (or a tuple or list of strings and/or expressions) that specifies the ordering of the elements in the result string.

Examples are the same as for *ArrayAgg.ordering*.

Deprecated since version 4.0: If there are no rows and *default* is not provided, *StringAgg* returns an empty string instead of *None*. This behavior is deprecated and will be removed in Django 5.0. If you need it, explicitly set *default* to *Value('')*.

**Aggregate functions for statistics**

*y* and *x*

The arguments *y* and *x* for all these functions can be the name of a field or an expression returning a numeric data. Both are required.

**Corr**

```python
class Corr(y, x, filter=None, default=None)
```

Returns the correlation coefficient as a *float*, or *default* if there aren’t any matching rows.

**CovarPop**

```python
class CovarPop(y, x, sample=False, filter=None, default=None)
```

Returns the population covariance as a *float*, or *default* if there aren’t any matching rows.

*sample*

Optional. By default *CovarPop* returns the general population covariance. However, if *sample=True*, the return value will be the sample population covariance.

**RegrAvgX**

```python
class RegrAvgX(y, x, filter=None, default=None)
```

Returns the average of the independent variable (*sum(x)/N*) as a *float*, or *default* if there aren’t any matching rows.
RegrAvgY

class RegrAvgY(y, x, filter=None, default=None)

    Returns the average of the dependent variable (sum(y)/N) as a float, or default if there aren’t any matching rows.

RegrCount

class RegrCount(y, x, filter=None)

    Returns an int of the number of input rows in which both expressions are not null.

    Note: The default argument is not supported.

RegrIntercept

class RegrIntercept(y, x, filter=None, default=None)

    Returns the y-intercept of the least-squares-fit linear equation determined by the (x, y) pairs as a float, or default if there aren’t any matching rows.

RegrR2

class RegrR2(y, x, filter=None, default=None)

    Returns the square of the correlation coefficient as a float, or default if there aren’t any matching rows.

RegrSlope

class RegrSlope(y, x, filter=None, default=None)

    Returns the slope of the least-squares-fit linear equation determined by the (x, y) pairs as a float, or default if there aren’t any matching rows.
RegrSXX

class RegrSXX(y, x, filter=None, default=None)

Returns \(\sum(x^2) - \frac{\sum(x)^2}{N}\) ("sum of squares" of the independent variable) as a float, or default if there aren’t any matching rows.

RegrSXY

class RegrSXY(y, x, filter=None, default=None)

Returns \(\sum(xy) - \frac{\sum(x) \sum(y)}{N}\) ("sum of products" of independent times dependent variable) as a float, or default if there aren’t any matching rows.

RegrSYY

class RegrSYY(y, x, filter=None, default=None)

Returns \(\sum(y^2) - \frac{\sum(y)^2}{N}\) ("sum of squares" of the dependent variable) as a float, or default if there aren’t any matching rows.

Usage examples

We will use this example table:

<table>
<thead>
<tr>
<th>FIELD1</th>
<th>FIELD2</th>
<th>FIELD3</th>
</tr>
</thead>
<tbody>
<tr>
<td>--------</td>
<td>--------</td>
<td>--------</td>
</tr>
<tr>
<td>foo</td>
<td>1</td>
<td>13</td>
</tr>
<tr>
<td>bar</td>
<td>2</td>
<td>(null)</td>
</tr>
<tr>
<td>test</td>
<td>3</td>
<td>13</td>
</tr>
</tbody>
</table>

Here’s some examples of some of the general-purpose aggregation functions:

```python
>>> TestModel.objects.aggregate(result=StringAgg('field1', delimiter=';'))
{'result': 'foo;bar;test'}
>>> TestModel.objects.aggregate(result=ArrayAgg('field2'))
{'result': [1, 2, 3]}
>>> TestModel.objects.aggregate(result=ArrayAgg('field1'))
{'result': ['foo', 'bar', 'test']}
```

The next example shows the usage of statistical aggregate functions. The underlying math will be not described (you can read about this, for example, at wikipedia):
TestModel.objects.aggregate(count=RegrCount(y='field3', x='field2'))
{'count': 2}

TestModel.objects.aggregate(avgx=RegrAvgX(y='field3', x='field2'),
avgy=RegrAvgY(y='field3', x='field2'))
{'avgx': 2, 'avgy': 13}

### PostgreSQL specific database constraints

PostgreSQL supports additional data integrity constraints available from the `django.contrib.postgres.constraints` module. They are added in the model `Meta.constraints` option.

#### ExclusionConstraint

```python
class ExclusionConstraint(*, name, expressions, index_type=None, condition=None, deferrable=None, include=None, opclasses=(), violation_error_message=None)
```

Creates an exclusion constraint in the database. Internally, PostgreSQL implements exclusion constraints using indexes. The default index type is GiST. To use them, you need to activate the `btree_gist` extension on PostgreSQL. You can install it using the `BtreeGistExtension` migration operation.

If you attempt to insert a new row that conflicts with an existing row, an `IntegrityError` is raised. Similarly, when update conflicts with an existing row.

Exclusion constraints are checked during the model validation.

In older versions, exclusion constraints were not checked during model validation.

#### name

`ExclusionConstraint.name`

See `BaseConstraint.name`.

#### expressions

`ExclusionConstraint.expressions`

An iterable of 2-tuples. The first element is an expression or string. The second element is an SQL operator represented as a string. To avoid typos, you may use `RangeOperators` which maps the operators with strings. For example:
expressions=[
    ('timespan', RangeOperators.ADJACENT_TO),
    (F('room'), RangeOperators.EQUAL),
]

Restrictions on operators.

Only commutative operators can be used in exclusion constraints.

The \texttt{OpClass()} expression can be used to specify a custom \texttt{operator class} for the constraint expressions. For example:

```python
expressions=[
    (OpClass('circle', name='circle_ops'), RangeOperators.OVERLAPS),
]
```

creates an exclusion constraint on \texttt{circle} using \texttt{circle_ops}.

Support for the \texttt{OpClass()} expression was added.

\texttt{index\_type}

\texttt{ExclusionConstraint.index\_type}

The index type of the constraint. Accepted values are \texttt{GIST} or \texttt{SPGIST}. Matching is case insensitive. If not provided, the default index type is \texttt{GIST}.

\texttt{condition}

\texttt{ExclusionConstraint.condition}

A \texttt{Q} object that specifies the condition to restrict a constraint to a subset of rows. For example, `condition=Q(cancelled=False)`.

These conditions have the same database restrictions as \texttt{django.db.models.Index.condition}. 
deferrable

ExclusionConstraint.deferrable

Set this parameter to create a deferrable exclusion constraint. Accepted values are Deferrable.DEFERRED or Deferrable.IMMEDIATE. For example:

```python
from django.contrib.postgres.constraints import ExclusionConstraint
from django.contrib.postgres.fields import RangeOperators
from django.db.models import Deferrable

ExclusionConstraint(
    name='exclude_overlapping_deferred',
    expressions=[
        ('timespan', RangeOperators.OVERLAPS),
    ],
    deferrable=Deferrable.DEFERRED,
)
```

By default constraints are not deferred. A deferred constraint will not be enforced until the end of the transaction. An immediate constraint will be enforced immediately after every command.

Warning: Deferred exclusion constraints may lead to a performance penalty.

include

ExclusionConstraint.include

A list or tuple of the names of the fields to be included in the covering exclusion constraint as non-key columns. This allows index-only scans to be used for queries that select only included fields (include) and filter only by indexed fields (expressions).

include is supported for GiST indexes. PostgreSQL 14+ also supports include for SP-GiST indexes. Support for covering exclusion constraints using SP-GiST indexes on PostgreSQL 14+ was added.
opclasses

ExclusionConstraint.opclasses

The names of the PostgreSQL operator classes to use for this constraint. If you require a custom operator class, you must provide one for each expression in the constraint.

For example:

```python
ExclusionConstraint(
    name='exclude_overlapping_opclasses',
    expressions=[('circle', RangeOperators.OVERLAPS)],
    opclasses=['circle_ops'],
)
```

creates an exclusion constraint on circle using circle_ops.

Deprecated since version 4.1: The opclasses parameter is deprecated in favor of using `OpClass()` in expressions.

violation_error_message

The error message used when `ValidationError` is raised during model validation. Defaults to `BaseConstraint.violation_error_message`.

Examples

The following example restricts overlapping reservations in the same room, not taking canceled reservations into account:

```python
from django.contrib.postgres.constraints import ExclusionConstraint
from django.contrib.postgres.fields import DateTimeRangeField, RangeOperators
from django.db import models
from django.db.models import Q

class Room(models.Model):
    number = models.IntegerField()

class Reservation(models.Model):
    room = models.ForeignKey('Room', on_delete=models.CASCADE)
    timespan = DateTimeRangeField()
    cancelled = models.BooleanField(default=False)
```

(continues on next page)
class Meta:
    constraints = [
        ExclusionConstraint(
            name='exclude_overlapping_reservations',
            expressions=[
                ('timespan', RangeOperators.OVERLAPS),
                ('room', RangeOperators.EQUAL),
            ],
            condition=Q(cancelled=False),
        ),
    ]

In case your model defines a range using two fields, instead of the native PostgreSQL range types, you should write an expression that uses the equivalent function (e.g. TsTzRange()), and use the delimiters for the field. Most often, the delimiters will be '()', meaning that the lower bound is inclusive and the upper bound is exclusive. You may use the RangeBoundary that provides an expression mapping for the range boundaries. For example:

from django.contrib.postgres.constraints import ExclusionConstraint
from django.contrib.postgres.fields import (DateTimeRangeField, RangeBoundary, RangeOperators,)
from django.db import models
from django.db.models import Func, Q

class TsTzRange(Func):
    function = 'TSTZRANGE'
    output_field = DateTimeRangeField()

class Reservation(models.Model):
    room = models.ForeignKey('Room', on_delete=models.CASCADE)
    start = models.DateTimeField()
    end = models.DateTimeField()
    cancelled = models.BooleanField(default=False)

    class Meta:
        constraints = [
            ExclusionConstraint(
                name='exclude_overlapping_reservations',
            ),
        ]
expressions=
    (TsTzRange('start', 'end', RangeBoundary()), RangeOperators.OVERLAPS),
    ('room', RangeOperators.EQUAL),
),
    condition=Q(cancelled=False),
),
]

PostgreSQL specific query expressions

These expressions are available from the django.contrib.postgres.expressions module.

ArraySubquery() expressions

class ArraySubquery(queryset)

ArraySubquery is a Subquery that uses the PostgreSQL ARRAY constructor to build a list of values from the queryset, which must use QuerySet.values() to return only a single column.

This class differs from ArrayAgg in the way that it does not act as an aggregate function and does not require an SQL GROUP BY clause to build the list of values.

For example, if you want to annotate all related books to an author as JSON objects:

```python
>>> from django.db.models import OuterRef
>>> from django.db.models.functions import JSONObject
>>> from django.contrib.postgres.expressions import ArraySubquery
>>> books = Book.objects.filter(author=OuterRef('pk')).values(
...     json=JSONObject(title='title', pages='pages')
... )
>>> author = Author.objects.annotate(books=ArraySubquery(books)).first()
>>> author.books
[{'title': 'Solaris', 'pages': 204}, {'title': 'The Cyberiad', 'pages': 295}]
```

PostgreSQL specific model fields

All of these fields are available from the django.contrib.postgres.fields module.
Indexing these fields

Index and Field.db_index both create a B-tree index, which isn’t particularly helpful when querying complex data types. Indexes such as GinIndex and GistIndex are better suited, though the index choice is dependent on the queries that you’re using. Generally, GiST may be a good choice for the range fields and HStoreField, and GIN may be helpful for ArrayField.

ArrayField

class ArrayField(base_field, size=None, **options)

A field for storing lists of data. Most field types can be used, and you pass another field instance as the base_field. You may also specify a size. ArrayField can be nested to store multi-dimensional arrays.

If you give the field a default, ensure it’s a callable such as list (for an empty default) or a callable that returns a list (such as a function). Incorrectly using default=[] creates a mutable default that is shared between all instances of ArrayField.

base_field

This is a required argument.

Specifies the underlying data type and behavior for the array. It should be an instance of a sub-class of Field. For example, it could be an IntegerField or a CharField. Most field types are permitted, with the exception of those handling relational data (ForeignKey, OneToOneField and ManyToManyField).

It is possible to nest array fields - you can specify an instance of ArrayField as the base_field. For example:

```python
from django.contrib.postgres.fields import ArrayField
from django.db import models

class ChessBoard(models.Model):
    board = ArrayField(
        ArrayField(
            models.CharField(max_length=10, blank=True),
            size=8,
        ),
        size=8,
    )
```

Transformation of values between the database and the model, validation of data and configuration, and serialization are all delegated to the underlying base field.
**size**

This is an optional argument.

If passed, the array will have a maximum size as specified. This will be passed to the database, although PostgreSQL at present does not enforce the restriction.

**Note:** When nesting `ArrayField`, whether you use the `size` parameter or not, PostgreSQL requires that the arrays are rectangular:

```python
from django.contrib.postgres.fields import ArrayField
from django.db import models

class Board(models.Model):
    pieces = ArrayField(ArrayField(models.IntegerField()))

# Valid
Board(pieces=[
    [2, 3],
    [2, 1],
])

# Not valid
Board(pieces=[
    [2, 3],
    [2],
])
```

If irregular shapes are required, then the underlying field should be made nullable and the values padded with `None`.

**Querying ArrayField**

There are a number of custom lookups and transforms for `ArrayField`. We will use the following example model:

```python
from django.contrib.postgres.fields import ArrayField
from django.db import models

class Post(models.Model):
    name = models.CharField(max_length=200)
    tags = ArrayField(models.CharField(max_length=200), blank=True)
```

(continues on next page)
contains

The `contains` lookup is overridden on `ArrayField`. The returned objects will be those where the values passed are a subset of the data. It uses the SQL operator `@>`. For example:

```python
>>> Post.objects.create(name='First post', tags=['thoughts', 'django'])
>>> Post.objects.create(name='Second post', tags=['thoughts'])
>>> Post.objects.create(name='Third post', tags=['tutorial', 'django'])

>>> Post.objects.filter(tags__contains=['thoughts'])
<QuerySet [<Post: First post>, <Post: Second post>]>  

>>> Post.objects.filter(tags__contains=['django'])
<QuerySet [<Post: First post>, <Post: Third post>]>  

>>> Post.objects.filter(tags__contains=['django', 'thoughts'])
<QuerySet [<Post: First post>]>  
```

contained_by

This is the inverse of the `contains` lookup - the objects returned will be those where the data is a subset of the values passed. It uses the SQL operator `<@`. For example:

```python
>>> Post.objects.create(name='First post', tags=['thoughts', 'django'])
>>> Post.objects.create(name='Second post', tags=['thoughts'])
>>> Post.objects.create(name='Third post', tags=['tutorial', 'django'])

>>> Post.objects.filter(tags__contained_by=['thoughts', 'django'])
<QuerySet [<Post: First post>, <Post: Second post>]>  

>>> Post.objects.filter(tags__contained_by=['thoughts', 'django', 'tutorial'])
<QuerySet [<Post: First post>, <Post: Second post>, <Post: Third post>]>  
```
overlap

Returns objects where the data shares any results with the values passed. Uses the SQL operator `&&`. For example:

```python
>>> Post.objects.create(name='First post', tags=['thoughts', 'django'])
>>> Post.objects.create(name='Second post', tags=['thoughts'])
>>> Post.objects.create(name='Third post', tags=['tutorial', 'django'])

>>> Post.objects.filter(tags__overlap=['thoughts'])
<QuerySet [<Post: First post>, <Post: Second post]>>

>>> Post.objects.filter(tags__overlap=['thoughts', 'tutorial'])
<QuerySet [<Post: First post>, <Post: Second post>, <Post: Third post]>>
```

len

Returns the length of the array. The lookups available afterward are those available for `IntegerField`. For example:

```python
>>> Post.objects.create(name='First post', tags=['thoughts', 'django'])
>>> Post.objects.create(name='Second post', tags=['thoughts'])

>>> Post.objects.filter(tags__len=1)
<QuerySet [<Post: Second post]>>
```

Index transforms

Index transforms index into the array. Any non-negative integer can be used. There are no errors if it exceeds the `size` of the array. The lookups available after the transform are those from the `base_field`. For example:

```python
>>> Post.objects.create(name='First post', tags=['thoughts', 'django'])
>>> Post.objects.create(name='Second post', tags=['thoughts'])

>>> Post.objects.filter(tags__0='thoughts')
<QuerySet [<Post: First post>, <Post: Second post]>>

>>> Post.objects.filter(tags__1__iexact='Django')
<QuerySet [<Post: First post]>>
```
Note: PostgreSQL uses 1-based indexing for array fields when writing raw SQL. However these indexes and those used in slices use 0-based indexing to be consistent with Python.

### Slice transforms

Slice transforms take a slice of the array. Any two non-negative integers can be used, separated by a single underscore. The lookups available after the transform do not change. For example:

```python
>>> Post.objects.create(name='First post', tags=['thoughts', 'django'])
>>> Post.objects.create(name='Second post', tags=['thoughts'])
>>> Post.objects.create(name='Third post', tags=['django', 'python', 'thoughts'])

>>> Post.objects.filter(tags__0_1=['thoughts'])
<QuerySet [<Post: First post>, <Post: Second post>]>  

>>> Post.objects.filter(tags__0_2__contains=['thoughts'])
<QuerySet [<Post: First post>, <Post: Second post>]>  
```

Note: PostgreSQL uses 1-based indexing for array fields when writing raw SQL. However these slices and those used in indexes use 0-based indexing to be consistent with Python.

### Multidimensional arrays with indexes and slices

PostgreSQL has some rather esoteric behavior when using indexes and slices on multidimensional arrays. It will always work to use indexes to reach down to the final underlying data, but most other slices behave strangely at the database level and cannot be supported in a logical, consistent fashion by Django.
CIText fields

class CIText(**options)

A mixin to create case-insensitive text fields backed by the citext type. Read about the performance considerations prior to using it.

To use citext, use the CITextExtension operation to set up the citext extension in PostgreSQL before the first CreateModel migration operation.

If you’re using an ArrayField of CIText fields, you must add 'django.contrib.postgres' in your INSTALLED_APPS, otherwise field values will appear as strings like '{thoughts,django}'

Several fields that use the mixin are provided:

class CIC CharField(**options)
class CIEmailField(**options)
class CITextField(**options)

These fields subclass CharField, EmailField, and TextField, respectively.

max_length won’t be enforced in the database since citext behaves similar to PostgreSQL’s text type.

Case-insensitive collations

It’s preferable to use non-deterministic collations instead of the citext extension. You can create them using the CreateCollation migration operation. For more details, see Managing collations using migrations and the PostgreSQL documentation about non-deterministic collations.

HStoreField

class HStoreField(**options)

A field for storing key-value pairs. The Python data type used is a dict. Keys must be strings, and values may be either strings or nulls (None in Python).

To use this field, you’ll need to:

1. Add 'django.contrib.postgres' in your INSTALLED_APPS.
2. Set up the hstore extension in PostgreSQL.

You’ll see an error like can’t adapt type 'dict' if you skip the first step, or type "hstore" does not exist if you skip the second.
Note: On occasion it may be useful to require or restrict the keys which are valid for a given field. This can be done using the `KeysValidator`.

**Querying HStoreField**

In addition to the ability to query by key, there are a number of custom lookups available for `HStoreField`.

We will use the following example model:

```python
from django.contrib.postgres.fields import HStoreField
from django.db import models

class Dog(models.Model):
    name = models.CharField(max_length=200)
    data = HStoreField()

    def __str__(self):
        return self.name
```

**Key lookups**

To query based on a given key, you can use that key as the lookup name:

```python
>>> Dog.objects.create(name='Rufus', data={'breed': 'labrador'})
>>> Dog.objects.create(name='Meg', data={'breed': 'collie'})

>>> Dog.objects.filter(data__breed='collie')
<QuerySet [<Dog: Meg]>>
```

You can chain other lookups after key lookups:

```python
>>> Dog.objects.filter(data__breed__contains='l')
<QuerySet [<Dog: Rufus>, <Dog: Meg]>>
```

If the key you wish to query by clashes with the name of another lookup, you need to use the `hstorefield.contains` lookup instead.

Note: Key transforms can also be chained with: `contains`, `icontains`, `endswith`, `iendswith`, `iexact`, `regex`, `iregex`, `startswith`, and `istartswith` lookups.
Warning: Since any string could be a key in a hstore value, any lookup other than those listed below will be interpreted as a key lookup. No errors are raised. Be extra careful for typing mistakes, and always check your queries work as you intend.

contains

The contains lookup is overridden on HStoreField. The returned objects are those where the given dict of key-value pairs are all contained in the field. It uses the SQL operator @>. For example:

```python
>>> Dog.objects.create(name='Rufus', data={'breed': 'labrador', 'owner': 'Bob'})
>>> Dog.objects.create(name='Meg', data={'breed': 'collie', 'owner': 'Bob'})
>>> Dog.objects.create(name='Fred', data={})

>>> Dog.objects.filter(data__contains={'owner': 'Bob'})
<QuerySet [<Dog: Rufus>, <Dog: Meg]>>

>>> Dog.objects.filter(data__contains={'breed': 'collie'})
<QuerySet [<Dog: Meg]>>
```

contained_by

This is the inverse of the contains lookup - the objects returned will be those where the key-value pairs on the object are a subset of those in the value passed. It uses the SQL operator @<. For example:

```python
>>> Dog.objects.create(name='Rufus', data={'breed': 'labrador', 'owner': 'Bob'})
>>> Dog.objects.create(name='Meg', data={'breed': 'collie', 'owner': 'Bob'})
>>> Dog.objects.create(name='Fred', data={})

>>> Dog.objects.filter(data__contained_by={'breed': 'collie', 'owner': 'Bob'})
<QuerySet [<Dog: Meg>, <Dog: Fred]>>

>>> Dog.objects.filter(data__contained_by={'breed': 'collie'})
<QuerySet [<Dog: Fred]>>
```
has_key

Returns objects where the given key is in the data. Uses the SQL operator `?`. For example:

```python
>>> Dog.objects.create(name='Rufus', data={'breed': 'labrador'})
>>> Dog.objects.create(name='Meg', data={'breed': 'collie', 'owner': 'Bob'})

>>> Dog.objects.filter(data__has_key='owner')
<QuerySet [<Dog: Meg]>>
```

has_any_keys

Returns objects where any of the given keys are in the data. Uses the SQL operator `?|`. For example:

```python
>>> Dog.objects.create(name='Rufus', data={'breed': 'labrador'})
>>> Dog.objects.create(name='Meg', data={'owner': 'Bob'})

>>> Dog.objects.create(name='Fred', data={})

>>> Dog.objects.filter(data__has_any_keys=['owner', 'breed'])
<QuerySet [<Dog: Rufus>, <Dog: Meg]>>
```

has_keys

Returns objects where all of the given keys are in the data. Uses the SQL operator `?&`. For example:

```python
>>> Dog.objects.create(name='Rufus', data={})
>>> Dog.objects.create(name='Meg', data={'breed': 'collie', 'owner': 'Bob'})

>>> Dog.objects.filter(data__has_keys=['breed', 'owner'])
<QuerySet [<Dog: Meg]>>
```

keys

Returns objects where the array of keys is the given value. Note that the order is not guaranteed to be reliable, so this transform is mainly useful for using in conjunction with lookups on `ArrayField`. Uses the SQL function `akeys()`. For example:

```python
>>> Dog.objects.create(name='Rufus', data={'toy': 'bone'})
>>> Dog.objects.create(name='Meg', data={'breed': 'collie', 'owner': 'Bob'})

>>> Dog.objects.filter(data__keys__overlap=['breed', 'toy'])
<QuerySet [<Dog: Rufus>, <Dog: Meg]>>
```
values

Returns objects where the array of values is the given value. Note that the order is not guaranteed to be reliable, so this transform is mainly useful for using in conjunction with lookups on `ArrayField`. Uses the SQL function `avals()`. For example:

```python
>>> Dog.objects.create(name='Rufus', data={'breed': 'labrador'})
>>> Dog.objects.create(name='Meg', data={'breed': 'collie', 'owner': 'Bob'})

>>> Dog.objects.filter(data__values__contains=['collie'])
<QuerySet [<Dog: Meg>>
```

Range Fields

There are five range field types, corresponding to the built-in range types in PostgreSQL. These fields are used to store a range of values; for example the start and end timestamps of an event, or the range of ages an activity is suitable for.

All of the range fields translate to `psycopg2 Range objects` in Python, but also accept tuples as input if no bounds information is necessary. The default is lower bound included, upper bound excluded, that is \((\)
\) (see the PostgreSQL documentation for details about different bounds). The default bounds can be changed for non-discrete range fields (`DateTimeRangeField` and `DecimalRangeField`) by using the `default_bounds` argument.

**IntegerRangeField**

```python
class IntegerRangeField(**options)
    Stores a range of integers. Based on an `IntegerField`. Represented by an `int4range` in the database and a `NumericRange` in Python.
    Regardless of the bounds specified when saving the data, PostgreSQL always returns a range in a canonical form that includes the lower bound and excludes the upper bound, that is \([\)\).
```

**BigIntegerRangeField**

```python
class BigIntegerRangeField(**options)
    Stores a range of large integers. Based on a `BigIntegerField`. Represented by an `int8range` in the database and a `NumericRange` in Python.
    Regardless of the bounds specified when saving the data, PostgreSQL always returns a range in a canonical form that includes the lower bound and excludes the upper bound, that is \([\)\).
```
DecimalRangeField

```python
class DecimalRangeField(default_bounds='[)', **options)

Stores a range of floating point values. Based on a `DecimalField`. Represented by a `numrange` in the
database and a `NumericRange` in Python.

default_bounds

Optional. The value of bounds for list and tuple inputs. The default is lower bound included,
upper bound excluded, that is [) (see the PostgreSQL documentation for details about different
bounds). `default_bounds` is not used for `NumericRange` inputs.
```

DateTimeRangeField

```python
class DateTimeRangeField(default_bounds='[)', **options)

Stores a range of timestamps. Based on a `DateTimeField`. Represented by a `tstzrange` in the database
and a `DateTimeTZRange` in Python.

default_bounds

Optional. The value of bounds for list and tuple inputs. The default is lower bound included,
upper bound excluded, that is [) (see the PostgreSQL documentation for details about different
bounds). `default_bounds` is not used for `DateTimeTZRange` inputs.
```

DateRangeField

```python
class DateRangeField(**options)

Stores a range of dates. Based on a `DateField`. Represented by a `daterange` in the database and a
`DateRange` in Python.

Regardless of the bounds specified when saving the data, PostgreSQL always returns a range in a canonical
form that includes the lower bound and excludes the upper bound, that is [)
```

Querying Range Fields

There are a number of custom lookups and transforms for range fields. They are available on all the above
fields, but we will use the following example model:

```python
from django.contrib.postgres.fields import IntegerRangeField
from django.db import models

class Event(models.Model):
    name = models.CharField(max_length=200)
```

(continues on next page)
ages = IntegerRangeField()
start = models.DateTimeField()

def __str__(self):
    return self.name

We will also use the following example objects:

```python
>>> import datetime
>>> from django.utils import timezone
>>> now = timezone.now()
>>> Event.objects.create(name='Soft play', ages=(0, 10), start=now)
>>> Event.objects.create(name='Pub trip', ages=(21, None), start=now - datetime.timedelta(days=1))
```

and NumericRange:

```python
>>> from psycopg2.extras import NumericRange
```

### Containment functions

As with other PostgreSQL fields, there are three standard containment operators: `contains`, `contained_by` and `overlap`, using the SQL operators `@>`, `<@`, and `&&` respectively.

#### contains

```python
>>> Event.objects.filter(ages__contains=NumericRange(4, 5))
<QuerySet [<Event: Soft play]>}
```

#### contained_by

```python
>>> Event.objects.filter(ages__contained_by=NumericRange(0, 15))
<QuerySet [<Event: Soft play>]>}
```

The `contained_by` lookup is also available on the non-range field types: `SmallAutoField`, `AutoField`, `BigAutoField`, `SmallIntegerField`, `IntegerField`, `BigIntegerField`, `DecimalField`, `FloatField`, `DateField`, and `DateTimeField`. For example:

```python
>>> from psycopg2.extras import DateTimeTZRange
>>> Event.objects.filter(
...    start__contained_by=DateTimeTZRange(
```
timezone.now() - datetime.timedelta(hours=1),
... timezone.now() + datetime.timedelta(hours=1),
... ),
... )
<QuerySet [<Event: Soft play]>}

overlap

```python
>>> Event.objects.filter(ages__overlap=NumericRange(8, 12))
<QuerySet [<Event: Soft play]>}
```

Comparison functions

Range fields support the standard lookups: `lt`, `gt`, `lte` and `gte`. These are not particularly helpful - they compare the lower bounds first and then the upper bounds only if necessary. This is also the strategy used to order by a range field. It is better to use the specific range comparison operators.

**fully_lt**

The returned ranges are strictly less than the passed range. In other words, all the points in the returned range are less than all those in the passed range.

```python
>>> Event.objects.filter(ages__fully_lt=NumericRange(11, 15))
<QuerySet [<Event: Soft play]>}
```

**fully_gt**

The returned ranges are strictly greater than the passed range. In other words, all the points in the returned range are greater than all those in the passed range.

```python
>>> Event.objects.filter(ages__fully_gt=NumericRange(11, 15))
<QuerySet [<Event: Pub trip]>}
```
not_lt

The returned ranges do not contain any points less than the passed range, that is the lower bound of the returned range is at least the lower bound of the passed range.

```python
>>> Event.objects.filter(ages__not_lt=NumericRange(0, 15))
<QuerySet [<Event: Soft play>, <Event: Pub trip>]>  
```

not_gt

The returned ranges do not contain any points greater than the passed range, that is the upper bound of the returned range is at most the upper bound of the passed range.

```python
>>> Event.objects.filter(ages__not_gt=NumericRange(3, 10))
<QuerySet [<Event: Soft play>]>
```

adjacent_to

The returned ranges share a bound with the passed range.

```python
>>> Event.objects.filter(ages__adjacent_to=NumericRange(10, 21))
<QuerySet [<Event: Soft play>, <Event: Pub trip>]>  
```

Querying using the bounds

Range fields support several extra lookups.

startswith

Returned objects have the given lower bound. Can be chained to valid lookups for the base field.

```python
>>> Event.objects.filter(ages__startswith=21)
<QuerySet [<Event: Pub trip>]>
```
endswith

Returned objects have the given upper bound. Can be chained to valid lookups for the base field.

```python
>>> Event.objects.filter(ages__endswith=10)
<QuerySet [<Event: Soft play]>>
```

isempty

Returned objects are empty ranges. Can be chained to valid lookups for a `BooleanField`.

```python
>>> Event.objects.filter(ages__isempty=True)
<QuerySet []>
```

lower_inc

Returns objects that have inclusive or exclusive lower bounds, depending on the boolean value passed. Can be chained to valid lookups for a `BooleanField`.

```python
>>> Event.objects.filter(ages__lower_inc=True)
<QuerySet [<Event: Soft play>, <Event: Pub trip]>>
```

lower_inf

Returns objects that have unbounded (infinite) or bounded lower bound, depending on the boolean value passed. Can be chained to valid lookups for a `BooleanField`.

```python
>>> Event.objects.filter(ages__lower_inf=True)
<QuerySet []>
```

upper_inc

Returns objects that have inclusive or exclusive upper bounds, depending on the boolean value passed. Can be chained to valid lookups for a `BooleanField`.

```python
>>> Event.objects.filter(ages__upper_inc=True)
<QuerySet []>
```
upper_inf

Returns objects that have unbounded (infinite) or bounded upper bound, depending on the boolean value passed. Can be chained to valid lookups for a BooleanField.

```python
>>> Event.objects.filter(ages__upper_inf=True)
<QuerySet [<Event: Pub trip]>]
```

Defining your own range types

PostgreSQL allows the definition of custom range types. Django’s model and form field implementations use base classes below, and psycopg2 provides a register_range() to allow use of custom range types.

```python
class RangeField(**options)
    Base class for model range fields.
    base_field
        The model field class to use.
    range_type
        The psycopg2 range type to use.
    form_field
        The form field class to use. Should be a subclass of django.contrib.postgres.forms.BaseRangeField.

class django.contrib.postgres.forms.BaseRangeField
    Base class for form range fields.
    base_field
        The form field to use.
    range_type
        The psycopg2 range type to use.
```

Range operators

```python
class RangeOperators
    PostgreSQL provides a set of SQL operators that can be used together with the range data types (see the PostgreSQL documentation for the full details of range operators). This class is meant as a convenient method to avoid typos. The operator names overlap with the names of corresponding lookups.
```
class RangeOperators:
    EQUAL = '=='
    NOT_EQUAL = '<>'
    CONTAINS = '[@]
    CONTAINED_BY = '@[)
    OVERLAPS = '&&'
    FULLY_LT = '<<'
    FULLY_GT = '>>'
    NOT_LT = '>&'
    NOT_GT = '&<'
    ADJACENT_TO = '-|-'

RangeBoundary() expressions

class RangeBoundary(inclusive_lower=True, inclusive_upper=False)

    inclusive_lower
        If True (default), the lower bound is inclusive '[', otherwise it’s exclusive '('.

    inclusive_upper
        If False (default), the upper bound is exclusive ')', otherwise it’s inclusive ']'.

A RangeBoundary() expression represents the range boundaries. It can be used with a custom range functions that expected boundaries, for example to define ExclusionConstraint. See the PostgreSQL documentation for the full details.

PostgreSQL specific form fields and widgets

All of these fields and widgets are available from the django.contrib.postgres.forms module.

Fields

SimpleArrayField

class SimpleArrayField(base_field, delimiter='\'', max_length=None, min_length=None)

    A field which maps to an array. It is represented by an HTML <input>.

    base_field
        This is a required argument.

        It specifies the underlying form field for the array. This is not used to render any HTML, but it is used to process the submitted data and validate it. For example:
```python
>>> from django import forms
>>> from django.contrib.postgres.forms import SimpleArrayField

>>> class NumberListForm(forms.Form):
...     numbers = SimpleArrayField(forms.IntegerField())

>>> form = NumberListForm({'numbers': '1,2,3'})
>>> form.is_valid()
True
>>> form.cleaned_data
{'numbers': [1, 2, 3]}

>>> form = NumberListForm({'numbers': '1,2,a'})
>>> form.is_valid()
False

delimiter

This is an optional argument which defaults to a comma: ,. This value is used to split the submitted data. It allows you to chain SimpleArrayField for multidimensional data:

```python
>>> from django import forms
>>> from django.contrib.postgres.forms import SimpleArrayField

>>> class GridForm(forms.Form):
...     places = SimpleArrayField(SimpleArrayField(IntegerField()), delimiter='|')

>>> form = GridForm({'places': '1,2|2,1|4,3'})
>>> form.is_valid()
True
>>> form.cleaned_data
{'places': [[1, 2], [2, 1], [4, 3]]}
```

Note: The field does not support escaping of the delimiter, so be careful in cases where the delimiter is a valid character in the underlying field. The delimiter does not need to be only one character.

```python
max_length

This is an optional argument which validates that the array does not exceed the stated length.

min_length

This is an optional argument which validates that the array reaches at least the stated length.
```
User friendly forms

SimpleArrayField is not particularly user friendly in most cases, however it is a useful way to format data from a client-side widget for submission to the server.

SplitArrayField

class SplitArrayField(base_field, size, remove_trailing_nulls=False)

This field handles arrays by reproducing the underlying field a fixed number of times.

base_field

This is a required argument. It specifies the form field to be repeated.

size

This is the fixed number of times the underlying field will be used.

remove_trailing_nulls

By default, this is set to False. When False, each value from the repeated fields is stored. When set to True, any trailing values which are blank will be stripped from the result. If the underlying field has required=True, but remove_trailing_nulls is True, then null values are only allowed at the end, and will be stripped.

Some examples:

```python
SplitArrayField(IntegerField(required=True), size=3, remove_trailing_nulls=False)
```

```
[1, 2, '3']  # -> [1, 2, 3]
[1, 2, '']  # -> ValidationError - third entry required.
[1, '', '3']  # -> ValidationError - second entry required.
['', '2', '']  # -> ValidationError - first and third entries required.
```

```python
SplitArrayField(IntegerField(required=False), size=3, remove_trailing_nulls=False)
```

```
[1, 2, '3']  # -> [1, 2, 3]
[1, 2, '']  # -> [1, 2, None]
[1, '', '3']  # -> [1, None, 3]
['', '2', '']  # -> [None, 2, None]
```

```python
SplitArrayField(IntegerField(required=True), size=3, remove_trailing_nulls=True)
```

```
[1, 2, '3']  # -> [1, 2, 3]
[1, 2, '']  # -> [1, 2]
[1, '', '3']  # -> ValidationError - second entry required.
```
SplitArrayField(IntegerField(required=False), size=3, remove_trailing_nulls=True)

\[
[1, 2, 3] \rightarrow [1, 2, 3] \\
[1, 2, None] \rightarrow [1, 2] \\
[1, None, 3] \rightarrow [1, None, 3] \\
[None, 2] \rightarrow [None, 2]
\]

HStoreField

class HStoreField

A field which accepts JSON encoded data for an HStoreField. It casts all values (except nulls) to strings. It is represented by an HTML <textarea>

User friendly forms

HStoreField is not particularly user friendly in most cases, however it is a useful way to format data from a client-side widget for submission to the server.

Note: On occasions it may be useful to require or restrict the keys which are valid for a given field. This can be done using the KeysValidator.

Range Fields

This group of fields all share similar functionality for accepting range data. They are based on MultiValueField. They treat one omitted value as an unbounded range. They also validate that the lower bound is not greater than the upper bound. All of these fields use RangeWidget.

IntegerRangeField

class IntegerRangeField

Based on IntegerField and translates its input into NumericRange. Default for IntegerRangeField and BigIntegerRangeField.
DecimalRangeField

```python
class DecimalRangeField
```
Based on `DecimalField` and translates its input into `NumericRange`. Default for `DecimalRangeField`.

DateTimeRangeField

```python
class DateTimeRangeField
```
Based on `DateTimeField` and translates its input into `DateTimeTZRange`. Default for `DateTimeRangeField`.

DateRangeField

```python
class DateRangeField
```
Based on `DateField` and translates its input into `DateRange`. Default for `DateRangeField`.

Widgets

RangeWidget

```python
class RangeWidget(base_widget, attrs=None)
```
Widget used by all of the range fields. Based on `MultiWidget`.

`RangeWidget` has one required argument:

`base_widget`

A `RangeWidget` comprises a 2-tuple of `base_widget`.

`decompress(value)`

Takes a single “compressed” value of a field, for example a `DateRangeField`, and returns a tuple representing a lower and upper bound.

PostgreSQL specific database functions

All of these functions are available from the `django.contrib.postgres.functions` module.
RandomUUID

class RandomUUID

Returns a version 4 UUID.

On PostgreSQL < 13, the `pgcrypto extension` must be installed. You can use the `CryptoExtension` migration operation to install it.

Usage example:

```python
>>> from django.contrib.postgres.functions import RandomUUID
>>> Article.objects.update(uuid=RandomUUID())
```

TransactionNow

class TransactionNow

Returns the date and time on the database server that the current transaction started. If you are not in a transaction it will return the date and time of the current statement. This is a complement to `django.db.models.functions.Now`, which returns the date and time of the current statement.

Note that only the outermost call to `atomic()` sets up a transaction and thus sets the time that `TransactionNow()` will return; nested calls create savepoints which do not affect the transaction time.

Usage example:

```python
>>> from django.contrib.postgres.functions import TransactionNow
>>> Article.objects.filter(published__lte=TransactionNow())
<QuerySet [<Article: How to Django>]>}
```

PostgreSQL specific model indexes

The following are PostgreSQL specific indexes available from the `django.contrib.postgres.indexes` module.

BloomIndex

class BloomIndex(*expressions, length=None, columns=(), **options)

Creates a bloom index.

To use this index access you need to activate the `bloom` extension on PostgreSQL. You can install it using the `BloomExtension` migration operation.
Provide an integer number of bits from 1 to 4096 to the `length` parameter to specify the length of each index entry. PostgreSQL’s default is 80.

The `columns` argument takes a tuple or list of up to 32 values that are integer number of bits from 1 to 4095.

**BrinIndex**

```python
class BrinIndex(*expressions, autosummarize=None, pages_per_range=None, **options)
```

Creates a BRIN index.

Set the `autosummarize` parameter to `True` to enable automatic summarization to be performed by autovacuum.

The `pages_per_range` argument takes a positive integer.

**BTreeIndex**

```python
class BTreeIndex(*expressions, fillfactor=None, **options)
```

Creates a B-Tree index.

Provide an integer value from 10 to 100 to the `fillfactor` parameter to tune how packed the index pages will be. PostgreSQL’s default is 90.

**GinIndex**

```python
class GinIndex(*expressions, fastupdate=None, gin_pending_list_limit=None, **options)
```

Creates a gin index.

To use this index on data types not in the built-in operator classes, you need to activate the `btree_gin` extension on PostgreSQL. You can install it using the `BtreeGinExtension` migration operation.

Set the `fastupdate` parameter to `False` to disable the GIN Fast Update Technique that’s enabled by default in PostgreSQL.

Provide an integer number of kilobytes to the `gin_pending_list_limit` parameter to tune the maximum size of the GIN pending list which is used when `fastupdate` is enabled.
GistIndex

```python
class GistIndex(*expressions, buffering=None, fillfactor=None, **options)
```

Creates a GiST index. These indexes are automatically created on spatial fields with `spatial_index=True`. They’re also useful on other types, such as `HStoreField` or the range fields.

To use this index on data types not in the built-in gist operator classes, you need to activate the `btree_gist` extension on PostgreSQL. You can install it using the `BtreeGistExtension` migration operation.

Set the `buffering` parameter to `True` or `False` to manually enable or disable buffering build of the index.

Provide an integer value from 10 to 100 to the `fillfactor` parameter to tune how packed the index pages will be. PostgreSQL’s default is 90.

HashIndex

```python
class HashIndex(*expressions, fillfactor=None, **options)
```

Creates a hash index.

Provide an integer value from 10 to 100 to the `fillfactor` parameter to tune how packed the index pages will be. PostgreSQL’s default is 90.

SpGistIndex

```python
class SpGistIndex(*expressions, fillfactor=None, **options)
```

Creates an SP-GiST index.

Provide an integer value from 10 to 100 to the `fillfactor` parameter to tune how packed the index pages will be. PostgreSQL’s default is 90.

Support for covering SP-GiST indexes on PostgreSQL 14+ was added.

OpClass() expressions

```python
class OpClass(expression, name)
```

An OpClass() expression represents the expression with a custom operator class that can be used to define functional indexes, functional unique constraints, or exclusion constraints. To use it, you need to add `'django.contrib.postgres'` in your `INSTALLED_APPS`. Set the `name` parameter to the name of the operator class.

For example:
Index(
    OpClass(Lower('username'), name='varchar_pattern_ops'),
    name='lower_username_idx',
)

creates an index on Lower('username') using varchar_pattern_ops.

UniqueConstraint(
    OpClass(Upper('description'), name='text_pattern_ops'),
    name='upper_description_unique',
)

creates a unique constraint on Upper('description') using text_pattern_ops.

ExclusionConstraint(
    name='exclude_overlapping_ops',
    expressions=[
        (OpClass('circle', name='circle_ops'), RangeOperators.OVERLAPS),
    ],
)

creates an exclusion constraint on circle using circle_ops.

Support for exclusion constraints was added.

PostgreSQL specific lookups

Trigram similarity

trigram_similar

The trigram_similar lookup allows you to perform trigram lookups, measuring the number of trigrams (three consecutive characters) shared, using a dedicated PostgreSQL extension. A trigram lookup is given an expression and returns results that have a similarity measurement greater than the current similarity threshold.

To use it, add 'django.contrib.postgres' in your INSTALLED_APPS and activate the pg_trgm extension on PostgreSQL. You can install the extension using the TrigramExtension migration operation.

The trigram_similar lookup can be used on CharField and TextField:

```python
>>> City.objects.filter(name__trigram_similar="Middlesborough")
[<City: Middlesbrough>]
```
trigram_word_similar

The trigram_word_similar lookup allows you to perform trigram word similarity lookups using a dedicated PostgreSQL extension. It can be approximately understood as measuring the greatest number of trigrams shared between the parameter and any substring of the field. A trigram word lookup is given an expression and returns results that have a word similarity measurement greater than the current similarity threshold.

To use it, add 'django.contrib.postgres' in your INSTALLED_APPS and activate the pg_trgm extension on PostgreSQL. You can install the extension using the TrigramExtension migration operation.

The trigram_word_similar lookup can be used on CharField and TextField:

```python
>>> Sentence.objects.filter(name__trigram_word_similar='Middlesborough')
[<Sentence: Gumby rides on the path of Middlesbrough>]
```

trigram_strict_word_similar

Similar to trigram_word_similar, except that it forces extent boundaries to match word boundaries.

To use it, add 'django.contrib.postgres' in your INSTALLED_APPS and activate the pg_trgm extension on PostgreSQL. You can install the extension using the TrigramExtension migration operation.

The trigram_strict_word_similar lookup can be used on CharField and TextField.

Unaccent

The unaccent lookup allows you to perform accent-insensitive lookups using a dedicated PostgreSQL extension.

This lookup is implemented using Transform, so it can be chained with other lookup functions. To use it, you need to add 'django.contrib.postgres' in your INSTALLED_APPS and activate the unaccent extension on PostgreSQL. The UnaccentExtension migration operation is available if you want to perform this activation using migrations).

The unaccent lookup can be used on CharField and TextField:

```python
>>> City.objects.filter(name__unaccent='México')
[<City: Mexico>]

>>> User.objects.filter(first_name__unaccent__startswith='Jerem')
[<User: Jeremy>, <User: Jérémy>, <User: Jérémie>, <User: Jeremie>]
```
Warning: `unaccent` lookups should perform fine in most use cases. However, queries using this filter will generally perform full table scans, which can be slow on large tables. In those cases, using dedicated full text indexing tools might be appropriate.

Database migration operations

All of these operations are available from the `django.contrib.postgres.operations` module.

Creating extension using migrations

You can create a PostgreSQL extension in your database using a migration file. This example creates an hstore extension, but the same principles apply for other extensions.

Set up the hstore extension in PostgreSQL before the first `CreateModel` or `AddField` operation that involves `HStoreField` by adding a migration with the `HStoreExtension` operation. For example:

```python
from django.contrib.postgres.operations import HStoreExtension

class Migration(migrations.Migration):
    ...

    operations = [
        HStoreExtension(),
        ...
    ]
```

The operation skips adding the extension if it already exists.

For most extensions, this requires a database user with superuser privileges. If the Django database user doesn’t have the appropriate privileges, you’ll have to create the extension outside of Django migrations with a user that has them. In that case, connect to your Django database and run the query `CREATE EXTENSION IF NOT EXISTS hstore;`.

CreateExtension

```python
class CreateExtension(name):
    An Operation subclass which installs a PostgreSQL extension. For common extensions, use one of the more specific subclasses below.

    name
    This is a required argument. The name of the extension to be installed.
```
BloomExtension

class BloomExtension
    Installs the bloom extension.

BtreeGinExtension

class BtreeGinExtension
    Installs the btree_gin extension.

BtreeGistExtension

class BtreeGistExtension
    Installs the btree_gist extension.

CITextExtension

class CITextExtension
    Installs the citext extension.

CryptoExtension

class CryptoExtension
    Installs the pgcrypto extension.

HStoreExtension

class HStoreExtension
    Installs the hstore extension and also sets up the connection to interpret hstore data for possible use in subsequent migrations.

TrigramExtension

class TrigramExtension
    Installs the pg_trgm extension.
UnaccentExtension

class UnaccentExtension
    Installs the unaccent extension.

Managing collations using migrations

If you need to filter or order a column using a particular collation that your operating system provides but PostgreSQL does not, you can manage collations in your database using a migration file. These collations can then be used with the `db_collation` parameter on `CharField`, `TextField`, and their subclasses.

For example, to create a collation for German phone book ordering:

```python
from django.contrib.postgres.operations import CreateCollation

class Migration(migrations.Migration):
    ...,

    operations = [
        CreateCollation(
            'german_phonebook',
            provider='icu',
            locale='und-u-ks-level2',
        ),
    ...,
    ]

class CreateCollation(name, locale, *, provider='libc', deterministic=True)
    Creates a collation with the given name, locale and provider.
    
    Set the deterministic parameter to False to create a non-deterministic collation, such as for case-insensitive filtering.

class RemoveCollation(name, locale, *, provider='libc', deterministic=True)
    Removes the collations named name.
    
    When reversed this is creating a collation with the provided locale, provider, and deterministic arguments. Therefore, locale is required to make this operation reversible.
```
Concurrent index operations

PostgreSQL supports the CONCURRENTLY option to CREATE INDEX and DROP INDEX statements to add and remove indexes without locking out writes. This option is useful for adding or removing an index in a live production database.

```python
class AddIndexConcurrently(model_name, index)
```

Like `AddIndex`, but creates an index with the CONCURRENTLY option. This has a few caveats to be aware of when using this option, see the PostgreSQL documentation of building indexes concurrently.

```python
class RemoveIndexConcurrently(model_name, name)
```

Like `RemoveIndex`, but removes the index with the CONCURRENTLY option. This has a few caveats to be aware of when using this option, see the PostgreSQL documentation.

Note: The CONCURRENTLY option is not supported inside a transaction (see non-atomic migration).

Adding constraints without enforcing validation

PostgreSQL supports the NOT VALID option with the ADD CONSTRAINT statement to add check constraints without enforcing validation on existing rows. This option is useful if you want to skip the potentially lengthy scan of the table to verify that all existing rows satisfy the constraint.

To validate check constraints created with the NOT VALID option at a later point of time, use the `ValidateConstraint` operation.

See the PostgreSQL documentation for more details.

```python
class AddConstraintNotValid(model_name, constraint)
```

Like `AddConstraint`, but avoids validating the constraint on existing rows.

```python
class ValidateConstraint(model_name, name)
```

Scans through the table and validates the given check constraint on existing rows.

Note: `AddConstraintNotValid` and `ValidateConstraint` operations should be performed in two separate migrations. Performing both operations in the same atomic migration has the same effect as `AddConstraint`, whereas performing them in a single non-atomic migration, may leave your database in an inconsistent state if the `ValidateConstraint` operation fails.
Full text search

The database functions in the `django.contrib.postgres.search` module ease the use of PostgreSQL’s full text search engine.

For the examples in this document, we’ll use the models defined in Making queries.

See also:

For a high-level overview of searching, see the topic documentation.

The search lookup

A common way to use full text search is to search a single term against a single column in the database. For example:

```python
>>> Entry.objects.filter(body_text__search='Cheese')
[<Entry: Cheese on Toast recipes>, <Entry: Pizza Recipes>]
```

This creates a `to_tsvector` in the database from the `body_text` field and a `plainto_tsquery` from the search term ‘Cheese’, both using the default database search configuration. The results are obtained by matching the query and the vector.

To use the `search` lookup, 'django.contrib.postgres' must be in your `INSTALLED_APPS`.

SearchVector

```python
class SearchVector(*expressions, config=None, weight=None)
```

Searching against a single field is great but rather limiting. The Entry instances we’re searching belong to a Blog, which has a tagline field. To query against both fields, use a `SearchVector`:

```python
>>> from django.contrib.postgres.search import SearchVector
>>> Entry.objects.annotate(...    search=SearchVector('body_text', 'blog__tagline'),
... ).filter(search='Cheese')
[<Entry: Cheese on Toast recipes>, <Entry: Pizza Recipes>]
```

The arguments to `SearchVector` can be any `Expression` or the name of a field. Multiple arguments will be concatenated together using a space so that the search document includes them all.

`SearchVector` objects can be combined together, allowing you to reuse them. For example:

```python
>>> Entry.objects.annotate(...    search=SearchVector('body_text') + SearchVector('blog__tagline'),
```

(continues on next page)
(...).filter(search='Cheese')
[<Entry: Cheese on Toast recipes>, <Entry: Pizza Recipes>]

See Changing the search configuration and Weighting queries for an explanation of the config and weight parameters.

SearchQuery

class SearchQuery(value, config=None, search_type='plain')

SearchQuery translates the terms the user provides into a search query object that the database compares to a search vector. By default, all the words the user provides are passed through the stemming algorithms, and then it looks for matches for all of the resulting terms.

If search_type is 'plain', which is the default, the terms are treated as separate keywords. If search_type is 'phrase', the terms are treated as a single phrase. If search_type is 'raw', then you can provide a formatted search query with terms and operators. If search_type is 'websearch', then you can provide a formatted search query, similar to the one used by web search engines. 'websearch' requires PostgreSQL ≥ 11. Read PostgreSQL’s Full Text Search docs to learn about differences and syntax. Examples:

```python
>>> from django.contrib.postgres.search import SearchQuery
>>> SearchQuery('red tomato')  # two keywords
>>> SearchQuery('tomato red')  # same results as above
>>> SearchQuery('red tomato', search_type='phrase')  # a phrase
>>> SearchQuery('tomato red', search_type='phrase')  # a different phrase
>>> SearchQuery('"tomato & ("red" | "green")', search_type='raw')  # boolean operators
>>> SearchQuery('"tomato ("red" OR "green")", search_type='websearch')  # websearch operators
```

SearchQuery terms can be combined logically to provide more flexibility:

```python
>>> from django.contrib.postgres.search import SearchQuery
>>> SearchQuery('meat') & SearchQuery('cheese')  # AND
>>> SearchQuery('meat') | SearchQuery('cheese')  # OR
>>> ~SearchQuery('meat')  # NOT
```

See Changing the search configuration for an explanation of the config parameter.
SearchRank

class SearchRank(vector, query, weights=None, normalization=None, cover_density=False)

So far, we’ve returned the results for which any match between the vector and the query are possible. It’s likely you may wish to order the results by some sort of relevancy. PostgreSQL provides a ranking function which takes into account how often the query terms appear in the document, how close together the terms are in the document, and how important the part of the document is where they occur. The better the match, the higher the value of the rank. To order by relevancy:

```python
>>> from django.contrib.postgres.search import SearchQuery, SearchRank, SearchVector
>>> vector = SearchVector('body_text')
>>> query = SearchQuery('cheese')
>>> Entry.objects.annotate(rank=SearchRank(vector, query)).order_by('-rank')
[<Entry: Cheese on Toast recipes>, <Entry: Pizza recipes>]
```

See Weighting queries for an explanation of the weights parameter.

Set the cover_density parameter to True to enable the cover density ranking, which means that the proximity of matching query terms is taken into account.

Provide an integer to the normalization parameter to control rank normalization. This integer is a bit mask, so you can combine multiple behaviors:

```python
>>> from django.db.models import Value
>>> Entry.objects.annotate(
...     rank=SearchRank(
...         vector,
...         query,
...         normalization=Value(2).bitor(Value(4)),
...     )
... )
```

The PostgreSQL documentation has more details about different rank normalization options.

SearchHeadline

class SearchHeadline(expression, query, config=None, start_sel=None, stop_sel=None, max_words=None, min_words=None, short_word=None, highlight_all=None, max_fragments=None, fragment_delimiter=None)

Accepts a single text field or an expression, a query, a config, and a set of options. Returns highlighted search results.

Set the start_sel and stop_sel parameters to the string values to be used to wrap highlighted query terms in the document. PostgreSQL’s defaults are `<b>` and `</b>`.
Provide integer values to the `max_words` and `min_words` parameters to determine the longest and shortest headlines. PostgreSQL’s defaults are 35 and 15.

Provide an integer value to the `short_word` parameter to discard words of this length or less in each headline. PostgreSQL’s default is 3.

Set the `highlight_all` parameter to `True` to use the whole document in place of a fragment and ignore `max_words`, `min_words`, and `short_word` parameters. That’s disabled by default in PostgreSQL.

Provide a non-zero integer value to the `max_fragments` to set the maximum number of fragments to display. That’s disabled by default in PostgreSQL.

Set the `fragment_delimiter` string parameter to configure the delimiter between fragments. PostgreSQL’s default is " ... ".

The PostgreSQL documentation has more details on highlighting search results.

Usage example:

```python
>>> from django.contrib.postgres.search import SearchHeadline, SearchQuery
>>> query = SearchQuery('red tomato')
>>> entry = Entry.objects.annotate(
...     headline=SearchHeadline(
...         'body_text',
...         query,
...         start_sel='<span>',
...         stop_sel='</span>',
...     ),
... ).get()
>>> print(entry.headline)
Sandwich with <span>tomato</span> and <span>red</span> cheese.
```

See Changing the search configuration for an explanation of the `config` parameter.

**Changing the search configuration**

You can specify the `config` attribute to a `SearchVector` and `SearchQuery` to use a different search configuration. This allows using different language parsers and dictionaries as defined by the database:

```python
>>> from django.contrib.postgres.search import SearchQuery, SearchVector
>>> Entry.objects.annotate(
...     search=SearchVector('body_text', config='french'),
... ).filter(search=SearchQuery('œuf', config='french'))
[<Entry: Pain perdu>]
```

The value of `config` could also be stored in another column:
>>> from django.db.models import F
>>> Entry.objects.annotate(
...    search=SearchVector('body_text', config=F('blog__language')),
... ).filter(search=SearchQuery('œuf', config=F('blog__language'))))
[<Entry: Pain perdu>]

Weighting queries

Every field may not have the same relevance in a query, so you can set weights of various vectors before you combine them:

```python
>>> from django.contrib.postgres.search import SearchQuery, SearchRank, SearchVector
>>> vector = SearchVector('body_text', weight='A') + SearchVector('blog__tagline', weight='B')
>>> query = SearchQuery('cheese')
>>> Entry.objects.annotate(rank=SearchRank(vector, query)).filter(rank__gte=0.3).order_by('-rank')
```

The weight should be one of the following letters: D, C, B, A. By default, these weights refer to the numbers 0.1, 0.2, 0.4, and 1.0, respectively. If you wish to weight them differently, pass a list of four floats to `SearchRank` as `weights` in the same order above:

```python
>>> rank = SearchRank(vector, query, weights=[0.2, 0.4, 0.6, 0.8])
>>> Entry.objects.annotate(rank=rank).filter(rank__gte=0.3).order_by('-rank')
```

Performance

Special database configuration isn’t necessary to use any of these functions, however, if you’re searching more than a few hundred records, you’re likely to run into performance problems. Full text search is a more intensive process than comparing the size of an integer, for example.

In the event that all the fields you’re querying on are contained within one particular model, you can create a functional `GIN` or `GiST` index which matches the search vector you wish to use. For example:

```python
GinIndex(SearchVector('body_text'), name='body_search_vector_idx')
```

The PostgreSQL documentation has details on creating indexes for full text search.
SearchVectorField

class SearchVectorField

If this approach becomes too slow, you can add a `SearchVectorField` to your model. You’ll need to keep it populated with triggers, for example, as described in the PostgreSQL documentation. You can then query the field as if it were an annotated `SearchVector`:

```python
>>> Entry.objects.update(search_vector=SearchVector('body_text'))
>>> Entry.objects.filter(search_vector='cheese')
[<Entry: Cheese on Toast recipes>, <Entry: Pizza recipes>]
```

Trigram similarity

Another approach to searching is trigram similarity. A trigram is a group of three consecutive characters. In addition to the `trigram_similar`, `trigram_word_similar`, and `trigram_strict_word_similar` lookups, you can use a couple of other expressions.

To use them, you need to activate the `pg_trgm` extension on PostgreSQL. You can install it using the `TrigramExtension` migration operation.

TrigramSimilarity

class TrigramSimilarity(expression, string, **extra)

Accepts a field name or expression, and a string or expression. Returns the trigram similarity between the two arguments.

Usage example:

```python
>>> from django.contrib.postgres.search import TrigramSimilarity
>>> Author.objects.create(name='Katy Stevens')
>>> Author.objects.create(name='Stephen Keats')
>>> test = 'Katie Stephens'
>>> Author.objects.annotate(
...     similarity=TrigramSimilarity('name', test),
...     ).filter(similarity__gt=0.3).order_by('-similarity')
[<Author: Katy Stevens>, <Author: Stephen Keats>]
```
TrigramWordSimilarity

class TrigramWordSimilarity(string, expression, **extra)

Accepts a string or expression, and a field name or expression. Returns the trigram word similarity between the two arguments.

Usage example:

```python
>>> from django.contrib.postgres.search import TrigramWordSimilarity
>>> Author.objects.create(name='Katy Stevens')
>>> Author.objects.create(name='Stephen Keats')
>>> test = 'Kat'
>>> Author.objects.annotate(
...     similarity=TrigramWordSimilarity(test, 'name'),
... ).filter(similarity__gt=0.3).order_by('-similarity')
[<Author: Katy Stevens>]
```

TrigramStrictWordSimilarity

class TrigramStrictWordSimilarity(string, expression, **extra)

Accepts a string or expression, and a field name or expression. Returns the trigram strict word similarity between the two arguments. Similar to TrigramWordSimilarity(), except that it forces extent boundaries to match word boundaries.

TrigramDistance

class TrigramDistance(expression, string, **extra)

Accepts a field name or expression, and a string or expression. Returns the trigram distance between the two arguments.

Usage example:

```python
>>> from django.contrib.postgres.search import TrigramDistance
>>> Author.objects.create(name='Katy Stevens')
>>> Author.objects.create(name='Stephen Keats')
>>> test = 'Katie Stephens'
>>> Author.objects.annotate(
...     distance=TrigramDistance('name', test),
... ).filter(distance__lte=0.7).order_by('distance')
[<Author: Katy Stevens>, <Author: Stephen Keats>]
```
TrigramWordDistance

class TrigramWordDistance(string, expression, **extra)

Accepts a string or expression, and a field name or expression. Returns the trigram word distance between the two arguments.

Usage example:

```python
>>> from django.contrib.postgres.search import TrigramWordDistance
>>> Author.objects.create(name='Katy Stevens')
>>> Author.objects.create(name='Stephen Keats')
>>> test = 'Kat'
>>> Author.objects.annotate(
...     distance=TrigramWordDistance(test, 'name'),
... ).filter(distance__lte=0.7).order_by('distance')
[<Author: Katy Stevens>]
```

TrigramStrictWordDistance

class TrigramStrictWordDistance(string, expression, **extra)

Accepts a string or expression, and a field name or expression. Returns the trigram strict word distance between the two arguments.

Validators

These validators are available from the `django.contrib.postgres.validators` module.

KeysValidator

class KeysValidator(keys, strict=False, messages=None)

Validates that the given keys are contained in the value. If `strict` is True, then it also checks that there are no other keys present.

The `messages` passed should be a dict containing the keys `missing_keys` and/or `extra_keys`.

Note: Note that this checks only for the existence of a given key, not that the value of a key is non-empty.
Range validators

RangeMaxValueValidator

class RangeMaxValueValidator(limit_value, message=None)

Validates that the upper bound of the range is not greater than limit_value.

RangeMinValueValidator

class RangeMinValueValidator(limit_value, message=None)

Validates that the lower bound of the range is not less than the limit_value.

6.5.9 The redirects app

Django comes with an optional redirects application. It lets you store redirects in a database and handles the redirecting for you. It uses the HTTP response status code 301 Moved Permanently by default.

Installation

To install the redirects app, follow these steps:

1. Ensure that the `django.contrib.sites` framework is installed.
2. Add `django.contrib.redirects` to your `INSTALLED_APPS` setting.
3. Add `django.contrib.redirects.middleware.RedirectFallbackMiddleware` to your `MIDDLEWARE` setting.
4. Run the command `manage.py migrate`.

How it works

`manage.py migrate` creates a `django_redirect` table in your database. This is a lookup table with `site_id`, `old_path` and `new_path` fields.

The `RedirectFallbackMiddleware` does all of the work. Each time any Django application raises a 404 error, this middleware checks the redirects database for the requested URL as a last resort. Specifically, it checks for a redirect with the given `old_path` with a site ID that corresponds to the `SITE_ID` setting.

- If it finds a match, and `new_path` is not empty, it redirects to `new_path` using a 301 ("Moved Permanently") redirect. You can subclass `RedirectFallbackMiddleware` and set `response_redirect_class` to `django.http.HttpResponseRedirect` to use a 302 Moved Temporarily redirect instead.
- If it finds a match, and `new_path` is empty, it sends a 410 ("Gone") HTTP header and empty (content-less) response.
• If it doesn’t find a match, the request continues to be processed as usual.

The middleware only gets activated for 404s—not for 500s or responses of any other status code.

Note that the order of MIDDLEWARE matters. Generally, you can put RedirectFallbackMiddleware at the end of the list, because it’s a last resort.

For more on middleware, read the middleware docs.

How to add, change and delete redirects

Via the admin interface

If you’ve activated the automatic Django admin interface, you should see a “Redirects” section on the admin index page. Edit redirects as you edit any other object in the system.

Via the Python API

class models.Redirect

Redirects are represented by a standard Django model, which lives in django/contrib/redirects/models.py. You can access redirect objects via the Django database API. For example:

```python
>>> from django.conf import settings
>>> from django.contrib.redirects.models import Redirect
>>> # Add a new redirect.
>>> redirect = Redirect.objects.create(
...     site_id=1,
...     old_path='/contact-us/',
...     new_path='/contact/',
... )
>>> # Change a redirect.
>>> redirect.new_path = '/contact-details/'
>>> redirect.save()
>>> # Delete a redirect.
>>> Redirect.objects.filter(slide_id=1, old_path='/contact-us/').delete()
(1, {'redirects.Redirect': 1})
```
Middleware

class middleware.RedirectFallbackMiddleware

    You can change the HttpResponse classes used by the middleware by creating a sub-class of RedirectFallbackMiddleware and overriding response_gone_class and/or response_redirect_class.

response_gone_class

    The HttpResponse class used when a Redirect is not found for the requested path or has a blank new_path value.

    Defaults to HttpResponseGone.

response_redirect_class

    The HttpResponse class that handles the redirect.

    Defaults to HttpResponsePermanentRedirect.

6.5.10 The sitemap framework

Django comes with a high-level sitemap-generating framework to create sitemap XML files.

Overview

A sitemap is an XML file on your website that tells search-engine indexers how frequently your pages change and how “important” certain pages are in relation to other pages on your site. This information helps search engines index your site.

The Django sitemap framework automates the creation of this XML file by letting you express this information in Python code.

It works much like Django’s syndication framework. To create a sitemap, write a Sitemap class and point to it in your URLconf.

Installation

To install the sitemap app, follow these steps:

1. Add 'django.contrib.sitemaps' to your INSTALLED_APPS setting.

2. Make sure your TEMPLATES setting contains a DjangoTemplates backend whose APP_DIRS options is set to True. It’s in there by default, so you’ll only need to change this if you’ve changed that setting.

3. Make sure you’ve installed the sites framework.

(Note: The sitemap application doesn’t install any database tables. The only reason it needs to go into INSTALLED_APPS is so that the Loader() template loader can find the default templates.)
Initialization

views.sitemap(request, sitemaps, section=None, template_name='sitemap.xml', content_type='application/xml')

To activate sitemap generation on your Django site, add this line to your URLconf:

```python
from django.contrib.sitemaps.views import sitemap
path('sitemap.xml', sitemap, {'sitemaps': sitemaps},
    name='django.contrib.sitemaps.views.sitemap')
```

This tells Django to build a sitemap when a client accesses /sitemap.xml.

The name of the sitemap file is not important, but the location is. Search engines will only index links in your sitemap for the current URL level and below. For instance, if sitemap.xml lives in your root directory, it may reference any URL in your site. However, if your sitemap lives at /content/sitemap.xml, it may only reference URLs that begin with /content/.

The sitemap view takes an extra, required argument: {'sitemaps': sitemaps}. sitemaps should be a dictionary that maps a short section label (e.g., blog or news) to its Sitemap class (e.g., BlogSitemap or NewsSitemap). It may also map to an instance of a Sitemap class (e.g., BlogSitemap(some_var)).

Sitemap classes

A Sitemap class is a Python class that represents a “section” of entries in your sitemap. For example, one Sitemap class could represent all the entries of your blog, while another could represent all of the events in your events calendar.

In the simplest case, all these sections get lumped together into one sitemap.xml, but it’s also possible to use the framework to generate a sitemap index that references individual sitemap files, one per section. (See Creating a sitemap index below.)

Sitemap classes must subclass django.contrib.sitemaps.Sitemap. They can live anywhere in your code-base.

An example

Let’s assume you have a blog system, with an Entry model, and you want your sitemap to include all the links to your individual blog entries. Here’s how your sitemap class might look:

```python
from django.contrib.sitemaps import Sitemap
from blog.models import Entry

class BlogSitemap(Sitemap):
```

changefreq = "never"
priority = 0.5

def items(self):
    return Entry.objects.filter(is_draft=False)

def lastmod(self, obj):
    return obj.pub_date

Note:

- `changefreq` and `priority` are class attributes corresponding to `<changefreq>` and `<priority>` elements, respectively. They can be made callable as functions, as `lastmod` was in the example.

- `items()` is a method that returns a sequence or QuerySet of objects. The objects returned will get passed to any callable methods corresponding to a sitemap property (`location`, `lastmod`, `changefreq`, and `priority`).

- `lastmod` should return a datetime.

- There is no `location` method in this example, but you can provide it in order to specify the URL for your object. By default, `location()` calls `get_absolute_url()` on each object and returns the result.

Sitemap class reference

class Sitemap

A Sitemap class can define the following methods/attributes:

**items**

Required. A method that returns a sequence or QuerySet of objects. The framework doesn’t care what type of objects they are; all that matters is that these objects get passed to the `location()`, `lastmod()`, `changefreq()` and `priority()` methods.

**location**

Optional. Either a method or attribute.

If it’s a method, it should return the absolute path for a given object as returned by `items()`.

If it’s an attribute, its value should be a string representing an absolute path to use for every object returned by `items()`.

In both cases, “absolute path” means a URL that doesn’t include the protocol or domain. Examples:

- Good: '/foo/bar/
- Bad: 'example.com/foo/bar/'
Bad: 'https://example.com/foo/bar/'

If location isn’t provided, the framework will call the get_absolute_url() method on each object as returned by items().

To specify a protocol other than 'http', use protocol.

lastmod

Optional. Either a method or attribute.

If it’s a method, it should take one argument – an object as returned by items() – and return that object’s last-modified date/time as a datetime.

If it’s an attribute, its value should be a datetime representing the last-modified date/time for every object returned by items().

If all items in a sitemap have a lastmod, the sitemap generated by views.sitemap() will have a Last-Modified header equal to the latest lastmod. You can activate the ConditionalGetMiddleware to make Django respond appropriately to requests with an If-Modified-Since header which will prevent sending the sitemap if it hasn’t changed.

paginate

Optional.

This property returns a Paginator for items(). If you generate sitemaps in a batch you may want to override this as a cached property in order to avoid multiple items() calls.

changefreq

Optional. Either a method or attribute.

If it’s a method, it should take one argument – an object as returned by items() – and return that object’s change frequency as a string.

If it’s an attribute, its value should be a string representing the change frequency of every object returned by items().

Possible values for changefreq, whether you use a method or attribute, are:

- 'always'
- 'hourly'
- 'daily'
- 'weekly'
- 'monthly'
- 'yearly'
- 'never'
priority
Optional. Either a method or attribute.
If it’s a method, it should take one argument—an object as returned by `items()`—and return that object’s priority as either a string or float.
If it’s an attribute, its value should be either a string or float representing the priority of every object returned by `items()`.
Example values for `priority`: `0.4`, `1.0`. The default priority of a page is `0.5`. See the sitemaps.org documentation for more.

protocol
Optional.
This attribute defines the protocol (‘http’ or ‘https’) of the URLs in the sitemap. If it isn’t set, the protocol with which the sitemap was requested is used. If the sitemap is built outside the context of a request, the default is ‘http’.
Deprecated since version 4.0: The default protocol for sitemaps built outside the context of a request will change from ‘http’ to ‘https’ in Django 5.0.

limit
Optional.
This attribute defines the maximum number of URLs included on each page of the sitemap. Its value should not exceed the default value of 50000, which is the upper limit allowed in the Sitemaps protocol.

i18n
Optional.
A boolean attribute that defines if the URLs of this sitemap should be generated using all of your `LANGUAGES`. The default is `False`.

languages
Optional.
A sequence of language codes to use for generating alternate links when `i18n` is enabled. Defaults to `LANGUAGES`.

alternates
Optional.
A boolean attribute. When used in conjunction with `i18n` generated URLs will each have a list of alternate links pointing to other language versions using the `hreflang` attribute. The default is `False`.
x_default

Optional.

A boolean attribute. When True the alternate links generated by alternates will contain a hreflang="x-default" fallback entry with a value of LANGUAGE_CODE. The default is False.

get_latest_lastmod()

Optional. A method that returns the latest value returned by lastmod. This function is used to add the lastmod attribute to Sitemap index context variables.

By default get_latest_lastmod() returns:

• If lastmod is an attribute: lastmod.
• If lastmod is a method: The latest lastmod returned by calling the method with all items returned by Sitemap.items().

Shortcuts

The sitemap framework provides a convenience class for a common case:

class GenericSitemap(info_dict, priority=None, changefreq=None, protocol=None)

The django.contrib.sitemaps.GenericSitemap class allows you to create a sitemap by passing it a dictionary which has to contain at least a queryset entry. This queryset will be used to generate the items of the sitemap. It may also have a date_field entry that specifies a date field for objects retrieved from the queryset. This will be used for the lastmod attribute and get_latest_lastmod() methods in the in generated sitemap.

The priority, changefreq, and protocol keyword arguments allow specifying these attributes for all URLs.

Example

Here’s an example of a URLconf using GenericSitemap:

```
from django.contrib.sitemaps import GenericSitemap
from django.contrib.sitemaps.views import sitemap
from django.urls import path
from blog.models import Entry

info_dict = {
    'queryset': Entry.objects.all(),
    'date_field': 'pub_date',
}
```
urlpatterns = [

    # some generic view using info_dict
    # ...

    # the sitemap
    path('sitemap.xml', sitemap,
         {'sitemaps': {'blog': GenericSitemap(info_dict, priority=0.6)}},
         name='django.contrib.sitemaps.views.sitemap'),
    ]

Sitemap for static views

Often you want the search engine crawlers to index views which are neither object detail pages nor flatpages. The solution is to explicitly list URL names for these views in *items* and call *reverse()* in the location method of the sitemap. For example:

```python
# sitemaps.py
from django.contrib import sitemaps
from django.urls import reverse

class StaticViewSitemap(sitemaps.Sitemap):
    priority = 0.5
    changefreq = 'daily'

    def items(self):
        return ['main', 'about', 'license']

    def location(self, item):
        return reverse(item)

# urls.py
from django.contrib.sitemaps.views import sitemap
from django.urls import path

from .sitemaps import StaticViewSitemap
from . import views

sitemaps = {
    'static': StaticViewSitemap,
}

urlpatterns = [

(continues on next page)
Creating a sitemap index

views.index(request, sitemaps, template_name='sitemap_index.xml', content_type='application/xml',
            sitemap_url_name='django.contrib.sitemaps.views.sitemap')

The sitemap framework also has the ability to create a sitemap index that references individual sitemap files, one per each section defined in your sitemaps dictionary. The only differences in usage are:

- You use two views in your URLconf: django.contrib.sitemaps.views.index() and django.contrib.sitemaps.views.sitemap().
- The django.contrib.sitemaps.views.sitemap() view should take a section keyword argument.

Here’s what the relevant URLconf lines would look like for the example above:

```python
from django.contrib.sitemaps import views

urlpatterns = [
    path('sitemap.xml', views.index, {'sitemaps': sitemaps},
         name='django.contrib.sitemaps.views.sitemap'),
    path('sitemap-<section>.xml', views.sitemap, {'sitemaps': sitemaps},
         name='django.contrib.sitemaps.views.sitemap'),
]
```

This will automatically generate a sitemap.xml file that references both sitemap-flatpages.xml and sitemap-blog.xml. The Sitemap classes and the sitemaps dict don’t change at all.

If all sitemaps have a lastmod returned by Sitemap.get_latest_lastmod() the sitemap index will have a Last-Modified header equal to the latest lastmod.

You should create an index file if one of your sitemaps has more than 50,000 URLs. In this case, Django will automatically paginate the sitemap, and the index will reflect that.

If you’re not using the vanilla sitemap view—for example, if it’s wrapped with a caching decorator—you must name your sitemap view and pass sitemap_url_name to the index view:
from django.contrib.sitemaps import views as sitemaps_views
from django.views.decorators.cache import cache_page

urlpatterns = [
    path('sitemap.xml', cache_page(86400)(sitemaps_views.index),
         {'sitemaps': sitemaps, 'sitemap_url_name': 'sitemaps'}),
    path('sitemap-<section>.xml', cache_page(86400)(sitemaps_views.sitemap),
         {'sitemaps': sitemaps, name='sitemaps'}),
]

Use of the Last-Modified header was added.

**Template customization**

If you wish to use a different template for each sitemap or sitemap index available on your site, you may specify it by passing a `template_name` parameter to the `sitemap` and `index` views via the URLconf:

```python
from django.contrib.sitemaps import views

urlpatterns = [
    path('custom-sitemap.xml', views.index, {
        'sitemaps': sitemaps,
        'template_name': 'custom_sitemap.html'
    }, name='django.contrib.sitemaps.views.index'),
    path('custom-sitemap-<section>.xml', views.sitemap, {
        'sitemaps': sitemaps,
        'template_name': 'custom_sitemap.html'
    }, name='django.contrib.sitemaps.views.sitemap'),
]
```

These views return `TemplateResponse` instances which allow you to easily customize the response data before rendering. For more details, see the `TemplateResponse` documentation.

**Context variables**

When customizing the templates for the `index()` and `sitemap()` views, you can rely on the following context variables.
The variable `sitemaps` is a list of objects containing the `location` and `lastmod` attribute for each of the sitemaps. Each URL exposes the following attributes:

- **location**: The location (url & page) of the sitemap.
- **lastmod**: Populated by the `get_latest_lastmod()` method for each sitemap.

The context was changed to a list of objects with `location` and optional `lastmod` attributes.

The variable `urlset` is a list of URLs that should appear in the sitemap. Each URL exposes attributes as defined in the `Sitemap` class:

- **alternates**
- **changefreq**
- **item**
- **lastmod**
- **location**
- **priority**

The `alternates` attribute is available when `i18n` and `alternates` are enabled. It is a list of other language versions, including the optional `x_default` fallback, for each URL. Each alternate is a dictionary with `location` and `lang_code` keys.

The `item` attribute has been added for each URL to allow more flexible customization of the templates, such as Google news sitemaps. Assuming Sitemap’s `items()` would return a list of items with `publication_data` and a `tags` field something like this would generate a Google News compatible sitemap:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<urlset
  xmlns="https://www.sitemaps.org/schemas/sitemap/0.9"
  xmlns:news="http://www.google.com/schemas/sitemap-news/0.9"
%(spaceless %%)
%(for url in urlset %%)
<url>
  <loc>{{ url.location }}</loc>
%(if url.lastmod %%)
    <lastmod>{{ url.lastmod|date:'Y-m-d' }}</lastmod>
%(endif %)
%(if url.changefreq %%)
    <changefreq>{{ url.changefreq }}</changefreq>
%(endif %)
%(if url.priority %%)
    <priority>{{ url.priority }}</priority>
%(endif %)
%(news:news %)
%(if url.item.publication_date %%)
    <news:publication_date>{{ url.item.publication_date|date:'Y-m-d' }}</news:publication_date>
%(endif %)
```
Pinging Google

You may want to “ping” Google when your sitemap changes, to let it know to reindex your site. The sitemaps framework provides a function to do just that: `django.contrib.sitemaps.ping_google()`.

`ping_google(sitemap_url=None, ping_url=PING_URL, sitemap_uses_https=True)`

`ping_google` takes these optional arguments:

- **sitemap_url** - The absolute path to your site’s sitemap (e.g., '/sitemap.xml').
  - If this argument isn’t provided, `ping_google` will perform a reverse lookup in your URL-conf, for URLs named 'django.contrib.sitemaps.views.index' and then 'django.contrib.sitemaps.views.sitemap' (without further arguments) to automatically determine the sitemap URL.

- **ping_url** - Defaults to Google’s Ping Tool: https://www.google.com/webmasters/tools/ping.

- **sitemap_uses_https** - Set to False if your site uses http rather than https.

`ping_google()` raises the exception `django.contrib.sitemaps.SitemapNotFound` if it cannot determine your sitemap URL.

Register with Google first!

The `ping_google()` command only works if you have registered your site with Google Search Console.

One useful way to call `ping_google()` is from a model’s `save()` method:

```python
from django.contrib.sitemaps import ping_google

class Entry(models.Model):
    # ...
    def save(self, force_insert=False, force_update=False):
        super().save(force_insert, force_update)
        try:
            ping_google()
        except Exception:
            # Handle exception
```

(continues on next page)
A more efficient solution, however, would be to call `ping_google()` from a cron script, or some other scheduled task. The function makes an HTTP request to Google’s servers, so you may not want to introduce that network overhead each time you call `save()`.

**Pinging Google via manage.py**

```
django-admin ping_google [sitemap_url]
```

Once the sitemaps application is added to your project, you may also ping Google using the `ping_google` management command:

```
python manage.py ping_google [/sitemap.xml]
```

```
--sitemap-uses-http
```

Use this option if your sitemap uses http rather than https.

### 6.5.11 The “sites” framework

Django comes with an optional “sites” framework. It’s a hook for associating objects and functionality to particular websites, and it’s a holding place for the domain names and “verbose” names of your Django-powered sites.

Use it if your single Django installation powers more than one site and you need to differentiate between those sites in some way.

The sites framework is mainly based on this model:

```python
class models.Site
    A model for storing the domain and name attributes of a website.

    domain
        The fully qualified domain name associated with the website. For example, www.example.com.

    name
        A human-readable “verbose” name for the website.
```

The `SITE_ID` setting specifies the database ID of the `Site` object associated with that particular settings file. If the setting is omitted, the `get_current_site()` function will try to get the current site by comparing the `domain` with the host name from the `request.get_host()` method.

How you use this is up to you, but Django uses it in a couple of ways automatically via a couple of conventions.
Example usage

Why would you use sites? It’s best explained through examples.

Associating content with multiple sites

The LJWorld.com and Lawrence.com sites are operated by the same news organization—the Lawrence Journal-World newspaper in Lawrence, Kansas. LJWorld.com focused on news, while Lawrence.com focused on local entertainment. But sometimes editors wanted to publish an article on both sites.

The naive way of solving the problem would be to require site producers to publish the same story twice: once for LJWorld.com and again for Lawrence.com. But that’s inefficient for site producers, and it’s redundant to store multiple copies of the same story in the database.

A better solution removes the content duplication: Both sites use the same article database, and an article is associated with one or more sites. In Django model terminology, that’s represented by a ManyToManyField in the Article model:

```python
from django.contrib.sites.models import Site
from django.db import models

class Article(models.Model):
    headline = models.CharField(max_length=200)
    # ...
    sites = models.ManyToManyField(Site)
```

This accomplishes several things quite nicely:

- It lets the site producers edit all content—on both sites—in a single interface (the Django admin).
- It means the same story doesn’t have to be published twice in the database; it only has a single record in the database.
- It lets the site developers use the same Django view code for both sites. The view code that displays a given story checks to make sure the requested story is on the current site. It looks something like this:

```python
from django.contrib.sites.shortcuts import get_current_site

def article_detail(request, article_id):
    try:
        a = Article.objects.get(id=article_id, sites__id=get_current_site(request).id)
    except Article.DoesNotExist:
        raise Http404("Article does not exist on this site")
    # ...
```
Associating content with a single site

Similarly, you can associate a model to the `Site` model in a many-to-one relationship, using `ForeignKey`.

For example, if an article is only allowed on a single site, you’d use a model like this:

```python
from django.contrib.sites.models import Site
from django.db import models

class Article(models.Model):
    headline = models.CharField(max_length=200)
    # ...
    site = models.ForeignKey(Site, on_delete=models.CASCADE)
```

This has the same benefits as described in the last section.

Hooking into the current site from views

You can use the sites framework in your Django views to do particular things based on the site in which the view is being called. For example:

```python
from django.conf import settings

def my_view(request):
    if settings.SITE_ID == 3:
        # Do something.
        pass
    else:
        # Do something else.
        pass
```

It’s fragile to hard-code the site IDs like that, in case they change. The cleaner way of accomplishing the same thing is to check the current site’s domain:

```python
from django.contrib.sites.shortcuts import get_current_site

def my_view(request):
    current_site = get_current_site(request)
    if current_site.domain == 'foo.com':
        # Do something
        pass
    else:
        # Do something else.
        pass
```
This has also the advantage of checking if the sites framework is installed, and return a `RequestSite` instance if it is not.

If you don’t have access to the request object, you can use the `get_current()` method of the `Site` model’s manager. You should then ensure that your settings file does contain the `SITE_ID` setting. This example is equivalent to the previous one:

```python
from django.contrib.sites.models import Site

def my_function_without_request():
    current_site = Site.objects.get_current()
    if current_site.domain == 'foo.com':
        # Do something
        pass
    else:
        # Do something else.
        pass
```

### Getting the current domain for display

LJWorld.com and Lawrence.com both have email alert functionality, which lets readers sign up to get notifications when news happens. It’s pretty basic: A reader signs up on a web form and immediately gets an email saying, “Thanks for your subscription.”

It’d be inefficient and redundant to implement this sign up processing code twice, so the sites use the same code behind the scenes. But the “thank you for signing up” notice needs to be different for each site. By using `Site` objects, we can abstract the “thank you” notice to use the values of the current site’s `name` and `domain`.

Here’s an example of what the form-handling view looks like:

```python
from django.contrib.sites.shortcuts import get_current_site
from django.core.mail import send_mail

def register_for_newsletter(request):
    # Check form values, etc., and subscribe the user.
    # ...

    current_site = get_current_site(request)
    send_mail('Thanks for subscribing to %s alerts' % current_site.name,
              'Thanks for your subscription. We appreciate it.
               The %s team.' % (current_site.name,
                              ),
```

(continues on next page)
On Lawrence.com, this email has the subject line “Thanks for subscribing to lawrence.com alerts.” On LJWorld.com, the email has the subject “Thanks for subscribing to LJWorld.com alerts.” Same goes for the email’s message body.

Note that an even more flexible (but more heavyweight) way of doing this would be to use Django’s template system. Assuming Lawrence.com and LJWorld.com have different template directories (DIRS), you could farm out to the template system like so:

```python
from django.core.mail import send_mail
from django.template import loader

def register_for_newsletter(request):
    # Check form values, etc., and subscribe the user.
    # ...

    subject = loader.get_template('alerts/subject.txt').render({})
    message = loader.get_template('alerts/message.txt').render({})
    send_mail(subject, message, 'editor@ljworld.com', [user.email])
    # ...
```

In this case, you’d have to create subject.txt and message.txt template files for both the LJWorld.com and Lawrence.com template directories. That gives you more flexibility, but it’s also more complex.

It’s a good idea to exploit the Site objects as much as possible, to remove unneeded complexity and redundancy.

### Getting the current domain for full URLs

Django’s get_absolute_url() convention is nice for getting your objects’ URL without the domain name, but in some cases you might want to display the full URL – with http:// and the domain and everything – for an object. To do this, you can use the sites framework. An example:

```python
>>> from django.contrib.sites.models import Site
>>> obj = MyModel.objects.get(id=3)
>>> obj.get_absolute_url()
'/mymodel/objects/3/'
```
Enabling the sites framework

To enable the sites framework, follow these steps:

1. Add 'django.contrib.sites' to your `INSTALLED_APPS` setting.

2. Define a `SITE_ID` setting:

   ```
   SITE_ID = 1
   ```

3. Run `migrate`.

django.contrib.sites registers a `post_migrate` signal handler which creates a default site named example.com with the domain example.com. This site will also be created after Django creates the test database. To set the correct name and domain for your project, you can use a data migration.

In order to serve different sites in production, you’d create a separate settings file with each SITE_ID (perhaps importing from a common settings file to avoid duplicating shared settings) and then specify the appropriate `DJANGO_SETTINGS_MODULE` for each site.

Caching the current Site object

As the current site is stored in the database, each call to `Site.objects.get_current()` could result in a database query. But Django is a little cleverer than that: on the first request, the current site is cached, and any subsequent call returns the cached data instead of hitting the database.

If for any reason you want to force a database query, you can tell Django to clear the cache using `Site.objects.clear_cache()`:

```python
# First call; current site fetched from database.
current_site = Site.objects.get_current()
# ...

# Second call; current site fetched from cache.
current_site = Site.objects.get_current()
# ...

# Force a database query for the third call.
```
Site.objects.clear_cache()
current_site = Site.objects.get_current()

The CurrentSiteManager

class managers.CurrentSiteManager

If `Site` plays a key role in your application, consider using the helpful `CurrentSiteManager` in your model(s). It’s a model manager that automatically filters its queries to include only objects associated with the current `Site`.

Mandatory SITE_ID

The `CurrentSiteManager` is only usable when the `SITE_ID` setting is defined in your settings.

Use `CurrentSiteManager` by adding it to your model explicitly. For example:

```python
from django.contrib.sites.models import Site
from django.contrib.sites.managers import CurrentSiteManager
from django.db import models

class Photo(models.Model):
    photo = models.FileField(upload_to='photos')
    photographer_name = models.CharField(max_length=100)
    pub_date = models.DateField()
    site = models.ForeignKey(Site, on_delete=models.CASCADE)
    objects = models.Manager()
    on_site = CurrentSiteManager()
```

With this model, `Photo.objects.all()` will return all Photo objects in the database, but `Photo.on_site.all()` will return only the Photo objects associated with the current site, according to the `SITE_ID` setting.

Put another way, these two statements are equivalent:

```python
Photo.objects.filter(site=settings.SITE_ID)
Photo.on_site.all()
```

How did `CurrentSiteManager` know which field of Photo was the `Site`? By default, `CurrentSiteManager` looks for a either a `ForeignKey` called `site` or a `ManyToManyField` called `sites` to filter on. If you use a field named something other than `site` or `sites` to identify which `Site` objects your object is related to, then you need to explicitly pass the custom field name as a parameter to `CurrentSiteManager` on your model. The following model, which has a field called `publish_on`, demonstrates this:
from django.contrib.sites.models import Site
from django.contrib.sites.managers import CurrentSiteManager
from django.db import models

class Photo(models.Model):
    photo = models.FileField(upload_to='photos')
    photographer_name = models.CharField(max_length=100)
    pub_date = models.DateField()
    publish_on = models.ForeignKey(Site, on_delete=models.CASCADE)
    objects = models.Manager()
    on_site = CurrentSiteManager('publish_on')

If you attempt to use `CurrentSiteManager` and pass a field name that doesn’t exist, Django will raise a `ValueError`.

Finally, note that you’ll probably want to keep a normal (non-site-specific) `Manager` on your model, even if you use `CurrentSiteManager`. As explained in the manager documentation, if you define a manager manually, then Django won’t create the automatic `objects = models.Manager()` manager for you. Also note that certain parts of Django – namely, the Django admin site and generic views – use whichever manager is defined first in the model, so if you want your admin site to have access to all objects (not just site-specific ones), put `objects = models.Manager()` in your model, before you define `CurrentSiteManager`.

Site middleware

If you often use this pattern:

```python
from django.contrib.sites.models import Site

def my_view(request):
    site = Site.objects.get_current()
    ...
```

To avoid repetitions, add `django.contrib.sites.middleware.CurrentSiteMiddleware` to `MIDDLEWARE`. The middleware sets the `site` attribute on every request object, so you can use `request.site` to get the current site.
How Django uses the sites framework

Although it’s not required that you use the sites framework, it’s strongly encouraged, because Django takes advantage of it in a few places. Even if your Django installation is powering only a single site, you should take the two seconds to create the site object with your domain and name, and point to its ID in your SITE_ID setting.

Here’s how Django uses the sites framework:

- In the redirects framework, each redirect object is associated with a particular site. When Django searches for a redirect, it takes into account the current site.

- In the flatpages framework, each flatpage is associated with a particular site. When a flatpage is created, you specify its Site, and the FlatpageFallbackMiddleware checks the current site in retrieving flatpages to display.

- In the syndication framework, the templates for title and description automatically have access to a variable {{ site }}, which is the Site object representing the current site. Also, the hook for providing item URLs will use the domain from the current Site object if you don’t specify a fully-qualified domain.

- In the authentication framework, django.contrib.auth.views.LoginView passes the current Site name to the template as {{ site_name }}.

- The shortcut view (django.contrib.contenttypes.views.shortcut) uses the domain of the current Site object when calculating an object’s URL.

- In the admin framework, the “view on site” link uses the current Site to work out the domain for the site that it will redirect to.

RequestSite objects

Some django.contrib applications take advantage of the sites framework but are architected in a way that doesn’t require the sites framework to be installed in your database. (Some people don’t want to, or just aren’t able to install the extra database table that the sites framework requires.) For those cases, the framework provides a django.contrib.sites.requests.RequestSite class, which can be used as a fallback when the database-backed sites framework is not available.

class requests.RequestSite

A class that shares the primary interface of Site (i.e., it has domain and name attributes) but gets its data from a Django HttpRequest object rather than from a database.

__init__(request)

Sets the name and domain attributes to the value of get_host().

A RequestSite object has a similar interface to a normal Site object, except its __init__() method takes an HttpRequest object. It’s able to deduce the domain and name by looking at the request’s domain. It has
save() and delete() methods to match the interface of Site, but the methods raise NotImplementedError.

**get_current_site shortcut**

Finally, to avoid repetitive fallback code, the framework provides a django.contrib.sites.shortcuts.get_current_site() function.

shortcuts.get_current_site(request)

A function that checks if django.contrib.sites is installed and returns either the current Site object or a RequestSite object based on the request. It looks up the current site based on request.get_host() if the SITE_ID setting is not defined.

Both a domain and a port may be returned by request.get_host() when the Host header has a port explicitly specified, e.g. example.com:80. In such cases, if the lookup fails because the host does not match a record in the database, the port is stripped and the lookup is retried with the domain part only. This does not apply to RequestSite which will always use the unmodified host.

### 6.5.12 The staticfiles app

django.contrib.staticfiles collects static files from each of your applications (and any other places you specify) into a single location that can easily be served in production.

See also:

For an introduction to the static files app and some usage examples, see How to manage static files (e.g. images, JavaScript, CSS). For guidelines on deploying static files, see How to deploy static files.

**Settings**

See staticfiles settings for details on the following settings:

- STATIC_ROOT
- STATIC_URL
- STATICFILES_DIRS
- STATICFILES_STORAGE
- STATICFILES_FINDERS
Management Commands

django.contrib.staticfiles exposes three management commands.

collectstatic

django-admin collectstatic

Collects the static files into STATIC_ROOT.

Duplicate file names are by default resolved in a similar way to how template resolution works: the file that is first found in one of the specified locations will be used. If you’re confused, the findstatic command can help show you which files are found.

On subsequent collectstatic runs (if STATIC_ROOT isn’t empty), files are copied only if they have a modified timestamp greater than the timestamp of the file in STATIC_ROOT. Therefore if you remove an application from INSTALLED_APPS, it’s a good idea to use the collectstatic --clear option in order to remove stale static files.

Files are searched by using the enabled finders. The default is to look in all locations defined in STATICFILES_DIRS and in the ‘static’ directory of apps specified by the INSTALLED_APPS setting.

The collectstatic management command calls the post_process() method of the STATICFILES_STORAGE after each run and passes a list of paths that have been found by the management command. It also receives all command line options of collectstatic. This is used by the ManifestStaticFilesStorage by default.

By default, collected files receive permissions from FILE_UPLOAD_PERMISSIONS and collected directories receive permissions from FILE_UPLOAD_DIRECTORY_PERMISSIONS. If you would like different permissions for these files and/or directories, you can subclass either of the static files storage classes and specify the file_permissions_mode and/or directory_permissions_mode parameters, respectively. For example:

```python
from django.contrib.staticfiles import storage

class MyStaticFilesStorage(storage.StaticFilesStorage):
    def __init__(self, *args, **kwargs):
        kwargs['file_permissions_mode'] = 0o640
        kwargs['directory_permissions_mode'] = 0o760
        super().__init__(*args, **kwargs)

Then set the STATICFILES_STORAGE setting to 'path.to.MyStaticFilesStorage'.

Some commonly used options are:

--noinput, --no-input

Do NOT prompt the user for input of any kind.
--ignore PATTERN, -i PATTERN
Ignore files, directories, or paths matching this glob-style pattern. Use multiple times to ignore more. When specifying a path, always use forward slashes, even on Windows.

--dry-run, -n
Do everything except modify the filesystem.

--clear, -c
Clear the existing files before trying to copy or link the original file.

--link, -l
Create a symbolic link to each file instead of copying.

--no-post-process
Don’t call the post_process() method of the configured STATICFILES_STORAGE storage backend.

--no-default-ignore
Don’t ignore the common private glob-style patterns ‘CVS’, ‘.’ and ‘*~’.

For a full list of options, refer to the commands own help by running:

```
$ python manage.py collectstatic --help
```

**Customizing the ignored pattern list**

The default ignored pattern list, `['CVS', '.', '*~']`, can be customized in a more persistent way than providing the `--ignore` command option at each `collectstatic` invocation. Provide a custom AppConfig class, override the `ignore_patterns` attribute of this class and replace 'django.contrib.staticfiles' with that class path in your INSTALLED_APPS setting:

```
from django.contrib.staticfiles.apps import StaticFilesConfig

class MyStaticFilesConfig(StaticFilesConfig):
    ignore_patterns = [...] # your custom ignore list
```

**findstatic**

```
django-admin findstatic staticfile [staticfile ...]
```

Searches for one or more relative paths with the enabled finders.

For example:
$ python manage.py findstatic css/base.css admin/js/core.js

Found 'css/base.css' here:
  /home/special.polls.com/core/static/css/base.css
  /home/polls.com/core/static/css/base.css

Found 'admin/js/core.js' here:
  /home/polls.com/src/django/contrib/admin/media/js/core.js

**findstatic --first**

By default, all matching locations are found. To only return the first match for each relative path, use the `--first` option:

```
$ python manage.py findstatic css/base.css --first
```

This is a debugging aid; it’ll show you exactly which static file will be collected for a given path.

By setting the `--verbosity` flag to 0, you can suppress the extra output and just get the path names:

```
$ python manage.py findstatic css/base.css --verbosity 0
/home/special.polls.com/core/static/css/base.css
/home/polls.com/core/static/css/base.css
```

On the other hand, by setting the `--verbosity` flag to 2, you can get all the directories which were searched:

```
$ python manage.py findstatic css/base.css --verbosity 2
```

**runserver**

```
django-admin runserver [addrport]
```

Overrides the core `runserver` command if the `staticfiles` app is installed and adds automatic serving of static files. File serving doesn’t run through MIDDLEWARE.

The command adds these options:

`--nostaic`
Use the --nostatic option to disable serving of static files with the staticfiles app entirely. This option is only available if the staticfiles app is in your project’s INSTALLED_APPS setting.

Example usage:

```
$ django-admin runserver --nstatic
```

--insecure

Use the --insecure option to force serving of static files with the staticfiles app even if the DEBUG setting is False. By using this you acknowledge the fact that it’s grossly inefficient and probably insecure. This is only intended for local development, should never be used in production and is only available if the staticfiles app is in your project’s INSTALLED_APPS setting.

--insecure doesn’t work with ManifestStaticFilesStorage.

Example usage:

```
$ django-admin runserver --insecure
```

**Storages**

**StaticFilesStorage**

class storage.StaticFilesStorage

A subclass of the FileSystemStorage storage backend that uses the STATIC_ROOT setting as the base file system location and the STATIC_URL setting respectively as the base URL.

storage.StaticFilesStorage.post_process(paths, **options)

If this method is defined on a storage, it’s called by the collectstatic management command after each run and gets passed the local storages and paths of found files as a dictionary, as well as the command line options. It yields tuples of three values: original_path, processed_path, processed. The path values are strings and processed is a boolean indicating whether or not the value was post-processed, or an exception if post-processing failed.

The ManifestStaticFilesStorage uses this behind the scenes to replace the paths with their hashed counterparts and update the cache appropriately.
ManifestStaticFilesStorage

class storage.ManifestStaticFilesStorage

A subclass of the StaticFilesStorage storage backend which stores the file names it handles by appending the MD5 hash of the file’s content to the filename. For example, the file css/styles.css would also be saved as css/styles.55e7cbb9ba48.css.

The purpose of this storage is to keep serving the old files in case some pages still refer to those files, e.g. because they are cached by you or a 3rd party proxy server. Additionally, it’s very helpful if you want to apply far future Expires headers to the deployed files to speed up the load time for subsequent page visits.

The storage backend automatically replaces the paths found in the saved files matching other saved files with the path of the cached copy (using the post_process() method). The regular expressions used to find those paths (django.contrib.staticfiles.storage.HashedFilesMixin.patterns) cover:

- The @import rule and url() statement of Cascading Style Sheets.
- Source map comments in CSS and JavaScript files.

For example, the 'css/styles.css' file with this content:

```python
@import url("../admin/css/base.css");
```

...would be replaced by calling the url() method of the ManifestStaticFilesStorage storage backend, ultimately saving a 'css/styles.55e7cbb9ba48.css' file with the following content:

```python
@import url("../admin/css/base.27e20196a850.css");
```

You can change the location of the manifest file by using a custom ManifestStaticFilesStorage subclass that sets the manifest_storage argument. For example:

```python
from django.conf import settings
from django.contrib.staticfiles.storage import (  
    ManifestStaticFilesStorage, StaticFilesStorage,  
)

class MyManifestStaticFilesStorage(ManifestStaticFilesStorage):
    def __init__(self, *args, **kwargs):
        manifest_storage = StaticFilesStorage(location=settings.BASE_DIR)
        super().__init__(*args, manifest_storage=manifest_storage, **kwargs)
```

Support for finding paths in CSS source map comments was added.

storage.ManifestStaticFilesStorage.max_post_process_passes

Since static files might reference other static files that need to have their paths replaced, multiple passes of replacing paths may be needed until the file hashes converge. To prevent an infinite loop due to hashes
not converging (for example, if 'foo.css' references 'bar.css' which references 'foo.css') there is a maximum number of passes before post-processing is abandoned. In cases with a large number of references, a higher number of passes might be needed. Increase the maximum number of passes by subclassing ManifestStaticFilesStorage and setting the max_post_process_passes attribute. It defaults to 5.

To enable the ManifestStaticFilesStorage you have to make sure the following requirements are met:

- the STATICFILES_STORAGE setting is set to 'django.contrib.staticfiles.storage.ManifestStaticFilesStorage'
- the DEBUG setting is set to False
- you’ve collected all your static files by using the collectstatic management command

Since creating the MD5 hash can be a performance burden to your website during runtime, staticfiles will automatically store the mapping with hashed names for all processed files in a file called staticfiles.json. This happens once when you run the collectstatic management command.

storage.ManifestStaticFilesStorage.manifest_strict

If a file isn’t found in the staticfiles.json manifest at runtime, a ValueError is raised. This behavior can be disabled by subclassing ManifestStaticFilesStorage and setting the manifest_strict attribute to False – nonexistent paths will remain unchanged.

Due to the requirement of running collectstatic, this storage typically shouldn’t be used when running tests as collectstatic isn’t run as part of the normal test setup. During testing, ensure that the STATICFILES_STORAGE setting is set to something else like 'django.contrib.staticfiles.storage.StaticFilesStorage' (the default).

storage.ManifestStaticFilesStorage.file_hash(name, content=None)

The method that is used when creating the hashed name of a file. Needs to return a hash for the given file name and content. By default it calculates a MD5 hash from the content’s chunks as mentioned above. Feel free to override this method to use your own hashing algorithm.

ManifestFilesMixin

class storage.ManifestFilesMixin

Use this mixin with a custom storage to append the MD5 hash of the file’s content to the filename as ManifestStaticFilesStorage does.
Finders Module

staticfiles finders has a searched_locations attribute which is a list of directory paths in which the finders searched. Example usage:

```python
from django.contrib.staticfiles import finders

result = finders.find('css/base.css')
searched_locations = finders.searched_locations
```

Other Helpers

There are a few other helpers outside of the staticfiles app to work with static files:

- The `django.template.context_processors.static() context processor which adds STATIC_URL to every template context rendered with RequestContext contexts.`
- The builtin template tag `static` which takes a path and urljoins it with the static prefix STATIC_URL. If `django.contrib.staticfiles` is installed, the tag uses the `url()` method of the STATICFILES_STORAGE instead.
- The builtin template tag `get_static_prefix` which populates a template variable with the static prefix STATIC_URL to be used as a variable or directly.
- The similar template tag `get_media_prefix` which works like `get_static_prefix` but uses MEDIA_URL.

Static file development view

The static files tools are mostly designed to help with getting static files successfully deployed into production. This usually means a separate, dedicated static file server, which is a lot of overhead to mess with when developing locally. Thus, the staticfiles app ships with a quick and dirty helper view that you can use to serve files locally in development.

```python
views.serve(request, path)
```

This view function serves static files in development.

**Warning:** This view will only work if DEBUG is True.

That’s because this view is grossly inefficient and probably insecure. This is only intended for local development, and should never be used in production.

**Note:** To guess the served files’ content types, this view relies on the mimetypes module from the Python standard library, which itself relies on the underlying platform’s map files. If you find that this view doesn’t
return proper content types for certain files, it is most likely that the platform’s map files are incorrect or need to be updated. This can be achieved, for example, by installing or updating the mailcap package on a Red Hat distribution, mime-support on a Debian distribution, or by editing the keys under HKEY_CLASSES_ROOT in the Windows registry.

This view is automatically enabled by `runserver` (with a DEBUG setting set to True). To use the view with a different local development server, add the following snippet to the end of your primary URL configuration:

```python
from django.conf import settings
from django.contrib.staticfiles import views
from django.urls import re_path

if settings.DEBUG:
    urlpatterns += [
        re_path(r'^static/(?P<path>.*)$', views.serve),
    ]

Note, the beginning of the pattern (r'^static/') should be your STATIC_URL setting.

Since this is a bit finicky, there’s also a helper function that’ll do this for you:

```python
urls.staticfiles_urlpatterns()
```

This will return the proper URL pattern for serving static files to your already defined pattern list. Use it like this:

```python
from django.contrib.staticfiles.urls import staticfiles_urlpatterns

# ... the rest of your URLconf here ...

urlpatterns += staticfiles_urlpatterns()
```

This will inspect your STATIC_URL setting and wire up the view to serve static files accordingly. Don’t forget to set the STATICFILES_DIRS setting appropriately to let django.contrib.staticfiles know where to look for files in addition to files in app directories.

Warning: This helper function will only work if DEBUG is True and your STATIC_URL setting is neither empty nor a full URL such as http://static.example.com/.

That’s because this view is grossly inefficient and probably insecure. This is only intended for local development, and should never be used in production.
Specialized test case to support ‘live testing’

class testing StaticLiveServerTestCase

This unittest TestCase subclass extends django.test.LiveServerTestCase. Just like its parent, you can use it to write tests that involve running the code under test and consuming it with testing tools through HTTP (e.g. Selenium, PhantomJS, etc.), because of which it’s needed that the static assets are also published.

But given the fact that it makes use of the django.contrib.staticfiles.views.serve() view described above, it can transparently overlay at test execution-time the assets provided by the staticfiles finders. This means you don’t need to run collectstatic before or as a part of your tests setup.

6.5.13 The syndication feed framework

Django comes with a high-level syndication-feed-generating framework for creating RSS and Atom feeds.

To create any syndication feed, all you have to do is write a short Python class. You can create as many feeds as you want.

Django also comes with a lower-level feed-generating API. Use this if you want to generate feeds outside of a web context, or in some other lower-level way.

The high-level framework

Overview

The high-level feed-generating framework is supplied by the Feed class. To create a feed, write a Feed class and point to an instance of it in your URLconf.

Feed classes

A Feed class is a Python class that represents a syndication feed. A feed can be simple (e.g., a “site news” feed, or a basic feed displaying the latest entries of a blog) or more complex (e.g., a feed displaying all the blog entries in a particular category, where the category is variable).

Feed classes subclass django.contrib.syndication.views.Feed. They can live anywhere in your codebase. Instances of Feed classes are views which can be used in your URLconf.
A simple example

This simple example, taken from a hypothetical police beat news site describes a feed of the latest five news items:

```python
from django.contrib.syndication.views import Feed
from django.urls import reverse
from policebeat.models import NewsItem

class LatestEntriesFeed(Feed):
    title = "Police beat site news"
    link = "/sitenews/"
    description = "Updates on changes and additions to police beat central."

    def items(self):
        return NewsItem.objects.order_by('-pub_date')[:5]

    def item_title(self, item):
        return item.title

    def item_description(self, item):
        return item.description

    # item_link is only needed if NewsItem has no get_absolute_url method.
    def item_link(self, self, item):
        return reverse('news-item', args=[item.pk])
```

To connect a URL to this feed, put an instance of the Feed object in your URLconf. For example:

```python
from django.urls import path
from myproject.feeds import LatestEntriesFeed

urlpatterns = [
    # ...
    path('latest/feed/', LatestEntriesFeed()),
    # ...
]
```

Note:

- The Feed class subclasses `django.contrib.syndication.views.Feed`.
- `title`, `link` and `description` correspond to the standard RSS `<title>`, `<link>` and `<description>` elements, respectively.
- `items()` is a method that returns a list of objects that should be included in the feed as `<item>` elements. Although this example returns `NewsItem` objects using Django’s object-relational mapper, `items()`
doesn’t have to return model instances. Although you get a few bits of functionality “for free” by using Django models, `items()` can return any type of object you want.

- If you’re creating an Atom feed, rather than an RSS feed, set the `subtitle` attribute instead of the `description` attribute. See Publishing Atom and RSS feeds in tandem, later, for an example.

One thing is left to do. In an RSS feed, each `<item>` has a `<title>`, `<link>` and `<description>`. We need to tell the framework what data to put into those elements.

- For the contents of `<title>` and `<description>`, Django tries calling the methods `item_title()` and `item_description()` on the `Feed` class. They are passed a single parameter, `item`, which is the object itself. These are optional; by default, the string representation of the object is used for both.

If you want to do any special formatting for either the title or description, Django templates can be used instead. Their paths can be specified with the `title_template` and `description_template` attributes on the `Feed` class. The templates are rendered for each item and are passed two template context variables:

- `{% obj %}` – The current object (one of whichever objects you returned in `items()`).
- `{% site %}` – A `django.contrib.sites.models.Site` object representing the current site. This is useful for `{% site.domain %}` or `{% site.name %}`. If you do not have the Django sites framework installed, this will be set to a `RequestSite` object. See the RequestSite section of the sites framework documentation for more.

See a complex example below that uses a description template.

**Feed.get_context_data(**kwargs)**

There is also a way to pass additional information to title and description templates, if you need to supply more than the two variables mentioned before. You can provide your implementation of `get_context_data` method in your `Feed` subclass. For example:

```python
from mysite.models import Article
from django.contrib.syndication.views import Feed

class ArticlesFeed(Feed):
    title = "My articles"
    description_template = "feeds/articles.html"

    def items(self):
        return Article.objects.order_by('-pub_date')[:5]

    def get_context_data(self, **kwargs):
        context = super().get_context_data(**kwargs)
        context['foo'] = 'bar'
        return context
```

And the template:
This method will be called once per each item in the list returned by `items()` with the following keyword arguments:

- **item**: the current item. For backward compatibility reasons, the name of this context variable is `{{ obj }}`.
- **obj**: the object returned by `get_object()`. By default this is not exposed to the templates to avoid confusion with `{{ obj }}` (see above), but you can use it in your implementation of `get_context_data()`.
- **site**: current site as described above.
- **request**: current request.

The behavior of `get_context_data()` mimics that of [generic views](https://docs.djangoproject.com/en/3.2/topics/class-based-views/generic-display/) - you’re supposed to call `super()` to retrieve context data from parent class, add your data and return the modified dictionary.

- To specify the contents of `<link>`, you have two options. For each item in `items()`, Django first tries calling the `item_link()` method on the `Feed` class. In a similar way to the title and description, it is passed it a single parameter, **item**. If that method doesn’t exist, Django tries executing a `get_absolute_url()` method on that object. Both `get_absolute_url()` and `item_link()` should return the item’s URL as a normal Python string. As with `get_absolute_url()`, the result of `item_link()` will be included directly in the URL, so you are responsible for doing all necessary URL quoting and conversion to ASCII inside the method itself.

### A complex example

The framework also supports more complex feeds, via arguments.

For example, a website could offer an RSS feed of recent crimes for every police beat in a city. It’d be silly to create a separate `Feed` class for each police beat; that would violate the [DRY principle](https://en.wikipedia.org/wiki/Don%27t_repeat_yourself) and would couple data to programming logic. Instead, the syndication framework lets you access the arguments passed from your URLconf so feeds can output items based on information in the feed’s URL.

The police beat feeds could be accessible via URLs like this:

- `/beats/613/rss/` - Returns recent crimes for beat 613.
- `/beats/1424/rss/` - Returns recent crimes for beat 1424.

These can be matched with a URLconf line such as:

```python
path('beats/<int:beat_id>/rss/', BeatFeed()),
```

Like a view, the arguments in the URL are passed to the `get_object()` method along with the request object. Here’s the code for these beat-specific feeds:
from django.contrib.syndication.views import Feed

class BeatFeed(Feed):
    description_template = 'feeds/beat_description.html'

def get_object(self, request, beat_id):
    return Beat.objects.get(pk=beat_id)

def title(self, obj):
    return "Police beat central: Crimes for beat %s" % obj.beat

def link(self, obj):
    return obj.get_absolute_url()

def description(self, obj):
    return "Crimes recently reported in police beat %s" % obj.beat

def items(self, obj):
    return Crime.objects.filter(beat=obj).order_by('-crime_date')[:30]

To generate the feed’s <title>, <link> and <description>, Django uses the title(), link() and description() methods. In the previous example, they were string class attributes, but this example illustrates that they can be either strings or methods. For each of title, link and description, Django follows this algorithm:

- First, it tries to call a method, passing the obj argument, where obj is the object returned by get_object().
- Failing that, it tries to call a method with no arguments.
- Failing that, it uses the class attribute.

Also note that items() also follows the same algorithm – first, it tries items(obj), then items(), then finally an items class attribute (which should be a list).

We are using a template for the item descriptions. It can be as minimal as this:

```html
{{ obj.description }}
```

However, you are free to add formatting as desired.

The ExampleFeed class below gives full documentation on methods and attributes of Feed classes.
Specifying the type of feed

By default, feeds produced in this framework use RSS 2.0.

To change that, add a `feed_type` attribute to your `Feed` class, like so:

```python
from django.utils.feedgenerator import Atom1Feed

class MyFeed(Feed):
    feed_type = Atom1Feed
```

Note that you set `feed_type` to a class object, not an instance.

Currently available `feed_type` to a class object, not an instance.

Currently available `feed_type` are:

- `django.utils.feedgenerator.Rss201rev2Feed` (RSS 2.0.1. Default.)
- `django.utils.feedgenerator.RssUserland091Feed` (RSS 0.91.)
- `django.utils.feedgenerator.Atom1Feed` (Atom 1.0.)

Enclosures

To specify enclosures, such as those used in creating podcast feeds, use the `item_enclosures` hook or, alternatively and if you only have a single enclosure per item, the `item_enclosure_url`, `item_enclosure_length`, and `item_enclosure_mime_type` hooks. See the `ExampleFeed` class below for usage examples.

Language

Feeds created by the syndication framework automatically include the appropriate `<language>` tag (RSS 2.0) or `xml:lang` attribute (Atom). By default, this is `django.utils.translation.get_language()`. You can change it by setting the `language` class attribute.

URLs

The `link` method/attribute can return either an absolute path (e.g. `"/blog/"`) or a URL with the fully-qualified domain and protocol (e.g. "https://www.example.com/blog/"). If `link` doesn’t return the domain, the syndication framework will insert the domain of the current site, according to your `SITE_ID setting`.

Atom feeds require a `<link rel="self">` that defines the feed’s current location. The syndication framework populates this automatically, using the domain of the current site according to the `SITE_ID setting`. 
Publishing Atom and RSS feeds in tandem

Some developers like to make available both Atom and RSS versions of their feeds. To do that, you can create a subclass of your `Feed` class and set the `feed_type` to something different. Then update your URLconf to add the extra versions.

Here’s a full example:

```python
from django.contrib.syndication.views import Feed
from policebeat.models import NewsItem
from django.utils.feedgenerator import Atom1Feed

class RssSiteNewsFeed(Feed):
    title = "Police beat site news"
    link = "/sitenews/"
    description = "Updates on changes and additions to police beat central."

    def items(self):
        return NewsItem.objects.order_by('-pub_date')[:5]

class AtomSiteNewsFeed(RssSiteNewsFeed):
    feed_type = Atom1Feed
    subtitle = RssSiteNewsFeed.description

Note: In this example, the RSS feed uses a description while the Atom feed uses a subtitle. That’s because Atom feeds don’t provide for a feed-level “description,” but they do provide for a “subtitle.”

If you provide a description in your `Feed` class, Django will not automatically put that into the subtitle element, because a subtitle and description are not necessarily the same thing. Instead, you should define a subtitle attribute.

In the above example, we set the Atom feed’s subtitle to the RSS feed’s description, because it’s quite short already.

And the accompanying URLconf:

```python
from django.urls import path
from myproject.feeds import AtomSiteNewsFeed, RssSiteNewsFeed

urlpatterns = [
    # ...
    path('sitenews/rss/', RssSiteNewsFeed()),
    path('sitenews/atom/', AtomSiteNewsFeed()),
    # ...
]"
Feed class reference

class views.Feed

This example illustrates all possible attributes and methods for a Feed class:

```python
from django.contrib.syndication.views import Feed
from django.utils import feedgenerator

class ExampleFeed(Feed):
    # FEED TYPE -- Optional. This should be a class that subclasses
    # django.utils.feedgenerator.SyndicationFeed. This designates
    # which type of feed this should be: RSS 2.0, Atom 1.0, etc. If
    # you don't specify feed_type, your feed will be RSS 2.0. This
    # should be a class, not an instance of the class.
    feed_type = feedgenerator.Rss201rev2Feed

    # TEMPLATE NAMES -- Optional. These should be strings
    # representing names of Django templates that the system should
    # use in rendering the title and description of your feed items.
    # Both are optional. If a template is not specified, the
    # item_title() or item_description() methods are used instead.
    title_template = None
    description_template = None

    # LANGUAGE -- Optional. This should be a string specifying a language
    # code. Defaults to django.utils.translation.get_language().
    language = 'de'

    # TITLE -- One of the following three is required. The framework
    # looks for them in this order.
    def title(self, obj):
        """
        Takes the object returned by get_object() and returns the
        feed's title as a normal Python string.
        """
```

(continues on next page)
```python
def title(self):
    """Returns the feed's title as a normal Python string."""
    title = 'foo'  # Hard-coded title.

    # LINK -- One of the following three is required. The framework # looks for them in this order.
    def link(self, obj):
        """# Takes the object returned by get_object() and returns the URL # of the HTML version of the feed as a normal Python string."""
        def link(self):
            """Returns the URL of the HTML version of the feed as a normal Python string."""
            link = '/blog/'  # Hard-coded URL.

            # FEED_URL -- One of the following three is optional. The framework # looks for them in this order.

# a hook that specifies how to get the URL of a page for comments for a

(continues on next page)
The low-level framework

Behind the scenes, the high-level RSS framework uses a lower-level framework for generating feeds’ XML. This framework lives in a single module: `django/utils/feedgenerator.py`.

You use this framework on your own, for lower-level feed generation. You can also create custom feed generator subclasses for use with the `feed_type Feed` option.

SyndicationFeed classes

The `feedgenerator` module contains a base class:

- `django.utils.feedgenerator.SyndicationFeed`

and several subclasses:

- `django.utils.feedgenerator.RssUserland091Feed`
- `django.utils.feedgenerator.Rss201rev2Feed`
- `django.utils.feedgenerator.Atom1Feed`

Each of these three classes knows how to render a certain type of feed as XML. They share this interface:

`SyndicationFeed.__init__()`

Initialize the feed with the given dictionary of metadata, which applies to the entire feed. Required keyword arguments are:

- `title`
- `link`
There’s also a bunch of other optional keywords:

- description
- language
- author_email
- author_name
- author_link
- subtitle
- categories
- feed_url
- feed_copyright
- feed_guid
- ttl

Any extra keyword arguments you pass to `__init__` will be stored in `self.feed` for use with custom feed generators.

All parameters should be strings, except `categories`, which should be a sequence of strings. Beware that some control characters are not allowed in XML documents. If your content has some of them, you might encounter a `ValueError` when producing the feed.

`SyndicationFeed.add_item()`

Add an item to the feed with the given parameters.

Required keyword arguments are:

- title
- link
- description

Optional keyword arguments are:

- author_email
- author_name
- author_link
- pubdate
- comments
- unique_id
- enclosures
• categories
• item_copyright
• ttl
• updateddate

Extra keyword arguments will be stored for custom feed generators.

All parameters, if given, should be strings, except:
• pubdate should be a Python datetime object.
• updateddate should be a Python datetime object.
• enclosures should be a list of django.utils.feedgenerator.Enclosure instances.
• categories should be a sequence of strings.

SyndicationFeed.write()
Outputsthefeedinthegivenencodingtooutfile,whichisafilee-likeobject.

SyndicationFeed.writeString()
Returns the feed as a string in the given encoding.

For example, to create an Atom 1.0 feed and print it to standard output:

```python
>>> from django.utils import feedgenerator
>>> from datetime import datetime
>>> f = feedgenerator.Atom1Feed(
...     title="My Blog",
...     link="https://www.example.com/",
...     description="In which I write about what I ate today.",
...     language="en",
...     author_name="Myself",
...     feed_url="https://example.com/atom.xml")
>>> f.add_item(title="Hot dog today",
...     link="https://www.example.com/entries/1/",
...     pubdate=datetime.now(),
...     description="<p>Today I had a Vienna Beef hot dog. It was pink, plump and perfect.</p>"
)
>>> print(f.writeString('UTF-8'))
<?xml version="1.0" encoding="UTF-8"?>
<feed xmlns="http://www.w3.org/2005/Atom" xml:lang="en">
...  
</feed>
```
Custom feed generators

If you need to produce a custom feed format, you’ve got a couple of options.

If the feed format is totally custom, you’ll want to subclass `SyndicationFeed` and completely replace the `write()` and `writeString()` methods.

However, if the feed format is a spin-off of RSS or Atom (i.e. GeoRSS, Apple’s iTunes podcast format, etc.), you’ve got a better choice. These types of feeds typically add extra elements and/or attributes to the underlying format, and there are a set of methods that `SyndicationFeed` calls to get these extra attributes. Thus, you can subclass the appropriate feed generator class (Atom1Feed or Rss201rev2Feed) and extend these callbacks. They are:

`SyndicationFeed.root_attributes(self)`

Return a dict of attributes to add to the root feed element (feed/channel).

`SyndicationFeed.add_root_elements(self, handler)`

Callback to add elements inside the root feed element (feed/channel). `handler` is an `XMLGenerator` from Python’s built-in SAX library; you’ll call methods on it to add to the XML document in process.

`SyndicationFeed.item_attributes(self, item)`

Return a dict of attributes to add to each item (item/entry) element. The argument, `item`, is a dictionary of all the data passed to `SyndicationFeed.add_item()`.

`SyndicationFeed.add_item_elements(self, handler, item)`

Callback to add elements to each item (item/entry) element. `handler` and `item` are as above.

Warning: If you override any of these methods, be sure to call the superclass methods since they add the required elements for each feed format.

For example, you might start implementing an iTunes RSS feed generator like so:

```python
class iTunesFeed(Rss201rev2Feed):
    def root_attributes(self):
        attrs = super().root_attributes()
        attrs['xmlns:itunes'] = 'http://www.itunes.com/dtds/podcast-1.0.dtd'
        return attrs

    def add_root_elements(self, handler):
        super().add_root_elements(handler)
        handler.addQuickElement('itunes:explicit', 'clean')
```

There’s a lot more work to be done for a complete custom feed class, but the above example should demonstrate the basic idea.
6.5.14 admin

The automatic Django administrative interface. For more information, see Tutorial 2 and the admin documentation.
Requires the auth and contenttypes contrib packages to be installed.

6.5.15 auth

Django’s authentication framework.
See User authentication in Django.

6.5.16 contenttypes

A light framework for hooking into “types” of content, where each installed Django model is a separate content type.
See the contenttypes documentation.

6.5.17 flatpages

A framework for managing “flat” HTML content in a database.
See the flatpages documentation.
Requires the sites contrib package to be installed as well.

6.5.18 gis

A world-class geospatial framework built on top of Django, that enables storage, manipulation and display of spatial data.
See the GeoDjango documentation for more.

6.5.19 humanize

A set of Django template filters useful for adding a “human touch” to data.
See the humanize documentation.
6.5.20 messages

A framework for storing and retrieving temporary cookie- or session-based messages.
See the messages documentation.

6.5.21 postgres

A collection of PostgreSQL specific features.
See the contrib.postgres documentation.

6.5.22 redirects

A framework for managing redirects.
See the redirects documentation.

6.5.23 sessions

A framework for storing data in anonymous sessions.
See the sessions documentation.

6.5.24 sites

A light framework that lets you operate multiple websites off of the same database and Django installation. It gives you hooks for associating objects to one or more sites.
See the sites documentation.

6.5.25 sitemaps

A framework for generating Google sitemap XML files.
See the sitemaps documentation.
6.5.26 syndication

A framework for generating syndication feeds, in RSS and Atom, quite easily.
See the syndication documentation.

6.5.27 Other add-ons

If you have an idea for functionality to include in contrib, let us know! Code it up, and post it to the django-users mailing list.

6.6 Cross Site Request Forgery protection

The CSRF middleware and template tag provides easy-to-use protection against Cross Site Request Forgeries. This type of attack occurs when a malicious website contains a link, a form button or some JavaScript that is intended to perform some action on your website, using the credentials of a logged-in user who visits the malicious site in their browser. A related type of attack, ‘login CSRF’, where an attacking site tricks a user’s browser into logging into a site with someone else’s credentials, is also covered.

The first defense against CSRF attacks is to ensure that GET requests (and other ‘safe’ methods, as defined by RFC 7231#section-4.2.1) are side effect free. Requests via ‘unsafe’ methods, such as POST, PUT, and DELETE, can then be protected by the steps outlined in How to use Django’s CSRF protection.

6.6.1 How it works

The CSRF protection is based on the following things:

1. A CSRF cookie that is a random secret value, which other sites will not have access to.

   CsrfViewMiddleware sends this cookie with the response whenever django.middleware.csrf.get_token() is called. It can also send it in other cases. For security reasons, the value of the secret is changed each time a user logs in.

2. A hidden form field with the name ‘csrfmiddlewaretoken’, present in all outgoing POST forms.

   In order to protect against BREACH attacks, the value of this field is not simply the secret. It is scrambled differently with each response using a mask. The mask is generated randomly on every call to get_token(), so the form field value is different each time.

   This part is done by the template tag.

3. For all incoming requests that are not using HTTP GET, HEAD, OPTIONS or TRACE, a CSRF cookie must be present, and the ‘csrfmiddlewaretoken’ field must be present and correct. If it isn’t, the user will get a 403 error.
When validating the ‘csrfmiddlewaretoken’ field value, only the secret, not the full token, is compared with the secret in the cookie value. This allows the use of ever-changing tokens. While each request may use its own token, the secret remains common to all.

This check is done by CsrfViewMiddleware.

4. CsrfViewMiddleware verifies the Origin header, if provided by the browser, against the current host and the CSRF_TRUSTED_ORIGINS setting. This provides protection against cross-subdomain attacks.

5. In addition, for HTTPS requests, if the Origin header isn’t provided, CsrfViewMiddleware performs strict referer checking. This means that even if a subdomain can set or modify cookies on your domain, it can’t force a user to post to your application since that request won’t come from your own exact domain.

This also addresses a man-in-the-middle attack that’s possible under HTTPS when using a session independent secret, due to the fact that HTTP Set-Cookie headers are (unfortunately) accepted by clients even when they are talking to a site under HTTPS. (Referer checking is not done for HTTP requests because the presence of the Referer header isn’t reliable enough under HTTP.)

If the CSRF_COOKIE_DOMAIN setting is set, the referer is compared against it. You can allow cross-subdomain requests by including a leading dot. For example, CSRF_COOKIE_DOMAIN = ‘.example.com’ will allow POST requests from www.example.com and api.example.com. If the setting is not set, then the referer must match the HTTP Host header.

Expanding the accepted referers beyond the current host or cookie domain can be done with the CSRF_TRUSTED_ORIGINS setting.

In older versions, the CSRF cookie value was masked.

This ensures that only forms that have originated from trusted domains can be used to POST data back.

It deliberately ignores GET requests (and other requests that are defined as ‘safe’ by RFC 7231#section-4.2.1). These requests ought never to have any potentially dangerous side effects, and so a CSRF attack with a GET request ought to be harmless. RFC 7231#section-4.2.1 defines POST, PUT, and DELETE as ‘unsafe’, and all other methods are also assumed to be unsafe, for maximum protection.

The CSRF protection cannot protect against man-in-the-middle attacks, so use HTTPS with HTTP Strict Transport Security. It also assumes validation of the HOST header and that there aren’t any cross-site scripting vulnerabilities on your site (because XSS vulnerabilities already let an attacker do anything a CSRF vulnerability allows and much worse).

Removing the Referer header

To avoid disclosing the referer URL to third-party sites, you might want to disable the referer on your site’s <a> tags. For example, you might use the <meta name="referrer" content="no-referrer"> tag or include the Referer-Policy: no-referrer header. Due to the CSRF protection’s strict referer checking on HTTPS requests, those techniques cause a CSRF failure on requests with ‘unsafe’ methods. Instead, use
alternatives like `<a rel="noreferrer" ...>` for links to third-party sites.

### 6.6.2 Limitations

Subdomains within a site will be able to set cookies on the client for the whole domain. By setting the cookie and using a corresponding token, subdomains will be able to circumvent the CSRF protection. The only way to avoid this is to ensure that subdomains are controlled by trusted users (or, are at least unable to set cookies). Note that even without CSRF, there are other vulnerabilities, such as session fixation, that make giving subdomains to untrusted parties a bad idea, and these vulnerabilities cannot easily be fixed with current browsers.

### 6.6.3 Utilities

The examples below assume you are using function-based views. If you are working with class-based views, you can refer to [Decorating class-based views](#).

**csrf_exempt**(view)

This decorator marks a view as being exempt from the protection ensured by the middleware. Example:

```python
from django.http import HttpResponse
from django.views.decorators.csrf import csrf_exempt

@csrf_exempt
def my_view(request):
    return HttpResponse('Hello world')
```

**csrf_protect**(view)

Decorator that provides the protection of `CsrfViewMiddleware` to a view. Usage:

```python
from django.shortcuts import render
from django.views.decorators.csrf import csrf_protect

@csrf_protect
def my_view(request):
    c = {}
    # ...
    return render(request, "a_template.html", c)
```

**requires_csrf_token**(view)

Normally the `csrf_token` template tag will not work if `CsrfViewMiddleware.process_view` or an equivalent like `csrf_protect` has not run. The view decorator `requires_csrf_token` can be used to
ensure the template tag does work. This decorator works similarly to **csrf_protect**, but never rejects an incoming request.

Example:

```python
from django.shortcuts import render
from django.views.decorators.csrf import requires_csrf_token

@requires_csrf_token
def my_view(request):
    c = {}
    # ...
    return render(request, "a_template.html", c)
```

**ensure_csrf_cookie(view)**

This decorator forces a view to send the CSRF cookie.

### 6.6.4 Settings

A number of settings can be used to control Django’s CSRF behavior:

- **CSRF_COOKIE_AGE**
- **CSRF_COOKIE_DOMAIN**
- **CSRF_COOKIE_HTTPONLY**
- **CSRF_COOKIE_NAME**
- **CSRF_COOKIE_PATH**
- **CSRF_COOKIE_SAMESITE**
- **CSRF_COOKIE_SECURE**
- **CSRF_FAILURE_VIEW**
- **CSRF_HEADER_NAME**
- **CSRF_TRUSTED_ORIGINS**
- **CSRF_USE_SESSIONS**
6.6.5 Frequently Asked Questions

Is posting an arbitrary CSRF token pair (cookie and POST data) a vulnerability?

No, this is by design. Without a man-in-the-middle attack, there is no way for an attacker to send a CSRF token cookie to a victim’s browser, so a successful attack would need to obtain the victim’s browser’s cookie via XSS or similar, in which case an attacker usually doesn’t need CSRF attacks.

Some security audit tools flag this as a problem but as mentioned before, an attacker cannot steal a user’s browser’s CSRF cookie. “Stealing” or modifying your own token using Firebug, Chrome dev tools, etc. isn’t a vulnerability.

Is it a problem that Django’s CSRF protection isn’t linked to a session by default?

No, this is by design. Not linking CSRF protection to a session allows using the protection on sites such as a pastebin that allow submissions from anonymous users which don’t have a session.

If you wish to store the CSRF token in the user’s session, use the CSRF_USE_SESSIONS setting.

Why might a user encounter a CSRF validation failure after logging in?

For security reasons, CSRF tokens are rotated each time a user logs in. Any page with a form generated before a login will have an old, invalid CSRF token and need to be reloaded. This might happen if a user uses the back button after a login or if they log in a different browser tab.

6.7 Databases

Django officially supports the following databases:

- PostgreSQL
- MariaDB
- MySQL
- Oracle
- SQLite

There are also a number of database backends provided by third parties.

Django attempts to support as many features as possible on all database backends. However, not all database backends are alike, and we’ve had to make design decisions on which features to support and which assumptions we can make safely.

This file describes some of the features that might be relevant to Django usage. It is not intended as a replacement for server-specific documentation or reference manuals.
6.7.1 General notes

Persistent connections

Persistent connections avoid the overhead of reestablishing a connection to the database in each request. They’re controlled by the `CONN_MAX_AGE` parameter which defines the maximum lifetime of a connection. It can be set independently for each database.

The default value is 0, preserving the historical behavior of closing the database connection at the end of each request. To enable persistent connections, set `CONN_MAX_AGE` to a positive integer of seconds. For unlimited persistent connections, set it to `None`.

Connection management

Django opens a connection to the database when it first makes a database query. It keeps this connection open and reuses it in subsequent requests. Django closes the connection once it exceeds the maximum age defined by `CONN_MAX_AGE` or when it isn’t usable any longer.

In detail, Django automatically opens a connection to the database whenever it needs one and doesn’t have one already — either because this is the first connection, or because the previous connection was closed.

At the beginning of each request, Django closes the connection if it has reached its maximum age. If your database terminates idle connections after some time, you should set `CONN_MAX_AGE` to a lower value, so that Django doesn’t attempt to use a connection that has been terminated by the database server. (This problem may only affect very low traffic sites.)

At the end of each request, Django closes the connection if it has reached its maximum age or if it is in an unrecoverable error state. If any database errors have occurred while processing the requests, Django checks whether the connection still works, and closes it if it doesn’t. Thus, database errors affect at most one request per each application’s worker thread; if the connection becomes unusable, the next request gets a fresh connection.

Setting `CONN_HEALTH_CHECKS` to `True` can be used to improve the robustness of connection reuse and prevent errors when a connection has been closed by the database server which is now ready to accept and serve new connections, e.g. after database server restart. The health check is performed only once per request and only if the database is being accessed during the handling of the request.

The `CONN_HEALTH_CHECKS` setting was added.
Caveats

Since each thread maintains its own connection, your database must support at least as many simultaneous connections as you have worker threads.

Sometimes a database won’t be accessed by the majority of your views, for example because it’s the database of an external system, or thanks to caching. In such cases, you should set `CONN_MAX_AGE` to a low value or even 0, because it doesn’t make sense to maintain a connection that’s unlikely to be reused. This will help keep the number of simultaneous connections to this database small.

The development server creates a new thread for each request it handles, negating the effect of persistent connections. Don’t enable them during development.

When Django establishes a connection to the database, it sets up appropriate parameters, depending on the backend being used. If you enable persistent connections, this setup is no longer repeated every request. If you modify parameters such as the connection’s isolation level or time zone, you should either restore Django’s defaults at the end of each request, force an appropriate value at the beginning of each request, or disable persistent connections.

Encoding

Django assumes that all databases use UTF-8 encoding. Using other encodings may result in unexpected behavior such as “value too long” errors from your database for data that is valid in Django. See the database specific notes below for information on how to set up your database correctly.

6.7.2 PostgreSQL notes

Django supports PostgreSQL 12 and higher. `psycopg2` 2.8.4 or higher is required, though the latest release is recommended.

PostgreSQL connection settings

See `HOST` for details.

To connect using a service name from the connection service file and a password from the password file, you must specify them in the `OPTIONS` part of your database configuration in `DATABASES`:

```
Listing 7: settings.py

DATABASES = {
    'default': {
        'ENGINE': 'django.db.backends.postgresql',
        'OPTIONS': {
            'service': 'my_service',
        }
    }
}
```

(continues on next page)
'passfile': '.my_pgpass',
}
}

Listing 8: `.pg_service.conf`

```python
[my_service]
host=localhost
user=USER
dbname=NAME
port=5432
```

Listing 9: `.my_pgpass`

```
localhost:5432:NAME:USER:PASSWORD
```

Warning: Using a service name for testing purposes is not supported. This may be implemented later.

Optimizing PostgreSQL’s configuration

Django needs the following parameters for its database connections:

- **client_encoding**: 'UTF8',
- **default_transaction_isolation**: 'read committed' by default, or the value set in the connection options (see below),
- **timezone**:
  - when *USE_TZ* is True, 'UTC' by default, or the *TIME_ZONE* value set for the connection,
  - when *USE_TZ* is False, the value of the global *TIME_ZONE* setting.

If these parameters already have the correct values, Django won’t set them for every new connection, which improves performance slightly. You can configure them directly in `postgresql.conf` or more conveniently per database user with `ALTER ROLE`.

Django will work just fine without this optimization, but each new connection will do some additional queries to set these parameters.
Isolation level

Like PostgreSQL itself, Django defaults to the \texttt{READ COMMITTED} isolation level. If you need a higher isolation level such as \texttt{REPEATABLE READ} or \texttt{SERIALIZABLE}, set it in the \texttt{OPTIONS} part of your database configuration in \texttt{DATABASES}:

```python
import psycopg2.extensions

DATABASES = {
    # ...
    'OPTIONS': {
        'isolation_level': psycopg2.extensions.ISOLATION_LEVEL_SERIALIZABLE,
    },
}
```

Note: Under higher isolation levels, your application should be prepared to handle exceptions raised on serialization failures. This option is designed for advanced uses.

Indexes for \texttt{varchar} and \texttt{text} columns

When specifying \texttt{db_index=True} on your model fields, Django typically outputs a single \texttt{CREATE INDEX} statement. However, if the database type for the field is either \texttt{varchar} or \texttt{text} (e.g., used by \texttt{CharField}, \texttt{TextField}, and \texttt{TextField}), then Django will create an additional index that uses an appropriate PostgreSQL \texttt{operator class} for the column. The extra index is necessary to correctly perform lookups that use the \texttt{LIKE} operator in their SQL, as is done with the \texttt{contains} and \texttt{startswith} lookup types.

Migration operation for adding extensions

If you need to add a PostgreSQL extension (like \texttt{hstore}, \texttt{postgis}, etc.) using a migration, use the \texttt{CreateExtension} operation.

Server-side cursors

When using \texttt{QuerySet.iterator()}, Django opens a server-side cursor. By default, PostgreSQL assumes that only the first 10\% of the results of cursor queries will be fetched. The query planner spends less time planning the query and starts returning results faster, but this could diminish performance if more than 10\% of the results are retrieved. PostgreSQL’s assumptions on the number of rows retrieved for a cursor query is controlled with the \texttt{cursor_tuple_fraction} option.

6.7. Databases 1347
Transaction pooling and server-side cursors

Using a connection pooler in transaction pooling mode (e.g. PgBouncer) requires disabling server-side cursors for that connection.

Server-side cursors are local to a connection and remain open at the end of a transaction when AUTO_COMMIT is True. A subsequent transaction may attempt to fetch more results from a server-side cursor. In transaction pooling mode, there’s no guarantee that subsequent transactions will use the same connection. If a different connection is used, an error is raised when the transaction references the server-side cursor, because server-side cursors are only accessible in the connection in which they were created.

One solution is to disable server-side cursors for a connection in DATABASES by setting DISABLE_SERVER_SIDE_CURSORS to True.

To benefit from server-side cursors in transaction pooling mode, you could set up another connection to the database in order to perform queries that use server-side cursors. This connection needs to either be directly to the database or to a connection pooler in session pooling mode.

Another option is to wrap each QuerySet using server-side cursors in an atomic() block, because it disables autocommit for the duration of the transaction. This way, the server-side cursor will only live for the duration of the transaction.

Manually-specifying values of auto-incrementing primary keys

Django uses PostgreSQL’s SERIAL data type to store auto-incrementing primary keys. A SERIAL column is populated with values from a sequence that keeps track of the next available value. Manually assigning a value to an auto-incrementing field doesn’t update the field’s sequence, which might later cause a conflict.

For example:

```python
>>> from django.contrib.auth.models import User
>>> User.objects.create(username='alice', pk=1)
<User: alice>
>>> # The sequence hasn't been updated; its next value is 1.
>>> User.objects.create(username='bob')
... IntegrityError: duplicate key value violates unique constraint
"auth_user_pkey" DETAIL: Key (id)=(1) already exists.
```

If you need to specify such values, reset the sequence afterward to avoid reusing a value that’s already in the table. The sqlsequencereset management command generates the SQL statements to do that.
Test database templates

You can use the `TEST['TEMPLATE']` setting to specify a `template` (e.g. 'template0') from which to create a test database.

Speeding up test execution with non-durable settings

You can speed up test execution times by configuring PostgreSQL to be non-durable.

Warning: This is dangerous: it will make your database more susceptible to data loss or corruption in the case of a server crash or power loss. Only use this on a development machine where you can easily restore the entire contents of all databases in the cluster.

6.7.3 MariaDB notes

Django supports MariaDB 10.4 and higher.

To use MariaDB, use the MySQL backend, which is shared between the two. See the MySQL notes for more details.

6.7.4 MySQL notes

Version support

Django supports MySQL 5.7 and higher.

Django’s `inspectdb` feature uses the `information_schema` database, which contains detailed data on all database schemas.

Django expects the database to support Unicode (UTF-8 encoding) and delegates to it the task of enforcing transactions and referential integrity. It is important to be aware of the fact that the two latter ones aren’t actually enforced by MySQL when using the MyISAM storage engine, see the next section.

Storage engines

MySQL has several storage engines. You can change the default storage engine in the server configuration.

MySQL’s default storage engine is InnoDB. This engine is fully transactional and supports foreign key references. It’s the recommended choice. However, the InnoDB autoincrement counter is lost on a MySQL restart because it does not remember the `AUTO_INCREMENT` value, instead recreating it as “max(id)+1”. This may result in an inadvertent reuse of `AutoField` values.

The main drawbacks of MyISAM are that it doesn’t support transactions or enforce foreign-key constraints.
MySQL DB API Drivers

MySQL has a couple drivers that implement the Python Database API described in PEP 249:

- **mysqlclient** is a native driver. It’s the recommended choice.
- **MySQL Connector/Python** is a pure Python driver from Oracle that does not require the MySQL client library or any Python modules outside the standard library.

These drivers are thread-safe and provide connection pooling.

In addition to a DB API driver, Django needs an adapter to access the database drivers from its ORM. Django provides an adapter for mysqlclient while MySQL Connector/Python includes its own.

**mysqlclient**

Django requires mysqlclient 1.4.0 or later.

**MySQL Connector/Python**

MySQL Connector/Python is available from the download page. The Django adapter is available in versions 1.1.X and later. It may not support the most recent releases of Django.

**Time zone definitions**

If you plan on using Django’s timezone support, use mysql_tzinfo_to_sql to load time zone tables into the MySQL database. This needs to be done just once for your MySQL server, not per database.

**Creating your database**

You can create your database using the command-line tools and this SQL:

```
CREATE DATABASE <dbname> CHARACTER SET utf8;
```

This ensures all tables and columns will use UTF-8 by default.

**Collation settings**

The collation setting for a column controls the order in which data is sorted as well as what strings compare as equal. You can specify the `db_collation` parameter to set the collation name of the column for `CharField` and `TextField`. 
The collation can also be set on a database-wide level and per-table. This is documented thoroughly in the MySQL documentation. In such cases, you must set the collation by directly manipulating the database settings or tables. Django doesn’t provide an API to change them.

By default, with a UTF-8 database, MySQL will use the `utf8_general_ci` collation. This results in all string equality comparisons being done in a case-insensitive manner. That is, "Fred" and "freD" are considered equal at the database level. If you have a unique constraint on a field, it would be illegal to try to insert both "aa" and "AA" into the same column, since they compare as equal (and, hence, non-unique) with the default collation. If you want case-sensitive comparisons on a particular column or table, change the column or table to use the `utf8_bin` collation.

Please note that according to MySQL Unicode Character Sets, comparisons for the `utf8_general_ci` collation are faster, but slightly less correct, than comparisons for `utf8_unicode_ci`. If this is acceptable for your application, you should use `utf8_general_ci` because it is faster. If this is not acceptable (for example, if you require German dictionary order), use `utf8_unicode_ci` because it is more accurate.

---

**Warning:** Model formsets validate unique fields in a case-sensitive manner. Thus when using a case-insensitive collation, a formset with unique field values that differ only by case will pass validation, but upon calling `save()`, an `IntegrityError` will be raised.

---

### Connecting to the database

Refer to the settings documentation.

Connection settings are used in this order:

1. `OPTIONS`.
2. `NAME, USER, PASSWORD, HOST, PORT`.
3. MySQL option files.

In other words, if you set the name of the database in `OPTIONS`, this will take precedence over `NAME`, which would override anything in a MySQL option file.

Here’s a sample configuration which uses a MySQL option file:

```python
# settings.py
DATABASES = {
    'default': {
        'ENGINE': 'django.db.backends.mysql',
        'OPTIONS': {
            'read_default_file': '/path/to/my.cnf',
        },
    },
}
```

(continues on next page)
Several other MySQLdb connection options may be useful, such as ssl, init_command, and sql_mode.

**Setting sql_mode**

From MySQL 5.7 onward, the default value of the sql_mode option contains STRICT_TRANS_TABLES. That option escalates warnings into errors when data are truncated upon insertion, so Django highly recommends activating a strict mode for MySQL to prevent data loss (either STRICT_TRANS_TABLES or STRICT_ALL_TABLES).

If you need to customize the SQL mode, you can set the sql_mode variable like other MySQL options: either in a config file or with the entry 'init_command': "SET sql_mode='STRICT_TRANS_TABLES'" in the OPTIONS part of your database configuration in DATABASES.

**Isolation level**

When running concurrent loads, database transactions from different sessions (say, separate threads handling different requests) may interact with each other. These interactions are affected by each session’s transaction isolation level. You can set a connection’s isolation level with an 'isolation_level' entry in the OPTIONS part of your database configuration in DATABASES. Valid values for this entry are the four standard isolation levels:

- 'read uncommitted'
- 'read committed'
- 'repeatable read'
- 'serializable'

or None to use the server’s configured isolation level. However, Django works best with and defaults to read committed rather than MySQL’s default, repeatable read. Data loss is possible with repeatable read. In particular, you may see cases where get_or_create() will raise an IntegrityError but the object won’t appear in a subsequent get() call.
Creating your tables

When Django generates the schema, it doesn’t specify a storage engine, so tables will be created with whatever default storage engine your database server is configured for. The easiest solution is to set your database server’s default storage engine to the desired engine.

If you’re using a hosting service and can’t change your server’s default storage engine, you have a couple of options.

- After the tables are created, execute an `ALTER TABLE` statement to convert a table to a new storage engine (such as InnoDB):

  ```
  ALTER TABLE <tablename> ENGINE=INNODB;
  ```

  This can be tedious if you have a lot of tables.

- Another option is to use the `init_command` option for MySQLdb prior to creating your tables:

  ```
  'OPTIONS': {
    'init_command': 'SET default_storage_engine=INNODB',
  }
  ```

  This sets the default storage engine upon connecting to the database. After your tables have been created, you should remove this option as it adds a query that is only needed during table creation to each database connection.

Table names

There are known issues in even the latest versions of MySQL that can cause the case of a table name to be altered when certain SQL statements are executed under certain conditions. It is recommended that you use lowercase table names, if possible, to avoid any problems that might arise from this behavior. Django uses lowercase table names when it auto-generates table names from models, so this is mainly a consideration if you are overriding the table name via the `db_table` parameter.

Savepoints

Both the Django ORM and MySQL (when using the InnoDB storage engine) support database savepoints. If you use the MyISAM storage engine please be aware of the fact that you will receive database-generated errors if you try to use the savepoint-related methods of the transactions API. The reason for this is that detecting the storage engine of a MySQL database/table is an expensive operation so it was decided it isn’t worth to dynamically convert these methods in no-op’s based in the results of such detection.
Notes on specific fields

Character fields

Any fields that are stored with VARCHAR column types may have their max_length restricted to 255 characters if you are using unique=True for the field. This affects CharField, SlugField. See the MySQL documentation for more details.

TextField limitations

MySQL can index only the first N chars of a BLOB or TEXT column. Since TextField doesn’t have a defined length, you can’t mark it as unique=True. MySQL will report: “BLOB/TEXT column ‘<db_column>’ used in key specification without a key length”.

Fractional seconds support for Time and DateTime fields

MySQL can store fractional seconds, provided that the column definition includes a fractional indication (e.g. DATETIME(6)).

Django will not upgrade existing columns to include fractional seconds if the database server supports it. If you want to enable them on an existing database, it’s up to you to either manually update the column on the target database, by executing a command like:

```
ALTER TABLE `your_table` MODIFY `your_datetime_column` DATETIME(6)
```

or using a RunSQL operation in a data migration.

TIMESTAMP columns

If you are using a legacy database that contains TIMESTAMP columns, you must set USE_TZ = False to avoid data corruption. inspectdb maps these columns to DateTimeField and if you enable timezone support, both MySQL and Django will attempt to convert the values from UTC to local time.

Row locking with QuerySet.select_for_update()

MySQL and MariaDB do not support some options to the SELECT ... FOR UPDATE statement. If select_for_update() is used with an unsupported option, then a NotSupportedException is raised.
When using `select_for_update()` on MySQL, make sure you filter a queryset against at least a set of fields contained in unique constraints or only against fields covered by indexes. Otherwise, an exclusive write lock will be acquired over the full table for the duration of the transaction.

**Automatic typecasting can cause unexpected results**

When performing a query on a string type, but with an integer value, MySQL will coerce the types of all values in the table to an integer before performing the comparison. If your table contains the values 'abc', 'def' and you query for `WHERE mycolumn=0`, both rows will match. Similarly, `WHERE mycolumn=1` will match the value 'abc1'. Therefore, string type fields included in Django will always cast the value to a string before using it in a query.

If you implement custom model fields that inherit from `Field` directly, are overriding `get_prep_value()`, or use `RawSQL, extra()`, or `raw()`, you should ensure that you perform appropriate typecasting.

### 6.7.5 SQLite notes

Django supports SQLite 3.9.0 and later.

SQLite provides an excellent development alternative for applications that are predominantly read-only or require a smaller installation footprint. As with all database servers, though, there are some differences that are specific to SQLite that you should be aware of.

**Substring matching and case sensitivity**

For all SQLite versions, there is some slightly counter-intuitive behavior when attempting to match some types of strings. These are triggered when using the `iexact` or `contains` filters in Querysets. The behavior splits into two cases:

1. For substring matching, all matches are done case-insensitively. That is a filter such as `filter(name__contains="aa")` will match a name of "Aabb".

2. For strings containing characters outside the ASCII range, all exact string matches are performed case-sensitively, even when the case-insensitive options are passed into the query. So the `iexact` filter will behave exactly the same as the `exact` filter in these cases.
Some possible workarounds for this are documented at sqlite.org, but they aren’t utilized by the default SQLite backend in Django, as incorporating them would be fairly difficult to do robustly. Thus, Django exposes the default SQLite behavior and you should be aware of this when doing case-insensitive or substring filtering.

**Decimal handling**

SQLite has no real decimal internal type. Decimal values are internally converted to the REAL data type (8-byte IEEE floating point number), as explained in the SQLite datatypes documentation, so they don’t support correctly-rounded decimal floating point arithmetic.

**“Database is locked” errors**

SQLite is meant to be a lightweight database, and thus can’t support a high level of concurrency. OperationalError: database is locked errors indicate that your application is experiencing more concurrency than sqlite can handle in default configuration. This error means that one thread or process has an exclusive lock on the database connection and another thread timed out waiting for the lock to be released.

Python’s SQLite wrapper has a default timeout value that determines how long the second thread is allowed to wait on the lock before it times out and raises the OperationalError: database is locked error.

If you’re getting this error, you can solve it by:

- Switching to another database backend. At a certain point SQLite becomes too “lite” for real-world applications, and these sorts of concurrency errors indicate you’ve reached that point.

- Rewriting your code to reduce concurrency and ensure that database transactions are short-lived.

- Increase the default timeout value by setting the timeout database option:

```python
'OPTIONS': {
    # ...
    'timeout': 20,
    # ...
}
```

This will make SQLite wait a bit longer before throwing “database is locked” errors; it won’t really do anything to solve them.
QuerySet.select_for_update() not supported

SQLite does not support the SELECT ... FOR UPDATE syntax. Calling it will have no effect.

“pyformat” parameter style in raw queries not supported

For most backends, raw queries (Manager.raw() or cursor.execute()) can use the “pyformat” parameter style, where placeholders in the query are given as '%(name)s' and the parameters are passed as a dictionary rather than a list. SQLite does not support this.

Isolation when using QuerySet.iterator()

There are special considerations described in Isolation In SQLite when modifying a table while iterating over it using QuerySet.iterator(). If a row is added, changed, or deleted within the loop, then that row may or may not appear, or may appear twice, in subsequent results fetched from the iterator. Your code must handle this.

Enabling JSON1 extension on SQLite

To use JSONField on SQLite, you need to enable the JSON1 extension on Python’s sqlite3 library. If the extension is not enabled on your installation, a system error (fields.E180) will be raised.

To enable the JSON1 extension you can follow the instruction on the wiki page.

6.7.6 Oracle notes

Django supports Oracle Database Server versions 19c and higher. Version 7.0 or higher of the cx_Oracle Python driver is required.

In order for the python manage.py migrate command to work, your Oracle database user must have privileges to run the following commands:

- CREATE TABLE
- CREATE SEQUENCE
- CREATE PROCEDURE
- CREATE TRIGGER

To run a project’s test suite, the user usually needs these additional privileges:

- CREATE USER
- ALTER USER
- DROP USER
• CREATE TABLESPACE
• DROP TABLESPACE
• CREATE SESSION WITH ADMIN OPTION
• CREATE TABLE WITH ADMIN OPTION
• CREATE SEQUENCE WITH ADMIN OPTION
• CREATE PROCEDURE WITH ADMIN OPTION
• CREATE TRIGGER WITH ADMIN OPTION

While the RESOURCE role has the required CREATE TABLE, CREATE SEQUENCE, CREATE PROCEDURE, and CREATE TRIGGER privileges, and a user granted RESOURCE WITH ADMIN OPTION can grant RESOURCE, such a user cannot grant the individual privileges (e.g. CREATE TABLE), and thus RESOURCE WITH ADMIN OPTION is not usually sufficient for running tests.

Some test suites also create views or materialized views; to run these, the user also needs CREATE VIEW WITH ADMIN OPTION and CREATE MATERIALIZED VIEW WITH ADMIN OPTION privileges. In particular, this is needed for Django’s own test suite.

All of these privileges are included in the DBA role, which is appropriate for use on a private developer’s database.

The Oracle database backend uses the SYS.DBMS_LOB and SYS.DBMS_RANDOM packages, so your user will require execute permissions on it. It’s normally accessible to all users by default, but in case it is not, you’ll need to grant permissions like so:

```
GRANT EXECUTE ON SYS.DBMS_LOB TO user;
GRANT EXECUTE ON SYS.DBMS_RANDOM TO user;
```

**Connecting to the database**

To connect using the service name of your Oracle database, your settings.py file should look something like this:

```python
DATABASES = {
    'default': {
        'ENGINE': 'django.db.backends.oracle',
        'NAME': 'xe',
        'USER': 'a_user',
        'PASSWORD': 'a_password',
        'HOST': '',
        'PORT': '',
    }
}
```
In this case, you should leave both **HOST** and **PORT** empty. However, if you don’t use a tnsnames.ora file or a similar naming method and want to connect using the SID ( “xe” in this example), then fill in both **HOST** and **PORT** like so:

```python
DATABASES = {
    'default': {
        'ENGINE': 'django.db.backends.oracle',
        'NAME': 'xe',
        'USER': 'a_user',
        'PASSWORD': 'a_password',
        'HOST': 'dbprod01ned.mycompany.com',
        'PORT': '1540',
    }
}
```

You should either supply both **HOST** and **PORT**, or leave both as empty strings. Django will use a different connect descriptor depending on that choice.

### Full DSN and Easy Connect

A Full DSN or Easy Connect string can be used in **NAME** if both **HOST** and **PORT** are empty. This format is required when using RAC or pluggable databases without tnsnames.ora, for example.

Example of an Easy Connect string:

```
'NAME': 'localhost:1521/orclpdb1',
```

Example of a full DSN string:

```
'NAME': (
    '(DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=localhost)(PORT=1521))'
    '(CONNECT_DATA=(SERVICE_NAME=orclpdb1)))'
),
```

### Threaded option

If you plan to run Django in a multithreaded environment (e.g. Apache using the default MPM module on any modern operating system), then you must set the **threaded** option of your Oracle database configuration to True:

```
'OVERRIDE': {
    'threaded': True,
},
```
Failure to do this may result in crashes and other odd behavior.

**INSERT ... RETURNING INTO**

By default, the Oracle backend uses a `RETURNING INTO` clause to efficiently retrieve the value of an `AutoField` when inserting new rows. This behavior may result in a `DatabaseError` in certain unusual setups, such as when inserting into a remote table, or into a view with an `INSTEAD OF` trigger. The `RETURNING INTO` clause can be disabled by setting the `use_returning_into` option of the database configuration to `False`:

```
'OPTIONS': {
    'use_returning_into': False,
},
```

In this case, the Oracle backend will use a separate `SELECT` query to retrieve `AutoField` values.

**Naming issues**

Oracle imposes a name length limit of 30 characters. To accommodate this, the backend truncates database identifiers to fit, replacing the final four characters of the truncated name with a repeatable MD5 hash value. Additionally, the backend turns database identifiers to all-uppercase.

To prevent these transformations (this is usually required only when dealing with legacy databases or accessing tables which belong to other users), use a quoted name as the value for `db_table`:

```python
class LegacyModel(models.Model):
    class Meta:
        db_table = "name_left_in_lowercase"

class ForeignModel(models.Model):
    class Meta:
        db_table = "OTHER_USER"."NAME_ONLY_SEEMS_OVER_30"
```

Quoted names can also be used with Django’s other supported database backends; except for Oracle, however, the quotes have no effect.

When running `migrate`, an ORA-06552 error may be encountered if certain Oracle keywords are used as the name of a model field or the value of a `db_column` option. Django quotes all identifiers used in queries to prevent most such problems, but this error can still occur when an Oracle datatype is used as a column name. In particular, take care to avoid using the names `date`, `timestamp`, `number` or `float` as a field name.
NULL and empty strings

Django generally prefers to use the empty string ('') rather than NULL, but Oracle treats both identically. To get around this, the Oracle backend ignores an explicit null option on fields that have the empty string as a possible value and generates DDL as if null=True. When fetching from the database, it is assumed that a NULL value in one of these fields really means the empty string, and the data is silently converted to reflect this assumption.

TextField limitations

The Oracle backend stores TextFields as NCLOB columns. Oracle imposes some limitations on the usage of such LOB columns in general:

- LOB columns may not be used as primary keys.
- LOB columns may not be used in indexes.
- LOB columns may not be used in a SELECT DISTINCT list. This means that attempting to use the QuerySet.distinct method on a model that includes TextField columns will result in an ORA-00932 error when run against Oracle. As a workaround, use the QuerySet.defer method in conjunction with distinct() to prevent TextField columns from being included in the SELECT DISTINCT list.

6.7.7 Subclassing the built-in database backends

Django comes with built-in database backends. You may subclass an existing database backends to modify its behavior, features, or configuration.

Consider, for example, that you need to change a single database feature. First, you have to create a new directory with a base module in it. For example:

```
mysite/
  ...
  mydbengine/
    __init__.py
    base.py
```

The base.py module must contain a class named DatabaseWrapper that subclasses an existing engine from the django.db.backends module. Here’s an example of subclassing the PostgreSQL engine to change a feature class allows_group_by_selected_pks_on_model:

```
Listing 10: mysite/mydbengine/base.py

from django.db.backends.postgresql import base, features

class DatabaseFeatures(features.DatabaseFeatures):

(continues on next page)
```
def allows_group_by_selected_pks_on_model(self, model):
    return True

class DatabaseWrapper(base.DatabaseWrapper):
    features_class = DatabaseFeatures

Finally, you must specify a `DATABASE-ENGINE` in your `settings.py` file:

```python
DATABASES = {
    'default': {
        'ENGINE': 'mydbengine',
        ...
    },
}
```

You can see the current list of database engines by looking in `django/db/backends`.

### 6.7.8 Using a 3rd-party database backend

In addition to the officially supported databases, there are backends provided by 3rd parties that allow you to use other databases with Django:

- CockroachDB
- Firebird
- Google Cloud Spanner
- Microsoft SQL Server
- TiDB
- YugabyteDB

The Django versions and ORM features supported by these unofficial backends vary considerably. Queries regarding the specific capabilities of these unofficial backends, along with any support queries, should be directed to the support channels provided by each 3rd party project.

### 6.8 django-admin and manage.py

django-admin is Django’s command-line utility for administrative tasks. This document outlines all it can do.

In addition, manage.py is automatically created in each Django project. It does the same thing as django-admin but also sets the `DJANGO_SETTINGS_MODULE` environment variable so that it points to your project’s `settings.py` file.
The `django-admin` script should be on your system path if you installed Django via `pip`. If it’s not in your path, ensure you have your virtual environment activated.

Generally, when working on a single Django project, it’s easier to use `manage.py` than `django-admin`. If you need to switch between multiple Django settings files, use `django-admin` with `DJANGO_SETTINGS_MODULE` or the `--settings` command line option.

The command-line examples throughout this document use `django-admin` to be consistent, but any example can use `manage.py` or `python -m django` just as well.

### 6.8.1 Usage

```bash
$ django-admin <command> [options]
$ manage.py <command> [options]
$ python -m django <command> [options]
```

*command* should be one of the commands listed in this document. *options*, which is optional, should be zero or more of the options available for the given command.

**Getting runtime help**

`django-admin help`

Run `django-admin help` to display usage information and a list of the commands provided by each application.

Run `django-admin help --commands` to display a list of all available commands.

Run `django-admin help <command>` to display a description of the given command and a list of its available options.

**App names**

Many commands take a list of “app names.” An “app name” is the basename of the package containing your models. For example, if your `INSTALLED_APPS` contains the string `mysite.blog`, the app name is `blog`.

**Determining the version**

`django-admin version`

Run `django-admin version` to display the current Django version.

The output follows the schema described in PEP 440:
Displaying debug output

Use `--verbosity`, where it is supported, to specify the amount of notification and debug information that `django-admin` prints to the console.

6.8.2 Available commands

check

django-admin check [app_label [app_label ...]]

Uses the system check framework to inspect the entire Django project for common problems.

By default, all apps will be checked. You can check a subset of apps by providing a list of app labels as arguments:

```
django-admin check auth admin myapp
```

`--tag TAGS, -t TAGS`

The system check framework performs many different types of checks that are categorized with tags. You can use these tags to restrict the checks performed to just those in a particular category. For example, to perform only models and compatibility checks, run:

```
django-admin check --tag models --tag compatibility
```

`--database DATABASE`

Specifies the database to run checks requiring database access:

```
django-admin check --database default --database other
```

By default, these checks will not be run.

`--list-tags`

Lists all available tags.

`--deploy`
Activates some additional checks that are only relevant in a deployment setting.

You can use this option in your local development environment, but since your local development settings module may not have many of your production settings, you will probably want to point the `check` command at a different settings module, either by setting the `DJANGO_SETTINGS_MODULE` environment variable, or by passing the `--settings` option:

```
django-admin check --deploy --settings=production_settings
```

Or you could run it directly on a production or staging deployment to verify that the correct settings are in use (omitting `--settings`). You could even make it part of your integration test suite.

```
--fail-level {CRITICAL,ERROR,WARNING,INFO,DEBUG}
```

Specifies the message level that will cause the command to exit with a non-zero status. Default is `ERROR`.

### compilemessages

```
django-admin compilemessages
```

Compiles `.po` files created by `makemessages` to `.mo` files for use with the built-in gettext support. See Internationalization and localization.

```
--locale LOCALE, -l LOCALE
```

Specifies the locale(s) to process. If not provided, all locales are processed.

```
--exclude EXCLUDE, -x EXCLUDE
```

Specifies the locale(s) to exclude from processing. If not provided, no locales are excluded.

```
--use-fuzzy, -f
```

Includes fuzzy translations into compiled files.

Example usage:

```
django-admin compilemessages --locale=pt_BR
django-admin compilemessages --locale=pt_BR --locale=fr -f
django-admin compilemessages -l pt_BR
django-admin compilemessages -l pt_BR -l fr --use-fuzzy
django-admin compilemessages --exclude=pt_BR
django-admin compilemessages --exclude=pt_BR --exclude=fr
django-admin compilemessages -x pt_BR
django-admin compilemessages -x pt_BR -x fr
```

```
--ignore PATTERN, -i PATTERN
```
Ignores directories matching the given glob-style pattern. Use multiple times to ignore more.

Example usage:

```bash
django-admin compilemessages --ignore=cache --ignore=outdated/*/locale
```

createcachetable

django-admin createcachetable

Creates the cache tables for use with the database cache backend using the information from your settings file. See Django’s cache framework for more information.

```bash
--database DATABASE
```

Specifies the database in which the cache table(s) will be created. Defaults to default.

```bash
--dry-run
```

Prints the SQL that would be run without actually running it, so you can customize it or use the migrations framework.

dbshell

django-admin dbshell

Runs the command-line client for the database engine specified in your ENGINE setting, with the connection parameters specified in your USER, PASSWORD, etc., settings.

- For PostgreSQL, this runs the psql command-line client.
- For MySQL, this runs the mysql command-line client.
- For SQLite, this runs the sqlite3 command-line client.
- For Oracle, this runs the sqlplus command-line client.

This command assumes the programs are on your PATH so that a call to the program name (psql, mysql, sqlite3, sqlplus) will find the program in the right place. There’s no way to specify the location of the program manually.

```bash
--database DATABASE
```

Specifies the database onto which to open a shell. Defaults to default.

```bash
-- ARGUMENTS
```

Any arguments following a -- divider will be passed on to the underlying command-line client. For example, with PostgreSQL you can use the psql command’s -c flag to execute a raw SQL query directly:
On MySQL/MariaDB, you can do this with the `mysql` command’s `-e` flag:

```
$ django-admin dbshell -- -e "select user()"
+----------------------+
| user() |
+----------------------+
| djangonaut@localhost |
+----------------------+
```

Note: Be aware that not all options set in the `OPTIONS` part of your database configuration in `DATABASES` are passed to the command-line client, e.g. `'isolation_level'`.

### diffsettings

**django-admin diffsettings**

Displays differences between the current settings file and Django’s default settings (or another settings file specified by `--default`).

Settings that don’t appear in the defaults are followed by "###". For example, the default settings don’t define `ROOT_URLCONF`, so `ROOT_URLCONF` is followed by "###" in the output of `diffsettings`.

```
--all
```

Displays all settings, even if they have Django’s default value. Such settings are prefixed by "###".

```
--default MODULE
```

The settings module to compare the current settings against. Leave empty to compare against Django’s default settings.

```
--output {hash,unified}
```

Specifies the output format. Available values are `hash` and `unified`. `hash` is the default mode that displays the output that’s described above. `unified` displays the output similar to `diff -u`. Default settings are prefixed with a minus sign, followed by the changed setting prefixed with a plus sign.
dumpdata

django-admin dumpdata [app_label[.ModelName] [app_label[.ModelName] ...]]

Outputs to standard output all data in the database associated with the named application(s).
If no application name is provided, all installed applications will be dumped.
The output of dumpdata can be used as input for loaddata.

Note that dumpdata uses the default manager on the model for selecting the records to dump. If you’re using a custom manager as the default manager and it filters some of the available records, not all of the objects will be dumped.

--all, -a

Uses Django’s base manager, dumping records which might otherwise be filtered or modified by a custom manager.

--format FORMAT

Specifies the serialization format of the output. Defaults to JSON. Supported formats are listed in Serialization formats.

--indent INDENT

Specifies the number of indentation spaces to use in the output. Defaults to None which displays all data on single line.

--exclude EXCLUDE, -e EXCLUDE

Prevents specific applications or models (specified in the form of app_label.ModelName) from being dumped.
If you specify a model name, then only that model will be excluded, rather than the entire application. You can also mix application names and model names.

If you want to exclude multiple applications, pass --exclude more than once:

django-admin dumpdata --exclude=auth --exclude=contenttypes

--database DATABASE

Specifies the database from which data will be dumped. Defaults to default.

--natural-foreign

Uses the natural_key() method to serialize any foreign key and many-to-many relationship to objects of the type that defines the method. If you’re dumping contrib.auth Permission objects or contrib.contenttypes ContentType objects, you should probably use this flag. See the natural keys documentation for more details on this and the next option.
- --natural-primary

Omits the primary key in the serialized data of this object since it can be calculated during deserialization.

- --pkp PRIMARY_KEYS

Outputs only the objects specified by a comma separated list of primary keys. This is only available when dumping one model. By default, all the records of the model are output.

- --output OUTPUT, -o OUTPUT

Specifies a file to write the serialized data to. By default, the data goes to standard output.

When this option is set and --verbosity is greater than 0 (the default), a progress bar is shown in the terminal.

**Fixtures compression**

The output file can be compressed with one of the `bz2`, `gz`, `lzma`, or `xz` formats by ending the filename with the corresponding extension. For example, to output the data as a compressed JSON file:

```
django-admin dumpdata -o mydata.json.gz
```

**flush**

**django-admin flush**

Removes all data from the database and re-executes any post-synchronization handlers. The table of which migrations have been applied is not cleared.

If you would rather start from an empty database and rerun all migrations, you should drop and recreate the database and then run `migrate` instead.

- --noinput, --no-input

Suppresses all user prompts.

- --database DATABASE

Specifies the database to flush. Defaults to `default`. 

```bash
6.8. django-admin and manage.py  1369
```
inspectdb

django-admin inspectdb [table [table ...]]

Introspects the database tables in the database pointed to by the NAME setting and outputs a Django model module (a models.py file) to standard output.

You may choose what tables or views to inspect by passing their names as arguments. If no arguments are provided, models are created for views only if the --include-views option is used. Models for partition tables are created on PostgreSQL if the --include-partitions option is used.

Use this if you have a legacy database with which you'd like to use Django. The script will inspect the database and create a model for each table within it.

As you might expect, the created models will have an attribute for every field in the table. Note that inspectdb has a few special cases in its field-name output:

- If inspectdb cannot map a column's type to a model field type, it'll use TextField and will insert the Python comment 'This field type is a guess.' next to the field in the generated model. The recognized fields may depend on apps listed in INSTALLED_APPS. For example, django.contrib.postgres adds recognition for several PostgreSQL-specific field types.

- If the database column name is a Python reserved word (such as 'pass', 'class' or 'for'), inspectdb will append '_field' to the attribute name. For example, if a table has a column 'for', the generated model will have a field 'for_field', with the db_column attribute set to 'for'. inspectdb will insert the Python comment 'Field renamed because it was a Python reserved word.' next to the field.

This feature is meant as a shortcut, not as definitive model generation. After you run it, you’ll want to look over the generated models yourself to make customizations. In particular, you’ll need to rearrange models’ order, so that models that refer to other models are ordered properly.

Django doesn’t create database defaults when a default is specified on a model field. Similarly, database defaults aren’t translated to model field defaults or detected in any fashion by inspectdb.

By default, inspectdb creates unmanaged models. That is, managed = False in the model’s Meta class tells Django not to manage each table’s creation, modification, and deletion. If you do want to allow Django to manage the table’s lifecycle, you’ll need to change the managed option to True (or remove it because True is its default value).
Database-specific notes

Oracle

- Models are created for materialized views if `--include-views` is used.

PostgreSQL

- Models are created for foreign tables.
- Models are created for materialized views if `--include-views` is used.
- Models are created for partition tables if `--include-partitions` is used.

`--database DATABASE`

Specifies the database to introspect. Defaults to `default`.

`--include-partitions`

If this option is provided, models are also created for partitions.

Only support for PostgreSQL is implemented.

`--include-views`

If this option is provided, models are also created for database views.

`loaddata`

django-admin loaddata fixture [fixture ...]

Searches for and loads the contents of the named fixture into the database.

`--database DATABASE`

Specifies the database into which the data will be loaded. Defaults to `default`.

`--ignorenonexistent, -i`

Ignores fields and models that may have been removed since the fixture was originally generated.

`--app APP_LABEL`

Specifies a single app to look for fixtures in rather than looking in all apps.

`--format FORMAT`

Specifies the serialization format (e.g., `json` or `xml`) for fixtures read from stdin.
--exclude EXCLUDE, -e EXCLUDE

Excludes loading the fixtures from the given applications and/or models (in the form of app_label or app_label.ModelName). Use the option multiple times to exclude more than one app or model.

What’s a “fixture”? 

A fixture is a collection of files that contain the serialized contents of the database. Each fixture has a unique name, and the files that comprise the fixture can be distributed over multiple directories, in multiple applications.

Django will search in three locations for fixtures:

1. In the fixtures directory of every installed application
2. In any directory named in the FIXTURE_DIRS setting
3. In the literal path named by the fixture

Django will load any and all fixtures it finds in these locations that match the provided fixture names.

If the named fixture has a file extension, only fixtures of that type will be loaded. For example:

```
django-admin loaddata mydata.json
```

would only load JSON fixtures called mydata. The fixture extension must correspond to the registered name of a serializer (e.g., json or xml).

If you omit the extensions, Django will search all available fixture types for a matching fixture. For example:

```
django-admin loaddata mydata
```

would look for any fixture of any fixture type called mydata. If a fixture directory contained mydata.json, that fixture would be loaded as a JSON fixture.

The fixtures that are named can include directory components. These directories will be included in the search path. For example:

```
django-admin loaddata foo/bar/mydata.json
```

would search <app_label>/fixtures/foo/bar/mydata.json for each installed application, <dirname>/foo/bar/mydata.json for each directory in FIXTURE_DIRS, and the literal path foo/bar/mydata.json.

When fixture files are processed, the data is saved to the database as is. Model defined save() methods are not called, and any pre_save or post_save signals will be called with raw=True since the instance only contains attributes that are local to the model. You may, for example, want to disable handlers that access related fields that aren’t present during fixture loading and would otherwise raise an exception:
from django.db.models.signals import post_save
from .models import MyModel

def my_handler(**kwargs):
    # disable the handler during fixture loading
    if kwargs['raw']:
        return ...

post_save.connect(my_handler, sender=MyModel)

You could also write a decorator to encapsulate this logic:

from functools import wraps

def disable_for_loaddata(signal_handler):
    """
    Decorator that turns off signal handlers when loading fixture data.
    """
    @wraps(signal_handler)
    def wrapper(*args,**kwargs):
        if kwargs['raw']:
            return signal_handler(*args,**kwargs)
        return wrapper

@disable_for_loaddata
def my_handler(**kwargs):
    ...

Just be aware that this logic will disable the signals whenever fixtures are deserialized, not just during loaddata.

Note that the order in which fixture files are processed is undefined. However, all fixture data is installed as a single transaction, so data in one fixture can reference data in another fixture. If the database backend supports row-level constraints, these constraints will be checked at the end of the transaction.

The dumpdata command can be used to generate input for loaddata.
Compressed fixtures

Fixtures may be compressed in zip, gz, bz2, lzma, or xz format. For example:

```bash
django-admin loaddata mydata.json
```

would look for any of `mydata.json`, `mydata.json.zip`, `mydata.json.gz`, `mydata.json.bz2`, `mydata.json.lzma`, or `mydata.json.xz`. The first file contained within a compressed archive is used.

Note that if two fixtures with the same name but different fixture type are discovered (for example, if `mydata.json` and `mydata.xml.gz` were found in the same fixture directory), fixture installation will be aborted, and any data installed in the call to `loaddata` will be removed from the database.

MySQL with MyISAM and fixtures

The MyISAM storage engine of MySQL doesn’t support transactions or constraints, so if you use MyISAM, you won’t get validation of fixture data, or a rollback if multiple transaction files are found.

Database-specific fixtures

If you’re in a multi-database setup, you might have fixture data that you want to load onto one database, but not onto another. In this situation, you can add a database identifier into the names of your fixtures.

For example, if your `DATABASES` setting has a ‘users’ database defined, name the fixture `mydata.users.json` or `mydata.users.json.gz` and the fixture will only be loaded when you specify you want to load data into the `users` database.

Loading fixtures from stdin

You can use a dash as the fixture name to load input from `sys.stdin`. For example:

```bash
django-admin loaddata --format=json -
```

When reading from `stdin`, the `--format` option is required to specify the serialization format of the input (e.g., json or xml).

Loading from `stdin` is useful with standard input and output redirections. For example:

```bash
django-admin dumpdata --format=json --database=test app_label.ModelName | django-admin loaddata --format=json --database=prod -
```
makemessages

django-admin makemessages

Runs over the entire source tree of the current directory and pulls out all strings marked for translation. It creates (or updates) a message file in the conf/locale (in the Django tree) or locale (for project and application) directory. After making changes to the messages files you need to compile them with compilemessages for use with the built-in gettext support. See the i18n documentation for details.

This command doesn’t require configured settings. However, when settings aren’t configured, the command can’t ignore the MEDIA_ROOT and STATIC_ROOT directories or include LOCALE_PATHS.

--all, -a

Updates the message files for all available languages.

--extension EXTENSIONS, -e EXTENSIONS

Specifies a list of file extensions to examine (default: html, txt, py or js if --domain is js).

Example usage:

```
django-admin makemessages --locale=de --extension xhtml
```

Separate multiple extensions with commas or use -e or --extension multiple times:

```
django-admin makemessages --locale=de --extension=html,txt --extension xml
```

--locale LOCALE, -l LOCALE

Specifies the locale(s) to process.

--exclude EXCLUDE, -x EXCLUDE

Specifies the locale(s) to exclude from processing. If not provided, no locales are excluded.

Example usage:

```
django-admin makemessages --locale=pt_BR
django-admin makemessages --locale=pt_BR --locale=fr
django-admin makemessages -l pt_BR
django-admin makemessages -l pt_BR -l fr
django-admin makemessages --exclude=pt_BR
django-admin makemessages --exclude=pt_BR --exclude=fr
django-admin makemessages -x pt_BR
django-admin makemessages -x pt_BR -x fr
```

--domain DOMAIN, -d DOMAIN

Specifies the domain of the messages files. Supported options are:
• django for all *.py, *.html and *.txt files (default)
• djangojs for *.js files

--symlinks, -s

Follows symlinks to directories when looking for new translation strings.

Example usage:

```
django-admin makemessages --locale=de --symlinks
```

--ignore PATTERN, -i PATTERN

Ignores files or directories matching the given glob-style pattern. Use multiple times to ignore more.

These patterns are used by default: 'CVS', '*.js', '*.~', '*.pyc'.

Example usage:

```
django-admin makemessages --locale=en_US --ignore=apps/* --ignore=secret/*html
```

--no-default-ignore

Disables the default values of --ignore.

--no-wrap

Disables breaking long message lines into several lines in language files.

--no-location

Suppresses writing ‘#: filename:line’ comment lines in language files. Using this option makes it harder for technically skilled translators to understand each message’s context.

--add-location [{{full, file, never}}]

Controls ‘#: filename:line’ comment lines in language files. If the option is:

- full (the default if not given): the lines include both file name and line number.
- file: the line number is omitted.
- never: the lines are suppressed (same as --no-location).

Requires gettext 0.19 or newer.

--keep-pot

Prevents deleting the temporary .pot files generated before creating the .po file. This is useful for debugging errors which may prevent the final language files from being created.
See also:

See Customizing the makemessages command for instructions on how to customize the keywords that makemessages passes to xgettext.

makemigrations

django-admin makemigrations [app_label [app_label ...]]

Creates new migrations based on the changes detected to your models. Migrations, their relationship with apps and more are covered in depth in the migrations documentation.

Providing one or more app names as arguments will limit the migrations created to the app(s) specified and any dependencies needed (the table at the other end of a ForeignKey, for example).

To add migrations to an app that doesn’t have a migrations directory, run makemigrations with the app’s app_label.

--noinput, --no-input

Suppresses all user prompts. If a suppressed prompt cannot be resolved automatically, the command will exit with error code 3.

--empty

Outputs an empty migration for the specified apps, for manual editing. This is for advanced users and should not be used unless you are familiar with the migration format, migration operations, and the dependencies between your migrations.

--dry-run

Shows what migrations would be made without actually writing any migrations files to disk. Using this option along with --verbosity 3 will also show the complete migrations files that would be written.

--merge

Enables fixing of migration conflicts.

--name NAME, -n NAME

Allows naming the generated migration(s) instead of using a generated name. The name must be a valid Python identifier.

--no-header

Generate migration files without Django version and timestamp header.

--check

Makes makemigrations exit with a non-zero status when model changes without migrations are detected.
--scriptable

Diverts log output and input prompts to stderr, writing only paths of generated migration files to stdout.

--update

Merges model changes into the latest migration and optimize the resulting operations.

migrate

django-admin migrate [app_label] [migration_name]

Synchronizes the database state with the current set of models and migrations. Migrations, their relationship with apps and more are covered in depth in the migrations documentation.

The behavior of this command changes depending on the arguments provided:

- No arguments: All apps have all of their migrations run.
- <app_label>: The specified app has its migrations run, up to the most recent migration. This may involve running other apps’ migrations too, due to dependencies.
- <app_label> <migration_name>: Brings the database schema to a state where the named migration is applied, but no later migrations in the same app are applied. This may involve unapplying migrations if you have previously migrated past the named migration. You can use a prefix of the migration name, e.g. 0001, as long as it’s unique for the given app name. Use the name zero to migrate all the way back i.e. to revert all applied migrations for an app.

Warning: When unapplying migrations, all dependent migrations will also be unapplied, regardless of <app_label>. You can use --plan to check which migrations will be unapplied.

--database DATABASE

Specifies the database to migrate. Defaults to default.

--fake

Marks the migrations up to the target one (following the rules above) as applied, but without actually running the SQL to change your database schema.

This is intended for advanced users to manipulate the current migration state directly if they’re manually applying changes; be warned that using --fake runs the risk of putting the migration state table into a state where manual recovery will be needed to make migrations run correctly.

--fake-initial

Allows Django to skip an app’s initial migration if all database tables with the names of all models created by all CreateModel operations in that migration already exist. This option is intended for use when first running
migrations against a database that preexisted the use of migrations. This option does not, however, check for matching database schema beyond matching table names and so is only safe to use if you are confident that your existing schema matches what is recorded in your initial migration.

--plan

Shows the migration operations that will be performed for the given migrate command.

--run-syncdb

Allows creating tables for apps without migrations. While this isn’t recommended, the migrations framework is sometimes too slow on large projects with hundreds of models.

--noinput, --no-input

Suppresses all user prompts. An example prompt is asking about removing stale content types.

--check

Makes migrate exit with a non-zero status when unapplied migrations are detected.

--prune

Deletes nonexistent migrations from the django_migrations table. This is useful when migration files replaced by a squashed migration have been removed. See Squashing migrations for more details.

optimizemigration

django-admin optimizemigration app_label migration_name

Optimizes the operations for the named migration and overrides the existing file. If the migration contains functions that must be manually copied, the command creates a new migration file suffixed with _optimized that is meant to replace the named migration.

--check

Makes optimizemigration exit with a non-zero status when a migration can be optimized.

runserver

django-admin runserver [addrport]

Starts a lightweight development web server on the local machine. By default, the server runs on port 8000 on the IP address 127.0.0.1. You can pass in an IP address and port number explicitly.

If you run this script as a user with normal privileges (recommended), you might not have access to start a port on a low port number. Low port numbers are reserved for the superuser (root).

This server uses the WSGI application object specified by the WSGI_APPLICATION setting.
DO NOT USE THIS SERVER IN A PRODUCTION SETTING. It has not gone through security audits or performance tests. (And that’s how it’s gonna stay. We’re in the business of making web frameworks, not web servers, so improving this server to be able to handle a production environment is outside the scope of Django.)

The development server automatically reloads Python code for each request, as needed. You don’t need to restart the server for code changes to take effect. However, some actions like adding files don’t trigger a restart, so you’ll have to restart the server in these cases.

If you’re using Linux or MacOS and install both pywatchman and the Watchman service, kernel signals will be used to autoreload the server (rather than polling file modification timestamps each second). This offers better performance on large projects, reduced response time after code changes, more robust change detection, and a reduction in power usage. Django supports pywatchman 1.2.0 and higher.

Large directories with many files may cause performance issues

When using Watchman with a project that includes large non-Python directories like node_modules, it’s advisable to ignore this directory for optimal performance. See the watchman documentation for information on how to do this.

Watchman timeout

**DJANGO_WATCHMAN_TIMEOUT**

The default timeout of Watchman client is 5 seconds. You can change it by setting the DJANGO_WATCHMAN_TIMEOUT environment variable.

When you start the server, and each time you change Python code while the server is running, the system check framework will check your entire Django project for some common errors (see the check command). If any errors are found, they will be printed to standard output. You can use the --skip-checks option to skip running system checks.

You can run as many concurrent servers as you want, as long as they’re on separate ports by executing django-admin runserver more than once.

Note that the default IP address, 127.0.0.1, is not accessible from other machines on your network. To make your development server viewable to other machines on the network, use its own IP address (e.g. 192.168.2.1) or 0.0.0.0 or :: (with IPv6 enabled).

You can provide an IPv6 address surrounded by brackets (e.g. [200a::1]:8000). This will automatically enable IPv6 support.

A hostname containing ASCII-only characters can also be used.
If the `staticfiles` contrib app is enabled (default in new projects) the `runserver` command will be overridden with its own `runserver` command.

Logging of each request and response of the server is sent to the `django.server` logger.

`--noreload`  
Disables the auto-reloader. This means any Python code changes you make while the server is running will not take effect if the particular Python modules have already been loaded into memory.

`--nothreading`  
Disables use of threading in the development server. The server is multithreaded by default.

`--ipv6`, `-6`  
Uses IPv6 for the development server. This changes the default IP address from `127.0.0.1` to `::1`.

**Examples of using different ports and addresses**

Port 8000 on IP address `127.0.0.1`:

```
django-admin runserver
```

Port 8000 on IP address `1.2.3.4`:

```
django-admin runserver 1.2.3.4:8000
```

Port 7000 on IP address `127.0.0.1`:

```
django-admin runserver 7000
```

Port 7000 on IP address `1.2.3.4`:

```
django-admin runserver 1.2.3.4:7000
```

Port 8000 on IPv6 address `::1`:

```
django-admin runserver -6
```

Port 7000 on IPv6 address `::1`:

```
django-admin runserver -6 7000
```

Port 7000 on IPv6 address `2001:0db8:1234:5678::9`:

```
django-admin runserver [2001:0db8:1234:5678::9]:7000
```
Port 8000 on IPv4 address of host localhost:

```bash
django-admin runserver localhost:8000
```

Port 8000 on IPv6 address of host localhost:

```bash
django-admin runserver -6 localhost:8000
```

Serving static files with the development server

By default, the development server doesn’t serve any static files for your site (such as CSS files, images, things under `MEDIA_URL` and so forth). If you want to configure Django to serve static media, read How to manage static files (e.g. images, JavaScript, CSS).

```bash
django-admin sendtestemail [email [email ...]]
```

Sends a test email (to confirm email sending through Django is working) to the recipient(s) specified. For example:

```bash
django-admin sendtestemail foo@example.com bar@example.com
```

There are a couple of options, and you may use any combination of them together:

```bash
--managers
```

Mails the email addresses specified in `MANAGERS` using `mail_managers()`.

```bash
--admins
```

Mails the email addresses specified in `ADMINS` using `mail_admins()`.

```bash
django-admin shell
```

Starts the Python interactive interpreter.

```bash
--interface {ipython,bpython,python}, -i {ipython,bpython,python}
```

Specifies the shell to use. By default, Django will use IPython or bpython if either is installed. If both are installed, specify which one you want like so:

IPython:
bpython:

django-admin shell -i bpython

If you have a “rich” shell installed but want to force use of the “plain” Python interpreter, use python as the interface name, like so:

django-admin shell -i python

--nostartup

Disables reading the startup script for the “plain” Python interpreter. By default, the script pointed to by the PYTHONSTARTUP environment variable or the ~/.pythonrc.py script is read.

--command COMMAND, -c COMMAND

Lets you pass a command as a string to execute it as Django, like so:

django-admin shell --command="import django; print(django.__version__)"

You can also pass code in on standard input to execute it. For example:

$ django-admin shell <<EOF
> import django
> print(django.__version__)
> EOF

On Windows, the REPL is output due to implementation limits of select.select() on that platform.

showmigrations

django-admin showmigrations [app_label [app_label ...]]

Shows all migrations in a project. You can choose from one of two formats:

--list, -l

Lists all of the apps Django knows about, the migrations available for each app, and whether or not each migration is applied (marked by an [X] next to the migration name). For a --verbosity of 2 and above, the applied datetimes are also shown.

Apps without migrations are also listed, but have (no migrations) printed under them.

This is the default output format.
--plan, -p

Shows the migration plan Django will follow to apply migrations. Like --list, applied migrations are marked by an [X]. For a --verbosity of 2 and above, all dependencies of a migration will also be shown.

app_labels arguments limit the output, however, dependencies of provided apps may also be included.

--database DATABASE

Specifies the database to examine. Defaults to default.

sqlflush

django-admin sqlflush

Prints the SQL statements that would be executed for the flush command.

--database DATABASE

Specifies the database for which to print the SQL. Defaults to default.

sqlmigrate

django-admin sqlmigrate app_label migration_name

Prints the SQL for the named migration. This requires an active database connection, which it will use to resolve constraint names; this means you must generate the SQL against a copy of the database you wish to later apply it on.

Note that sqlmigrate doesn’t colorize its output.

--backwards

Generates the SQL for unapplying the migration. By default, the SQL created is for running the migration in the forwards direction.

--database DATABASE

Specifies the database for which to generate the SQL. Defaults to default.

sqlsequencereset

django-admin sqlsequencereset app_label [app_label ...]

Prints the SQL statements for resetting sequences for the given app name(s).

Sequences are indexes used by some database engines to track the next available number for automatically incremented fields.
Use this command to generate SQL which will fix cases where a sequence is out of sync with its automatically incremented field data.

```
--database DATABASE
```

Specifies the database for which to print the SQL. Defaults to default.

### squashmigrations

```
django-admin squashmigrations app_label [start_migration_name] migration_name
```

Squashes the migrations for `app_label` up to and including `migration_name` down into fewer migrations, if possible. The resulting squashed migrations can live alongside the unsquashed ones safely. For more information, please read Squashing migrations.

When `start_migration_name` is given, Django will only include migrations starting from and including this migration. This helps to mitigate the squashing limitation of RunPython and `django.db.migrations.operations.RunSQL` migration operations.

```
--no-optimize
```

Disables the optimizer when generating a squashed migration. By default, Django will try to optimize the operations in your migrations to reduce the size of the resulting file. Use this option if this process is failing or creating incorrect migrations, though please also file a Django bug report about the behavior, as optimization is meant to be safe.

```
--noinput, --no-input
```

Suppresses all user prompts.

```
--squashed-name SQUASHED_NAME
```

Sets the name of the squashed migration. When omitted, the name is based on the first and last migration, with _squashed_ in between.

```
--no-header
```

Generate squashed migration file without Django version and timestamp header.

### startapp

```
django-admin startapp name [directory]
```

Creates a Django app directory structure for the given app name in the current directory or the given destination.

By default, the new directory contains a `models.py` file and other app template files. If only the app name is given, the app directory will be created in the current working directory.
If the optional destination is provided, Django will use that existing directory rather than creating a new one. You can use ‘.’ to denote the current working directory.

For example:

```
django-admin startapp myapp /Users/jezdez/Code/myapp
```

```
--template TEMPLATE
```

Provides the path to a directory with a custom app template file, or a path to an uncompressed archive (.tar) or a compressed archive (.tar.gz, .tar.bz2, .tar.xz, .tar.lzma, .tgz, .tbz2, .txz, .tlz, .zip) containing the app template files.

For example, this would look for an app template in the given directory when creating the myapp app:

```
django-admin startapp --template=/Users/jezdez/Code/my_app_template myapp
```

Django will also accept URLs (http, https, ftp) to compressed archives with the app template files, downloading and extracting them on the fly.

For example, taking advantage of GitHub’s feature to expose repositories as zip files, you can use a URL like:

```
django-admin startapp --template=https://github.com/githubuser/django-app-template/archive/main.--zip myapp
```

```
--extension EXTENSIONS, -e EXTENSIONS
```

Specifies which file extensions in the app template should be rendered with the template engine. Defaults to .py.

```
--name FILES, -n FILES
```

Specifies which files in the app template (in addition to those matching `--extension`) should be rendered with the template engine. Defaults to an empty list.

```
--exclude DIRECTORIES, -x DIRECTORIES
```

Specifies which directories in the app template should be excluded, in addition to .git and __pycache__. If this option is not provided, directories named __pycache__ or starting with . will be excluded.

The `template context` used for all matching files is:

- Any option passed to the `startapp` command (among the command’s supported options)
- `app_name` – the app name as passed to the command
- `app_directory` – the full path of the newly created app
- `camel_case_app_name` – the app name in camel case format
- `docs_version` – the version of the documentation: 'dev' or '1.x'
Warning: When the app template files are rendered with the Django template engine (by default all *.py files), Django will also replace all stray template variables contained. For example, if one of the Python files contains a docstring explaining a particular feature related to template rendering, it might result in an incorrect example.

To work around this problem, you can use the `templatetag` template tag to “escape” the various parts of the template syntax.

In addition, to allow Python template files that contain Django template language syntax while also preventing packaging systems from trying to byte-compile invalid *.py files, template files ending with .py-tpl will be renamed to .py.

### startproject

**django-admin startproject name [directory]**

Creates a Django project directory structure for the given project name in the current directory or the given destination.

By default, the new directory contains `manage.py` and a project package (containing a `settings.py` and other files).

If only the project name is given, both the project directory and project package will be named `<projectname>` and the project directory will be created in the current working directory.

If the optional destination is provided, Django will use that existing directory as the project directory, and create `manage.py` and the project package within it. Use ‘.’ to denote the current working directory.

For example:

```bash
django-admin startproject myproject /Users/jezdez/Code/myproject_repo
```

**--template TEMPLATE**

Specifies a directory, file path, or URL of a custom project template. See the `startapp --template` documentation for examples and usage.

**--extension EXTENSIONS, -e EXTENSIONS**

Specifies which file extensions in the project template should be rendered with the template engine. Defaults to py.

**--name FILES, -n FILES**

Specifies which files in the project template (in addition to those matching --extension) should be rendered with the template engine. Defaults to an empty list.
--exclude DIRECTORIES, -x DIRECTORIES

Specifies which directories in the project template should be excluded, in addition to .git and __pycache__. If this option is not provided, directories named __pycache__ or starting with . will be excluded.

The template context used is:
- Any option passed to the startproject command (among the command’s supported options)
- project_name – the project name as passed to the command
- project_directory – the full path of the newly created project
- secret_key – a random key for the SECRET_KEY setting
- docs_version – the version of the documentation: 'dev' or '1.x'
- django_version – the version of Django, e.g. '2.0.3'

Please also see the rendering warning as mentioned for startapp.

test
django-admin test [test_label [test_label ...]]

Runs tests for all installed apps. See Testing in Django for more information.

--failfast

Stops running tests and reports the failure immediately after a test fails.

--testrunner TESTRUNNER

Controls the test runner class that is used to execute tests. This value overrides the value provided by the TEST_RUNNER setting.

--noinput, --no-input

Suppresses all user prompts. A typical prompt is a warning about deleting an existing test database.

Test runner options

The test command receives options on behalf of the specified --testrunner. These are the options of the default test runner: DiscoverRunner.

--keepdb

Preserves the test database between test runs. This has the advantage of skipping both the create and destroy actions which can greatly decrease the time to run tests, especially those in a large test suite. If the test database does not exist, it will be created on the first run and then preserved for each subsequent run. Unless
the `MIGRATE` test setting is `False`, any unapplied migrations will also be applied to the test database before running the test suite.

`--shuffle [SEED]`

Randomizes the order of tests before running them. This can help detect tests that aren’t properly isolated. The test order generated by this option is a deterministic function of the integer seed given. When no seed is passed, a seed is chosen randomly and printed to the console. To repeat a particular test order, pass a seed. The test orders generated by this option preserve Django’s guarantees on test order. They also keep tests grouped by test case class.

The shuffled orderings also have a special consistency property useful when narrowing down isolation issues. Namely, for a given seed and when running a subset of tests, the new order will be the original shuffling restricted to the smaller set. Similarly, when adding tests while keeping the seed the same, the order of the original tests will be the same in the new order.

`--reverse, -r`

Sorts test cases in the opposite execution order. This may help in debugging the side effects of tests that aren’t properly isolated. Grouping by test class is preserved when using this option. This can be used in conjunction with `--shuffle` to reverse the order for a particular seed.

`--debug-mode`

Sets the `DEBUG` setting to `True` prior to running tests. This may help troubleshoot test failures.

`--debug-sql, -d`

Enables SQL logging for failing tests. If `--verbosity` is 2, then queries in passing tests are also output.

`--parallel [N]`

`DJANGO_TEST PROCESSES`

Runs tests in separate parallel processes. Since modern processors have multiple cores, this allows running tests significantly faster.

Using `--parallel` without a value, or with the value `auto`, runs one test process per core according to `multiprocessing.cpu_count()`. You can override this by passing the desired number of processes, e.g. `--parallel 4`, or by setting the `DJANGO_TEST PROCESSES` environment variable.

Django distributes test cases —`unittest.TestCase` subclasses — to subprocesses. If there are fewer test cases than configured processes, Django will reduce the number of processes accordingly.

Each process gets its own database. You must ensure that different test cases don’t access the same resources. For instance, test cases that touch the filesystem should create a temporary directory for their own use.

Note: If you have test classes that cannot be run in parallel, you can use `SerializeMixin` to run them sequentially. See Enforce running test classes sequentially.
This option requires the third-party tblib package to display tracebacks correctly:

```bash
$ python -m pip install tblib
```

This feature isn’t available on Windows. It doesn’t work with the Oracle database backend either.

If you want to use pdb while debugging tests, you must disable parallel execution (`--parallel=1`). You’ll see something like `bdb.BdbQuit` if you don’t.

---

Warning: When test parallelization is enabled and a test fails, Django may be unable to display the exception traceback. This can make debugging difficult. If you encounter this problem, run the affected test without parallelization to see the traceback of the failure.

This is a known limitation. It arises from the need to serialize objects in order to exchange them between processes. See What can be pickled and unpickled? for details.

---

`--tag TAGS`

Runs only tests marked with the specified tags. May be specified multiple times and combined with `test --exclude-tag`.

Tests that fail to load are always considered matching.

`--exclude-tag EXCLUDE_TAGS`

Excludes tests marked with the specified tags. May be specified multiple times and combined with `test --tag`.

`-k TEST_NAME_PATTERNS`

Runs test methods and classes matching test name patterns, in the same way as `unittest's -k option`. Can be specified multiple times.

`--pdb`

Spawns a pdb debugger at each test error or failure. If you have it installed, `ipdb` is used instead.

`--buffer, -b`

Discards output (stdout and stderr) for passing tests, in the same way as `unittest's --buffer option`.

`--no-faulthandler`

Django automatically calls `faulthandler.enable()` when starting the tests, which allows it to print a traceback if the interpreter crashes. Pass `--no-faulthandler` to disable this behavior.

`--timing`

Outputs timings, including database setup and total run time.
**testserver**

`django-admin testserver [fixture [fixture ...]]`

Runs a Django development server (as in `runserver`) using data from the given fixture(s).

For example, this command:

```
django-admin testserver mydata.json
```

...would perform the following steps:

1. Create a test database, as described in The test database.
2. Populate the test database with fixture data from the given fixtures. (For more on fixtures, see the documentation for loaddata above.)
3. Runs the Django development server (as in `runserver`), pointed at this newly created test database instead of your production database.

This is useful in a number of ways:

- When you’re writing unit tests of how your views act with certain fixture data, you can use testserver to interact with the views in a web browser, manually.
- Let’s say you’re developing your Django application and have a “pristine” copy of a database that you’d like to interact with. You can dump your database to a fixture (using the dumpdata command, explained above), then use testserver to run your web application with that data. With this arrangement, you have the flexibility of messing up your data in any way, knowing that whatever data changes you’re making are only being made to a test database.

Note that this server does not automatically detect changes to your Python source code (as runserver does). It does, however, detect changes to templates.

**--addrport ADDRPORT**

Specifies a different port, or IP address and port, from the default of `127.0.0.1:8000`. This value follows exactly the same format and serves exactly the same function as the argument to the runserver command.

Examples:

To run the test server on port 7000 with fixture1 and fixture2:

```
django-admin testserver --addrport 7000 fixture1 fixture2
```

(The above statements are equivalent. We include both of them to demonstrate that it doesn’t matter whether the options come before or after the fixture arguments.)

To run on 1.2.3.4:7000 with a test fixture:
Suppresses all user prompts. A typical prompt is a warning about deleting an existing test database.

### 6.8.3 Commands provided by applications

Some commands are only available when the `django.contrib` application that implements them has been enabled. This section describes them grouped by their application.

#### django.contrib.auth

**changepassword**

```bash
django-admin changepassword [username]
```

This command is only available if Django’s authentication system (`django.contrib.auth`) is installed.

Allows changing a user’s password. It prompts you to enter a new password twice for the given user. If the entries are identical, this immediately becomes the new password. If you do not supply a user, the command will attempt to change the password whose username matches the current user.

```bash
--database DATABASE
```

Specifies the database to query for the user. Defaults to `default`.

Example usage:

```bash
django-admin changepassword ringo
```

**createsuperuser**

```bash
django-admincreatesuperuser
```

This command is only available if Django’s authentication system (`django.contrib.auth`) is installed.

Creates a superuser account (a user who has all permissions). This is useful if you need to create an initial superuser account or if you need to programmatically generate superuser accounts for your site(s).

When run interactively, this command will prompt for a password for the new superuser account. When run non-interactively, you can provide a password by setting the `DJANGO_SUPERUSER_PASSWORD` environment variable. Otherwise, no password will be set, and the superuser account will not be able to log in until a password has been manually set for it.
In non-interactive mode, the `USERNAME_FIELD` and required fields (listed in `REQUIRED_FIELDS`) fall back to `DJANGO_SUPERUSER_<uppercase_field_name>` environment variables, unless they are overridden by a command line argument. For example, to provide an email field, you can use `DJANGO_SUPERUSER_EMAIL` environment variable.

`--noinput`, `--no-input`

Suppresses all user prompts. If a suppressed prompt cannot be resolved automatically, the command will exit with error code 1.

`--username USERNAME`

`--email EMAIL`

The username and email address for the new account can be supplied by using the `--username` and `--email` arguments on the command line. If either of those is not supplied, `createsuperuser` will prompt for it when running interactively.

`--database DATABASE`

Specifies the database into which the superuser object will be saved.

You can subclass the management command and override `get_input_data()` if you want to customize data input and validation. Consult the source code for details on the existing implementation and the method’s parameters. For example, it could be useful if you have a `ForeignKey` in `REQUIRED_FIELDS` and want to allow creating an instance instead of entering the primary key of an existing instance.

```
django.contrib.contenttypes

remove_stale_contenttypes
```

```
django-admin remove_stale_contenttypes
```

This command is only available if Django’s `contenttypes` app (`django.contrib.contenttypes`) is installed.

Deletes stale content types (from deleted models) in your database. Any objects that depend on the deleted content types will also be deleted. A list of deleted objects will be displayed before you confirm it’s okay to proceed with the deletion.

`--database DATABASE`

Specifies the database to use. Defaults to `default`.

`--include-stale-apps`

Deletes stale content types including ones from previously installed apps that have been removed from `INSTALLED_APPS`. Defaults to `False`.
django.contrib.gis

ogrinspect

This command is only available if GeoDjango (django.contrib.gis) is installed. Please refer to its description in the GeoDjango documentation.

django.contrib.sessions

clearsessions

django-admin clearsessions

Can be run as a cron job or directly to clean out expired sessions.

django.contrib.sitemaps

ping_google

This command is only available if the Sitemaps framework (django.contrib.sitemaps) is installed. Please refer to its description in the Sitemaps documentation.

django.contrib.staticfiles

collectstatic

This command is only available if the static files application (django.contrib.staticfiles) is installed. Please refer to its description in the staticfiles documentation.

findstatic

This command is only available if the static files application (django.contrib.staticfiles) is installed. Please refer to its description in the staticfiles documentation.
6.8.4 Default options

Although some commands may allow their own custom options, every command allows for the following options by default:

--pythonpath PYTHONPATH

Add the given filesystem path to the Python import search path. If this isn’t provided, django-admin will use the PYTHONPATH environment variable. This option is unnecessary in manage.py, because it takes care of setting the Python path for you.

Example usage:

```
django-admin migrate --pythonpath="/home/djangoprojects/myproject"
```

--settings SETTINGS

Specifies the settings module to use. The settings module should be in Python package syntax, e.g. mysite.settings. If this isn’t provided, django-admin will use the DJANGO_SETTINGS_MODULE environment variable. This option is unnecessary in manage.py, because it uses settings.py from the current project by default.

Example usage:

```
django-admin migrate --settings=mysite.settings
```

--traceback

Displays a full stack trace when a CommandError is raised. By default, django-admin will show an error message when a CommandError occurs and a full stack trace for any other exception.

This option is ignored by runserver.

Example usage:

```
django-admin migrate --traceback
```

--verbosity {0,1,2,3}, -v {0,1,2,3}

Specifies the amount of notification and debug information that a command should print to the console.

- 0 means no output.
- 1 means normal output (default).
- 2 means verbose output.
- 3 means very verbose output.

This option is ignored by runserver.

Example usage:
**--no-color**

Disables colorized command output. Some commands format their output to be colorized. For example, errors will be printed to the console in red and SQL statements will be syntax highlighted.

Example usage:

```
django-admin runserver --no-color
```

**--force-color**

Forces colorization of the command output if it would otherwise be disabled as discussed in Syntax coloring. For example, you may want to pipe colored output to another command.

**--skip-checks**

Skips running system checks prior to running the command. This option is only available if the `requires_systemChecks` command attribute is not an empty list or tuple.

Example usage:

```
django-admin migrate --skip-checks
```

### 6.8.5 Extra niceties

**Syntax coloring**

**DJANGO_COLORS**

The `django-admin/manage.py` commands will use pretty color-coded output if your terminal supports ANSI-colored output. It won’t use the color codes if you’re piping the command’s output to another program unless the `--force-color` option is used.

**Windows support**

On Windows 10, the Windows Terminal application, VS Code, and PowerShell (where virtual terminal processing is enabled) allow colored output, and are supported by default.

Under Windows, the legacy `cmd.exe` native console doesn’t support ANSI escape sequences so by default there is no color output. In this case either of two third-party libraries are needed:

- Install colorama, a Python package that translates ANSI color codes into Windows API calls. Django commands will detect its presence and will make use of its services to color output just like on Unix-based platforms. `colorama` can be installed via pip:
...\> py -m pip install colorama

- Install **ANSICON**, a third-party tool that allows `cmd.exe` to process ANSI color codes. Django commands will detect its presence and will make use of its services to color output just like on Unix-based platforms.

Other modern terminal environments on Windows, that support terminal colors, but which are not automatically detected as supported by Django, may “fake” the installation of **ANSICON** by setting the appropriate environmental variable, `ANSICON="on"`.

**Custom colors**

The colors used for syntax highlighting can be customized. Django ships with three color palettes:

- **dark**, suited to terminals that show white text on a black background. This is the default palette.
- **light**, suited to terminals that show black text on a white background.
- **nocolor**, which disables syntax highlighting.

You select a palette by setting a `DJANGO_COLORS` environment variable to specify the palette you want to use. For example, to specify the `light` palette under a Unix or OS/X BASH shell, you would run the following at a command prompt:

```bash
export DJANGO_COLORS="light"
```

You can also customize the colors that are used. Django specifies a number of roles in which color is used:

- **error** - A major error.
- **notice** - A minor error.
- **success** - A success.
- **warning** - A warning.
- **sql_field** - The name of a model field in SQL.
- **sql_coltype** - The type of a model field in SQL.
- **sql_keyword** - An SQL keyword.
- **sql_table** - The name of a model in SQL.
- **http_info** - A 1XX HTTP Informational server response.
- **http_success** - A 2XX HTTP Success server response.
- **http_not_modified** - A 304 HTTP Not Modified server response.
- **http_redirect** - A 3XX HTTP Redirect server response other than 304.
- **http_not_found** - A 404 HTTP Not Found server response.
- http_bad_request - A 4XX HTTP Bad Request server response other than 404.
- http_server_error - A 5XX HTTP Server Error response.
- migrate_heading - A heading in a migrations management command.
- migrate_label - A migration name.

Each of these roles can be assigned a specific foreground and background color, from the following list:

- black
- red
- green
- yellow
- blue
- magenta
- cyan
- white

Each of these colors can then be modified by using the following display options:

- bold
- underscore
- blink
- reverse
- conceal

A color specification follows one of the following patterns:

- role=fg
- role=fg/bg
- role=fg,option,option
- role=fg/bg,option,option

where role is the name of a valid color role, fg is the foreground color, bg is the background color and each option is one of the color modifying options. Multiple color specifications are then separated by a semicolon. For example:

```
export DJANGO_COLORS="error=yellow/blue,blink;notice=magenta"
```

would specify that errors be displayed using blinking yellow on blue, and notices displayed using magenta. All other color roles would be left uncolored.
Colors can also be specified by extending a base palette. If you put a palette name in a color specification, all the colors implied by that palette will be loaded. So:

```bash
export DJANGO_COLORS="light;error=yellow/blue,blink;notice=magenta"
```

would specify the use of all the colors in the light color palette, except for the colors for errors and notices which would be overridden as specified.

### Bash completion

If you use the Bash shell, consider installing the Django bash completion script, which lives in `extras/django_bash_completion` in the Django source distribution. It enables tab-completion of `django-admin` and `manage.py` commands, so you can, for instance...

- Type `django-admin`.
- Press `[TAB]` to see all available options.
- Type `sql`, then `[TAB]`, to see all available options whose names start with `sql`.

See [How to create custom django-admin commands](https://docs.djangoproject.com/en/4.2/topics/django-admin/) for how to add customized actions.

### Black formatting

The Python files created by `startproject`, `startapp`, `optimizemigration`, `makemigrations`, and `squashmigrations` are formatted using the `black` command if it is present on your `PATH`.

If you have `black` globally installed, but do not wish it used for the current project, you can set the `PATH` explicitly:

```
PATH=path/to/venv/bin django-admin makemigrations
```

For commands using `stdout` you can pipe the output to `black` if needed:

```
django-admin inspectdb | black -
```

### 6.9 Running management commands from your code

`django.core.management.call_command(name, *args, **options)`

To call a management command from code use `call_command`.

- `name`
  - the name of the command to call or a command object. Passing the name is preferred unless the object is required for testing.
*args

A list of arguments accepted by the command. Arguments are passed to the argument parser, so you can use the same style as you would on the command line. For example, `call_command('flush', '--verbosity=0').`

**options

Named options accepted on the command-line. Options are passed to the command without triggering the argument parser, which means you’ll need to pass the correct type. For example, `call_command('flush', verbosity=0)` (zero must be an integer rather than a string).

Examples:

```python
from django.core import management
from django.core.management.commands import loaddata

management.call_command('flush', verbosity=0, interactive=False)
management.call_command('loaddata', 'test_data', verbosity=0)
management.call_command(loaddata.Command(), 'test_data', verbosity=0)
```

Note that command options that take no arguments are passed as keywords with True or False, as you can see with the `interactive` option above.

Named arguments can be passed by using either one of the following syntaxes:

```python
# Similar to the command line
management.call_command('dumpdata', '--natural-foreign')

# Named argument similar to the command line minus the initial dashes and
# with internal dashes replaced by underscores
management.call_command('dumpdata', natural_foreign=True)

# 'use_natural_foreign_keys' is the option destination variable
management.call_command('dumpdata', use_natural_foreign_keys=True)
```

Some command options have different names when using `call_command()` instead of `django-admin` or `manage.py`. For example, `django-admin createsuperuser --no-input` translates to `call_command('createsuperuser', interactive=False)`. To find what keyword argument name to use for `call_command()`, check the command’s source code for the `dest` argument passed to `parser.add_argument()`.

Command options which take multiple options are passed a list:

```python
management.call_command('dumpdata', exclude=['contenttypes', 'auth'])
```

The return value of the `call_command()` function is the same as the return value of the `handle()` method of the command.
6.9.1 Output redirection

Note that you can redirect standard output and error streams as all commands support the `stdout` and `stderr` options. For example, you could write:

```python
with open('/path/to/command_output', 'w') as f:
    management.call_command('dumpdata', stdout=f)
```

6.10 Django Exceptions

Django raises some of its own exceptions as well as standard Python exceptions.

6.10.1 Django Core Exceptions

Django core exception classes are defined in `django.core.exceptions`.

**AppRegistryNotReady**

exception `AppRegistryNotReady`

This exception is raised when attempting to use models before the app loading process, which initializes the ORM, is complete.

**ObjectDoesNotExist**

exception `ObjectDoesNotExist`

The base class for `Model.DoesNotExist` exceptions. A `try/except` for `ObjectDoesNotExist` will catch `DoesNotExist` exceptions for all models.

See `get()`.

**EmptyResultSet**

exception `EmptyResultSet`

`EmptyResultSet` may be raised during query generation if a query won’t return any results. Most Django projects won’t encounter this exception, but it might be useful for implementing custom lookups and expressions.
FieldDoesNotExist

exception FieldDoesNotExist

The FieldDoesNotExist exception is raised by a model’s _meta.get_field() method when the requested field does not exist on the model or on the model’s parents.

MultipleObjectsReturned

exception MultipleObjectsReturned

The base class for Model.MultipleObjectsReturned exceptions. A try/except for MultipleObjectsReturned will catch MultipleObjectsReturned exceptions for all models.

See get().

SuspiciousOperation

exception SuspiciousOperation

The SuspiciousOperation exception is raised when a user has performed an operation that should be considered suspicious from a security perspective, such as tampering with a session cookie. Subclasses of SuspiciousOperation include:

- DisallowedHost
- DisallowedModelAdminLookup
- DisallowedModelAdminToField
- DisallowedRedirect
- InvalidSessionKey
- RequestDataTooBig
- SuspiciousFileOperation
- SuspiciousMultipartForm
- SuspiciousSession
- TooManyFieldsSent

If a SuspiciousOperation exception reaches the ASGI/WSGI handler level it is logged at the Error level and results in a HttpResponseBadRequest. See the logging documentation for more information.
PermissionDenied

exception PermissionDenied

    The `PermissionDenied` exception is raised when a user does not have permission to perform the action requested.

ViewDoesNotExist

exception ViewDoesNotExist

    The `ViewDoesNotExist` exception is raised by `django.urls` when a requested view does not exist.

MiddlewareNotUsed

exception MiddlewareNotUsed

    The `MiddlewareNotUsed` exception is raised when a middleware is not used in the server configuration.

ImproperlyConfigured

exception ImproperlyConfigured

    The `ImproperlyConfigured` exception is raised when Django is somehow improperly configured—for example, if a value in `settings.py` is incorrect or unparsable.

FieldError

exception FieldError

    The `FieldError` exception is raised when there is a problem with a model field. This can happen for several reasons:

    • A field in a model clashes with a field of the same name from an abstract base class
    • An infinite loop is caused by ordering
    • A keyword cannot be parsed from the filter parameters
    • A field cannot be determined from a keyword in the query parameters
    • A join is not permitted on the specified field
    • A field name is invalid
    • A query contains invalid order_by arguments
ValidationErrors

ValidationErrors

exception ValidationError

The `ValidationError` exception is raised when data fails form or model field validation. For more information about validation, see Form and Field Validation, Model Field Validation and the Validator Reference.

NON_FIELD_ERRORS

NON_FIELD_ERRORS

ValidationErrors that don’t belong to a particular field in a form or model are classified as NON_FIELD_ERRORS. This constant is used as a key in dictionaries that otherwise map fields to their respective list of errors.

BadRequest

exception BadRequest

The `BadRequest` exception is raised when the request cannot be processed due to a client error. If a `BadRequest` exception reaches the ASGI/WSGI handler level it results in a `HttpResponseBadRequest`.

RequestAborted

exception RequestAborted

The `RequestAborted` exception is raised when an HTTP body being read in by the handler is cut off midstream and the client connection closes, or when the client does not send data and hits a timeout where the server closes the connection.

It is internal to the HTTP handler modules and you are unlikely to see it elsewhere. If you are modifying HTTP handling code, you should raise this when you encounter an aborted request to make sure the socket is closed cleanly.

SynchronousOnlyOperation

exception SynchronousOnlyOperation

The `SynchronousOnlyOperation` exception is raised when code that is only allowed in synchronous Python code is called from an asynchronous context (a thread with a running asynchronous event loop). These parts of Django are generally heavily reliant on thread-safety to function and don’t work correctly under coroutines sharing the same thread.

If you are trying to call code that is synchronous-only from an asynchronous thread, then create a synchronous thread and call it in that. You can accomplish this with `asgiref.sync.sync_to_async()`.
6.10.2 URL Resolver exceptions

URL Resolver exceptions are defined in `django.urls`.

`Resolver404`

**exception Resolver404**

The `Resolver404` exception is raised by `resolve()` if the path passed to `resolve()` doesn’t map to a view. It’s a subclass of `django.http.Http404`.

`NoReverseMatch`

**exception NoReverseMatch**

The `NoReverseMatch` exception is raised by `django.urls` when a matching URL in your URLconf cannot be identified based on the parameters supplied.

6.10.3 Database Exceptions

Database exceptions may be imported from `django.db`.

Django wraps the standard database exceptions so that your Django code has a guaranteed common implementation of these classes.

**exception Error**

**exception InterfaceError**

**exception DatabaseError**

**exception DataError**

**exception OperationalError**

**exception IntegrityError**

**exception InternalError**

**exception ProgrammingError**

**exception NotSupportedError**

The Django wrappers for database exceptions behave exactly the same as the underlying database exceptions. See PEP 249, the Python Database API Specification v2.0, for further information.

As per PEP 3134, a `__cause__` attribute is set with the original (underlying) database exception, allowing access to any additional information provided.
exception models.ProtectedError

Raised to prevent deletion of referenced objects when using `django.db.models.PROTECT`. `ProtectedError` is a subclass of `IntegrityError`.

exception models.RestrictedError

Raised to prevent deletion of referenced objects when using `django.db.models.RESTRICT`. `RestrictedError` is a subclass of `IntegrityError`.

### 6.10.4 HTTP Exceptions

HTTP exceptions may be imported from `django.http`.

UnreadablePostError

exception UnreadablePostError

`UnreadablePostError` is raised when a user cancels an upload.

### 6.10.5 Sessions Exceptions

Sessions exceptions are defined in `django.contrib.sessions.exceptions`.

SessionInterrupted

exception SessionInterrupted

`SessionInterrupted` is raised when a session is destroyed in a concurrent request. It’s a subclass of `BadRequest`.

### 6.10.6 Transaction Exceptions

Transaction exceptions are defined in `django.db.transaction`.

TransactionManagementError

exception TransactionManagementError

`TransactionManagementError` is raised for any and all problems related to database transactions.
6.10.7 Testing Framework Exceptions

Exceptions provided by the django.test package.

RedirectCycleError

```
exception client.RedirectCycleError
```

RedirectCycleError is raised when the test client detects a loop or an overly long chain of redirects.

6.10.8 Python Exceptions

Django raises built-in Python exceptions when appropriate as well. See the Python documentation for further information on the Built-in Exceptions.

6.11 File handling

6.11.1 The File object

The django.core.files module and its submodules contain built-in classes for basic file handling in Django.

The File class

```
class File(file_object, name=None)
```

The File class is a thin wrapper around a Python file object with some Django-specific additions. Internally, Django uses this class when it needs to represent a file.

File objects have the following attributes and methods:

- `name`
  - The name of the file including the relative path from MEDIA_ROOT.

- `size`
  - The size of the file in bytes.

- `file`
  - The underlying file object that this class wraps.

Be careful with this attribute in subclasses.

Some subclasses of File, including ContentFile and FieldFile, may replace this attribute with an object other than a Python file object. In these cases, this attribute may itself be a File subclass.
(and not necessarily the same subclass). Whenever possible, use the attributes and methods of the subclass itself rather than those of the subclass’s file attribute.

---

**mode**

The read/write mode for the file.

**open**(mode=None)

Open or reopen the file (which also does File.seek(0)). The mode argument allows the same values as Python’s built-in open().

When reopening a file, mode will override whatever mode the file was originally opened with; None means to reopen with the original mode.

It can be used as a context manager, e.g. with file.open() as f:

**__iter__**()

Iterate over the file yielding one line at a time.

**chunks**(chunk_size=None)

Iterate over the file yielding “chunks” of a given size. chunk_size defaults to 64 KB.

This is especially useful with very large files since it allows them to be streamed off disk and avoids storing the whole file in memory.

**multiple_chunks**(chunk_size=None)

Returns True if the file is large enough to require multiple chunks to access all of its content give some chunk_size.

**close**()

Close the file.

In addition to the listed methods, File exposes the following attributes and methods of its file object: encoding, fileno, flush, isatty, newlines, read, readinto, readline, readlines, seek, tell, truncate, write, writelines, readable(), writable(), and seekable().

---

### The ContentFile class

**class** ContentFile(content, name=None)

The ContentFile class inherits from File, but unlike File it operates on string content (bytes also supported), rather than an actual file. For example:

```python
from django.core.files.base import ContentFile

f1 = ContentFile("esta frase está en español")
f2 = ContentFile(b"these are bytes")
```
The **ImageFile** class

```python
class ImageFile(file_object, name=None)
```

Django provides a built-in class specifically for images. `django.core.files.images.ImageFile` inherits all the attributes and methods of `File`, and additionally provides the following:

- **width**
  Width of the image in pixels.

- **height**
  Height of the image in pixels.

### Additional methods on files attached to objects

Any `File` that is associated with an object (as with `Car.photo`, below) will also have a couple of extra methods:

- **File.save(name, content, save=True)**
  Saves a new file with the file name and contents provided. This will not replace the existing file, but will create a new file and update the object to point to it. If `save` is True, the model’s `save()` method will be called once the file is saved. That is, these two lines:

  ```python
  >>> car.photo.save('myphoto.jpg', content, save=False)
  >>> car.save()
  ```
  
  are equivalent to:

  ```python
  >>> car.photo.save('myphoto.jpg', content, save=True)
  ```

  Note that the `content` argument must be an instance of either `File` or of a subclass of `File`, such as `ContentFile`.

- **File.delete(save=True)**
  Removes the file from the model instance and deletes the underlying file. If `save` is True, the model’s `save()` method will be called once the file is deleted.

### 6.11.2 File storage API

#### Getting the current storage class

Django provides two convenient ways to access the current storage class:

```python
class DefaultStorage
```

`DefaultStorage` provides lazy access to the current default storage system as defined by `DEFAULT_FILE_STORAGE`. `DefaultStorage` uses `get_storage_class()` internally.
**get_storage_class** (import_path=None)

Returns a class or module which implements the storage API.

When called without the `import_path` parameter `get_storage_class` will return the current default storage system as defined by `DEFAULT_FILE_STORAGE`. If `import_path` is provided, `get_storage_class` will attempt to import the class or module from the given path and will return it if successful. An exception will be raised if the import is unsuccessful.

The **FileSystemStorage** class

```python
class FileSystemStorage(location=None, base_url=None, file_permissions_mode=None, directory_permissions_mode=None)
```

The `FileSystemStorage` class implements basic file storage on a local filesystem. It inherits from `Storage` and provides implementations for all the public methods thereof.

- **location**
  
  Absolute path to the directory that will hold the files. Defaults to the value of your `MEDIA_ROOT` setting.

- **base_url**

  URL that serves the files stored at this location. Defaults to the value of your `MEDIA_URL` setting.

- **file_permissions_mode**

  The file system permissions that the file will receive when it is saved. Defaults to `FILE_UPLOAD_PERMISSIONS`.

- **directory_permissions_mode**

  The file system permissions that the directory will receive when it is saved. Defaults to `FILE_UPLOAD_DIRECTORY_PERMISSIONS`.

Note: The `FileSystemStorage.delete()` method will not raise an exception if the given file name does not exist.

```python
get_created_time(name)
```

Returns a `datetime` of the system’s `ctime`, i.e. `os.path.getctime()`. On some systems (like Unix), this is the time of the last metadata change, and on others (like Windows), it’s the creation time of the file.
The **Storage** class

```python
class Storage

The **Storage** class provides a standardized API for storing files, along with a set of default behaviors that all other storage systems can inherit or override as necessary.
```

---

**Note:** When methods return naive `datetime` objects, the effective timezone used will be the current value of `os.environ['TZ']`; note that this is usually set from Django’s `TIME_ZONE`.

---

**delete**(name)

Deletes the file referenced by `name`. If deletion is not supported on the target storage system this will raise `NotImplementedError` instead.

**exists**(name)

Returns `True` if a file referenced by the given name already exists in the storage system, or `False` if the name is available for a new file.

**get_accessed_time**(name)

Returns a `datetime` of the last accessed time of the file. For storage systems unable to return the last accessed time this will raise `NotImplementedError`.

If `USE_TZ` is `True`, returns an aware `datetime`, otherwise returns a naive `datetime` in the local timezone.

**get_alternative_name**(file_root, file_ext)

Returns an alternative filename based on the `file_root` and `file_ext` parameters, an underscore plus a random 7 character alphanumeric string is appended to the filename before the extension.

**get_available_name**(name, max_length=None)

Returns a filename based on the `name` parameter that’s free and available for new content to be written to on the target storage system.

The length of the filename will not exceed `max_length`, if provided. If a free unique filename cannot be found, a `SuspiciousFileOperation` exception will be raised.

If a file with `name` already exists, `get_alternative_name()` is called to obtain an alternative name.

**get_created_time**(name)

Returns a `datetime` of the creation time of the file. For storage systems unable to return the creation time this will raise `NotImplementedError`.

If `USE_TZ` is `True`, returns an aware `datetime`, otherwise returns a naive `datetime` in the local timezone.
get_modified_time(name)

Returns a `datetime` of the last modified time of the file. For storage systems unable to return the last modified time this will raise `NotImplementedError`.

If `USE_TZ` is True, returns an aware `datetime`, otherwise returns a naive `datetime` in the local timezone.

get_valid_name(name)

Returns a filename based on the `name` parameter that’s suitable for use on the target storage system.

generate_filename(filename)

Validates the `filename` by calling `get_valid_name()` and returns a filename to be passed to the `save()` method.

The `filename` argument may include a path as returned by `FileField.upload_to`. In that case, the path won’t be passed to `get_valid_name()` but will be prepended back to the resulting name.

The default implementation uses `os.path` operations. Override this method if that’s not appropriate for your storage.

listdir(path)

Lists the contents of the specified path, returning a 2-tuple of lists; the first item being directories, the second item being files. For storage systems that aren’t able to provide such a listing, this will raise a `NotImplementedError` instead.

open(name, mode='rb')

Opens the file given by `name`. Note that although the returned file is guaranteed to be a `File` object, it might actually be some subclass. In the case of remote file storage this means that reading/writing could be quite slow, so be warned.

path(name)

The local filesystem path where the file can be opened using Python’s standard `open()`. For storage systems that aren’t accessible from the local filesystem, this will raise `NotImplementedError` instead.

save(name, content, max_length=None)

Saves a new file using the storage system, preferably with the name specified. If there already exists a file with this name `name`, the storage system may modify the filename as necessary to get a unique name. The actual name of the stored file will be returned.

The `max_length` argument is passed along to `get_available_name()`.

The `content` argument must be an instance of `django.core.files.File` or a file-like object that can be wrapped in `File`.  

size(name)

Returns the total size, in bytes, of the file referenced by name. For storage systems that aren’t able to return the file size this will raise NotImplementedError instead.

url(name)

Returns the URL where the contents of the file referenced by name can be accessed. For storage systems that don’t support access by URL this will raise NotImplementedError instead.

6.11.3 Uploaded Files and Upload Handlers

Uploaded files

class UploadedFile

During file uploads, the actual file data is stored in request.FILES. Each entry in this dictionary is an UploadedFile object (or a subclass) – a wrapper around an uploaded file. You’ll usually use one of these methods to access the uploaded content:

UploadedFile.read()

Read the entire uploaded data from the file. Be careful with this method: if the uploaded file is huge it can overwhelm your system if you try to read it into memory. You’ll probably want to use chunks() instead; see below.

UploadedFile.multiple_chunks(chunk_size=None)

Returns True if the uploaded file is big enough to require reading in multiple chunks. By default this will be any file larger than 2.5 megabytes, but that’s configurable; see below.

UploadedFile.chunks(chunk_size=None)

A generator returning chunks of the file. If multiple_chunks() is True, you should use this method in a loop instead of read().

In practice, it’s often easiest to use chunks() all the time. Looping over chunks() instead of using read() ensures that large files don’t overwhelm your system’s memory.

Here are some useful attributes of UploadedFile:

UploadedFile.name

The name of the uploaded file (e.g. my_file.txt).

UploadedFile.size

The size, in bytes, of the uploaded file.

UploadedFile.content_type

The content-type header uploaded with the file (e.g. text/plain or application/pdf). Like any data supplied by the user, you shouldn’t trust that the uploaded file is actually this type. You’ll still need to validate that the file contains the content that the content-type header claims – “trust but verify.”
UploadedFile.content_type_extra

A dictionary containing extra parameters passed to the content-type header. This is typically provided by services, such as Google App Engine, that intercept and handle file uploads on your behalf. As a result your handler may not receive the uploaded file content, but instead a URL or other pointer to the file (see RFC 2388).

UploadedFile.charset

For text/* content-types, the character set (i.e. utf8) supplied by the browser. Again, “trust but verify” is the best policy here.

Note: Like regular Python files, you can read the file line-by-line by iterating over the uploaded file:

```python
for line in uploadedfile:
    do_something_with(line)
```

Lines are split using universal newlines. The following are recognized as ending a line: the Unix end-of-line convention '
', the Windows convention '
', and the old Macintosh convention ''.

Subclasses of UploadedFile include:

**class TemporaryUploadedFile**

A file uploaded to a temporary location (i.e. stream-to-disk). This class is used by the TemporaryFileUploadHandler. In addition to the methods from UploadedFile, it has one additional method:

TemporaryUploadedFile.temporary_file_path()

Returns the full path to the temporary uploaded file.

**class InMemoryUploadedFile**

A file uploaded into memory (i.e. stream-to-memory). This class is used by the MemoryFileUploadHandler.

**Built-in upload handlers**

Together the MemoryFileUploadHandler and TemporaryFileUploadHandler provide Django’s default file upload behavior of reading small files into memory and large ones onto disk. They are located in django.core.files.uploadhandler.

**class MemoryFileUploadHandler**

File upload handler to stream uploads into memory (used for small files).

**class TemporaryFileUploadHandler**

Upload handler that streams data into a temporary file using TemporaryUploadedFile.
Writing custom upload handlers

class FileUploadHandler

All file upload handlers should be subclasses of `django.core.files.uploadhandler.FileUploadHandler`. You can define upload handlers wherever you wish.

Required methods

Custom file upload handlers must define the following methods:

FileUploadHandler.receive_data_chunk(raw_data, start)

Receives a “chunk” of data from the file upload.

- raw_data is a bytestring containing the uploaded data.
- start is the position in the file where this raw_data chunk begins.

The data you return will get fed into the subsequent upload handlers’ `receive_data_chunk` methods. In this way, one handler can be a “filter” for other handlers.

Return `None` from `receive_data_chunk` to short-circuit remaining upload handlers from getting this chunk. This is useful if you’re storing the uploaded data yourself and don’t want future handlers to store a copy of the data.

If you raise a StopUpload or a SkipFile exception, the upload will abort or the file will be completely skipped.

FileUploadHandler.file_complete(file_size)

Called when a file has finished uploading.

The handler should return an UploadedFile object that will be stored in `request.FILES`. Handlers may also return `None` to indicate that the UploadedFile object should come from subsequent upload handlers.

Optional methods

Custom upload handlers may also define any of the following optional methods or attributes:

FileUploadHandler.chunk_size

- Size, in bytes, of the “chunks” Django should store into memory and feed into the handler. That is, this attribute controls the size of chunks fed into `FileUploadHandler.receive_data_chunk`.

- For maximum performance the chunk sizes should be divisible by 4 and should not exceed 2 GB ($2^{31}$ bytes) in size. When there are multiple chunk sizes provided by multiple handlers, Django will use the smallest chunk size defined by any handler.

- The default is $64 \times 2^{10}$ bytes, or 64 KB.
**FileUploadHandler.new_file**

`new_file(field_name, file_name, content_type, content_length, charset, content_type_extra)`

Callback signaling that a new file upload is starting. This is called before any data has been fed to any upload handlers.

- **field_name** is a string name of the file `<input>` field.
- **file_name** is the filename provided by the browser.
- **content_type** is the MIME type provided by the browser – e.g. `'image/jpeg'`.
- **content_length** is the length of the image given by the browser. Sometimes this won’t be provided and will be `None`.
- **charset** is the character set (i.e. `utf8`) given by the browser. Like `content_length`, this sometimes won’t be provided.
- **content_type_extra** is extra information about the file from the `content-type` header. See `UploadedFile.content_type_extra`.

This method may raise a `StopFutureHandlers` exception to prevent future handlers from handling this file.

**FileUploadHandler.upload_complete**

Callback signaling that the entire upload (all files) has completed.

**FileUploadHandler.upload_interrupted**

Callback signaling that the upload was interrupted, e.g. when the user closed their browser during file upload.

**FileUploadHandler.handle_raw_input**

`handle_raw_input(input_data, META, content_length, boundary, encoding)`

Allows the handler to completely override the parsing of the raw HTTP input.

- **input_data** is a file-like object that supports `read()`-ing.
- **META** is the same object as `request.META`.
- **content_length** is the length of the data in `input_data`. Don’t read more than `content_length` bytes from `input_data`.
- **boundary** is the MIME boundary for this request.
- **encoding** is the encoding of the request.

Return `None` if you want upload handling to continue, or a tuple of `(POST, FILES)` if you want to return the new data structures suitable for the request directly.
6.12 Forms

Detailed form API reference. For introductory material, see the Working with forms topic guide.

6.12.1 The Forms API

Bound and unbound forms

A Form instance is either bound to a set of data, or unbound.

- If it’s bound to a set of data, it’s capable of validating that data and rendering the form as HTML with the data displayed in the HTML.
- If it’s unbound, it cannot do validation (because there’s no data to validate!), but it can still render the blank form as HTML.

```python
class Form

To create an unbound Form instance, instantiate the class:

```bash
>>> f = ContactForm()
```

To bind data to a form, pass the data as a dictionary as the first parameter to your Form class constructor:

```bash
>>> data = {'subject': 'hello',
...         'message': 'Hi there',
...         'sender': 'foo@example.com',
...         'cc_myself': True}
>>> f = ContactForm(data)
```

In this dictionary, the keys are the field names, which correspond to the attributes in your Form class. The values are the data you’re trying to validate. These will usually be strings, but there’s no requirement that they be strings; the type of data you pass depends on the Field, as we’ll see in a moment.

Form.is_bound

If you need to distinguish between bound and unbound form instances at runtime, check the value of the form’s is_bound attribute:
>>> f = ContactForm()
>>> f.is_bound
False
>>> f = ContactForm({'subject': 'hello'})
>>> f.is_bound
True

Note that passing an empty dictionary creates a bound form with empty data:

>>> f = ContactForm({})
>>> f.is_bound
True

If you have a bound `Form` instance and want to change the data somehow, or if you want to bind an unbound `Form` instance to some data, create another `Form` instance. There is no way to change data in a `Form` instance. Once a `Form` instance has been created, you should consider its data immutable, whether it has data or not.

**Using forms to validate data**

`Form.clean()`

Implement a `clean()` method on your `Form` when you must add custom validation for fields that are interdependent. See Cleaning and validating fields that depend on each other for example usage.

`Form.is_valid()`

The primary task of a `Form` object is to validate data. With a bound `Form` instance, call the `is_valid()` method to run validation and return a boolean designating whether the data was valid:

```python
>>> data = {'subject': 'hello',
...         'message': 'Hi there',
...         'sender': 'foo@example.com',
...         'cc_myself': True}
>>> f = ContactForm(data)
>>> f.is_valid()
True
```

Let’s try with some invalid data. In this case, `subject` is blank (an error, because all fields are required by default) and `sender` is not a valid email address:

```python
>>> data = {'subject': '',
...         'message': 'Hi there',
...         'sender': 'invalid email address',
...         'cc_myself': True}
>>> f = ContactForm(data)
```

Django Documentation, Release 4.2.dev20220706084552

(continued from previous page)

>>> f.is_valid()
False

Form.errors
Access the errors attribute to get a dictionary of error messages:
>>> f.errors
{'sender': ['Enter a valid email address.'], 'subject': ['This field is required.']}

In this dictionary, the keys are the field names, and the values are lists of strings representing the error
messages. The error messages are stored in lists because a field can have multiple error messages.
You can access errors without having to call is_valid() first. The form’s data will be validated the first
time either you call is_valid() or access errors.
The validation routines will only get called once, regardless of how many times you access errors or call
is_valid(). This means that if validation has side effects, those side effects will only be triggered once.
Form.errors.as_data()
Returns a dict that maps fields to their original ValidationError instances.
>>> f.errors.as_data()
{'sender': [ValidationError(['Enter a valid email address.'])],
'subject': [ValidationError(['This field is required.'])]}

Use this method anytime you need to identify an error by its code. This enables things like rewriting the error’
s message or writing custom logic in a view when a given error is present. It can also be used to serialize the
errors in a custom format (e.g. XML); for instance, as_json() relies on as_data().
The need for the as_data() method is due to backwards compatibility. Previously ValidationError instances were lost as soon as their rendered error messages were added to the Form.errors dictionary. Ideally
Form.errors would have stored ValidationError instances and methods with an as_ prefix could render
them, but it had to be done the other way around in order not to break code that expects rendered error
messages in Form.errors.
Form.errors.as_json(escape_html=False)
Returns the errors serialized as JSON.
>>> f.errors.as_json()
{"sender": [{"message": "Enter a valid email address.", "code": "invalid"}],
"subject": [{"message": "This field is required.", "code": "required"}]}

By default, as_json() does not escape its output. If you are using it for something like AJAX requests to a
form view where the client interprets the response and inserts errors into the page, you’ll want to be sure to
6.12. Forms

1419


escape the results on the client-side to avoid the possibility of a cross-site scripting attack. You can do this in JavaScript with `element.textContent = errorText` or with jQuery’s `$(el).text(errorText)` (rather than its `.html()` function).

If for some reason you don’t want to use client-side escaping, you can also set `escape_html=True` and error messages will be escaped so you can use them directly in HTML.

`Form.errors.get_json_data(escape_html=False)`

Returns the errors as a dictionary suitable for serializing to JSON. `Form.errors.as_json()` returns serialized JSON, while this returns the error data before it's serialized.

The `escape_html` parameter behaves as described in `Form.errors.as_json()`.

`Form.add_error(field, error)`

This method allows adding errors to specific fields from within the `Form.clean()` method, or from outside the form altogether; for instance from a view.

The `field` argument is the name of the field to which the errors should be added. If its value is `None` the error will be treated as a non-field error as returned by `Form.non_field_errors()`.

The `error` argument can be a string, or preferably an instance of `ValidationError`. See Raising Validation-Error for best practices when defining form errors.

Note that `Form.add_error()` automatically removes the relevant field from `cleaned_data`.

`Form.has_error(field, code=None)`

This method returns a boolean designating whether a field has an error with a specific error code. If `code` is `None`, it will return `True` if the field contains any errors at all.

To check for non-field errors use `NON_FIELD_ERRORS` as the `field` parameter.

`Form.non_field_errors()`

This method returns the list of errors from `Form.errors` that aren’t associated with a particular field. This includes `ValidationError`s that are raised in `Form.clean()` and errors added using `Form.add_error(None, "...").`  

**Behavior of unbound forms**

It’s meaningless to validate a form with no data, but, for the record, here’s what happens with unbound forms:

```python
>>> f = ContactForm()
>>> f.is_valid()
False
>>> f.errors
()
```
**Initial form values**

*Form.*initial

Use *initial* to declare the initial value of form fields at runtime. For example, you might want to fill in a *username* field with the username of the current session.

To accomplish this, use the *initial* argument to a *Form*. This argument, if given, should be a dictionary mapping field names to initial values. Only include the fields for which you’re specifying an initial value; it’s not necessary to include every field in your form. For example:

```python
>>> f = ContactForm(initial={'subject': 'Hi there!'}
```

These values are only displayed for unbound forms, and they’re not used as fallback values if a particular value isn’t provided.

If a *Field* defines *initial* and you include *initial* when instantiating the *Form*, then the latter *initial* will have precedence. In this example, *initial* is provided both at the field level and at the form instance level, and the latter gets precedence:

```python
>>> from django import forms

>>> class CommentForm(forms.Form):
...    name = forms.CharField(initial='class')
...    url = forms.URLField()
...    comment = forms.CharField()

>>> f = CommentForm(initial={'name': 'instance'}, auto_id=False)

>>> print(f)
<tr><th>Name:</th><td><input type="text" name="name" value="instance" required></td></tr>
<tr><th>Url:</th><td><input type="url" name="url" required></td></tr>
<tr><th>Comment:</th><td><input type="text" name="comment" required></td></tr>
```

*Form.get_initial_for_field(field, field_name)*

Returns the initial data for a form field. It retrieves the data from *Form.initial* if present, otherwise trying *Field.initial*. Callable values are evaluated.

It is recommended to use *BoundField.initial* over *get_initial_for_field()* because *BoundField.initial* has a simpler interface. Also, unlike *get_initial_for_field()*; *BoundField.initial* caches its values. This is useful especially when dealing with callables whose return values can change (e.g. datetime.now or uuid.uuid4):

```python
>>> import uuid

>>> class UUIDCommentForm(CommentForm):
...    identifier = forms.UUIDField(initial=uuid.uuid4)

>>> f = UUIDCommentForm()

>>> f.get_initial_for_field(f.fields['identifier'], 'identifier')
```

(continues on next page)
Checking which form data has changed

Form.has_changed()

Use the has_changed() method on your Form when you need to check if the form data has been changed from the initial data.

```python
>>> data = {'subject': 'hello',
...          'message': 'Hi there',
...          'sender': 'foo@example.com',
...          'cc_myself': True}
>>> f = ContactForm(data, initial=data)
>>> f.has_changed()
False
```

When the form is submitted, we reconstruct it and provide the original data so that the comparison can be done:

```python
>>> f = ContactForm(request.POST, initial=data)
>>> f.has_changed()
has_changed() will be True if the data from request.POST differs from what was provided in initial or False otherwise. The result is computed by calling Field.has_changed() for each field in the form.

Form.changed_data

The changed_data attribute returns a list of the names of the fields whose values in the form’s bound data (usually request.POST) differ from what was provided in initial. It returns an empty list if no data differs.

```python
>>> f = ContactForm(request.POST, initial=data)
>>> if f.has_changed():
...     print("The following fields changed: %s", " ", \n...     .join(f.changed_data))
>>> f.changed_data
['subject', 'message']
```
Accessing the fields from the form

Form.fields

You can access the fields of Form instance from its fields attribute:

```python
>>> for row in f.fields.values(): print(row)
...
<django.forms.fields.CharField object at 0x7ffaac632510>
<django.forms.fields.URLField object at 0x7ffaac632f90>
<django.forms.fields.CharField object at 0x7ffaac3aa050>
>>> f.fields['name']
<django.forms.fields.CharField object at 0x7ffaac6324d0>
```

You can alter the field of Form instance to change the way it is presented in the form:

```python
>>> f.as_table().split('
')[0]
'<'tr><th>Name:</th><td><input name="name" type="text" value="instance" required></td></tr>'
>>> f.fields['name'].label = "Username"
>>> f.as_table().split('
')[0]
'<'tr><th>Username:</th><td><input name="name" type="text" value="instance" required></td></tr>'
```

Beware not to alter the base_fields attribute because this modification will influence all subsequent ContactForm instances within the same Python process:

```python
>>> f.base_fields['name'].label = "Username"
>>> another_f = CommentForm(auto_id=False)
>>> another_f.as_table().split('
')[0]
'<'tr><th>Username:</th><td><input name="name" type="text" value="class" required></td></tr>'
```

Accessing “clean” data

Form.cleaned_data

Each field in a Form class is responsible not only for validating data, but also for “cleaning” it—normalizing it to a consistent format. This is a nice feature, because it allows data for a particular field to be input in a variety of ways, always resulting in consistent output.

For example, DateField normalizes input into a Python datetime.date object. Regardless of whether you pass it a string in the format '1994-07-15', a datetime.date object, or a number of other formats, DateField will always normalize it to a datetime.date object as long as it’s valid.

Once you’ve created a Form instance with a set of data and validated it, you can access the clean data via its cleaned_data attribute:
```python
>>> data = {'subject': 'hello',
...         'message': 'Hi there',
...         'sender': 'foo@example.com',
...         'cc_myself': True}
>>> f = ContactForm(data)
>>> f.is_valid()
True
>>> f.cleaned_data
{'cc_myself': True, 'message': 'Hi there', 'sender': 'foo@example.com', 'subject': 'hello'}
```

Note that any text-based field—such as CharField or EmailField—always cleans the input into a string. We'll cover the encoding implications later in this document.

If your data does not validate, the cleaned_data dictionary contains only the valid fields:

```python
>>> data = {'subject': '',
...         'message': 'Hi there',
...         'sender': 'invalid email address',
...         'cc_myself': True}
>>> f = ContactForm(data)
>>> f.is_valid()
False
>>> f.cleaned_data
{'cc_myself': True, 'message': 'Hi there'}
```

cleaned_data will always only contain a key for fields defined in the Form, even if you pass extra data when you define the Form. In this example, we pass a bunch of extra fields to the ContactForm constructor, but cleaned_data contains only the form’s fields:

```python
>>> data = {'subject': 'hello',
...         'message': 'Hi there',
...         'sender': 'foo@example.com',
...         'cc_myself': True,
...         'extra_field_1': 'foo',
...         'extra_field_2': 'bar',
...         'extra_field_3': 'baz'}
>>> f = ContactForm(data)
>>> f.is_valid()
True
>>> f.cleaned_data  # Doesn't contain extra_field_1, etc.
{'cc_myself': True, 'message': 'Hi there', 'sender': 'foo@example.com', 'subject': 'hello'}
```

When the Form is valid, cleaned_data will include a key and value for all its fields, even if the data didn’t include a value for some optional fields. In this example, the data dictionary didn’t include a value for the nick_name field, but cleaned_data includes it, with an empty value:
```python
>>> from django import forms

>>> class OptionalPersonForm(forms.Form):
    ...    first_name = forms.CharField()
    ...    last_name = forms.CharField()
    ...    nick_name = forms.CharField(required=False)

>>> data = {'first_name': 'John', 'last_name': 'Lennon'}

>>> f = OptionalPersonForm(data)

>>> f.is_valid()
True

>>> f.cleaned_data
{'nick_name': '', 'first_name': 'John', 'last_name': 'Lennon'}
```

In this above example, the `cleaned_data` value for `nick_name` is set to an empty string, because `nick_name` is `CharField`, and `CharField`s treat empty values as an empty string. Each field type knows what its “blank” value is — e.g., for `DateField`, it’s `None` instead of the empty string. For full details on each field’s behavior in this case, see the “Empty value” note for each field in the “Built-in Field classes” section below.

You can write code to perform validation for particular form fields (based on their name) or for the form as a whole (considering combinations of various fields). More information about this is in Form and field validation.

### Outputting forms as HTML

The second task of a Form object is to render itself as HTML. To do so, print it:

```python
>>> f = ContactForm()

>>> print(f)
<tr><th><label for="id_subject">Subject:</label></th><td><input id="id_subject" type="text" name="subject" maxlengt...required></td></tr>
<tr><th><label for="id_message">Message:</label></th><td><input type="text" name="message" id="id_message" required></td></tr>
<tr><th><label for="id_sender">Sender:</label></th><td><input type="email" name="sender" id="id_sender" required></td></tr>
<tr><th><label for="id_cc_myself">Cc myself:</label></th><td><input type="checkbox" name="cc_myself" id="id_cc_myself"></td></tr>
```

If the form is bound to data, the HTML output will include that data appropriately. For example, if a field is represented by an `<input type="text">`, the data will be in the `value` attribute. If a field is represented by an `<input type="checkbox">`, then that HTML will include checked if appropriate:

```python
>>> data = {'subject': 'hello',
    ...    'message': 'Hi there',
    ...    'sender': 'foo@example.com',
    ...    'cc_myself': True}
```
>>> f = ContactForm(data)

>>> print(f)

<tr><th><label for="id_subject">Subject:</label></th><td><input id="id_subject" type="text" name="subject" maxlength="100" value="hello" required></td></tr>
<tr><th><label for="id_message">Message:</label></th><td><input type="text" name="message" id="id_message" value="Hi there" required></td></tr>
<tr><th><label for="id_sender">Sender:</label></th><td><input type="email" name="sender" id="id_sender" value="foo@example.com" required></td></tr>
<tr><th><label for="id_cc_myself">Cc myself:</label></th><td><input type="checkbox" name="cc_myself" id="id_cc_myself" checked></td></tr>

This default output is a two-column HTML table, with a <tr> for each field. Notice the following:

- For flexibility, the output does not include the <table> and </table> tags, nor does it include the <form> and </form> tags or an <input type="submit"> tag. It’s your job to do that.

- Each field type has a default HTML representation. CharField is represented by an <input type="text"> and EmailField by an <input type="email">. BooleanField(null=False) is represented by an <input type="checkbox">. Note these are merely sensible defaults; you can specify which HTML to use for a given field by using widgets, which we’ll explain shortly.

- The HTML name for each tag is taken directly from its attribute name in the ContactForm class.

- The text label for each field—e.g. 'Subject:', 'Message:' and 'Cc myself:'—is generated from the field name by converting all underscores to spaces and upper-casing the first letter. Again, note these are merely sensible defaults; you can also specify labels manually.

- Each text label is surrounded in an HTML <label> tag, which points to the appropriate form field via its id. Its id, in turn, is generated by prepending 'id_' to the field name. The id attributes and <label> tags are included in the output by default, to follow best practices, but you can change that behavior.

- The output uses HTML5 syntax, targeting <!DOCTYPE html>. For example, it uses boolean attributes such as checked rather than the XHTML style of checked='checked'.

Although <table> output is the default output style when you print a form, other output styles are available. Each style is available as a method on a form object, and each rendering method returns a string.
Default rendering

The default rendering when you print a form uses the following methods and attributes.

template_name

Form.template_name

The name of the template rendered if the form is cast into a string, e.g. via print(form) or in a template via {{ form }}.

By default, a property returning the value of the renderer’s form_template_name. You may set it as a string template name in order to override that for a particular form class.

In older versions template_name defaulted to the string value 'django/forms/default.html'.

render()

Form.render(template_name=None, context=None, renderer=None)

The render method is called by __str__ as well as the Form.as_table(), Form.as_p(), and Form.as_ul() methods. All arguments are optional and default to:

- template_name: Form.template_name
- context: Value returned by Form.get_context()
- renderer: Value returned by Form.default_renderer

By passing template_name you can customize the template used for just a single call.

get_context()

Form.get_context()

Return the template context for rendering the form.

The available context is:

- form: The bound form.
- fields: All bound fields, except the hidden fields.
- hidden_fields: All hidden bound fields.
- errors: All non field related or hidden field related form errors.
template_name_label

Form.template_name_label

The template used to render a field’s `<label>`, used when calling `BoundField.label_tag()`/`legend_tag()`.
Can be changed per form by overriding this attribute or more generally by overriding the default template,
see also Overriding built-in form templates.

Output styles

As well as rendering the form directly, such as in a template with `{% form %}`, the following helper functions
serve as a proxy to `Form.render()` passing a particular `template_name` value.
These helpers are most useful in a template, where you need to override the form renderer or form provided
value but cannot pass the additional parameter to `render()`. For example, you can render a form as an
unordered list using `{% form.as_ul %}`.
Each helper pairs a form method with an attribute giving the appropriate template name.

as_div()

Form.template_name_div

The template used by `as_div()`. Default: `'django/forms/div.html'`.

Form.as_div()

as_div() renders the form as a series of `<div>` elements, with each `<div>` containing one field, such as:

```python
>>> f = ContactForm()
>>> f.as_div()
... gives HTML like:

```<div>
  <label for="id_subject">Subject:</label><input type="text" name="subject" maxlength="100" required id="id_subject">
</div>
```<div>
  <label for="id_message">Message:</label><input type="text" name="message" required id="id_message">
</div>
```<div>
  <label for="id_sender">Sender:</label><input type="email" name="sender" required id="id_sender">
```(continues on next page)
Note: Of the framework provided templates and output styles, as_div() is recommended over the as_p(), as_table(), and as_ul() versions as the template implements <fieldset> and <legend> to group related inputs and is easier for screen reader users to navigate.

as_p()

Form.template_name_p

The template used by as_p(). Default: 'django/forms/p.html'.

Form.as_p()

as_p() renders the form as a series of <p> tags, with each <p> containing one field:

```python
>>> f = ContactForm()
>>> f.as_p()
'<p><label for="id_subject">Subject:</label> <input id="id_subject" type="text" name="subject" maxl

...length="100" required></p>

<p><label for="id_message">Message:</label> <input type="text" name="message" id="id_message"

...required></p>

<p><label for="id_sender">Sender:</label> <input type="email" name="sender" id="id_sender" required></p>

<p><label for="id_cc_myself">Cc myself:</label> <input type="checkbox" name="cc_myself" id="id_cc_myself"></p>
```
as_ul()

Form.template_name_ul

The template used by as_ul(). Default: 'django/forms/ul.html'.

Form.as_ul()
as_ul() renders the form as a series of <li> tags, with each <li> containing one field. It does not include the <ul> or </ul>, so that you can specify any HTML attributes on the <ul> for flexibility:

```python
>>> f = ContactForm()
>>> f.as_ul()
'<li><label for="id_subject">Subject:</label> <input id="id_subject" type="text" name="subject" maxlength="100" required></li>

>>> print(f.as_ul())
'<li><label for="id_subject">Subject:</label> <input id="id_subject" type="text" name="subject" maxlength="100" required></li>'

as_table()

Form.template_name_table

The template used by as_table(). Default: 'django/forms/table.html'.

Form.as_table()
as_table() renders the form as an HTML <table>:

```python
>>> f = ContactForm()
>>> f.as_table()
'<tr><th><label for="id_subject">Subject:</label></th><td><input id="id_subject" type="text" name="subject" maxlength="100" required></td></tr>

>>> print(f.as_table())
'<tr><th><label for="id_subject">Subject:</label></th><td><input id="id_subject" type="text" name="subject" maxlength="100" required></td>'
```

(continues on next page)
Styling required or erroneous form rows

Form.error_css_class

Form.required_css_class

It’s pretty common to style form rows and fields that are required or have errors. For example, you might want to present required form rows in bold and highlight errors in red.

The Form class has a couple of hooks you can use to add class attributes to required rows or to rows with errors: set the Form.error_css_class and/or Form.required_css_class attributes:

```python
from django import forms

class ContactForm(forms.Form):
    error_css_class = 'error'
    required_css_class = 'required'

    # ... and the rest of your fields here
```

Once you’ve done that, rows will be given "error" and/or "required" classes, as needed. The HTML will look something like:

```python
>>> f = ContactForm(data)
>>> print(f.as_table())
<tr class="required"><th><label class="required" for=id_subject">Subject:</label> ...</tr>
<tr class="required"><th><label class="required" for=id_message">Message:</label> ...</tr>
<tr class="required error"><th><label class="required" for=id_sender">Sender:</label> ...</tr>
<tr><th><label for=id_cc_myself">Cc myself:</label> ...</tr>
```
Configuring form elements’ HTML id attributes and <label> tags

Form.auto_id

By default, the form rendering methods include:

- HTML id attributes on the form elements.
- The corresponding <label> tags around the labels. An HTML <label> tag designates which label text is associated with which form element. This small enhancement makes forms more usable and more accessible to assistive devices. It’s always a good idea to use <label> tags.

The id attribute values are generated by prepending id_ to the form field names. This behavior is configurable, though, if you want to change the id convention or remove HTML id attributes and <label> tags entirely.

Use the auto_id argument to the Form constructor to control the id and label behavior. This argument must be True, False or a string.

If auto_id is False, then the form output will not include <label> tags nor id attributes:

```python
>>> f = ContactForm(auto_id=False)
```

```html
<tr><th>Subject:</th><td><input type="text" name="subject" maxlength="100" required></td></tr>
<tr><th>Message:</th><td><input type="text" name="message" required></td></tr>
<tr><th>Sender:</th><td><input type="email" name="sender" required></td></tr>
<tr><th>Cc myself:</th><td><input type="checkbox" name="cc_myself"></td></tr>
```

If auto_id is set to True, then the form output will include <label> tags and will use the field name as its id for each form field:

```python
>>> f = ContactForm(auto_id=True)
```

```html
<tr><th>Subject: <label for="id_subject" class="foo required">Subject:</label></th><td><input type="text" name="subject" maxlength="100" required></td></tr>
<tr><th>Message: <label for="id_message" class="foo required">Message:</label></th><td><input type="text" name="message" required></td></tr>
<tr><th>Sender: <label for="id_sender" class="foo required">Sender:</label></th><td><input type="email" name="sender" required></td></tr>
<tr><th>Cc myself: <label for="id_cc_myself" class="foo required">Cc myself:</label></th><td><input type="checkbox" name="cc_myself"></td></tr>
```

```html
<tr><th>Subject: <legend for="id_subject" class="foo required">Subject:</legend></th><td><input type="text" name="subject" maxlength="100" required></td></tr>
<tr><th>Message: <legend for="id_message" class="foo required">Message:</legend></th><td><input type="text" name="message" required></td></tr>
<tr><th>Sender: <legend for="id_sender" class="foo required">Sender:</legend></th><td><input type="email" name="sender" required></td></tr>
<tr><th>Cc myself: <legend for="id_cc_myself" class="foo required">Cc myself:</legend></th><td><input type="checkbox" name="cc_myself"></td></tr>
```
>>> f = ContactForm(auto_id=True)
>>> print(f.as_table())
<tr><th><label for="subject">Subject:</label></th><td><input id="subject" type="text" name="subject" maxleng..."
required></td></tr>
<tr><th><label for="message">Message:</label></th><td><input type="text" name="message" id="message" required></td></tr>
<tr><th><label for="sender">Sender:</label></th><td><input type="email" name="sender" id="sender" required></td></tr>
<tr><th><label for="cc_myself">Cc myself:</label></th><td><input type="checkbox" name="cc_myself" id="cc_myself"></td></tr>

If auto_id is set to a string containing the format character '%s', then the form output will include <label> tags, and will generate id attributes based on the format string. For example, for a format string 'field_%s', a field named subject will get the id value 'field_subject'. Continuing our example:

```python
>>> f = ContactForm(auto_id='id_for_%s')
>>> print(f.as_table())
<tr><th><label for="id_for_subject">Subject:</label></th><td><input id="id_for_subject" type="text" name="subject" maxleng..." required></td></tr>
<tr><th><label for="id_for_message">Message:</label></th><td><input type="text" name="message" id="id_for_message" required></td></tr>
<tr><th><label for="id_for_sender">Sender:</label></th><td><input type="email" name="sender" id="id_for_sender" required></td></tr>
<tr><th><label for="id_for_cc_myself">Cc myself:</label></th><td><input type="checkbox" name="cc_myself" id="id_for_cc_myself"></td></tr>
```
If `auto_id` is set to any other true value – such as a string that doesn’t include `%s` – then the library will act as if `auto_id` is True.

By default, `auto_id` is set to the string 'id_%s'.

**Form.label_suffix**

A translatable string (defaults to a colon (:) in English) that will be appended after any label name when a form is rendered.

It’s possible to customize that character, or omit it entirely, using the `label_suffix` parameter:

```python
>>> f = ContactForm(auto_id='id_for_%s', label_suffix='')
>>> print(f.as_ul())
<li><label for="id_for_subject">Subject:
</label> <input id="id_for_subject" type="text" name="subject" maxlength="100" required></li>
<li><label for="id_for_message">Message:
</label> <input id="id_for_message" type="text" name="message" required></li>
<li><label for="id_for_sender">Sender:
</label> <input id="id_for_sender" type="email" name="sender" required></li>
<li><label for="id_for_cc_myself">Cc myself:
</label> <input id="id_for_cc_myself" type="checkbox" name="cc_myself"></li>
```

(continues on next page)
Field can also define their own label_suffix. This will take precedence over Form.label_suffix. The suffix can also be overridden at runtime using the label_suffix parameter to label_tag() / legend_tag().

Form.use_required_attribute

When set to True (the default), required form fields will have the required HTML attribute.

Formsets instantiate forms with use_required_attribute=False to avoid incorrect browser validation when adding and deleting forms from a formset.

Configuring the rendering of a form’s widgets

Form.default_renderer

Specifies the renderer to use for the form. Defaults to None which means to use the default renderer specified by the FORM_RENDERER setting.

You can set this as a class attribute when declaring your form or use the renderer argument to Form.__init__(). For example:

```python
from django import forms

class MyForm(forms.Form):
    default_renderer = MyRenderer()
```

or:

```python
form = MyForm(renderer=MyRenderer())
```

Notes on field ordering

In the as_p(), as_ul() and as_table() shortcuts, the fields are displayed in the order in which you define them in your form class. For example, in the ContactForm example, the fields are defined in the order subject, message, sender, cc_myself. To reorder the HTML output, change the order in which those fields are listed in the class.

There are several other ways to customize the order:
Form.field_order

By default `Form.field_order=None`, which retains the order in which you define the fields in your form class. If `field_order` is a list of field names, the fields are ordered as specified by the list and remaining fields are appended according to the default order. Unknown field names in the list are ignored. This makes it possible to disable a field in a subclass by setting it to `None` without having to redefine ordering.

You can also use the `Form.field_order` argument to a `Form` to override the field order. If a `Form` defines `field_order` and you include `field_order` when instantiating the `Form`, then the latter `field_order` will have precedence.

```
Form.order_fields(field_order)
```

You may rearrange the fields any time using `order_fields()` with a list of field names as in `field_order`.

How errors are displayed

If you render a bound `Form` object, the act of rendering will automatically run the form’s validation if it hasn’t already happened, and the HTML output will include the validation errors as a `<ul class="errorlist">` near the field. The particular positioning of the error messages depends on the output method you’re using:

```
>>> data = {'subject': '',
...          'message': 'Hi there',
...          'sender': 'invalid email address',
...          'cc_myself': True}
>>> f = ContactForm(data, auto_id=False)
>>> print(f.as_table())
<tr><th>Subject:</th><td><ul class="errorlist"><li>This field is required.</li></ul><input type="text" name="subject" maxlength="100" required></td></tr>
<tr><th>Message:</th><td><input type="text" name="message" value="Hi there" required></td></tr>
<tr><th>Sender:</th><td><ul class="errorlist"><li>Enter a valid email address.</li></ul><input type="email" name="sender" value="invalid email address" required></td></tr>
<tr><th>Cc myself:</th><td><input checked type="checkbox" name="cc_myself"></td></tr>
```

(continues on next page)
Customizing the error list format

class ErrorList(initlist=None, error_class=None, renderer=None)

By default, forms use `django.forms.utils.ErrorList` to format validation errors. `ErrorList` is a list like object where `initlist` is the list of errors. In addition this class has the following attributes and methods.

**error_class**

The CSS classes to be used when rendering the error list. Any provided classes are added to the default `errorlist` class.

**renderer**

Specifies the renderer to use for `ErrorList`. Defaults to `None` which means to use the default renderer specified by the `FORM_RENDERER` setting.

**template_name**

The name of the template used when calling `__str__` or `render()`. By default this is `'django/forms/errors/list/default.html'` which is a proxy for the `'ul.html'` template.

**template_name_text**

The name of the template used when calling `as_text()`. By default this is `'django/forms/errors/list/text.html'`. This template renders the errors as a list of bullet points.

**template_name_ul**

The name of the template used when calling `as_ul()`. By default this is `'django/forms/errors/list/ul.html'`. This template renders the errors in `<li>` tags with a wrapping `<ul>` with the CSS classes as defined by `error_class`.

**get_context()**

Return context for rendering of errors in a template.

The available context is:

- **errors**: A list of the errors.
- **error_class**: A string of CSS classes.

**render**(template_name=None, context=None, renderer=None)

The render method is called by `__str__` as well as by the `as_ul()` method. All arguments are optional and will default to:

- **template_name**: Value returned by `template_name`
• **context**: Value returned by `get_context()`

• **renderer**: Value returned by `renderer.as_text()`

  Renders the error list using the template defined by `template_name_text`.

  `as_ul()`

  Renders the error list using the template defined by `template_name_ul`.

  If you’d like to customize the rendering of errors this can be achieved by overriding the `template_name` attribute or more generally by overriding the default template, see also Overriding built-in form templates.

  **Deprecated since version 4.0**: The ability to return a `str` when calling the `__str__` method is deprecated. Use the template engine instead which returns a `SafeString`.

**More granular output**

The `as_p()`, `as_ul()`, and `as_table()` methods are shortcuts—they’re not the only way a form object can be displayed.

**class BoundField**

Used to display HTML or access attributes for a single field of a `Form` instance.

The `__str__()` method of this object displays the HTML for this field.

To retrieve a single `BoundField`, use dictionary lookup syntax on your form using the field’s name as the key:

```python
>>> form = ContactForm()
>>> print(form['subject'])
<input id="id_subject" type="text" name="subject" maxlength="100" required>
```

To retrieve all `BoundField` objects, iterate the form:

```python
>>> form = ContactForm()
>>> for boundfield in form: print(boundfield)
<input id="id_subject" type="text" name="subject" maxlength="100" required>
<input type="text" name="message" id="id_message" required>
<input type="email" name="sender" id="id_sender" required>
<input type="checkbox" name="cc_myself" id="id_cc_myself">
```

The field-specific output honors the form object’s `auto_id` setting:

```python
>>> f = ContactForm(auto_id=False)
>>> print(f['message'])
```

(continues on next page)
Attributes of BoundField

BoundField.auto_id

The HTML ID attribute for this BoundField. Returns an empty string if Form.auto_id is False.

BoundField.data

This property returns the data for this BoundField extracted by the widget’s `value_from_datadict()` method, or None if it wasn’t given:

```python
>>> unbound_form = ContactForm()
>>> print(unbound_form['subject'].data)
None
>>> bound_form = ContactForm(data={'subject': 'My Subject'})
>>> print(bound_form['subject'].data)
My Subject
```

BoundField.errors

A list-like object that is displayed as an HTML `<ul class="errorlist">` when printed:

```python
>>> data = {'subject': 'hi', 'message': '', 'sender': '', 'cc_myself': ''}
>>> f = ContactForm(data, auto_id=False)
>>> print(f['message'])
<input type="text" name="message" required>
>>> f['message'].errors
['This field is required. ']
>>> print(f['message'].errors)
<ul class="errorlist"><li>This field is required.</li></ul>
>>> f['subject'].errors
[]
>>> print(f['subject'].errors)
'
>>> str(f['subject'].errors)
'
```

BoundField.field

The form Field instance from the form class that this BoundField wraps.
Django Documentation, Release 4.2.dev20220706084552

BoundField.form
The Form instance this BoundField is bound to.
BoundField.help_text
The help_text of the field.
BoundField.html_name
The name that will be used in the widget’s HTML name attribute. It takes the form prefix into account.
BoundField.id_for_label
Use this property to render the ID of this field. For example, if you are manually constructing a <label>
in your template (despite the fact that label_tag()/legend_tag() will do this for you):
<label for="{{ form.my_field.id_for_label }}">...</label>{{ my_field }}

By default, this will be the field’s name prefixed by id_ (”id_my_field”for the example above). You
may modify the ID by setting attrs on the field’s widget. For example, declaring a field like this:
my_field = forms.CharField(widget=forms.TextInput(attrs={'id': 'myFIELD'}))

and using the template above, would render something like:
<label for="myFIELD">...</label><input id="myFIELD" type="text" name="my_field" required>

BoundField.initial
Use BoundField.initial to retrieve initial data for a form field. It retrieves the data from Form.
initial if present, otherwise trying Field.initial. Callable values are evaluated. See Initial form
values for more examples.
BoundField.initial caches its return value, which is useful especially when dealing with callables
whose return values can change (e.g. datetime.now or uuid.uuid4):
>>> from datetime import datetime
>>> class DatedCommentForm(CommentForm):
...

created = forms.DateTimeField(initial=datetime.now)

>>> f = DatedCommentForm()
>>> f['created'].initial
datetime.datetime(2021, 7, 27, 9, 5, 54)
>>> f['created'].initial
datetime.datetime(2021, 7, 27, 9, 5, 54)

Using BoundField.initial is recommended over get_initial_for_field().
BoundField.is_hidden
Returns True if this BoundField’s widget is hidden.

1440

Chapter 6. API Reference


BoundField.label

The label of the field. This is used in label_tag()/legend_tag().

BoundField.name

The name of this field in the form:

```python
>>> f = ContactForm()
>>> print(f['subject'].name)
subject
>>> print(f['message'].name)
message
```

BoundField.use_fieldset

Returns the value of this BoundField widget’s use_fieldset attribute.

BoundField.widget_type

Returns the lowercased class name of the wrapped field’s widget, with any trailing input or widget removed. This may be used when building forms where the layout is dependent upon the widget type. For example:

```python
{% for field in form %}
    {% if field.widget_type == 'checkbox' %}
        # render one way
    {% else %}
        # render another way
    {% endif %}
{% endfor %}
```

Methods of BoundField

BoundField.as_hidden(attrs=None, **kwargs)

Returns a string of HTML for representing this as an <input type="hidden">.

**kwargs are passed to as_widget().

This method is primarily used internally. You should use a widget instead.

BoundField.as_widget(widget=None, attrs=None, only_initial=False)

Renders the field by rendering the passed widget, adding any HTML attributes passed as attrs. If no widget is specified, then the field’s default widget will be used.

only_initial is used by Django internals and should not be set explicitly.

BoundField.css_classes(extra_classes=None)

When you use Django’s rendering shortcuts, CSS classes are used to indicate required form fields or
fields that contain errors. If you’re manually rendering a form, you can access these CSS classes using the `css_classes` method:

```python
>>> f = ContactForm(data={'message': ''})
>>> f['message'].css_classes()
'required'
```

If you want to provide some additional classes in addition to the error and required classes that may be required, you can provide those classes as an argument:

```python
>>> f = ContactForm(data={'message': ''})
>>> f['message'].css_classes('foo bar')
'foo bar required'
```

`BoundField.label_tag(contents=None, attrs=None, label_suffix=None, tag=None)`

Renders a label tag for the form field using the template specified by `Form.template_name_label`.

The available context is:

- `field`: This instance of the `BoundField`.
- `contents`: By default a concatenated string of `BoundField.label` and `Form.label_suffix` (or `Field.label_suffix`, if set). This can be overridden by the `contents` and `label_suffix` arguments.
- `attrs`: A dict containing `for`, `Form.required_css_class`, and `id`. `id` is generated by the field’s widget `attrs` or `BoundField.auto_id`. Additional attributes can be provided by the `attrs` argument.
- `use_tag`: A boolean which is True if the label has an id. If False the default template omits the tag.
- `tag`: An optional string to customize the tag, defaults to `label`.

Tip: In your template `field` is the instance of the `BoundField`. Therefore `field.field` accesses `BoundField.field` being the field you declare, e.g. `forms.CharField`.

To separately render the label tag of a form field, you can call its `label_tag()` method:

```python
>>> f = ContactForm(data={'message': ''})
>>> print(f['message'].label_tag())
<label for="id_message">Message:</label>
```

If you’d like to customize the rendering this can be achieved by overriding the `Form.template_name_label` attribute or more generally by overriding the default template, see also Overriding built-in form templates.
The `tag` argument was added.

**BoundField.legend_tag**(contents=None, attrs=None, label_suffix=None)

Calls `label_tag()` with `tag='legend'` to render the label with `<legend>` tags. This is useful when rendering radio and multiple checkbox widgets where `<legend>` may be more appropriate than a `<label>`.

**BoundField.value()**

Use this method to render the raw value of this field as it would be rendered by a `Widget`:

```python
>>> initial = {'subject': 'welcome'}
>>> unbound_form = ContactForm(initial=initial)
>>> bound_form = ContactForm(data={'subject': 'hi'}, initial=initial)
>>> print(unbound_form['subject'].value())
welcome
>>> print(bound_form['subject'].value())
hi
```

**Customizing BoundField**

If you need to access some additional information about a form field in a template and using a subclass of `Field` isn’t sufficient, consider also customizing `BoundField`.

A custom form field can override `get_bound_field()`:

**Field.get_bound_field**(form, field_name)

Takes an instance of `Form` and the name of the field. The return value will be used when accessing the field in a template. Most likely it will be an instance of a subclass of `BoundField`.

If you have a `GPSCoordinatesField`, for example, and want to be able to access additional information about the coordinates in a template, this could be implemented as follows:

```python
class GPSCoordinatesBoundField(BoundField):
    @property
def country(self):
        """Return the country the coordinates lie in or None if it can't be determined."
        value = self.value()
        if value:
            return get_country_from_coordinates(value)
        else:
            return None

class GPSCoordinatesField(Field):
```

(continues on next page)
def get_bound_field(self, form, field_name):
    return GPSCoordinatesBoundField(form, self, field_name)

Now you can access the country in a template with {{ form.coordinates.country }}.

**Binding uploaded files to a form**

Dealing with forms that have FileField and ImageField fields is a little more complicated than a normal form.

Firstly, in order to upload files, you’ll need to make sure that your `<form>` element correctly defines the `enctype` as "multipart/form-data":

```html
<form enctype="multipart/form-data" method="post" action="/foo/">
```

Secondly, when you use the form, you need to bind the file data. File data is handled separately to normal form data, so when your form contains a FileField and ImageField, you will need to specify a second argument when you bind your form. So if we extend our ContactForm to include an ImageField called `mugshot`, we need to bind the file data containing the mugshot image:

```python
# Bound form with an image field
>>> from django.core.files.uploadedfile import SimpleUploadedFile
>>> data = {
            'subject': 'hello',
            ...  'message': 'Hi there',
            ...  'sender': 'foo@example.com',
            ...  'cc_myself': True
            }
>>> file_data = {'mugshot': SimpleUploadedFile('face.jpg', <file data>)}
>>> f = ContactFormWithMugshot(data, file_data)
```

In practice, you will usually specify `request.FILES` as the source of file data (just like you use `request.POST` as the source of form data):

```python
# Bound form with an image field, data from the request
>>> f = ContactFormWithMugshot(request.POST, request.FILES)
```

Constructing an unbound form is the same as always – omit both form data and file data:

```python
# Unbound form with an image field
>>> f = ContactFormWithMugshot()
```
Testing for multipart forms

Form.is_multipart()

If you’re writing reusable views or templates, you may not know ahead of time whether your form is a multipart form or not. The is_multipart() method tells you whether the form requires multipart encoding for submission:

```python
>>> f = ContactFormWithMugshot()
>>> f.is_multipart()
True
```

Here’s an example of how you might use this in a template:

```html
{% if form.is_multipart %}
  <form enctype="multipart/form-data" method="post" action="/foo/">
{% else %}
  <form method="post" action="/foo/">
{% endif %}
  {{ form }}
</form>
```

Subclassing forms

If you have multiple Form classes that share fields, you can use subclassing to remove redundancy.

When you subclass a custom Form class, the resulting subclass will include all fields of the parent class(es), followed by the fields you define in the subclass.

In this example, ContactFormWithPriority contains all the fields from ContactForm, plus an additional field, priority. The ContactForm fields are ordered first:

```python
>>> class ContactFormWithPriority(ContactForm):
...     priority = forms.CharField()
>>> f = ContactFormWithPriority(auto_id=False)
>>> print(f.as_ul())
<li>Subject: <input type="text" name="subject" maxlength="100" required></li>
<li>Message: <input type="text" name="message" required></li>
<li>Sender: <input type="email" name="sender" required></li>
<li>Cc myself: <input type="checkbox" name="cc_myself"></li>
<li>Priority: <input type="text" name="priority" required></li>
```

It’s possible to subclass multiple forms, treating forms as mixins. In this example, BeatleForm subclasses both PersonForm and InstrumentForm (in that order), and its field list includes the fields from the parent classes:
>>> from django import forms
>>> class PersonForm(forms.Form):
...    first_name = forms.CharField()
...    last_name = forms.CharField()

>>> class InstrumentForm(forms.Form):
...    instrument = forms.CharField()

>>> class BeatleForm(InstrumentForm, PersonForm):
...    haircut_type = forms.CharField()

>>> b = BeatleForm(auto_id=False)
>>> print(b.as_ul())
<li>First name: <input type="text" name="first_name" required></li>
<li>Last name: <input type="text" name="last_name" required></li>
<li>Instrument: <input type="text" name="instrument" required></li>
<li>Haircut type: <input type="text" name="haircut_type" required></li>

It’s possible to declaratively remove a Field inherited from a parent class by setting the name of the field to None on the subclass. For example:

>>> from django import forms

>>> class ParentForm(forms.Form):
...    name = forms.CharField()
...    age = forms.IntegerField()

>>> class ChildForm(ParentForm):
...    name = None

>>> list(ChildForm().fields)
['age']

Prefixes for forms

Form.prefix

You can put several Django forms inside one <form> tag. To give each Form its own namespace, use the prefix keyword argument:

>>> mother = PersonForm(prefix="mother")
>>> father = PersonForm(prefix="father")
>>> print(mother.as_ul())
<li><label for="id_mother-first_name">First name:</label> <input type="text" name="mother-first_name" id="id_mother-first_name" required></li>
<li><label for="id_mother-last_name">Last name:</label> <input type="text" name="mother-last_name" id="id_mother-last_name" required></li>
<li><label for="id_father-first_name">First name:</label> <input type="text" name="father-first_name" id="id_father-first_name" required></li>
<li><label for="id_father-last_name">Last name:</label> <input type="text" name="father-last_name" id="id_father-last_name" required></li>

(continues on next page)
The prefix can also be specified on the form class:

```python
>>> class PersonForm(forms.Form):
    ...    prefix = 'person'
```

### 6.12.2 Form fields

**class Field(**kwargs)**

When you create a `Form` class, the most important part is defining the fields of the form. Each field has custom validation logic, along with a few other hooks.

**Field.clean(value)**

Although the primary way you’ll use `Field` classes is in `Form` classes, you can also instantiate them and use them directly to get a better idea of how they work. Each `Field` instance has a `clean()` method, which takes a single argument and either raises a `django.core.exceptions.ValidationError` exception or returns the clean value:

```python
>>> from django import forms
>>> f = forms.EmailField()
>>> f.clean('foo@example.com')
'foo@example.com'
>>> f.clean('invalid email address')
Traceback (most recent call last):
  ...
ValidationError: ['Enter a valid email address. ']
```

**Core field arguments**

Each `Field` class constructor takes at least these arguments. Some `Field` classes take additional, field-specific arguments, but the following should always be accepted:
required

Field.required

By default, each Field class assumes the value is required, so if you pass an empty value — either None or the empty string ("") — then clean() will raise a ValidationError exception:

```python
>>> from django import forms
>>> f = forms.CharField()
>>> f.clean('foo')
'foo'
>>> f.clean('')
Traceback (most recent call last):
 ...  
ValidationError: ['This field is required. ']
>>> f.clean(None)
Traceback (most recent call last):
 ...  
ValidationError: ['This field is required. ']
>>> f.clean('')
...  
>>> f.clean(0)
'0'
>>> f.clean(True)
'True'
>>> f.clean(False)
'False'
```

To specify that a field is not required, pass required=False to the Field constructor:

```python
>>> f = forms.CharField(required=False)
>>> f.clean('foo')
'foo'
>>> f.clean('')
...
>>> f.clean(None)
...
>>> f.clean(0)
'0'
>>> f.clean(True)
'True'
>>> f.clean(False)
'False'
```

If a Field has required=False and you pass clean() an empty value, then clean() will return a normalized empty value rather than raising ValidationError. For CharField, this will return empty_value which
defaults to an empty string. For other Field classes, it might be None. (This varies from field to field.) Widgets of required form fields have the required HTML attribute. Set the `Form.use_required_attribute` attribute to False to disable it. The required attribute isn’t included on forms of formsets because the browser validation may not be correct when adding and deleting formsets.

**label**

Field.label

The label argument lets you specify the “human-friendly” label for this field. This is used when the Field is displayed in a Form.

As explained in “Outputting forms as HTML” above, the default label for a Field is generated from the field name by converting all underscores to spaces and upper-casing the first letter. Specify label if that default behavior doesn’t result in an adequate label.

Here’s a full example Form that implements label for two of its fields. We’ve specified auto_id=False to simplify the output:

```python
>>> from django import forms

```}

```python
>> class CommentForm(forms.Form):
...    name = forms.CharField(label='Your name')
...    url = forms.URLField(label='Your website', required=False)
...    comment = forms.CharField()

```}

```python
>>> f = CommentForm(auto_id=False)
>>> print(f)
<tr><th>Your name:</th><td><input type="text" name="name" required></td></tr>
<tr><th>Your website:</th><td><input type="url" name="url"></td></tr>
<tr><th>Comment:</th><td><input type="text" name="comment" required></td></tr>
```

**label_suffix**

Field.label_suffix

The label_suffix argument lets you override the form’s label_suffix on a per-field basis:

```python
```}

```python
>> class ContactForm(forms.Form):
...    age = forms.IntegerField()
...    nationality = forms.CharField()
...    captcha_answer = forms.IntegerField(label='2 + 2', label_suffix='=')

```}

```python
>>> f = ContactForm(label_suffix='?')
>>> print(f.as_p())
```

(continues on next page)
Django Documentation, Release 4.2.dev20220706084552

(continued from previous page)

<p><label for="id_nationality">Nationality?</label> <input id="id_nationality" name="nationality"␣
,→

type="text" required></p>

<p><label for="id_captcha_answer">2 + 2 =</label> <input id="id_captcha_answer" name="captcha_
,→

answer" type="number" required></p>

initial
Field.initial
The initial argument lets you specify the initial value to use when rendering this Field in an unbound
Form.
To specify dynamic initial data, see the Form.initial parameter.
The use-case for this is when you want to display an“empty”form in which a field is initialized to a particular
value. For example:
>>> from django import forms
>>> class CommentForm(forms.Form):
...

name = forms.CharField(initial='Your name')

...

url = forms.URLField(initial='http://')

...

comment = forms.CharField()

>>> f = CommentForm(auto_id=False)
>>> print(f)
<tr><th>Name:</th><td><input type="text" name="name" value="Your name" required></td></tr>
<tr><th>Url:</th><td><input type="url" name="url" value="http://" required></td></tr>
<tr><th>Comment:</th><td><input type="text" name="comment" required></td></tr>

You may be thinking, why not just pass a dictionary of the initial values as data when displaying the form?
Well, if you do that, you’ll trigger validation, and the HTML output will include any validation errors:
>>> class CommentForm(forms.Form):
...

name = forms.CharField()

...

url = forms.URLField()

...

comment = forms.CharField()

>>> default_data = {'name': 'Your name', 'url': 'http://'}
>>> f = CommentForm(default_data, auto_id=False)
>>> print(f)
<tr><th>Name:</th><td><input type="text" name="name" value="Your name" required></td></tr>
<tr><th>Url:</th><td><ul class="errorlist"><li>Enter a valid URL.</li></ul><input type="url" name=
,→

"url" value="http://" required></td></tr>

<tr><th>Comment:</th><td><ul class="errorlist"><li>This field is required.</li></ul><input type=
,→

"text" name="comment" required></td></tr>

1450

Chapter 6. API Reference


This is why `initial` values are only displayed for unbound forms. For bound forms, the HTML output will use the bound data.

Also note that `initial` values are not used as “fallback” data in validation if a particular field’s value is not given. `initial` values are only intended for initial form display:

```python
>>> class CommentForm(forms.Form):
...     name = forms.CharField(initial='Your name')
...     url = forms.URLField(initial='http://')
...     comment = forms.CharField()
>>> data = {'name': '', 'url': '', 'comment': 'Foo'}
>>> f = CommentForm(data)
>>> f.is_valid()
False
# The form does *not* fall back to using the initial values.
>>> f.errors
{'url': ['This field is required.'], 'name': ['This field is required.']}  
```

Instead of a constant, you can also pass any callable:

```python
>>> import datetime
>>> class DateForm(forms.Form):
...     day = forms.DateField(initial=datetime.date.today)
>>> print(DateForm())
<tr><th>Day:</th><td><input type="text" name="day" value="12/23/2008" required><td></tr>
```

The callable will be evaluated only when the unbound form is displayed, not when it is defined.

`widget`

Field `widget`

The `widget` argument lets you specify a `Widget` class to use when rendering this Field. See `Widgets` for more information.

`help_text`

Field `help_text`

The `help_text` argument lets you specify descriptive text for this Field. If you provide `help_text`, it will be displayed next to the Field when the Field is rendered by one of the convenience `Form` methods (e.g., `as_ul()`).

Like the model field’s `help_text`, this value isn’t HTML-escaped in automatically-generated forms.
Here’s a full example Form that implements help_text for two of its fields. We’ve specified auto_id=False to simplify the output:

```python
>>> from django import forms
>>> class HelpTextContactForm(forms.Form):
...     subject = forms.CharField(max_length=100, help_text='100 characters max.')
...     message = forms.CharField()
...     sender = forms.EmailField(help_text='A valid email address, please.')
...     cc_myself = forms.BooleanField(required=False)

>>> f = HelpTextContactForm(auto_id=False)
>>> print(f.as_table())
<tr><th>Subject:</th><td><input type="text" name="subject" maxlength="100" required><br><span class="helptext">100 characters max.</span></td></tr>
<tr><th>Message:</th><td><input type="text" name="message" required></td></tr>
<tr><th>Sender:</th><td><input type="email" name="sender" required><br>A valid email address, please.</td></tr>
<tr><th>Cc myself:</th><td><input type="checkbox" name="cc_myself"></td></tr>
```

```python
>>> print(f.as_ul())
<li>Subject: <input type="text" name="subject" maxlength="100" required> <span class="helptext">100 characters max.</span></li>
<li>Message: <input type="text" name="message" required></li>
<li>Sender: <input type="email" name="sender" required> A valid email address, please.</li>
<li>Cc myself: <input type="checkbox" name="cc_myself"></li>
```

```python
>>> print(f.as_p())
<p>Subject: <input type="text" name="subject" maxlength="100" required> <span class="helptext">100 characters max.</span></p>
<p>Message: <input type="text" name="message" required></p>
<p>Sender: <input type="email" name="sender" required> A valid email address, please.</p>
<p>Cc myself: <input type="checkbox" name="cc_myself"></p>
```

### error_messages

**Field.error_messages**

The error_messages argument lets you override the default messages that the field will raise. Pass in a dictionary with keys matching the error messages you want to override. For example, here is the default error message:

```python
>>> from django import forms
>>> generic = forms.CharField()
>>> generic.clean('')
Traceback (most recent call last):
  ...
ValidationError: ['This field is required.']
```
And here is a custom error message:

```python
>>> name = forms.CharField(error_messages={'required': 'Please enter your name'})
>>> name.clean('')
Traceback (most recent call last):
  ...ValidationError: ['Please enter your name']
```

In the built-in Field classes section below, each Field defines the error message keys it uses.

**validators**

Field.validators

The validators argument lets you provide a list of validation functions for this field.

See the validators documentation for more information.

**localize**

Field.localize

The localize argument enables the localization of form data input, as well as the rendered output.

See the format localization documentation for more information.

**disabled**

Field.disabled

The disabled boolean argument, when set to True, disables a form field using the disabled HTML attribute so that it won’t be editable by users. Even if a user tampers with the field’s value submitted to the server, it will be ignored in favor of the value from the form’s initial data.

**Checking if the field data has changed**

Field.has_changed()

The has_changed() method is used to determine if the field value has changed from the initial value. Returns True or False.

See the Form.has_changed() documentation for more information.
Built-in Field classes

Naturally, the forms library comes with a set of Field classes that represent common validation needs. This section documents each built-in field.

For each field, we describe the default widget used if you don’t specify widget. We also specify the value returned when you provide an empty value (see the section on required above to understand what that means).

BooleanField

class BooleanField(**kwargs)

• Default widget: CheckboxInput
• Empty value: False
• Normalizes to: A Python True or False value.
• Validates that the value is True (e.g. the check box is checked) if the field has required=True.
• Error message keys: required

Note: Since all Field subclasses have required=True by default, the validation condition here is important. If you want to include a boolean in your form that can be either True or False (e.g. a checked or unchecked checkbox), you must remember to pass in required=False when creating the BooleanField.

CharField

class CharField(**kwargs)

• Default widget: TextInput
• Empty value: Whatever you’ve given as empty_value.
• Normalizes to: A string.
• Uses MaxLengthValidator and MinLengthValidator if max_length and min_length are provided. Otherwise, all inputs are valid.
• Error message keys: required, max_length, min_length

Has the following optional arguments for validation:

    max_length
**min_length**

If provided, these arguments ensure that the string is at most or at least the given length.

**strip**

If True (default), the value will be stripped of leading and trailing whitespace.

**empty_value**

The value to use to represent “empty”. Defaults to an empty string.

**ChoiceField**

class ChoiceField(**kwargs)

- Default widget: *Select*
- Empty value: `'` (an empty string)
- Normalizes to: A string.
- Validates that the given value exists in the list of choices.
- Error message keys: `required, invalid_choice`

The `invalid_choice` error message may contain `%\(value)s`, which will be replaced with the selected choice.

Takes one extra argument:

**choices**

Either an *iterable* of 2-tuples to use as choices for this field, *enumeration* choices, or a callable that returns such an iterable. This argument accepts the same formats as the `choices` argument to a model field. See the model field reference documentation on *choices* for more details. If the argument is a callable, it is evaluated each time the field’s form is initialized, in addition to during rendering. Defaults to an empty list.

**DateField**

class DateField(**kwargs)

- Default widget: *DateInput*
- Empty value: *None*
- Normalizes to: A Python `datetime.date` object.
- Validates that the given value is either a `datetime.date`, `datetime.datetime` or string formatted in a particular date format.
- Error message keys: `required, invalid`
Takes one optional argument:

```
input_formats
```

A list of formats used to attempt to convert a string to a valid `datetime.date` object.

If no `input_formats` argument is provided, the default input formats are taken from `DATE_INPUT_FORMATS` if `USE_L10N` is `False`, or from the active locale format `DATE_INPUT_FORMATS` key if localization is enabled. See also format localization.

---

### DateTimeField

```
class DateTimeField(**kwargs)
```

- Default widget: `DateTimeInput`
- Empty value: `None`
- Normalizes to: A Python `datetime.datetime` object.
- Validates that the given value is either a `datetime.datetime`, `datetime.date` or string formatted in a particular datetime format.
- Error message keys: `required`, `invalid`

Takes one optional argument:

```
input_formats
```

A list of formats used to attempt to convert a string to a valid `datetime.datetime` object, in addition to ISO 8601 formats.

The field always accepts strings in ISO 8601 formatted dates or similar recognized by `parse_datetime()`.

Some examples are:

```
* '2006-10-25 14:30:59'
* '2006-10-25T14:30:59'
* '2006-10-25 14:30'
* '2006-10-25T14:30'
* '2006-10-25T14:30Z'
* '2006-10-25T14:30+02:00'
* '2006-10-25'
```

If no `input_formats` argument is provided, the default input formats are taken from `DATETIME_INPUT_FORMATS` and `DATE_INPUT_FORMATS` if `USE_L10N` is `False`, or from the active locale format `DATETIME_INPUT_FORMATS` and `DATE_INPUT_FORMATS` keys if localization is enabled. See also format localization.
DecimalField

class DecimalField(**kwargs)

- Default widget: NumberInput when Field.localize is False, else TextInput.
- Empty value: None
- Normalizes to: A Python decimal.
- Validates that the given value is a decimal. Uses MaxValueValidator and MinValueValidator if max_value and min_value are provided. Uses StepValueValidator if step_size is provided. Leading and trailing whitespace is ignored.
- Error message keys: required, invalid, max_value, min_value, max_digits, max_decimal_places, max_whole_digits, step_size.

The max_value and min_value error messages may contain %(limit_value)s, which will be substituted by the appropriate limit. Similarly, the max_digits, max_decimal_places and max_whole_digits error messages may contain %(max)s.

Takes five optional arguments:

max_value

min_value

These control the range of values permitted in the field, and should be given as decimal.Decimal values.

max_digits

The maximum number of digits (those before the decimal point plus those after the decimal point, with leading zeros stripped) permitted in the value.

decimal_places

The maximum number of decimal places permitted.

step_size

Limit valid inputs to an integral multiple of step_size.

The step_size argument was added.
DurationField

class DurationField(**kwargs)

- Default widget: TextInput
- Empty value: None
- Normalizes to: A Python timedelta.
- Validates that the given value is a string which can be converted into a timedelta. The value must be between datetime.timedelta.min and datetime.timedelta.max.
- Error message keys: required, invalid, overflow.

Accepts any format understood by parse_duration().

EmailField

class EmailField(**kwargs)

- Default widget: EmailInput
- Empty value: Whatever you’ve given as empty_value.
- Normalizes to: A string.
- Uses EmailValidator to validate that the given value is a valid email address, using a moderately complex regular expression.
- Error message keys: required, invalid

Has the optional arguments max_length, min_length, and empty_value which work just as they do for CharField.

FileField

class FileField(**kwargs)

- Default widget: ClearableFileInput
- Empty value: None
- Normalizes to: An UploadedFile object that wraps the file content and file name into a single object.
- Can validate that non-empty file data has been bound to the form.
- Error message keys: required, invalid, missing, empty, max_length
Has the optional arguments for validation: `max_length` and `allow_empty_file`. If provided, these ensure that the file name is at most the given length, and that validation will succeed even if the file content is empty.

To learn more about the `UploadedFile` object, see the file uploads documentation.

When you use a `FileField` in a form, you must also remember to bind the file data to the form.

The `max_length` error refers to the length of the filename. In the error message for that key, `%(max)d` will be replaced with the maximum filename length and `%(length)d` will be replaced with the current filename length.

`FilePathField`

class `FilePathField(**kwargs)`

- Default widget: `Select`
- Empty value: `'` (an empty string)
- Normalizes to: A string.
- Validates that the selected choice exists in the list of choices.
- Error message keys: `required`, `invalid_choice`

The field allows choosing from files inside a certain directory. It takes five extra arguments; only `path` is required:

`path`

The absolute path to the directory whose contents you want listed. This directory must exist.

`recursive`

If `False` (the default) only the direct contents of `path` will be offered as choices. If `True`, the directory will be descended into recursively and all descendants will be listed as choices.

`match`

A regular expression pattern; only files with names matching this expression will be allowed as choices.

`allow_files`

Optional. Either `True` or `False`. Default is `True`. Specifies whether files in the specified location should be included. Either this or `allow_folders` must be `True`.

`allow_folders`

Optional. Either `True` or `False`. Default is `False`. Specifies whether folders in the specified location should be included. Either this or `allow_files` must be `True`.
FloatField

```ruby
class FloatField(**kwargs)
```

- Default widget: `NumberInput` when `Field.localize` is `False`, else `TextInput`.
- Empty value: `None`
- Normalizes to: A Python float.
- Validates that the given value is a float. Uses `MaxValueValidator` and `MinValueValidator` if `max_value` and `min_value` are provided. Uses `StepValueValidator` if `step_size` is provided.
  Leading and trailing whitespace is allowed, as in Python’s `float()` function.
- Error message keys: `required`, `invalid`, `max_value`, `min_value`, `step_size`.

  Takes three optional arguments:

  ```
  max_value
  min_value
  step_size
  ```

  These control the range of values permitted in the field.

GenericIPAddressField

```ruby
class GenericIPAddressField(**kwargs)
```

A field containing either an IPv4 or an IPv6 address.

- Default widget: `TextInput`
- Empty value: `'` (an empty string)
- Normalizes to: A string. IPv6 addresses are normalized as described below.
- Validates that the given value is a valid IP address.
- Error message keys: `required`, `invalid`

  The IPv6 address normalization follows `RFC 4291#section-2.2` section 2.2, including using the IPv4 format suggested in paragraph 3 of that section, like `::ffff:192.0.2.0`. For example, `2001::0:0:01` would be normalized to `2001::1`, and `::ffff:0a0a:0a0a` to `::ffff:10.10.10.10`. All characters are converted to lowercase.

  Takes two optional arguments:

  ```
  protocol
  ```

  Limits valid inputs to the specified protocol. Accepted values are `both` (default), `IPv4` or `IPv6`. Matching is case insensitive.
unpack_ipv4

Unpacks IPv4 mapped addresses like ::ffff:192.0.2.1. If this option is enabled that address would be unpacked to 192.0.2.1. Default is disabled. Can only be used when protocol is set to 'both'.

ImageField

class ImageField(**kwargs)

- Default widget: ClearableFileInput
- Empty value: None
- Normalizes to: An UploadedFile object that wraps the file content and file name into a single object.
- Validates that file data has been bound to the form. Also uses FileExtensionValidator to validate that the file extension is supported by Pillow.
- Error message keys: required, invalid, missing, empty, invalid_image

Using an ImageField requires that Pillow is installed with support for the image formats you use. If you encounter a corrupt image error when you upload an image, it usually means that Pillow doesn’t understand its format. To fix this, install the appropriate library and reinstall Pillow.

When you use an ImageField on a form, you must also remember to bind the file data to the form. After the field has been cleaned and validated, the UploadedFile object will have an additional image attribute containing the Pillow Image instance used to check if the file was a valid image. Pillow closes the underlying file descriptor after verifying an image, so while non-image data attributes, such as format, height, and width, are available, methods that access the underlying image data, such as getdata() or getpixel(), cannot be used without reopening the file. For example:

```python
>>> from PIL import Image
>>> from django import forms
>>> from django.core.files.uploadedfile import SimpleUploadedFile
>>> class ImageForm(forms.Form):
...     img = forms.ImageField()
>>> file_data = {'img': SimpleUploadedFile('test.png', <file data>)}
>>> form = ImageForm({}, file_data)
# Pillow closes the underlying file descriptor.
>>> form.is_valid()
True
>>> image_field = form.cleaned_data['img']
>>> image_field.image
<PIL.PngImagePlugin.PngImageFile image mode=RGBA size=191x287 at 0x7F5985045C18>
```
Additionally, UploadedFile.content_type will be updated with the image’s content type if Pillow can determine it, otherwise it will be set to None.

**IntegerField**

class IntegerField(**kwargs)

- Default widget: *NumberInput* when *Field.localization* is *False*, else *TextInput*.
- Empty value: *None*
- Normalizes to: A Python integer.
- Validates that the given value is an integer. Uses *MaxValueValidator* and *MinValueValidator* if *max_value* and *min_value* are provided. Uses *StepValueValidator* if *step_size* is provided. Leading and trailing whitespace is allowed, as in Python’s int() function.
- Error message keys: *required, invalid, max_value, min_value, step_size*

The *max_value, min_value* and *step_size* error messages may contain %(*limit_value*)s, which will be substituted by the appropriate limit.

Takes three optional arguments for validation:

**max_value**

**min_value**

These control the range of values permitted in the field.

**step_size**

Limit valid inputs to an integral multiple of *step_size*. 
JSONField

**class JSONField**(encoder=None, decoder=None, **kwargs)**

A field which accepts JSON encoded data for a JSONField.

- Default widget: `Textarea`
- Empty value: `None`
- Normalizes to: A Python representation of the JSON value (usually as a `dict`, `list`, or `None`), depending on `JSONField.decoder`.
- Validates that the given value is a valid JSON.
- Error message keys: `required`, `invalid`

Takes two optional arguments:

**encoder**

A `json.JSONEncoder` subclass to serialize data types not supported by the standard JSON serializer (e.g. `datetime.datetime` or `UUID`). For example, you can use the `DjangoJSONEncoder` class.

Defaults to `json.JSONEncoder`.

**decoder**

A `json.JSONDecoder` subclass to deserialize the input. Your deserialization may need to account for the fact that you can’t be certain of the input type. For example, you run the risk of returning a `datetime` that was actually a string that just happened to be in the same format chosen for `datetimes`.

The decoder can be used to validate the input. If `json.JSONDecodeError` is raised during the deserialization, a `ValidationError` will be raised.

Defaults to `json.JSONDecoder`.

---

**Note:** If you use a `ModelForm`, the `encoder` and `decoder` from `JSONField` will be used.

---

**User friendly forms**

`JSONField` is not particularly user friendly in most cases. However, it is a useful way to format data from a client-side widget for submission to the server.
MultipleChoiceField

class MultipleChoiceField(**kwargs)

- Default widget: SelectMultiple
- Empty value: [] (an empty list)
- Normalizes to: A list of strings.
- Validates that every value in the given list of values exists in the list of choices.
- Error message keys: required, invalid_choice, invalid_list

The invalid_choice error message may contain %(value)s, which will be replaced with the selected choice.

Takes one extra required argument, choices, as for ChoiceField.

NullBooleanField

class NullBooleanField(**kwargs)

- Default widget: NullBooleanSelect
- Empty value: None
- Normalizes to: A Python True, False or None value.
- Validates nothing (i.e., it never raises a ValidationError).

NullBooleanField may be used with widgets such as Select or RadioSelect by providing the widget choices:

```python
NullBooleanField(
    widget=Select(
        choices=[
            ('', 'Unknown'),
            (True, 'Yes'),
            (False, 'No'),
        ]
    )
)
```
**RegexField**

```python
class RegexField(**kwargs)
```

- Default widget: *TextInput*
- Empty value: Whatever you’ve given as `empty_value`.
- Normalizes to: A string.
- Uses `RegexValidator` to validate that the given value matches a certain regular expression.
- Error message keys: `required`, `invalid`

Takes one required argument:

`regex`

A regular expression specified either as a string or a compiled regular expression object.

Also takes `max_length`, `min_length`, `strip`, and `empty_value` which work just as they do for `CharField`.

`strip`

Defaults to `False`. If enabled, stripping will be applied before the regex validation.

**SlugField**

```python
class SlugField(**kwargs)
```

- Default widget: *TextInput*
- Empty value: Whatever you’ve given as `empty_value`.
- Normalizes to: A string.
- Uses `validate_slug` or `validate_unicode_slug` to validate that the given value contains only letters, numbers, underscores, and hyphens.
- Error messages: `required`, `invalid`

This field is intended for use in representing a model `SlugField` in forms.

Takes two optional parameters:

`allow_unicode`

A boolean instructing the field to accept Unicode letters in addition to ASCII letters. Defaults to `False`.

`empty_value`

The value to use to represent “empty”. Defaults to an empty string.
TimeField

class TimeField(**kwargs)

• Default widget: *TimeInput*
• Empty value: None
• Normalizes to: A Python `datetime.time` object.
• Validates that the given value is either a `datetime.time` or string formatted in a particular time format.
• Error message keys: *required*, *invalid*

Takes one optional argument:

**input_formats**

A list of formats used to attempt to convert a string to a valid `datetime.time` object.

If no `input_formats` argument is provided, the default input formats are taken from `TIME_INPUT_FORMATS` if `USE_L10N` is False, or from the active locale format `TIME_INPUT_FORMATS` key if localization is enabled. See also *format localization*.

TypedChoiceField

class TypedChoiceField(**kwargs)

Just like a `ChoiceField`, except `TypedChoiceField` takes two extra arguments, `coerce` and `empty_value`.

• Default widget: *Select*
• Empty value: Whatever you’ve given as `empty_value`.
• Normalizes to: A value of the type provided by the `coerce` argument.
• Validates that the given value exists in the list of choices and can be coerced.
• Error message keys: *required*, *invalid_choice*

Takes extra arguments:

**coerce**

A function that takes one argument and returns a coerced value. Examples include the built-in `int`, `float`, `bool` and other types. Defaults to an identity function. Note that coercion happens after input validation, so it is possible to coerce to a value not present in choices.

**empty_value**

The value to use to represent “empty.” Defaults to the empty string; `None` is another common
choice here. Note that this value will not be coerced by the function given in the `coerce` argument, so choose it accordingly.

**TypedMultipleChoiceField**

```python
class TypedMultipleChoiceField(**kwargs)
```

Just like a `MultipleChoiceField`, except `TypedMultipleChoiceField` takes two extra arguments, `coerce` and `empty_value`.

- Default widget: `Select Multiple`
- Empty value: Whatever you’ve given as `empty_value`
- Normalizes to: A list of values of the type provided by the `coerce` argument.
- Validates that the given values exists in the list of choices and can be coerced.
- Error message keys: `required`, `invalid_choice`

The `invalid_choice` error message may contain `%value`, which will be replaced with the selected choice.

Takes two extra arguments, `coerce` and `empty_value`, as for `TypedChoiceField`.

**URLField**

```python
class URLField(**kwargs)
```

- Default widget: `URLInput`
- Empty value: Whatever you’ve given as `empty_value`.
- Normalizes to: A string.
- Uses `URLValidator` to validate that the given value is a valid URL.
- Error message keys: `required`, `invalid`

Has the optional arguments `max_length`, `min_length`, and `empty_value` which work just as they do for `CharField`. 
UUIDField

class UUIDField(**kwargs)

- Default widget: TextInput
- Empty value: None
- Normalizes to: A UUID object.
- Error message keys: required, invalid

This field will accept any string format accepted as the hex argument to the UUID constructor.

Slightly complex built-in Field classes

ComboField

class ComboField(**kwargs)

- Default widget: TextInput
- Empty value: '' (an empty string)
- Normalizes to: A string.
- Validates the given value against each of the fields specified as an argument to the ComboField.
- Error message keys: required, invalid

Takes one extra required argument:

fields

The list of fields that should be used to validate the field’s value (in the order in which they are provided).

```python
>>> from django.forms import ComboField
>>> f = ComboField(fields=[CharField(max_length=20), EmailField()])
>>> f.clean('test@example.com')
'test@example.com'
>>> f.clean('longemailaddress@example.com')
Traceback (most recent call last):
...
ValidationError: ['Ensure this value has at most 20 characters (it has 28).']
```
MultiValueField

class MultiValueField(fields=(), **kwargs):

• Default widget: TextInput
• Empty value: '' (an empty string)
• Normalizes to: the type returned by the compress method of the subclass.
• Validates the given value against each of the fields specified as an argument to the MultiValueField.
• Error message keys: required, invalid, incomplete

Aggregates the logic of multiple fields that together produce a single value.

This field is abstract and must be subclassed. In contrast with the single-value fields, subclasses of MultiValueField must not implement clean() but instead implement compress().

Takes one extra required argument:

fields

A tuple of fields whose values are cleaned and subsequently combined into a single value. Each value of the field is cleaned by the corresponding field in fields—the first value is cleaned by the first field, the second value is cleaned by the second field, etc. Once all fields are cleaned, the list of clean values is combined into a single value by compress().

Also takes some optional arguments:

require_all_fields

Defaults to True, in which case a required validation error will be raised if no value is supplied for any field.

When set to False, the Field.required attribute can be set to False for individual fields to make them optional. If no value is supplied for a required field, an incomplete validation error will be raised.

A default incomplete error message can be defined on the MultiValueField subclass, or different messages can be defined on each individual field. For example:

```
from django.core.validators import RegexValidator

class PhoneField(MultiValueField):
    def __init__(self, **kwargs):
        # Define one message for all fields.
        error_messages = {
            'incomplete': 'Enter a country calling code and a phone number.',
        }
```
# Or define a different message for each field.

```python
fields = (  
    CharField(  
        error_messages={"incomplete": 'Enter a country calling code.'},  
        validators=[  
            RegexValidator(r'^[0-9]+$', 'Enter a valid country calling code.'),  
        ],  
    ),  
    CharField(  
        error_messages={"incomplete": 'Enter a phone number.'},  
        validators=[RegexValidator(r'^[0-9]+$', 'Enter a valid phone number.'),  
        ],  
    ),  
    CharField(  
        validators=[RegexValidator(r'^[0-9]+$', 'Enter a valid extension.'),  
        required=False,  
    ),  
)
```

super().__init__(
    error_messages=error_messages, fields=fields,
    require_all_fields=False, **kwargs
)

---

**widget**

Must be a subclass of `django.forms.MultiWidget`. Default value is `TextInput`, which probably is not very useful in this case.

**compress(data_list)**

Takes a list of valid values and returns a “compressed” version of those values—in a single value. For example, `SplitDateTimeField` is a subclass which combines a time field and a date field into a `datetime` object.

This method must be implemented in the subclasses.

**SplitDateTimeField**

```python
class SplitDateTimeField(**kwargs)
```

- Default widget: `SplitDateTimeWidget`
- Empty value: None
- Normalizes to: A Python `datetime.datetime` object.
- Validates that the given value is a `datetime.datetime` or string formatted in a particular datetime format.
• Error message keys: required, invalid, invalid_date, invalid_time

Takes two optional arguments:

**input_date_formats**

A list of formats used to attempt to convert a string to a valid `datetime.date` object.

If no `input_date_formats` argument is provided, the default input formats for `DateField` are used.

**input_time_formats**

A list of formats used to attempt to convert a string to a valid `datetime.time` object.

If no `input_time_formats` argument is provided, the default input formats for `TimeField` are used.

**Fields which handle relationships**

Two fields are available for representing relationships between models: `ModelChoiceField` and `ModelMultipleChoiceField`. Both of these fields require a single `queryset` parameter that is used to create the choices for the field. Upon form validation, these fields will place either one model object (in the case of `ModelChoiceField`) or multiple model objects (in the case of `ModelMultipleChoiceField`) into the `cleaned_data` dictionary of the form.

For more complex uses, you can specify `queryset=None` when declaring the form field and then populate the `queryset` in the form’s `__init__()` method:

```python
class FooMultipleChoiceForm(forms.Form):
    foo_select = forms.ModelMultipleChoiceField(queryset=None)

    def __init__(self, *args, **kwargs):
        super().__init__(*args, **kwargs)
        self.fields['foo_select'].queryset = ...
```

Both `ModelChoiceField` and `ModelMultipleChoiceField` have an `iterator` attribute which specifies the class used to iterate over the queryset when generating choices. See Iterating relationship choices for details.

**ModelChoiceField**

```python
class ModelChoiceField(**kwargs)
```

• Default widget: `Select`
• Empty value: `None`
• Normalizes to: A model instance.
• Validates that the given id exists in the queryset.
• Error message keys: `required`, `invalid_choice`
The `invalid_choice` error message may contain `%(value)s`, which will be replaced with the selected choice.

Allows the selection of a single model object, suitable for representing a foreign key. Note that the default widget for `ModelChoiceField` becomes impractical when the number of entries increases. You should avoid using it for more than 100 items.

A single argument is required:

```python
queryset
```

A `QuerySet` of model objects from which the choices for the field are derived and which is used to validate the user’s selection. It’s evaluated when the form is rendered.

`ModelChoiceField` also takes several optional arguments:

- **empty_label**
  - By default the `<select>` widget used by `ModelChoiceField` will have an empty choice at the top of the list. You can change the text of this label (which is "---------" by default) with the `empty_label` attribute, or you can disable the empty label entirely by setting `empty_label` to `None`:

```python
# A custom empty label
define1 = forms.ModelChoiceField(queryset=..., empty_label="(Nothing)")

# No empty label
define2 = forms.ModelChoiceField(queryset=..., empty_label=None)
```

Note that no empty choice is created (regardless of the value of `empty_label`) if a `ModelChoiceField` is required and has a default initial value, or a `widget` is set to `RadioSelect` and the `blank` argument is `False`.

- **to_field_name**
  - This optional argument is used to specify the field to use as the value of the choices in the field’s widget. Be sure it’s a unique field for the model, otherwise the selected value could match more than one object. By default it is set to `None`, in which case the primary key of each object will be used. For example:

```python
# No custom to_field_name
define1 = forms.ModelChoiceField(queryset=...)
```

would yield:

```html
<select id="id_field1" name="field1">
  <option value="obj1.pk">Object1</option>
  <option value="obj2.pk">Object2</option>
</select>
```

(continues on next page)
and:

```python
# to_field_name provided
field2 = forms.ModelChoiceField(queryset=..., to_field_name="name")
```

would yield:

```html
<select id="id_field2" name="field2">
  <option value="obj1.name">Object1</option>
  <option value="obj2.name">Object2</option>
  ...
</select>
```

**blank**

When using the `RadioSelect` widget, this optional boolean argument determines whether an empty choice is created. By default, `blank` is `False`, in which case no empty choice is created.

The iterator class used to generate field choices from `queryset`. By default, `ModelChoiceIterator`.

The `__str__` method of the model will be called to generate string representations of the objects for use in the field’s choices. To provide customized representations, subclass `ModelChoiceField` and override `label_from_instance`. This method will receive a model object and should return a string suitable for representing it. For example:

```python
from django.forms import ModelChoiceField

class MyModelChoiceField(ModelChoiceField):
    def label_from_instance(self, obj):
        return "My Object #%i" % obj.id
```
ModelMultipleChoiceField

```python
class ModelMultipleChoiceField(**kwargs):
    • Default widget: SelectMultiple
    • Empty value: An empty QuerySet (self.queryset.none())
    • Normalizes to: A QuerySet of model instances.
    • Validates that every id in the given list of values exists in the queryset.
    • Error message keys: required, invalid_list, invalid_choice, invalid_pk_value
```

The invalid_choice message may contain `%{value}s` and the invalid_pk_value message may contain `%{pk}s`, which will be substituted by the appropriate values.

Allows the selection of one or more model objects, suitable for representing a many-to-many relation. As with ModelChoiceField, you can use label_from_instance to customize the object representations.

A single argument is required:

```python
queryset
    Same as ModelChoiceField.queryset.
```

Takes one optional argument:

```python
to_field_name
    Same as ModelChoiceField.to_field_name.
```

ModelMultipleChoiceField also has the attribute:

```python
iterator
    Same as ModelChoiceField.iterator.
```

Iterating relationship choices

By default, ModelChoiceField and ModelMultipleChoiceField use ModelChoiceIterator to generate their field choices.

When iterated, ModelChoiceIterator yields 2-tuple choices containing ModelChoiceIteratorValue instances as the first value element in each choice. ModelChoiceIteratorValue wraps the choice value while maintaining a reference to the source model instance that can be used in custom widget implementations, for example, to add data-* attributes to <option> elements.

For example, consider the following models:
from django.db import models

class Topping(models.Model):
    name = models.CharField(max_length=100)
    price = models.DecimalField(decimal_places=2, max_digits=6)

    def __str__(self):
        return self.name

class Pizza(models.Model):
    topping = models.ForeignKey(Topping, on_delete=models.CASCADE)

You can use a Select widget subclass to include the value of Topping.price as the HTML attribute data-price for each <option> element:

from django import forms

class ToppingSelect(forms.Select):
    def create_option(self, name, value, label, selected, index, subindex=None, attrs=None):
        option = super().create_option(name, value, label, selected, index, subindex, attrs)
        if value:
            option['attrs']['data-price'] = value.instance.price
        return option

class PizzaForm(forms.ModelForm):
    class Meta:
        model = Pizza
        fields = ['topping']
        widgets = {'topping': ToppingSelect}

This will render the Pizza.topping select as:

<select id="id_topping" name="topping" required>
    <option value="" selected>--------</option>
    <option value="1" data-price="1.50">mushrooms</option>
    <option value="2" data-price="1.25">onions</option>
    <option value="3" data-price="1.75">peppers</option>
    <option value="4" data-price="2.00">pineapple</option>
</select>

For more advanced usage you may subclass ModelChoiceIterator in order to customize the yielded 2-tuple choices.
ModelChoiceIterator

class ModelChoiceIterator(field)

The default class assigned to the iterator attribute of ModelChoiceField and ModelMultipleChoiceField. An iterable that yields 2-tuple choices from the queryset.

A single argument is required:

field

The instance of ModelChoiceField or ModelMultipleChoiceField to iterate and yield choices.

ModelChoiceIterator has the following method:

__iter__()

Yields 2-tuple choices, in the (value, label) format used by ChoiceField.choices. The first value element is a ModelChoiceIteratorValue instance.

ModelChoiceIteratorValue

class ModelChoiceIteratorValue(value, instance)

Two arguments are required:

value

The value of the choice. This value is used to render the value attribute of an HTML <option> element.

instance

The model instance from the queryset. The instance can be accessed in custom ChoiceWidget. create_option() implementations to adjust the rendered HTML.

ModelChoiceIteratorValue has the following method:

__str__()

Return value as a string to be rendered in HTML.

Creating custom fields

If the built-in Field classes don’t meet your needs, you can create custom Field classes. To do this, create a subclass of django.forms.Field. Its only requirements are that it implement a clean() method and that its __init__() method accept the core arguments mentioned above (required, label, initial, widget, help_text).

You can also customize how a field will be accessed by overriding get_bound_field().
6.12.3 Model Form Functions

Model Form API reference. For introductory material about model forms, see the Creating forms from models topic guide.

modelform_factory

modelform_factory(model, form=ModelForm, fields=None, exclude=None, formfield_callback=None, widgets=None, localized_fields=None, labels=None, help_texts=None, error_messages=None, field_classes=None)

Returns a ModelForm class for the given model. You can optionally pass a form argument to use as a starting point for constructing the ModelForm.

fields is an optional list of field names. If provided, only the named fields will be included in the returned fields.

exclude is an optional list of field names. If provided, the named fields will be excluded from the returned fields, even if they are listed in the fields argument.

formfield_callback is a callable that takes a model field and returns a form field.

widgets is a dictionary of model field names mapped to a widget.

localized_fields is a list of names of fields which should be localized.

labels is a dictionary of model field names mapped to a label.

help_texts is a dictionary of model field names mapped to a help text.

error_messages is a dictionary of model field names mapped to a dictionary of error messages.

field_classes is a dictionary of model field names mapped to a form field class.

See ModelForm factory function for example usage.

You must provide the list of fields explicitly, either via keyword arguments fields or exclude, or the corresponding attributes on the form’s inner Meta class. See Selecting the fields to use for more information. Omitting any definition of the fields to use will result in an ImproperlyConfigured exception.

modelformset_factory

modelformset_factory(model, form=ModelForm, formfield_callback=None, formset=BaseModelFormSet, extra=1, can_delete=False, can_order=False, max_num=None, fields=None, exclude=None, widgets=None, validate_max=False, localized_fields=None, labels=None, help_texts=None, error_messages=None, min_num=None, validate_min=False, field_classes=None, absolute_max=None, can_delete_extra=True, renderer=None, edit_only=False)
Returns a FormSet class for the given model class.

Arguments model, form, fields, exclude, formfield_callback, widgets, localized_fields, labels, help_texts, error_messages, and field_classes are all passed through to modelform_factory().

Arguments formset, extra, can_delete, can_order, max_num, validate_max, min_num, validate_min, absolute_max, can_delete_extra, and renderer are passed through to formset_factory(). See formsets for details.

The edit_only argument allows preventing new objects creation.

See Model formsets for example usage.

The edit_only argument was added.

inlineformset_factory

inlineformset_factory(parent_model, model, form=ModelForm, formset=BaseInlineFormSet, 
    fk_name=None, fields=None, exclude=None, extra=3, can_order=False, 
    can_delete=True, max_num=None, formfield_callback=None, widgets=None, 
    validate_max=False, localized_fields=None, labels=None, help_texts=None, 
    error_messages=None, min_num=None, validate_min=False, 
    field_classes=None, absolute_max=None, can_delete_extra=True, 
    renderer=None, edit_only=False)

Returns an InlineFormSet using modelformset_factory() with defaults of formset=BaseInlineFormSet, can_delete=True, and extra=3.

If your model has more than one ForeignKey to the parent_model, you must specify a fk_name.

See Inline formsets for example usage.

The edit_only argument was added.

6.12.4 Formset Functions

Formset API reference. For introductory material about formsets, see the Formsets topic guide.
formset_factory

formset_factory(form, formset=BaseFormSet, extra=1, can_order=False, can_delete=False,
max_num=None, validate_max=False, min_num=None, validate_min=False,
absolute_max=None, can_delete_extra=True, renderer=None)

Returns a FormSet class for the given form class.

See formsets for example usage.

6.12.5 The form rendering API

Django’s form widgets are rendered using Django’s template engines system.

The form rendering process can be customized at several levels:

- Widgets can specify custom template names.
- Forms and widgets can specify custom renderer classes.
- A widget’s template can be overridden by a project. (Reusable applications typically shouldn’t override built-in templates because they might conflict with a project’s custom templates.)

The low-level render API

The rendering of form templates is controlled by a customizable renderer class. A custom renderer can be specified by updating the FORM_RENDERER setting. It defaults to 'django.forms.renderers.DjangoTemplates'.

By specifying a custom form renderer and overriding form_template_name you can adjust the default form markup across your project from a single place.

You can also provide a custom renderer per-form or per-widget by setting the Form.default_renderer attribute or by using the renderer argument of Form.render(), or Widget.render().

Matching points apply to formset rendering. See Using a formset in views and templates for discussion.

Use one of the built-in template form renderers or implement your own. Custom renderers must implement a render(template_name, context, request=None) method. It should return a rendered templates (as a string) or raise TemplateDoesNotExist.

class BaseRenderer

The base class for the built-in form renderers.

form_template_name

The default name of the template to use to render a form.

Defaults to "django/forms/default.html", which is a proxy for "django/forms/table.html".

Deprecated since version 4.1.
The "django/forms/default.html" template is deprecated and will be removed in Django 5.0. The default will become "django/forms/default.html" at that time.

**formset_template_name**

The default name of the template to use to render a formset.

Defaults to "django/forms/formsets/default.html", which is a proxy for "django/forms/formsets/table.html".

Deprecated since version 4.1.

The "django/forms/formset/default.html" template is deprecated and will be removed in Django 5.0. The default will become "django/forms/formset/div.html" template.

**get_template**(template_name)

Subclasses must implement this method with the appropriate template finding logic.

**render**(template_name, context, request=None)

Renders the given template, or raises TemplateDoesNotExist.

### Built-in-template form renderers

**DjangoTemplates**

class DjangoTemplates

This renderer uses a standalone DjangoTemplates engine (unconnected to what you might have configured in the TEMPLATES setting). It loads templates first from the built-in form templates directory in django/forms/templates and then from the installed apps’ templates directories using the app_directories loader.

If you want to render templates with customizations from your TEMPLATES setting, such as context processors for example, use the TemplatesSetting renderer.

class DjangoDivFormRenderer

Subclass of DjangoTemplates that specifies form_template_name and formset_template_name as "django/forms/div.html" and "django/forms/formset/div.html" respectively.

This is a transitional renderer for opt-in to the new <div> based templates, which are the default from Django 5.0.

Apply this via the FORM_RENDERER setting:

```
FORM_RENDERER = "django.forms.renderers.DjangoDivFormRenderer"
```

Once the <div> templates are the default, this transitional renderer will be deprecated, for removal in Django 6.0. The FORM_RENDERER declaration can be removed at that time.
Jinja2

class Jinja2

This renderer is the same as the DjangoTemplates renderer except that it uses a Jinja2 backend. Templates for the built-in widgets are located in django/forms/jinja2 and installed apps can provide templates in a jinja2 directory.

To use this backend, all the forms and widgets in your project and its third-party apps must have Jinja2 templates. Unless you provide your own Jinja2 templates for widgets that don’t have any, you can’t use this renderer. For example, django.contrib.admin doesn’t include Jinja2 templates for its widgets due to their usage of Django template tags.

class Jinja2DivFormRenderer

A transitional renderer as per DjangoDivFormRenderer above, but subclassing Jinja2 for use with the Jinja2 backend.

Apply this via the FORM_RENDERER setting:

```python
FORM_RENDERER = "django.forms.renderers.Jinja2DivFormRenderer"
```

TemplatesSetting

class TemplatesSetting

This renderer gives you complete control of how form and widget templates are sourced. It uses get_template() to find templates based on what’s configured in the TEMPLATES setting.

Using this renderer along with the built-in templates requires either:

- 'django.forms' in INSTALLED_APPS and at least one engine with APP_DIRS=True.
- Adding the built-in templates directory in DIRS of one of your template engines. To generate that path:

```python
import django
django.__path__[0] + '/forms/templates'  # or '/forms/jinja2'
```

Using this renderer requires you to make sure the form templates your project needs can be located.
Context available in formset templates

Formset templates receive a context from `BaseFormSet.get_context()`. By default, formsets receive a dictionary with the following values:

- `formset`: The formset instance.

Context available in form templates

Form templates receive a context from `Form.get_context()`. By default, forms receive a dictionary with the following values:

- `form`: The bound form.
- `fields`: All bound fields, except the hidden fields.
- `hidden_fields`: All hidden bound fields.
- `errors`: All non field related or hidden field related form errors.

Context available in widget templates

Widget templates receive a context from `Widget.get_context()`. By default, widgets receive a single value in the context, `widget`. This is a dictionary that contains values like:

- `name`
- `value`
- `attrs`
- `is_hidden`
- `template_name`

Some widgets add further information to the context. For instance, all widgets that subclass `Input` defines `widget['type']` and `MultiWidget` defines `widget['subwidgets']` for looping purposes.

Overriding built-in formset templates

`BaseFormSet.template_name`

To override formset templates, you must use the `TemplatesSetting` renderer. Then overriding widget templates works the same as overriding any other template in your project.
Overriding built-in form templates

*Form.template_name*

To override form templates, you must use the `TemplatesSetting` renderer. Then overriding widget templates works the same as overriding any other template in your project.

Overriding built-in widget templates

Each widget has a `template_name` attribute with a value such as `input.html`. Built-in widget templates are stored in the `django/forms/widgets` path. You can provide a custom template for `input.html` by defining `django/forms/widgets/input.html`, for example. See Built-in widgets for the name of each widget’s template.

To override widget templates, you must use the `TemplatesSetting` renderer. Then overriding widget templates works the same as overriding any other template in your project.

6.12.6 Widgets

A widget is Django’s representation of an HTML input element. The widget handles the rendering of the HTML, and the extraction of data from a GET/POST dictionary that corresponds to the widget.

The HTML generated by the built-in widgets uses HTML5 syntax, targeting `<!DOCTYPE html>`. For example, it uses boolean attributes such as `checked` rather than the XHTML style of `checked='checked'`.

Tip: Widgets should not be confused with the form fields. Form fields deal with the logic of input validation and are used directly in templates. Widgets deal with rendering of HTML form input elements on the web page and extraction of raw submitted data. However, widgets do need to be assigned to form fields.

Specifying widgets

Whenever you specify a field on a form, Django will use a default widget that is appropriate to the type of data that is to be displayed. To find which widget is used on which field, see the documentation about Built-in Field classes.

However, if you want to use a different widget for a field, you can use the `widget` argument on the field definition. For example:

```python
from django import forms

class CommentForm(forms.Form):
    name = forms.CharField()
```

(continues on next page)
This would specify a form with a comment that uses a larger `Textarea` widget, rather than the default `TextInput` widget.

### Setting arguments for widgets

Many widgets have optional extra arguments; they can be set when defining the widget on the field. In the following example, the `years` attribute is set for a `SelectDateWidget`:

```python
from django import forms

BIRTH_YEAR_CHOICES = ['1980', '1981', '1982']
FAVORITE_COLORS_CHOICES = [
    ('blue', 'Blue'),
    ('green', 'Green'),
    ('black', 'Black'),
]

class SimpleForm(forms.Form):
    birth_year = forms.DateField(widget=forms.SelectDateWidget(years=BIRTH_YEAR_CHOICES))
    favorite_colors = forms.MultipleChoiceField(
        required=False,
        widget=forms.CheckboxSelectMultiple,
        choices=FAVORITE_COLORS_CHOICES,
    )
```

See the Built-in widgets for more information about which widgets are available and which arguments they accept.

### Widgets inheriting from the Select widget

Widgets inheriting from the `Select` widget deal with choices. They present the user with a list of options to choose from. The different widgets present this choice differently; the `Select` widget itself uses a `<select>` HTML list representation, while `RadioSelect` uses radio buttons.

`Select` widgets are used by default on `ChoiceField` fields. The choices displayed on the widget are inherited from the `ChoiceField` and changing `ChoiceField.choices` will update `Select.choices`. For example:

```python
>>> from django import forms
>>> CHOICES = [('1', 'First'), ('2', 'Second')] >>> choice_field = forms.ChoiceField(widget=forms.RadioSelect, choices=CHOICES)
```
Widgets which offer a `choices` attribute can however be used with fields which are not based on choice – such as a `CharField` – but it is recommended to use a `ChoiceField`-based field when the choices are inherent to the model and not just the representational widget.

Customizing widget instances

When Django renders a widget as HTML, it only renders very minimal markup - Django doesn’t add class names, or any other widget-specific attributes. This means, for example, that all `TextInput` widgets will appear the same on your web pages.

There are two ways to customize widgets: per widget instance and per widget class.

Styling widget instances

If you want to make one widget instance look different from another, you will need to specify additional attributes at the time when the widget object is instantiated and assigned to a form field (and perhaps add some rules to your CSS files).

For example, take the following form:

```python
from django import forms

class CommentForm(forms.Form):
    name = forms.CharField()
    url = forms.URLField()
    comment = forms.CharField()
```

This form will include three default `TextInput` widgets, with default rendering – no CSS class, no extra attributes. This means that the input boxes provided for each widget will be rendered exactly the same:

```python
>>> f = CommentForm(auto_id=False)
>>> f.as_table()
<tr><th>Name:</th><td><input type="text" name="name" required"></td></tr>
```

(continues on next page)
On a real web page, you probably don’t want every widget to look the same. You might want a larger input element for the comment, and you might want the `name` widget to have some special CSS class. It is also possible to specify the ‘type’ attribute to take advantage of the new HTML5 input types. To do this, you use the `Widget.attrs` argument when creating the widget:

```python
class CommentForm(forms.Form):
    name = forms.CharField(widget=forms.TextInput(attrs={'class': 'special'}))
    url = forms.URLField()
    comment = forms.CharField(widget=forms.TextInput(attrs={'size': '40'}))
```

You can also modify a widget in the form definition:

```python
class CommentForm(forms.Form):
    name = forms.CharField()
    url = forms.URLField()
    comment = forms.CharField()

    name.widget.attrs.update({'class': 'special'})
    comment.widget.attrs.update(size='40')
```

Or if the field isn’t declared directly on the form (such as model form fields), you can use the `Form.fields` attribute:

```python
class CommentForm(forms.ModelForm):
    def __init__(self, *args, **kwargs):
        super().__init__(*args, **kwargs)
        self.fields['name'].widget.attrs.update({'class': 'special'})
        self.fields['comment'].widget.attrs.update(size='40')
```

Django will then include the extra attributes in the rendered output:

```python
>>> f = CommentForm(auto_id=False)
>>> f.as_table()
<tr><th>Name:</th><td><input type="text" name="name" class="special" required></td></tr>
<tr><th>Url:</th><td><input type="url" name="url" required></td></tr>
<tr><th>Comment:</th><td><input type="text" name="comment" size="40" required></td></tr>
```

You can also set the HTML `id` using `attrs`. See `BoundField.id_for_label` for an example.
Styling widget classes

With widgets, it is possible to add assets (css and javascript) and more deeply customize their appearance and behavior.

In a nutshell, you will need to subclass the widget and either define a “Media” inner class or create a “media” property.

These methods involve somewhat advanced Python programming and are described in detail in the Form Assets topic guide.

Base widget classes

Base widget classes Widget and MultiWidget are subclassed by all the built-in widgets and may serve as a foundation for custom widgets.

Widget

class Widget (attrs=None)

This abstract class cannot be rendered, but provides the basic attribute attrs. You may also implement or override the render() method on custom widgets.

attrs

A dictionary containing HTML attributes to be set on the rendered widget.

```python
>>> from django import forms
>>> name = forms.TextInput(attrs={'size': 10, 'title': 'Your name'})
>>> name.render('name', 'A name')
'<input title="Your name" type="text" name="name" value="A name" size="10">'
```

If you assign a value of True or False to an attribute, it will be rendered as an HTML5 boolean attribute:

```python
>>> name = forms.TextInput(attrs={'required': True})
>>> name.render('name', 'A name')
'<input name="name" type="text" value="A name" required>'

>>> name = forms.TextInput(attrs={'required': False})
>>> name.render('name', 'A name')
'<input name="name" type="text" value="A name">'
```

supports_milliseconds

An attribute that defaults to True. If set to False, the microseconds part of datetime and time values will be set to 0.
format_value(value)

Cleans and returns a value for use in the widget template. value isn’t guaranteed to be valid input, therefore subclass implementations should program defensively.

get_context(name, value, attrs)

Returns a dictionary of values to use when rendering the widget template. By default, the dictionary contains a single key, 'widget', which is a dictionary representation of the widget containing the following keys:

- 'name': The name of the field from the name argument.
- 'is_hidden': A boolean indicating whether or not this widget is hidden.
- 'required': A boolean indicating whether or not the field for this widget is required.
- 'value': The value as returned by format_value().
- 'attrs': HTML attributes to be set on the rendered widget. The combination of the attrs attribute and the attrs argument.
- 'template_name': The value of self.template_name.

Widget subclasses can provide custom context values by overriding this method.

id_for_label(id_)

Returns the HTML ID attribute of this widget for use by a <label>, given the ID of the field. Returns an empty string if an ID isn’t available.

This hook is necessary because some widgets have multiple HTML elements and, thus, multiple IDs. In that case, this method should return an ID value that corresponds to the first ID in the widget’s tags.

render(name, value, attrs=None, renderer=None)

Renders a widget to HTML using the given renderer. If renderer is None, the renderer from the FORM_RENDERER setting is used.

value_from_datadict(data, files, name)

Given a dictionary of data and this widget’s name, returns the value of this widget. files may contain data coming from request.FILES. Returns None if a value wasn’t provided. Note also that value_from_datadict may be called more than once during handling of form data, so if you customize it and add expensive processing, you should implement some caching mechanism yourself.

value_omitted_from_data(data, files, name)

Given data and files dictionaries and this widget’s name, returns whether or not there’s data or files for the widget.

The method’s result affects whether or not a field in a model form falls back to its default.
Special cases are `CheckboxInput`, `CheckboxSelectMultiple`, and `SelectMultiple`, which always return `False` because an unchecked checkbox and unselected `<select multiple>` don’t appear in the data of an HTML form submission, so it’s unknown whether or not the user submitted a value.

**use_fieldset**

An attribute to identify if the widget should be grouped in a `<fieldset>` with a `<legend>` when rendered. Defaults to `False` but is `True` when the widget contains multiple `<input>` tags such as `CheckboxSelectMultiple`, `RadioSelect`, `MultiWidget`, `SplitDateTimeWidget`, and `SelectDateWidget`.

**use_required_attribute**(initial)

Given a form field’s `initial` value, returns whether or not the widget can be rendered with the `required` HTML attribute. Forms use this method along with `Field.required` and `Form.use_required_attribute` to determine whether or not to display the `required` attribute for each field.

By default, returns `False` for hidden widgets and `True` otherwise. Special cases are `FileInput` and `ClearableFileInput`, which return `False` when `initial` is set, and `CheckboxSelectMultiple`, which always returns `False` because browser validation would require all checkboxes to be checked instead of at least one.

Override this method in custom widgets that aren’t compatible with browser validation. For example, a WSYSIWG text editor widget backed by a hidden textarea element may want to always return `False` to avoid browser validation on the hidden field.

**MultiWidget**

```python
>>> from django.forms import MultiWidget, TextInput
>>> widget = MultiWidget(widgets=[TextInput, TextInput])
>>> widget.render('name', ['john', 'paul'])
'<input type="text" name="name_0" value="john"><input type="text" name="name_1" value="paul">'
```

You may provide a dictionary in order to specify custom suffixes for the `name` attribute on each subwidget. In this case, for each `(key, widget)` pair, the key will be appended to the `name` of...
the widget in order to generate the attribute value. You may provide the empty string ("'") for a single key, in order to suppress the suffix for one widget. For example:

```python
>>> widget = MultiWidget(widgets={'' : TextInput, 'last' : TextInput})
>>> widget.render('name', [ 'john', 'paul' ])  
'<input type="text" name="name" value="john"><input type="text" name="name_last" value="paul">'
```

And one required method:

**decompress(value)**

This method takes a single “compressed” value from the field and returns a list of “decompressed” values. The input value can be assumed valid, but not necessarily non-empty.

This method must be implemented by the subclass, and since the value may be empty, the implementation must be defensive.

The rationale behind “decompression” is that it is necessary to “split” the combined value of the form field into the values for each widget.

An example of this is how `SplitDateTimeWidget` turns a `datetime` value into a list with date and time split into two separate values:

```python
from django.forms import MultiWidget

class SplitDateTimeWidget(MultiWidget):

    # ...

    def decompress(self, value):
        if value:
            return [value.date(), value.time()]
        return [None, None]
```

Tip: Note that `MultiValueField` has a complementary method `compress()` with the opposite responsibility - to combine cleaned values of all member fields into one.

It provides some custom context:

**get_context(name, value, attrs)**

In addition to the 'widget' key described in `Widget.get_context()`, `MultiWidget` adds a `widget['subwidgets']` key.

These can be looped over in the widget template:
Here’s a code snippet for the widget:

```python
from datetime import date
from django import forms

class DateSelectorWidget(forms.MultiWidget):
    def __init__(self, attrs=None):
        days = [(day, day) for day in range(1, 32)]
        months = [(month, month) for month in range(1, 13)]
        years = [(year, year) for year in [2018, 2019, 2020]]
        widgets = [
            forms.Select(attrs=attrs, choices=days),
            forms.Select(attrs=attrs, choices=months),
            forms.Select(attrs=attrs, choices=years),
        ]
        super().__init__(widgets, attrs)

    def decompress(self, value):
        if isinstance(value, date):
            return [value.day, value.month, value.year]
        elif isinstance(value, str):
            year, month, day = value.split('-')
            return [day, month, year]
        return [None, None, None]

    def value_from_datadict(self, data, files, name):
        day, month, year = super().value_from_datadict(data, files, name)
        # DateField expects a single string that it can parse into a date.
        return '{%}-{%}-{%}'.format(year, month, day)
```

The constructor creates several `Select` widgets in a list. The `super()` method uses this list to set up the widget.

The required method `decompress()` breaks up a `datetime.date` value into the day, month, and year values corresponding to each widget. If an invalid date was selected, such as the non-existent 30th February, the `DateField` passes this method a string instead, so that needs parsing. The final `return` handles when `value` is `None`, meaning we don’t have any defaults for our subwidgets.

The default implementation of `value_from_datadict()` returns a list of values corresponding to each...
Widget. This is appropriate when using a MultiWidget with a MultiValueField. But since we want to use this widget with a DateField, which takes a single value, we have overridden this method. The implementation here combines the data from the subwidgets into a string in the format that DateField expects.

**Built-in widgets**

Django provides a representation of all the basic HTML widgets, plus some commonly used groups of widgets in the `django.forms.widgets` module, including the input of text, various checkboxes and selectors, uploading files, and handling of multi-valued input.

**Widgets handling input of text**

These widgets make use of the HTML elements input and textarea.

**TextInput**

```python
class TextInput

• input_type: 'text'
• template_name: 'django/forms/widgets/text.html'
• Renders as: `<input type="text" ...>`
```

**NumberInput**

```python
class NumberInput

• input_type: 'number'
• template_name: 'django/forms/widgets/number.html'
• Renders as: `<input type="number" ...>`
```

Beware that not all browsers support entering localized numbers in number input types. Django itself avoids using them for fields having their localize property set to True.
EmailInput

class EmailInput

  • input_type: 'email'
  • template_name: 'django/forms/widgets/email.html'
  • Renders as: <input type="email" ...>

URLInput

class URLInput

  • input_type: 'url'
  • template_name: 'django/forms/widgets/url.html'
  • Renders as: <input type="url" ...>

PasswordInput

class PasswordInput

  • input_type: 'password'
  • template_name: 'django/forms/widgets/password.html'
  • Renders as: <input type="password" ...>

Takes one optional argument:

render_value

  Determines whether the widget will have a value filled in when the form is re-displayed after a validation error (default is False).

HiddenInput

class HiddenInput

  • input_type: 'hidden'
  • template_name: 'django/forms/widgets/hidden.html'
  • Renders as: <input type="hidden" ...>

  Note that there also is a `MultipleHiddenInput` widget that encapsulates a set of hidden input elements.
**DateInput**

*class* DateInput

- *input_type*: 'text'
- *template_name*: 'django/forms/widgets/date.html'
- Renders as: `<input type="text" ...>`

Takes same arguments as *TextInput*, with one more optional argument:

  **format**

  The format in which this field’s initial value will be displayed.

  If no *format* argument is provided, the default format is the first format found in *DATE_INPUT_FORMATS* and respects Format localization.

**DateTimeInput**

*class* DateTimeInput

- *input_type*: 'text'
- *template_name*: 'django/forms/widgets/datetime.html'
- Renders as: `<input type="text" ...>`

Takes same arguments as *TextInput*, with one more optional argument:

  **format**

  The format in which this field’s initial value will be displayed.

  If no *format* argument is provided, the default format is the first format found in *DATETIME_INPUT_FORMATS* and respects Format localization.

  By default, the microseconds part of the time value is always set to 0. If microseconds are required, use a subclass with the *supports_microseconds* attribute set to True.

**TimeInput**

*class* TimeInput

- *input_type*: 'text'
- *template_name*: 'django/forms/widgets/time.html'
- Renders as: `<input type="text" ...>`

Takes same arguments as *TextInput*, with one more optional argument:
format

The format in which this field’s initial value will be displayed.

If no format argument is provided, the default format is the first format found in \texttt{TIME_INPUT_FORMATS} and respects Format localization.

For the treatment of microseconds, see \texttt{DateTimeInput}.

Textarea

class Textarea

- template_name: 'django/forms/widgets/textarea.html'
- Renders as: <textarea>...</textarea>

Selector and checkbox widgets

These widgets make use of the HTML elements \texttt{<select>}, \texttt{<input type="checkbox">}, and \texttt{<input type="radio">}.

Widgets that render multiple choices have an option_template_name attribute that specifies the template used to render each choice. For example, for the Select widget, select_option.html renders the \texttt{<option>} for a \texttt{<select>}.

CheckboxInput

class CheckboxInput

- input_type: 'checkbox'
- template_name: 'django/forms/widgets/checkbox.html'
- Renders as: <input type="checkbox" ...>

Takes one optional argument:

check_test

A callable that takes the value of the CheckboxInput and returns True if the checkbox should be checked for that value.
Select

class Select

- template_name: 'django/forms/widgets/select.html'
- option_template_name: 'django/forms/widgets/select_option.html'
- Renders as: <select><option ...>...</select>

choices

This attribute is optional when the form field does not have a choices attribute. If it does, it will override anything you set here when the attribute is updated on the Field.

NullBooleanSelect

class NullBooleanSelect

- template_name: 'django/forms/widgets/select.html'
- option_template_name: 'django/forms/widgets/select_option.html'

Select widget with options ‘Unknown’, ‘Yes’ and ‘No’

SelectMultiple

class SelectMultiple

- template_name: 'django/forms/widgets/select.html'
- option_template_name: 'django/forms/widgets/select_option.html'

Similar to Select, but allows multiple selection: <select multiple>...</select>

RadioSelect

class RadioSelect

- template_name: 'django/forms/widgets/radio.html'
- option_template_name: 'django/forms/widgets/radio_option.html'

Similar to Select, but rendered as a list of radio buttons within <div> tags:

```html
<div>
  <div><input type="radio" name="..."></div>
  ...
</div>
```
For more granular control over the generated markup, you can loop over the radio buttons in the template. Assuming a form `myform` with a field `beatles` that uses a `RadioSelect` as its widget:

```html
<fieldset>
  <legend>{{ myform.beatles.label }}</legend>
  {% for radio in myform.beatles %}
    <div class="myradio">
      {{ radio }}
    </div>
  {% endfor %}
</fieldset>
```

This would generate the following HTML:

```html
<fieldset>
  <legend>Radio buttons</legend>
  <div class="myradio">
    <label for="id_beatles_0">
      <input id="id_beatles_0" name="beatles" type="radio" value="john" required>
      John
    </label>
  </div>
  <div class="myradio">
    <label for="id_beatles_1">
      <input id="id_beatles_1" name="beatles" type="radio" value="paul" required>
      Paul
    </label>
  </div>
  <div class="myradio">
    <label for="id_beatles_2">
      <input id="id_beatles_2" name="beatles" type="radio" value="george" required>
      George
    </label>
  </div>
  <div class="myradio">
    <label for="id_beatles_3">
      <input id="id_beatles_3" name="beatles" type="radio" value="ringo" required>
      Ringo
    </label>
  </div>
</fieldset>
```

That included the `<label>` tags. To get more granular, you can use each radio button’s `tag`, `choice_label` and `id_for_label` attributes. For example, this template...

```html
<fieldset>
  <legend>{{ myform.beatles.label }}</legend>
  {% for radio in myform.beatles %}
    <label for="{{ radio.id_for_label }}">
      <span class="radio">{{ radio.tag }}</span>
      {{ radio.choice_label }}
    </label>
  {% endfor %}
</fieldset>
```
...will result in the following HTML:

```html
<fieldset>
    <legend>Radio buttons</legend>
    <label for="id_beatles_0">
        John
        <span class="radio"><input id="id_beatles_0" name="beatles" type="radio" value="john" required></span>
    </label>
    <label for="id_beatles_1">
        Paul
        <span class="radio"><input id="id_beatles_1" name="beatles" type="radio" value="paul" required></span>
    </label>
    <label for="id_beatles_2">
        George
        <span class="radio"><input id="id_beatles_2" name="beatles" type="radio" value="george" required></span>
    </label>
    <label for="id_beatles_3">
        Ringo
        <span class="radio"><input id="id_beatles_3" name="beatles" type="radio" value="ringo" required></span>
    </label>
</fieldset>
```

If you decide not to loop over the radio buttons—e.g., if your template includes `{% myform.beatles %}`—they’ll be output in a `<div>` with `<div>` tags, as above.

The outer `<div>` container receives the `id` attribute of the widget, if defined, or `BoundField.auto_id` otherwise.

When looping over the radio buttons, the `label` and `input` tags include `for` and `id` attributes, respectively. Each radio button has an `id_for_label` attribute to output the element’s ID.
CheckboxSelectMultiple

class CheckboxSelectMultiple

• template_name: 'django/forms/widgets/checkbox_select.html'
• option_template_name: 'django/forms/widgets/checkbox_option.html'

Similar to SelectMultiple, but rendered as a list of checkboxes:

```html
<div>
  <div><input type="checkbox" name="..." /></div>
  ...
</div>
```

The outer <div> container receives the id attribute of the widget, if defined, or BoundField.auto_id otherwise.

Like RadioSelect, you can loop over the individual checkboxes for the widget’s choices. Unlike RadioSelect, the checkboxes won’t include the required HTML attribute if the field is required because browser validation would require all checkboxes to be checked instead of at least one.

When looping over the checkboxes, the label and input tags include for and id attributes, respectively. Each checkbox has an id_for_label attribute to output the element’s ID.

File upload widgets

FileInput

class FileInput

• template_name: 'django/forms/widgets/file.html'
• Renders as: <input type="file" ...>

ClearableFileInput

class ClearableFileInput

• template_name: 'django/forms/widgets/clearable_file_input.html'
• Renders as: <input type="file" ...> with an additional checkbox input to clear the field’s value, if the field is not required and has initial data.
Composite widgets

MultipleHiddenInput

class MultipleHiddenInput

  • template_name: 'django/forms/widgets/multiple_hidden.html'
  • Renders as: multiple <input type="hidden" ...> tags

A widget that handles multiple hidden widgets for fields that have a list of values.

SplitDateTimeWidget

class SplitDateTimeWidget

  • template_name: 'django/forms/widgets/splitdatetime.html'

Wrapper (using MultiWidget) around two widgets: DateInput for the date, and TimeInput for the time. Must be used with SplitDateTimeField rather than DateTimeField.

SplitDateTimeWidget has several optional arguments:

date_format
  Similar to DateInput.format

time_format
  Similar to TimeInput.format

date_attrs

time_attrs
  Similar to Widget.attrs. A dictionary containing HTML attributes to be set on the rendered DateInput and TimeInput widgets, respectively. If these attributes aren’t set, Widget.attrs is used instead.

SplitHiddenDateTimeWidget

class SplitHiddenDateTimeWidget

  • template_name: 'django/forms/widgets/splithiddendatetime.html'

Similar to SplitDateTimeWidget, but uses HiddenInput for both date and time.
SelectDateWidget

class SelectDateWidget

- template_name: 'django/forms/widgets/select_date.html'

Wrapper around three Select widgets: one each for month, day, and year.

Takes several optional arguments:

years

An optional list/tuple of years to use in the “year” select box. The default is a list containing the current year and the next 9 years.

months

An optional dict of months to use in the “months” select box.

The keys of the dict correspond to the month number (1-indexed) and the values are the displayed months:

```python
MONTHS = {
    1: _('jan'), 2: _('feb'), 3: _('mar'), 4: _('apr'),
    5: _('may'), 6: _('jun'), 7: _('jul'), 8: _('aug'),
    9: _('sep'), 10: _('oct'), 11: _('nov'), 12: _('dec')
}
```

empty_label

If the DateField is not required, SelectDateWidget will have an empty choice at the top of the list (which is --- by default). You can change the text of this label with the empty_label attribute. empty_label can be a string, list, or tuple. When a string is used, all select boxes will each have an empty choice with this label. If empty_label is a list or tuple of 3 string elements, the select boxes will have their own custom label. The labels should be in this order ('year_label', 'month_label', 'day_label').

```python
# A custom empty label with string
field1 = forms.DateField(widget=SelectDateWidget(empty_label="Nothing"))

# A custom empty label with tuple
field1 = forms.DateField(
    widget=SelectDateWidget(
        empty_label=("Choose Year", "Choose Month", "Choose Day"),
    ),
)
```
6.12.7 Form and field validation

Form validation happens when the data is cleaned. If you want to customize this process, there are various places to make changes, each one serving a different purpose. Three types of cleaning methods are run during form processing. These are normally executed when you call the `is_valid()` method on a form. There are other things that can also trigger cleaning and validation (accessing the `errors` attribute or calling `full_clean()` directly), but normally they won’t be needed.

In general, any cleaning method can raise `ValidationError` if there is a problem with the data it is processing, passing the relevant information to the `ValidationError` constructor. See below for the best practice in raising `ValidationError`. If no `ValidationError` is raised, the method should return the cleaned (normalized) data as a Python object.

Most validation can be done using `validators` - helpers that can be reused. Validators are functions (or callables) that take a single argument and raise `ValidationError` on invalid input. Validators are run after the field’s `to_python` and `validate` methods have been called.

Validation of a form is split into several steps, which can be customized or overridden:

- The `to_python()` method on a `Field` is the first step in every validation. It coerces the value to a correct datatype and raises `ValidationError` if that is not possible. This method accepts the raw value from the widget and returns the converted value. For example, a `FloatField` will turn the data into a Python `float` or raise a `ValidationError`.

- The `validate()` method on a `Field` handles field-specific validation that is not suitable for a validator. It takes a value that has been coerced to a correct datatype and raises `ValidationError` on any error. This method does not return anything and shouldn’t alter the value. You should override it to handle validation logic that you can’t or don’t want to put in a validator.

- The `run_validators()` method on a `Field` runs all of the field’s validators and aggregates all the errors into a single `ValidationError`. You shouldn’t need to override this method.

- The `clean()` method on a `Field` subclass is responsible for running `to_python()`, `validate()`, and `run_validators()` in the correct order and propagating their errors. If, at any time, any of the methods raise `ValidationError`, the validation stops and that error is raised. This method returns the clean data, which is then inserted into the `cleaned_data` dictionary of the form.

- The `clean_<fieldname>()` method is called on a form subclass – where `<fieldname>` is replaced with the name of the form field attribute. This method does any cleaning that is specific to that particular attribute, unrelated to the type of field that it is. This method is not passed any parameters. You will need to look up the value of the field in `self.cleaned_data` and remember that it will be a Python object at this point, not the original string submitted in the form (it will be in `cleaned_data` because the general field `clean()` method, above, has already cleaned the data once).

For example, if you wanted to validate that the contents of a `CharField` called `serialnumber` was unique, `clean_serialnumber()` would be the right place to do this. You don’t need a specific field (it’s a `CharField`), but you want a formfield-specific piece of validation and, possibly, cleaning normalizing
The return value of this method replaces the existing value in `cleaned_data`, so it must be the field’s value from `cleaned_data` (even if this method didn’t change it) or a new cleaned value.

- The form subclass’s `clean()` method can perform validation that requires access to multiple form fields. This is where you might put in checks such as “if field A is supplied, field B must contain a valid email address”. This method can return a completely different dictionary if it wishes, which will be used as the `cleaned_data`.

Since the field validation methods have been run by the time `clean()` is called, you also have access to the form’s `errors` attribute which contains all the errors raised by cleaning of individual fields.

Note that any errors raised by your `Form.clean()` override will not be associated with any field in particular. They go into a special “field” (called `__all__`), which you can access via the `non_field_errors()` method if you need to. If you want to attach errors to a specific field in the form, you need to call `add_error()`.

Also note that there are special considerations when overriding the `clean()` method of a `ModelForm` subclass. (see the `ModelForm` documentation for more information)

These methods are run in the order given above, one field at a time. That is, for each field in the form (in the order they are declared in the form definition), the `Field.clean()` method (or its override) is run, then `clean_<fieldname>()`. Finally, once those two methods are run for every field, the `Form.clean()` method, or its override, is executed whether or not the previous methods have raised errors.

Examples of each of these methods are provided below.

As mentioned, any of these methods can raise a `ValidationError`. For any field, if the `Field.clean()` method raises a `ValidationError`, any field-specific cleaning method is not called. However, the cleaning methods for all remaining fields are still executed.

### Raising `ValidationError`

In order to make error messages flexible and easy to override, consider the following guidelines:

- Provide a descriptive error code to the constructor:

  ```python
  # Good
  ValidationError(_('Invalid value'), code='invalid')
  
  # Bad
  ValidationError(_('Invalid value'))
  ```

- Don’t coerce variables into the message; use placeholders and the `params` argument of the constructor:

  ```python
  # Good
  ValidationError(
  ```

(continues on next page)
Use mapping keys instead of positional formatting. This enables putting the variables in any order or omitting them altogether when rewriting the message:

```python
# Good
ValidationError(_('Invalid value: %(value)s'),
    params={'value': '42'},
)

# Bad
ValidationError(_('Invalid value: %s') % value)
```

• Wrap the message with gettext to enable translation:

```python
# Good
ValidationError(_('Invalid value'))

# Bad
ValidationError('Invalid value')
```

Putting it all together:

```python
raise ValidationError(
    _('Invalid value: %(value)s'),
    code='invalid',
    params={'value': '42'},
)
```

Following these guidelines is particularly necessary if you write reusable forms, form fields, and model fields.

While not recommended, if you are at the end of the validation chain (i.e. your form `clean()` method) and you know you will never need to override your error message you can still opt for the less verbose:

```python
ValidationError(_('Invalid value: %s') % value)
```
The `Form.errors.as_data()` and `Form.errors.as_json()` methods greatly benefit from fully featured `ValidationError` (with a `code` name and a `params` dictionary).

### Raising multiple errors

If you detect multiple errors during a cleaning method and wish to signal all of them to the form submitter, it is possible to pass a list of errors to the `ValidationError` constructor.

As above, it is recommended to pass a list of `ValidationError` instances with `code` and `params` but a list of strings will also work:

```python
# Good
raise ValidationError([
    ValidationError(_('Error 1'), code='error1'),
    ValidationError(_('Error 2'), code='error2'),
])

# Bad
raise ValidationError([
    _('Error 1'),
    _('Error 2'),
])
```

### Using validation in practice

The previous sections explained how validation works in general for forms. Since it can sometimes be easier to put things into place by seeing each feature in use, here are a series of small examples that use each of the previous features.

#### Using validators

Django’s form (and model) fields support use of utility functions and classes known as validators. A validator is a callable object or function that takes a value and returns nothing if the value is valid or raises a `ValidationError` if not. These can be passed to a field’s constructor, via the field’s `validators` argument, or defined on the Field class itself with the `default_validators` attribute.

Validators can be used to validate values inside the field, let’s have a look at Django’s `SlugField`:

```python
from django.core import validators
from django.forms import CharField

class SlugField(CharField):
    default_validators = [validators.validate_slug]
```
As you can see, SlugField is a CharField with a customized validator that validates that submitted text obeys to some character rules. This can also be done on field definition so:

```python
slug = forms.SlugField()
```

is equivalent to:

```python
slug = forms.CharField(validators=[validators.validate_slug])
```

Common cases such as validating against an email or a regular expression can be handled using existing validator classes available in Django. For example, `validators.validate_slug` is an instance of a `RegexValidator` constructed with the first argument being the pattern: `^[\-a-zA-Z0-9_]+$`. See the section on writing validators to see a list of what is already available and for an example of how to write a validator.

**Form field default cleaning**

Let’s first create a custom form field that validates its input is a string containing comma-separated email addresses. The full class looks like this:

```python
from django import forms
from django.core.validators import validate_email

class MultiEmailField(forms.Field):
    def to_python(self, value):
        """Normalize data to a list of strings.""
        # Return an empty list if no input was given.
        if not value:
            return []
        return value.split(',

    def validate(self, value):
        """Check if value consists only of valid emails.""
        # Use the parent's handling of required fields, etc.
        super().validate(value)
        for email in value:
            validate_email(email)
```

Every form that uses this field will have these methods run before anything else can be done with the field’s data. This is cleaning that is specific to this type of field, regardless of how it is subsequently used.

Let’s create a ContactForm to demonstrate how you’d use this field:
class ContactForm(forms.Form):
    subject = forms.CharField(max_length=100)
    message = forms.CharField()
    sender = forms.EmailField()
    recipients = MultiEmailField()
    cc_myself = forms.BooleanField(required=False)

Use MultiEmailField like any other form field. When the is_valid() method is called on the form, the MultiEmailField.clean() method will be run as part of the cleaning process and it will, in turn, call the custom to_python() and validate() methods.

Cleaning a specific field attribute

Continuing on from the previous example, suppose that in our ContactForm, we want to make sure that the recipients field always contains the address "fred@example.com". This is validation that is specific to our form, so we don’t want to put it into the general MultiEmailField class. Instead, we write a cleaning method that operates on the recipients field, like so:

```python
from django import forms
from django.core.exceptions import ValidationError

class ContactForm(forms.Form):
    # Everything as before.
    ...

    def clean_recipients(self):
        data = self.cleaned_data['recipients']
        if "fred@example.com" not in data:
            raise ValidationError("You have forgotten about Fred!")

        # Always return a value to use as the new cleaned data, even if
        # this method didn't change it.
        return data
```

Cleaning and validating fields that depend on each other

Suppose we add another requirement to our contact form: if the cc_myself field is True, the subject must contain the word "help". We are performing validation on more than one field at a time, so the form’s clean() method is a good spot to do this. Notice that we are talking about the clean() method on the form here, whereas earlier we were writing a clean() method on a field. It’s important to keep the field and form difference clear when working out where to validate things. Fields are single data points, forms are a collection of fields.
By the time the form’s `clean()` method is called, all the individual field clean methods will have been run (the previous two sections), so `self.cleaned_data` will be populated with any data that has survived so far. So you also need to remember to allow for the fact that the fields you are wanting to validate might not have survived the initial individual field checks.

There are two ways to report any errors from this step. Probably the most common method is to display the error at the top of the form. To create such an error, you can raise a `ValidationError` from the `clean()` method. For example:

```python
from django import forms
from django.core.exceptions import ValidationError

class ContactForm(forms.Form):
    # Everything as before.
    ...

    def clean(self):
        cleaned_data = super().clean()
        cc_myself = cleaned_data.get("cc_myself")
        subject = cleaned_data.get("subject")

        if cc_myself and subject:
            # Only do something if both fields are valid so far.
            if "help" not in subject:
                raise ValidationError(
                    "Did not send for 'help' in the subject despite "
                    "CC'ing yourself."
                )

In this code, if the validation error is raised, the form will display an error message at the top of the form (normally) describing the problem. Such errors are non-field errors, which are displayed in the template with `{% form.non_field_errors %}`.

The call to `super().clean()` in the example code ensures that any validation logic in parent classes is maintained. If your form inherits another that doesn’t return a `cleaned_data` dictionary in its `clean()` method (doing so is optional), then don’t assign `cleaned_data` to the result of the `super()` call and use `self.cleaned_data` instead:

```python
def clean(self):
    super().clean()

    cc_myself = self.cleaned_data.get("cc_myself")
...
```

The second approach for reporting validation errors might involve assigning the error message to one of the fields. In this case, let’s assign an error message to both the “subject” and “cc_myself” rows in the form display. Be careful when doing this in practice, since it can lead to confusing form output. We’re showing
what is possible here and leaving it up to you and your designers to work out what works effectively in your particular situation. Our new code (replacing the previous sample) looks like this:

```python
from django import forms

class ContactForm(forms.Form):
    # Everything as before.
    ...

def clean(self):
    cleaned_data = super().clean()
    cc_myself = cleaned_data.get("cc_myself")
    subject = cleaned_data.get("subject")

    if cc_myself and subject and "help" not in subject:
        msg = "Must put 'help' in subject when cc'ing yourself."
        self.add_error('cc_myself', msg)
        self.add_error('subject', msg)
```

The second argument of `add_error()` can be a string, or preferably an instance of `ValidationError`. See `Raising ValidationError` for more details. Note that `add_error()` automatically removes the field from `cleaned_data`.

### 6.13 Logging

See also:
- How to configure and use logging
- Django logging overview

Django’s logging module extends Python’s builtin `logging`.

Logging is configured as part of the general Django `django.setup()` function, so it’s always available unless explicitly disabled.

#### 6.13.1 Django’s default logging configuration

By default, Django uses Python’s `logging.config.dictConfig` format.
Default logging conditions

The full set of default logging conditions are:

When \texttt{DEBUG} is True:

- The \texttt{django} logger sends messages in the \texttt{django} hierarchy (except \texttt{django.server}) at the \texttt{INFO} level or higher to the console.

When \texttt{DEBUG} is False:

- The \texttt{django} logger sends messages in the \texttt{django} hierarchy (except \texttt{django.server}) with \texttt{ERROR} or \texttt{CRITICAL} level to \texttt{AdminEmailHandler}.

Independently of the value of \texttt{DEBUG}:

- The \texttt{django.server} logger sends messages at the \texttt{INFO} level or higher to the console.

All loggers except \texttt{django.server} propagate logging to their parents, up to the root \texttt{django} logger. The \texttt{console} and \texttt{mail_admins} handlers are attached to the root logger to provide the behavior described above.

Python’s own defaults send records of level \texttt{WARNING} and higher to the console.

Default logging definition

Django’s default logging configuration inherits Python’s defaults. It’s available as \texttt{django.utils.log.DEFAULT_LOGGING} and defined in \texttt{django/utils/log.py}:

```python
{
    'version': 1,
    'disable_existing_loggers': False,
    'filters': {
        'require_debug_false': {
            '()': 'django.utils.log.RequireDebugFalse',
        },
        'require_debug_true': {
            '()': 'django.utils.log.RequireDebugTrue',
        },
    },
    'formatters': {
        'django.server': {
            '()': 'django.utils.log.ServerFormatter',
            'format': '')[server_time] {message}',
            'style': '{',
        },
    },
    'handlers': {
        'console': {
```
(continues on next page)
See `Configuring logging` on how to complement or replace this default logging configuration.

### 6.13.2 Django logging extensions

Django provides a number of utilities to handle the particular requirements of logging in a web server environment.
Loggers

Django provides several built-in loggers.

**django**

The parent logger for messages in the `django` named logger hierarchy. Django does not post messages using this name. Instead, it uses one of the loggers below.

**django.request**

Log messages related to the handling of requests. 5XX responses are raised as ERROR messages; 4XX responses are raised as WARNING messages. Requests that are logged to the `django.security` logger aren’t logged to `django.request`.

Messages to this logger have the following extra context:

- `status_code`: The HTTP response code associated with the request.
- `request`: The request object that generated the logging message.

**django.server**

Log messages related to the handling of requests received by the server invoked by the `runserver` command. HTTP 5XX responses are logged as ERROR messages, 4XX responses are logged as WARNING messages, and everything else is logged as INFO.

Messages to this logger have the following extra context:

- `status_code`: The HTTP response code associated with the request.
- `request`: The request object that generated the logging message.

**django.template**

Log messages related to the rendering of templates.

- Missing context variables are logged as DEBUG messages.
django.db.backends

Messages relating to the interaction of code with the database. For example, every application-level SQL statement executed by a request is logged at the DEBUG level to this logger.

Messages to this logger have the following extra context:

- **duration**: The time taken to execute the SQL statement.
- **sql**: The SQL statement that was executed.
- **params**: The parameters that were used in the SQL call.
- **alias**: The alias of the database used in the SQL call.

For performance reasons, SQL logging is only enabled when settings.DEBUG is set to True, regardless of the logging level or handlers that are installed.

This logging does not include framework-level initialization (e.g. `SET TIMEZONE`) or transaction management queries (e.g. `BEGIN`, `COMMIT`, and `ROLLBACK`). Turn on query logging in your database if you wish to view all database queries.

django.security.*

The security loggers will receive messages on any occurrence of `SuspiciousOperation` and other security-related errors. There is a sub-logger for each subtype of security error, including all `SuspiciousOperations`. The level of the log event depends on where the exception is handled. Most occurrences are logged as a warning, while any `SuspiciousOperation` that reaches the WSGI handler will be logged as an error. For example, when an HTTP Host header is included in a request from a client that does not match `ALLOWED_HOSTS`, Django will return a 400 response, and an error message will be logged to the `django.security.DisallowedHost` logger.

These log events will reach the django logger by default, which mails error events to admins when DEBUG=False. Requests resulting in a 400 response due to a `SuspiciousOperation` will not be logged to the `django.request` logger, but only to the `django.security` logger.

To silence a particular type of `SuspiciousOperation`, you can override that specific logger following this example:

```python
'handlers': {
    'null': {
        'class': 'logging.NullHandler',
    },
},
'loggers': {
    'django.security.DisallowedHost': {
        'handlers': ['null'],
    },
```

(continues on next page)
Other `django.security` loggers not based on `SuspiciousOperation` are:

- `django.security.csrf`: For CSRF failures.

### `django.db.backends.schema`

Logs the SQL queries that are executed during schema changes to the database by the migrations framework. Note that it won’t log the queries executed by `RunPython`. Messages to this logger have `params` and `sql` in their extra context (but unlike `django.db.backends`, not duration). The values have the same meaning as explained in `django.db.backends`.

#### Handlers

Django provides one log handler in addition to those provided by the Python logging module.

**class AdminEmailHandler** (include\_html=False, email\_backend=None, reporter\_class=None)

This handler sends an email to the site `ADMINS` for each log message it receives.

If the log record contains a `request` attribute, the full details of the request will be included in the email. The email subject will include the phrase “internal IP” if the client’s IP address is in the `INTERNAL_IPS` setting; if not, it will include “EXTERNAL IP”.

If the log record contains stack trace information, that stack trace will be included in the email.

The `include\_html` argument of `AdminEmailHandler` is used to control whether the traceback email includes an HTML attachment containing the full content of the debug web page that would have been produced if `DEBUG` were True. To set this value in your configuration, include it in the handler definition for `django.utils.log.AdminEmailHandler`, like this:

```
'mail_admins': {
    'level': 'ERROR',
    'class': 'django.utils.log.AdminEmailHandler',
    'params': True,

'handlers': {
    'mail_admins': {
        'level': 'ERROR',
        'class': 'django.utils.log.AdminEmailHandler',
        'params': True,
    }
},
```

Be aware of the security implications of logging when using the `AdminEmailHandler`.

By setting the `email\_backend` argument of `AdminEmailHandler`, the `email backend` that is being used by the handler can be overridden, like this:
By default, an instance of the email backend specified in `EMAIL_BACKEND` will be used.

The `reporter_class` argument of `AdminEmailHandler` allows providing an `django.views.debug.ExceptionReporter` subclass to customize the traceback text sent in the email body. You provide a string import path to the class you wish to use, like this:

```
'handlers': {
    'mail_admins': {
        'level': 'ERROR',
        'class': 'django.utils.log.AdminEmailHandler',
        'include_html': True,
        'reporter_class': 'somepackage.error_reporter.CustomErrorReporter',
    },
},
```

`send_mail(subject, message, *args, **kwargs)`

Sends emails to admin users. To customize this behavior, you can subclass the `AdminEmailHandler` class and override this method.

### Filters

Django provides some log filters in addition to those provided by the Python logging module.

**class CallbackFilter(callback)**

This filter accepts a callback function (which should accept a single argument, the record to be logged), and calls it for each record that passes through the filter. Handling of that record will not proceed if the callback returns False.

For instance, to filter out `UnreadablePostError` (raised when a user cancels an upload) from the admin emails, you would create a filter function:

```
from django.http import UnreadablePostError

def skip_unreadable_post(record):
    if record.exc_info:
        exc_type, exc_value = record.exc_info[:2]
```
if isinstance(exc_value, UnreadablePostError):
    return False
return True

and then add it to your logging config:

'filters': {
    'skip_unreadable_posts': {
        '()': 'django.utils.log.CallbackFilter',
        'callback': skip_unreadable_post,
    },
},
'handlers': {
    'mail_admins': {
        'level': 'ERROR',
        'filters': ['skip_unreadable_posts'],
        'class': 'django.utils.log.AdminEmailHandler',
    },
},

class RequireDebugFalse

This filter will only pass on records when settings.DEBUG is False.

This filter is used as follows in the default LOGGING configuration to ensure that the AdminEmailHandler only sends error emails to admins when DEBUG is False:

'filters': {
    'require_debug_false': {
        '()': 'django.utils.log.RequireDebugFalse',
    },
},
'handlers': {
    'mail_admins': {
        'level': 'ERROR',
        'filters': ['require_debug_false'],
        'class': 'django.utils.log.AdminEmailHandler',
    },
},

class RequireDebugTrue

This filter is similar to RequireDebugFalse, except that records are passed only when DEBUG is True.
6.14 Middleware

This document explains all middleware components that come with Django. For information on how to use them and how to write your own middleware, see the middleware usage guide.

6.14.1 Available middleware

Cache middleware

class UpdateCacheMiddleware

class FetchFromCacheMiddleware

Enable the site-wide cache. If these are enabled, each Django-powered page will be cached for as long as the CACHE_MIDDLEWARE_SECONDS setting defines. See the cache documentation.

“Common” middleware

class CommonMiddleware

Adds a few conveniences for perfectionists:

- Forbids access to user agents in the DISALLOWED_USER_AGENTS setting, which should be a list of compiled regular expression objects.
- Performs URL rewriting based on the APPEND_SLASH and PREPEND_WWW settings.

If APPEND_SLASH is True and the initial URL doesn’t end with a slash, and it is not found in the URLconf, then a new URL is formed by appending a slash at the end. If this new URL is found in the URLconf, then Django redirects the request to this new URL. Otherwise, the initial URL is processed as usual.

For example, foo.com/bar will be redirected to foo.com/bar/ if you don’t have a valid URL pattern for foo.com/bar but do have a valid pattern for foo.com/bar/.

If PREPEND_WWW is True, URLs that lack a leading “www.” will be redirected to the same URL with a leading “www.”

Both of these options are meant to normalize URLs. The philosophy is that each URL should exist in one, and only one, place. Technically a URL foo.com/bar is distinct from foo.com/bar/ — a search-engine indexer would treat them as separate URLs — so it’s best practice to normalize URLs.

If necessary, individual views may be excluded from the APPEND_SLASH behavior using the no_append_slash() decorator:
from django.views.decorators.common import no_append_slash

@no_append_slash
def sensitive_fbv(request, *args, **kwargs):
    """View to be excluded from APPEND_SLASH."""
    return HttpResponse()

• Sets the Content-Length header for non-streaming responses.

CommonMiddleware.response_redirect_class

Defaults to HttpResponsePermanentRedirect. Subclass CommonMiddleware and override the attribute to customize the redirects issued by the middleware.

class BrokenLinkEmailsMiddleware

• Sends broken link notification emails to MANAGERS (see How to manage error reporting).

GZip middleware

class GZipMiddleware

Warning: Security researchers recently revealed that when compression techniques (including GZipMiddleware) are used on a website, the site may become exposed to a number of possible attacks. Before using GZipMiddleware on your site, you should consider very carefully whether you are subject to these attacks. If you’re in any doubt about whether you’re affected, you should avoid using GZipMiddleware. For more details, see the the BREACH paper (PDF) and breachattack.com.

The django.middleware.gzip.GZipMiddleware compresses content for browsers that understand GZip compression (all modern browsers).

This middleware should be placed before any other middleware that need to read or write the response body so that compression happens afterward.

It will NOT compress content if any of the following are true:

• The content body is less than 200 bytes long.

• The response has already set the Content-Encoding header.

• The request (the browser) hasn’t sent an Accept-Encoding header containing gzip.

If the response has an ETag header, the ETag is made weak to comply with RFC 7232#section-2.1.

You can apply GZip compression to individual views using the gzip_page() decorator.
Conditional GET middleware

```python
class ConditionalGetMiddleware

Handles conditional GET operations. If the response doesn’t have an ETag header, the middleware adds one if needed. If the response has an ETag or Last-Modified header, and the request has If-None-Match or If-Modified-Since, the response is replaced by an HttpResponseNotModified.
```

Locale middleware

```python
class LocaleMiddleware

Enables language selection based on data from the request. It customizes content for each user. See the internationalization documentation.

LocaleMiddleware.response_redirect_class

Defaults to HttpResponseRedirect. Subclass LocaleMiddleware and override the attribute to customize the redirects issued by the middleware.
```

Message middleware

```python
class MessageMiddleware

Enables cookie- and session-based message support. See the messages documentation.
```

Security middleware

```python
Warning: If your deployment situation allows, it’s usually a good idea to have your front-end web server perform the functionality provided by the SecurityMiddleware. That way, if there are requests that aren’t served by Django (such as static media or user-uploaded files), they will have the same protections as requests to your Django application.

class SecurityMiddleware

The django.middleware.security.SecurityMiddleware provides several security enhancements to the request/response cycle. Each one can be independently enabled or disabled with a setting.

- `SECURE_CONTENT_TYPE_NOSNIFF`
- `SECURE_CROSS_ORIGIN_OPENER_POLICY`
- `SECURE_HSTS_INCLUDE_SUBDOMAINS`
- `SECURE_HSTS_PRELOAD`

6.14. Middleware
HTTP Strict Transport Security

For sites that should only be accessed over HTTPS, you can instruct modern browsers to refuse to connect to your domain name via an insecure connection (for a given period of time) by setting the “Strict-Transport-Security” header. This reduces your exposure to some SSL-stripping man-in-the-middle (MITM) attacks.

SecurityMiddleware will set this header for you on all HTTPS responses if you set the SECURE_HSTS_SECONDS setting to a non-zero integer value.

When enabling HSTS, it’s a good idea to first use a small value for testing, for example, SECURE_HSTS_SECONDS = 3600 for one hour. Each time a web browser sees the HSTS header from your site, it will refuse to communicate non-securely (using HTTP) with your domain for the given period of time. Once you confirm that all assets are served securely on your site (i.e. HSTS didn’t break anything), it’s a good idea to increase this value so that infrequent visitors will be protected (31536000 seconds, i.e. 1 year, is common).

Additionally, if you set the SECURE_HSTS_INCLUDE_SUBDOMAINS setting to True, SecurityMiddleware will add the includeSubDomains directive to the Strict-Transport-Security header. This is recommended (assuming all subdomains are served exclusively using HTTPS), otherwise your site may still be vulnerable via an insecure connection to a subdomain.

If you wish to submit your site to the browser preload list, set the SECURE_HSTS_PRELOAD setting to True. That appends the preload directive to the Strict-Transport-Security header.

Warning: The HSTS policy applies to your entire domain, not just the URL of the response that you set the header on. Therefore, you should only use it if your entire domain is served via HTTPS only.

Browsers properly respecting the HSTS header will refuse to allow users to bypass warnings and connect to a site with an expired, self-signed, or otherwise invalid SSL certificate. If you use HSTS, make sure your certificates are in good shape and stay that way!

Note: If you are deployed behind a load-balancer or reverse-proxy server, and the Strict-Transport-Security header is not being added to your responses, it may be because Django doesn’t realize that it’s on a secure connection; you may need to set the SECURE_PROXY_SSL_HEADER
Referrer Policy

Browsers use the **Referer header** as a way to send information to a site about how users got there. When a user clicks a link, the browser will send the full URL of the linking page as the referrer. While this can be useful for some purposes – like figuring out who’s linking to your site – it also can cause privacy concerns by informing one site that a user was visiting another site.

Some browsers have the ability to accept hints about whether they should send the HTTP **Referer** header when a user clicks a link; this hint is provided via the **Referrer-Policy header**. This header can suggest any of three behaviors to browsers:

- **Full URL:** send the entire URL in the **Referer** header. For example, if the user is visiting `https://example.com/page.html`, the **Referer** header would contain "https://example.com/page.html".

- **Origin only:** send only the "origin" in the referrer. The origin consists of the scheme, host and (optionally) port number. For example, if the user is visiting `https://example.com/page.html`, the origin would be `https://example.com/`.

- **No referrer:** do not send a **Referer** header at all.

There are two types of conditions this header can tell a browser to watch out for:

- **Same-origin versus cross-origin:** a link from `https://example.com/1.html` to `https://example.com/2.html` is same-origin. A link from `https://example.com/page.html` to `https://not.example.com/page.html` is cross-origin.

- **Protocol downgrade:** a downgrade occurs if the page containing the link is served via HTTPS, but the page being linked to is not served via HTTPS.

**Warning:** When your site is served via HTTPS, Django’s CSRF protection system requires the **Referer** header to be present, so completely disabling the **Referer** header will interfere with CSRF protection. To gain most of the benefits of disabling **Referer** headers while also keeping CSRF protection, consider enabling only same-origin referrers.

**SecurityMiddleware** can set the **Referrer-Policy** header for you, based on the **SECURE_REFERRER_POLICY** setting (note spelling: browsers send a **Referer** header when a user clicks a link, but the header instructing a browser whether to do so is spelled **Referrer-Policy**). The valid values for this setting are:

- **no-referrer**
  
  Instructs the browser to send no referrer for links clicked on this site.

- **no-referrer-when-downgrade**
  
  Instructs the browser to send a full URL as the referrer, but only when no protocol downgrade occurs.
origin
Instructs the browser to send only the origin, not the full URL, as the referrer.

origin-when-cross-origin
Instructs the browser to send the full URL as the referrer for same-origin links, and only the origin for cross-origin links.

same-origin
Instructs the browser to send a full URL, but only for same-origin links. No referrer will be sent for cross-origin links.

strict-origin
Instructs the browser to send only the origin, not the full URL, and to send no referrer when a protocol downgrade occurs.

strict-origin-when-cross-origin
Instructs the browser to send the full URL when the link is same-origin and no protocol downgrade occurs; send only the origin when the link is cross-origin and no protocol downgrade occurs; and no referrer when a protocol downgrade occurs.

unsafe-url
Instructs the browser to always send the full URL as the referrer.

Unknown Policy Values
Where a policy value is unknown by a user agent, it is possible to specify multiple policy values to provide a fallback. The last specified value that is understood takes precedence. To support this, an iterable or comma-separated string can be used with SECURE_REFERRER_POLICY.

Cross-Origin Opener Policy
Some browsers have the ability to isolate top-level windows from other documents by putting them in a separate browsing context group based on the value of the Cross-Origin Opener Policy (COOP) header. If a document that is isolated in this way opens a cross-origin popup window, the popup’s window.opener property will be null. Isolating windows using COOP is a defense-in-depth protection against cross-origin attacks, especially those like Spectre which allowed exfiltration of data loaded into a shared browsing context.

SecurityMiddleware can set the Cross-Origin-Opener-Policy header for you, based on the SECURE Cross-Origin Opener Policy setting. The valid values for this setting are:

same-origin
Isolates the browsing context exclusively to same-origin documents. Cross-origin documents are not loaded in the same browsing context. This is the default and most secure option.

same-origin-allow-popups
Isolates the browsing context to same-origin documents or those which either don’t set COOP or which opt out of isolation by setting a COOP of unsafe-none.

**unsafe-none**

Allows the document to be added to its opener’s browsing context group unless the opener itself has a COOP of same-origin or same-origin-allow-popups.

**X-Content-Type-Options: nosniff**

Some browsers will try to guess the content types of the assets that they fetch, overriding the Content-Type header. While this can help display sites with improperly configured servers, it can also pose a security risk.

If your site serves user-uploaded files, a malicious user could upload a specially-crafted file that would be interpreted as HTML or JavaScript by the browser when you expected it to be something harmless.

To prevent the browser from guessing the content type and force it to always use the type provided in the Content-Type header, you can pass the X-Content-Type-Options: nosniff header. SecurityMiddleware will do this for all responses if the SECURE_CONTENT_TYPE_NOSNIFF setting is True.

Note that in most deployment situations where Django isn’t involved in serving user-uploaded files, this setting won’t help you. For example, if your MEDIA_URL is served directly by your front-end web server (nginx, Apache, etc.) then you’d want to set this header there. On the other hand, if you are using Django to do something like require authorization in order to download files and you cannot set the header using your web server, this setting will be useful.

**SSL Redirect**

If your site offers both HTTP and HTTPS connections, most users will end up with an unsecured connection by default. For best security, you should redirect all HTTP connections to HTTPS.

If you set the SECURE_SSL_REDIRECT setting to True, SecurityMiddleware will permanently (HTTP 301) redirect all HTTP connections to HTTPS.

Note: For performance reasons, it’s preferable to do these redirects outside of Django, in a front-end load balancer or reverse-proxy server such as nginx. SECURE_SSL_REDIRECT is intended for the deployment situations where this isn’t an option.

If the SECURE_SSL_HOST setting has a value, all redirects will be sent to that host instead of the originally-requested host.

If there are a few pages on your site that should be available over HTTP, and not redirected to HTTPS, you can list regular expressions to match those URLs in the SECURE_REDIRECT_EXEMPT setting.
Note: If you are deployed behind a load-balancer or reverse-proxy server and Django can’t seem to tell when a request actually is already secure, you may need to set the `SECURE_PROXY_SSL_HEADER` setting.

**Session middleware**

```python
class SessionMiddleware
```

Enables session support. See the session documentation.

**Site middleware**

```python
class CurrentSiteMiddleware
```

Adds the `site` attribute representing the current site to every incoming `HttpRequest` object. See the sites documentation.

**Authentication middleware**

```python
class AuthenticationMiddleware
```

Adds the `user` attribute, representing the currently-logged-in user, to every incoming `HttpRequest` object. See Authentication in web requests.

```python
class RemoteUserMiddleware
```

Middleware for utilizing web server provided authentication. See How to authenticate using REMOTE_USER for usage details.

```python
class PersistentRemoteUserMiddleware
```

Middleware for utilizing web server provided authentication when enabled only on the login page. See Using REMOTE_USER on login pages only for usage details.

**CSRF protection middleware**

```python
class CsrfViewMiddleware
```

Adds protection against Cross Site Request Forgeries by adding hidden form fields to POST forms and checking requests for the correct value. See the Cross Site Request Forgery protection documentation.
X-Frame-Options middleware

class XFrameOptionsMiddleware

Simple clickjacking protection via the X-Frame-Options header.

6.14.2 Middleware ordering

Here are some hints about the ordering of various Django middleware classes:

1. SecurityMiddleware

   It should go near the top of the list if you’re going to turn on the SSL redirect as that avoids running through a bunch of other unnecessary middleware.

2. UpdateCacheMiddleware

   Before those that modify the Vary header (SessionMiddleware, GZipMiddleware, LocaleMiddleware).

3. GZipMiddleware

   Before any middleware that may change or use the response body.

   After UpdateCacheMiddleware: Modifies Vary header.

4. SessionMiddleware

   Before any middleware that may raise an exception to trigger an error view (such as PermissionDenied) if you’re using CSRF_USE_SESSIONS.

   After UpdateCacheMiddleware: Modifies Vary header.

5. ConditionalGetMiddleware

   Before any middleware that may change the response (it sets the ETag header).

   After GZipMiddleware so it won’t calculate an ETag header on gzipped contents.

6. LocaleMiddleware

   One of the topmost, after SessionMiddleware (uses session data) and UpdateCacheMiddleware (modifies Vary header).

7. CommonMiddleware

   Before any middleware that may change the response (it sets the Content-Length header). A middleware that appears before CommonMiddleware and changes the response must reset Content-Length.

   Close to the top: it redirects when APPEND_SLASH or PREPEND_WWW are set to True.

   After SessionMiddleware if you’re using CSRF_USE_SESSIONS.

8. CsrfViewMiddleware

   Before any view middleware that assumes that CSRF attacks have been dealt with.
Before `RemoteUserMiddleware`, or any other authentication middleware that may perform a login, and hence rotate the CSRF token, before calling down the middleware chain.

After `SessionMiddleware` if you’re using `CSRF_USE_SESSIONS`.

9. `AuthenticationMiddleware`
   After `SessionMiddleware`: uses session storage.

10. `MessageMiddleware`
    After `SessionMiddleware`: can use session-based storage.

11. `FetchFromCacheMiddleware`
    After any middleware that modifies the `Vary` header: that header is used to pick a value for the cache hash-key.

12. `FlatpageFallbackMiddleware`
    Should be near the bottom as it’s a last-resort type of middleware.

13. `RedirectFallbackMiddleware`
    Should be near the bottom as it’s a last-resort type of middleware.

### 6.15 Migration Operations

Migration files are composed of one or more `Operation` objects, objects that declaratively record what the migration should do to your database.

Django also uses these `Operation` objects to work out what your models looked like historically, and to calculate what changes you’ve made to your models since the last migration so it can automatically write your migrations; that’s why they’re declarative, as it means Django can easily load them all into memory and run through them without touching the database to work out what your project should look like.

There are also more specialized `Operation` objects which are for things like data migrations and for advanced manual database manipulation. You can also write your own `Operation` classes if you want to encapsulate a custom change you commonly make.

If you need an empty migration file to write your own `Operation` objects into, use `python manage.py makemigrations --empty yourappname`, but be aware that manually adding schema-altering operations can confuse the migration autodetector and make resulting runs of `makemigrations` output incorrect code.

All of the core Django operations are available from the `django.db.migrations.operations` module.

For introductory material, see the migrations topic guide.
6.15.1 Schema Operations

CreateDateModel

class CreateModel(name, fields, options=None, bases=None, managers=None)

Creates a new model in the project history and a corresponding table in the database to match it.

- **name** is the model name, as would be written in the models.py file.
- **fields** is a list of 2-tuples of (field_name, field_instance). The field instance should be an unbound field (so just models.CharField(...), rather than a field taken from another model).
- **options** is an optional dictionary of values from the model’s Meta class.
- **bases** is an optional list of other classes to have this model inherit from; it can contain both class objects as well as strings in the format "appname.ModelName" if you want to depend on another model (so you inherit from the historical version). If it’s not supplied, it defaults to inheriting from the standard models.Model.
- **managers** takes a list of 2-tuples of (manager_name, manager_instance). The first manager in the list will be the default manager for this model during migrations.

DeleteModel

class DeleteModel(name)

Deletes the model from the project history and its table from the database.

RenameModel

class RenameModel(old_name, new_name)

Renames the model from an old name to a new one.

You may have to manually add this if you change the model’s name and quite a few of its fields at once; to the autodetector, this will look like you deleted a model with the old name and added a new one with a different name, and the migration it creates will lose any data in the old table.

AlterModelTable

class AlterModelTable(name, table)

Changes the model’s table name (the db_table option on the Meta subclass).
AlterUniqueTogether

class AlterUniqueTogether(name, unique_together)

Changes the model’s set of unique constraints (the `unique_together` option on the `Meta` subclass).

AlterIndexTogether

class AlterIndexTogether(name, index_together)

Changes the model’s set of custom indexes (the `index_together` option on the `Meta` subclass).

AlterOrderWithRespectTo

class AlterOrderWithRespectTo(name, order_with_respect_to)

Makes or deletes the `_order` column needed for the `order_with_respect_to` option on the `Meta` subclass.

AlterModelOptions

class AlterModelOptions(name, options)

Stores changes to miscellaneous model options (settings on a model’s `Meta`) like `permissions` and `verbose_name`. Does not affect the database, but persists these changes for `RunPython` instances to use. `options` should be a dictionary mapping option names to values.

AlterModelManagers

class AlterModelManagers(name, managers)

Alters the managers that are available during migrations.

AddField

class AddField(model_name, name, field, preserve_default=True)

Adds a field to a model. `model_name` is the model’s name, `name` is the field’s name, and `field` is an unbound Field instance (the thing you would put in the field declaration in `models.py` - for example, `models.IntegerField(null=True)`).

The `preserve_default` argument indicates whether the field’s default value is permanent and should be baked into the project state (`True`), or if it is temporary and just for this migration (`False`) - usually because the migration is adding a non-nullable field to a table and needs a default value to put into existing rows. It
does not affect the behavior of setting defaults in the database directly - Django never sets database defaults and always applies them in the Django ORM code.

Warning: On older databases, adding a field with a default value may cause a full rewrite of the table. This happens even for nullable fields and may have a negative performance impact. To avoid that, the following steps should be taken.

- Add the nullable field without the default value and run the `makemigrations` command. This should generate a migration with an `AddField` operation.
- Add the default value to your field and run the `makemigrations` command. This should generate a migration with an `AlterField` operation.

---

### RemoveField

class RemoveField(model_name, name)

Removes a field from a model.

Bear in mind that when reversed, this is actually adding a field to a model. The operation is reversible (apart from any data loss, which is irreversible) if the field is nullable or if it has a default value that can be used to populate the recreated column. If the field is not nullable and does not have a default value, the operation is irreversible.

### AlterField

class AlterField(model_name, name, field, preserve_default=True)

Alters a field’s definition, including changes to its type, `null`, `unique`, `db_column` and other field attributes.

The `preserve_default` argument indicates whether the field’s default value is permanent and should be baked into the project state (`True`), or if it is temporary and just for this migration (`False`) - usually because the migration is altering a nullable field to a non-nullable one and needs a default value to put into existing rows. It does not affect the behavior of setting defaults in the database directly - Django never sets database defaults and always applies them in the Django ORM code.

Note that not all changes are possible on all databases - for example, you cannot change a text-type field like `models.TextField()` into a number-type field like `models.IntegerField()` on most databases.
RenameField

class RenameField(model_name, old_name, new_name)

Changes a field’s name (and, unless $db_column$ is set, its column name).

AddIndex

class AddIndex(model_name, index)

Creates an index in the database table for the model with $model_name$. $index$ is an instance of the $Index$ class.

RemoveIndex

class RemoveIndex(model_name, name)

Removes the index named $name$ from the model with $model_name$.

RenameIndex

class RenameIndex(model_name, new_name, old_name=None, old_fields=None)

Renames an index in the database table for the model with $model_name$. Exactly one of $old_name$ and $old_fields$ can be provided. $old_fields$ is an iterable of the strings, often corresponding to fields of $index_together$.

On databases that don’t support an index renaming statement (SQLite and MariaDB < 10.5.2), the operation will drop and recreate the index, which can be expensive.

AddConstraint

class AddConstraint(model_name, constraint)

Creates a constraint in the database table for the model with $model_name$.

RemoveConstraint

class RemoveConstraint(model_name, name)

Removes the constraint named $name$ from the model with $model_name$. 
6.15.2 Special Operations

RunSQL

class RunSQL(sql, reverse_sql=None, state_operations=None, hints=None, elidable=False)

Allows running of arbitrary SQL on the database - useful for more advanced features of database backends that Django doesn’t support directly.

sql, and reverse_sql if provided, should be strings of SQL to run on the database. On most database backends (all but PostgreSQL), Django will split the SQL into individual statements prior to executing them.

Warning: On PostgreSQL and SQLite, only use BEGIN or COMMIT in your SQL in non-atomic migrations, to avoid breaking Django’s transaction state.

You can also pass a list of strings or 2-tuples. The latter is used for passing queries and parameters in the same way as cursor.execute(). These three operations are equivalent:

```
import migrations

migrations.RunSQL("INSERT INTO musician (name) VALUES ('Reinhardt');")
migrations.RunSQL([("INSERT INTO musician (name) VALUES ('Reinhardt');", None)])
migrations.RunSQL([("INSERT INTO musician (name) VALUES (%s);", ['Reinhardt'])])
```

If you want to include literal percent signs in the query, you have to double them if you are passing parameters.

The reverse_sql queries are executed when the migration is unapplied. They should undo what is done by the sql queries. For example, to undo the above insertion with a deletion:

```
migrations.RunSQL(
    sql=(["INSERT INTO musician (name) VALUES (%s);", ['Reinhardt'])],
    reverse_sql=(["DELETE FROM musician where name=%s;", ['Reinhardt'])],
)
```

If reverse_sql is None (the default), the RunSQL operation is irreversible.

The state_operations argument allows you to supply operations that are equivalent to the SQL in terms of project state. For example, if you are manually creating a column, you should pass in a list containing an AddField operation here so that the autodetector still has an up-to-date state of the model. If you don’t, when you next run makemigrations, it won’t see any operation that adds that field and so will try to run it again. For example:

```
migrations.RunSQL(
    "ALTER TABLE musician ADD COLUMN name varchar(255) NOT NULL;",
    state_operations=[
```

(continues on next page)
migrations.AddField(
    'musician',
    'name',
    models.CharField(max_length=255),
),
],
}

The optional `hints` argument will be passed as `**hints` to the `allow_migrate()` method of database routers to assist them in making routing decisions. See `Hints` for more details on database hints.

The optional `elidable` argument determines whether or not the operation will be removed (elided) when squashing migrations.

**RunSQL**

Pass the `RunSQL.noop` attribute to `sql` or `reverse_sql` when you want the operation not to do anything in the given direction. This is especially useful in making the operation reversible.

**RunPython**

```python
def forwards_func(apps, schema_editor):
    # We get the model from the versioned app registry;
```

Runs custom Python code in a historical context. `code` (and `reverse_code` if supplied) should be callable objects that accept two arguments; the first is an instance of `django.apps.registry.Apps` containing historical models that match the operation’s place in the project history, and the second is an instance of `SchemaEditor`.

The `reverse_code` argument is called when unapplying migrations. This callable should undo what is done in the `code` callable so that the migration is reversible. If `reverse_code` is `None` (the default), the `RunPython` operation is irreversible.

The optional `hints` argument will be passed as `**hints` to the `allow_migrate()` method of database routers to assist them in making a routing decision. See `Hints` for more details on database hints.

The optional `elidable` argument determines whether or not the operation will be removed (elided) when squashing migrations.

You are advised to write the code as a separate function above the `Migration` class in the migration file, and pass it to `RunPython`. Here’s an example of using `RunPython` to create some initial objects on a Country model:
# if we directly import it, it'll be the wrong version
Country = apps.get_model("myapp", "Country")
db_alias = schema_editor.connection.alias
Country.objects.using(db_alias).bulk_create(
    
    Country(name="USA", code="us"),
    Country(name="France", code="fr"),
)

def reverse_func(apps, schema_editor):
    # forwards_func() creates two Country instances,
    # so reverse_func() should delete them.
    Country = apps.get_model("myapp", "Country")
db_alias = schema_editor.connection.alias
Country.objects.using(db_alias).filter(name="USA", code="us").delete()
Country.objects.using(db_alias).filter(name="France", code="fr").delete()

class Migration(migrations.Migration):
    dependencies = []

    operations = [
        migrations.RunPython(forwards_func, reverse_func),
    ]

This is generally the operation you would use to create data migrations, run custom data updates and alterations, and anything else you need access to an ORM and/or Python code for.

Much like RunSQL, ensure that if you change schema inside here you’re either doing it outside the scope of the Django model system (e.g. triggers) or that you use SeparateDatabaseAndState to add in operations that will reflect your changes to the model state - otherwise, the versioned ORM and the autodetector will stop working correctly.

By default, RunPython will run its contents inside a transaction on databases that do not support DDL transactions (for example, MySQL and Oracle). This should be safe, but may cause a crash if you attempt to use the schema_editor provided on these backends; in this case, pass atomic=False to the RunPython operation.

On databases that do support DDL transactions (SQLite and PostgreSQL), RunPython operations do not have any transactions automatically added besides the transactions created for each migration. Thus, on PostgreSQL, for example, you should avoid combining schema changes and RunPython operations in the same migration or you may hit errors like OperationalError: cannot ALTER TABLE "mytable" because it has pending trigger events.

If you have a different database and aren’t sure if it supports DDL transactions, check the django.db.connection.features.can_rollback_ddl attribute.

If the RunPython operation is part of a non-atomic migration, the operation will only be executed in a trans-
action if `atomic=True` is passed to the `RunPython` operation.

```
Warning: RunPython does not magically alter the connection of the models for you; any model methods you call will go to the default database unless you give them the current database alias (available from `schema_editor.connection.alias`, where `schema_editor` is the second argument to your function).
```

```python
static RunPython.noop()
```

Pass the `RunPython.noop` method to `code` or `reverse_code` when you want the operation not to do anything in the given direction. This is especially useful in making the operation reversible.

---

### SeparateDatabaseAndState

```python
class SeparateDatabaseAndState(database_operations=None, state_operations=None)
```

A highly specialized operation that lets you mix and match the database (schema-changing) and state (autodetector-powering) aspects of operations.

It accepts two lists of operations. When asked to apply state, it will use the `state_operations` list (this is a generalized version of `RunSQL`’s `state_operations` argument). When asked to apply changes to the database, it will use the `database_operations` list.

If the actual state of the database and Django’ s view of the state get out of sync, this can break the migration framework, even leading to data loss. It’s worth exercising caution and checking your database and state operations carefully. You can use `sqlmigrate` and `dbshell` to check your database operations. You can use `makemigrations`, especially with `--dry-run`, to check your state operations.

For an example using `SeparateDatabaseAndState`, see Changing a ManyToManyField to use a through model.

---

## 6.15.3 Writing your own

Operations have a relatively simple API, and they’re designed so that you can easily write your own to supplement the built-in Django ones. The basic structure of an `Operation` looks like this:

```python
from django.db.migrations.operations.base import Operation

class MyCustomOperation(Operation):

    # If this is False, it means that this operation will be ignored by
    # sqlmigrate; if true, it will be run and the SQL collected for its output.
    reduces_to_sql = False
```

(continues on next page)
reversible = False

def __init__(self, arg1, arg2):
    # Operations are usually instantiated with arguments in migration
    # files. Store the values of them on self for later use.
    pass

def state_forwards(self, app_label, state):
    # The Operation should take the 'state' parameter (an instance of
    # django.db.migrations.state.ProjectState) and mutate it to match
    # any schema changes that have occurred.
    pass

def database_forwards(self, app_label, schema_editor, from_state, to_state):
    # The Operation should use schema_editor to apply any changes it
    # wants to make to the database.
    pass

def database_backwards(self, app_label, schema_editor, from_state, to_state):
    # If reversible is True, this is called when the operation is reversed.
    pass

def describe(self):
    # This is used to describe what the operation does in console output.
    return "Custom Operation"

@property
def migration_name_fragment(self):
    # Optional. A filename part suitable for automatically naming a
    # migration containing this operation, or None if not applicable.
    return "custom_operation_%s_%s" % (self.arg1, self.arg2)

You can take this template and work from it, though we suggest looking at the built-in Django operations in
django.db.migrations.operations - they cover a lot of the example usage of semi-internal aspects of the
migration framework like ProjectState and the patterns used to get historical models, as well as ModelState
and the patterns used to mutate historical models in state_forwards().

Some things to note:

- You don’t need to learn too much about ProjectState to write migrations; just know that it has an
  apps property that gives access to an app registry (which you can then call get_model on).

- database_forwards and database_backwards both get two states passed to them; these represent the
difference the state_forwards method would have applied, but are given to you for convenience and
  speed reasons.
If you want to work with model classes or model instances from the `from_state` argument in `database_forwards()` or `database_backwards()`, you must render model states using the `clear_delayed_apps_cache()` method to make related models available:

```python
def database_forwards(self, app_label, schema_editor, from_state, to_state):
    # This operation should have access to all models. Ensure that all models are
    # reloaded in case any are delayed.
    from_state.clear_delayed_apps_cache()
    ...
```

- `to_state` in the `database_backwards` method is the older state; that is, the one that will be the current state once the migration has finished reversing.
- You might see implementations of `references_model` on the built-in operations; this is part of the autodetection code and does not matter for custom operations.

Warning: For performance reasons, the `Field` instances in `ModelState.fields` are reused across migrations. You must never change the attributes on these instances. If you need to mutate a field in `state_forwards()`, you must remove the old instance from `ModelState.fields` and add a new instance in its place. The same is true for the `Manager` instances in `ModelState.managers`.

As an example, let’s make an operation that loads PostgreSQL extensions (which contain some of PostgreSQL’s more exciting features). Since there’s no model state changes, all it does is run one command:

```python
from django.db.migrations.operations.base import Operation

class LoadExtension(Operation):

    reversible = True

    def __init__(self, name):
        self.name = name

    def state_forwards(self, app_label, state):
        pass

    def database_forwards(self, app_label, schema_editor, from_state, to_state):
        schema_editor.execute("CREATE EXTENSION IF NOT EXISTS %s" % self.name)

    def database_backwards(self, app_label, schema_editor, from_state, to_state):
        schema_editor.execute("DROP EXTENSION %s" % self.name)

    def describe(self):
```

(continues on next page)
return "Creates extension %s" % self.name

@property
def migration_name_fragment(self):
    return "create_extension_%s" % self.name

6.16 Models

Model API reference. For introductory material, see Models.

6.16.1 Model field reference

This document contains all the API references of Field including the field options and field types Django offers.

See also:

If the built-in fields don’t do the trick, you can try django-localflavor (documentation), which contains assorted pieces of code that are useful for particular countries and cultures.

Also, you can easily write your own custom model fields.

Note: Technically, these models are defined in django.db.models.fields, but for convenience they’re imported into django.db.models; the standard convention is to use from django.db import models and refer to fields as models.<Foo>Field.

Field options

The following arguments are available to all field types. All are optional.

null

Field.null

If True, Django will store empty values as NULL in the database. Default is False.

Avoid using null on string-based fields such as CharField and TextField. If a string-based field has null=True, that means it has two possible values for “no data”: NULL, and the empty string. In most cases, it’s redundant to have two possible values for “no data;” the Django convention is to use the empty
string, not NULL. One exception is when a CharField has both unique=True and blank=True set. In this situation, null=True is required to avoid unique constraint violations when saving multiple objects with blank values.

For both string-based and non-string-based fields, you will also need to set blank=True if you wish to permit empty values in forms, as the null parameter only affects database storage (see blank).

Note: When using the Oracle database backend, the value NULL will be stored to denote the empty string regardless of this attribute.

blank

Field.blank

If True, the field is allowed to be blank. Default is False.

Note that this is different than null. null is purely database-related, whereas blank is validation-related. If a field has blank=True, form validation will allow entry of an empty value. If a field has blank=False, the field will be required.

Supplying missing values

blank=True can be used with fields having null=False, but this will require implementing clean() on the model in order to programmatically supply any missing values.

choices

Field.choices

A sequence consisting itself of iterables of exactly two items (e.g. [(A, B), (A, B) ...]) to use as choices for this field. If choices are given, they’re enforced by model validation and the default form widget will be a select box with these choices instead of the standard text field.

The first element in each tuple is the actual value to be set on the model, and the second element is the human-readable name. For example:

```
YEAR_IN_SCHOOL_CHOICES = [
    ('FR', 'Freshman'),
    ('SO', 'Sophomore'),
    ('JR', 'Junior'),
    ('SR', 'Senior'),
]
```
Generally, it’s best to define choices inside a model class, and to define a suitably-named constant for each value:

```python
from django.db import models

class Student(models.Model):
    FRESHMAN = 'FR'
    SOPHOMORE = 'SO'
    JUNIOR = 'JR'
    SENIOR = 'SR'
    GRADUATE = 'GR'
    YEAR_IN_SCHOOL_CHOICES = [
        (FRESHMAN, 'Freshman'),
        (SOPHOMORE, 'Sophomore'),
        (JUNIOR, 'Junior'),
        (SENIOR, 'Senior'),
        (GRADUATE, 'Graduate'),
    ]
    year_in_school = models.CharField(
        max_length=2,
        choices=YEAR_IN_SCHOOL_CHOICES,
        default=FRESHMAN,
    )

    def is_upperclass(self):
        return self.year_in_school in {self.JUNIOR, self.SENIOR}
```

Though you can define a choices list outside of a model class and then refer to it, defining the choices and names for each choice inside the model class keeps all of that information with the class that uses it, and helps reference the choices (e.g., `Student.SOPHOMORE` will work anywhere that the `Student` model has been imported).

You can also collect your available choices into named groups that can be used for organizational purposes:

```python
MEDIA_CHOICES = [
    ('Audio', (  
        ('vinyl', 'Vinyl'),
        ('cd', 'CD'),
    ),),
    ('Video', (  
```

(continues on next page)
The first element in each tuple is the name to apply to the group. The second element is an iterable of 2-tuples, with each 2-tuple containing a value and a human-readable name for an option. Grouped options may be combined with ungrouped options within a single list (such as the 'unknown' option in this example).

For each model field that has choices set, Django will add a method to retrieve the human-readable name for the field’s current value. See get_FOO_display() in the database API documentation.

Note that choices can be any sequence object—not necessarily a list or tuple. This lets you construct choices dynamically. But if you find yourself hacking choices to be dynamic, you’re probably better off using a proper database table with a ForeignKey. choices is meant for static data that doesn’t change much, if ever.

Note: A new migration is created each time the order of choices changes.

Unless blank=False is set on the field along with a default then a label containing "----------" will be rendered with the select box. To override this behavior, add a tuple to choices containing None; e.g. (None, 'Your String For Display'). Alternatively, you can use an empty string instead of None where this makes sense—such as on a CharField.

**Enumeration types**

In addition, Django provides enumeration types that you can subclass to define choices in a concise way:

```python
from django.utils.translation import gettext_lazy as _

class Student(models.Model):

    class YearInSchool(models.TextChoices):
        FRESHMAN = 'FR', _('Freshman')
        SOPHOMORE = 'SO', _('Sophomore')
        JUNIOR = 'JR', _('Junior')
        SENIOR = 'SR', _('Senior')
        GRADUATE = 'GR', _('Graduate')

    year_in_school = models.CharField(
```

(continues on next page)
These work similar to `enum` from Python’s standard library, but with some modifications:

- Enum member values are a tuple of arguments to use when constructing the concrete data type. Django supports adding an extra string value to the end of this tuple to be used as the human-readable name, or `label`. The `label` can be a lazy translatable string. Thus, in most cases, the member value will be a `(value, label)` two-tuple. See below for an example of subclassing `choices` using a more complex data type. If a tuple is not provided, or the last item is not a (lazy) string, the `label` is automatically generated from the member name.

- A `.label` property is added on values, to return the human-readable name.

- A number of custom properties are added to the enumeration classes—`.choices`, `.labels`, `.values`, and `.names`—to make it easier to access lists of those separate parts of the enumeration. Use `.choices` as a suitable value to pass to `choices` in a field definition.

  Warning: These property names cannot be used as member names as they would conflict.

- The use of `enum.unique()` is enforced to ensure that values cannot be defined multiple times. This is unlikely to be expected in choices for a field.

Note that using `YearInSchool.SENIOR`, `YearInSchool['SENIOR']`, or `YearInSchool('SR')` to access or lookup enum members work as expected, as do the `.name` and `.value` properties on the members.

If you don’t need to have the human-readable names translated, you can have them inferred from the member name (replacing underscores with spaces and using title-case):

```python
>>> class Vehicle(models.TextChoices):
...     CAR = 'C'
...     TRUCK = 'T'
...     JET_SKI = 'J'
...
>>> Vehicle.JET_SKI.label
'Jet Ski'
```
Since the case where the enum values need to be integers is extremely common, Django provides an `IntegerChoices` class. For example:

```python
class Card(models.Model):

    class Suit(models.IntegerChoices):
        DIAMOND = 1
        SPADE = 2
        HEART = 3
        CLUB = 4

    suit = models.IntegerField(choices=Suit.choices)
```

It is also possible to make use of the Enum Functional API with the caveat that labels are automatically generated as highlighted above:

```python
>>> MedalType = models.TextChoices('MedalType', 'GOLD SILVER BRONZE')
>>> MedalType.choices
[('GOLD', 'Gold'), ('SILVER', 'Silver'), ('BRONZE', 'Bronze')]
>>> Place = models.IntegerChoices('Place', 'FIRST SECOND THIRD')
>>> Place.choices
[(1, 'First'), (2, 'Second'), (3, 'Third')]
```

If you require support for a concrete data type other than `int` or `str`, you can subclass `Choices` and the required concrete data type, e.g. `date` for use with `DateField`:

```python
class MoonLandings(datetime.date, models.Choices):
    APOLLO_11 = 1969, 7, 20, 'Apollo 11 (Eagle)'
    APOLLO_12 = 1969, 11, 19, 'Apollo 12 (Intrepid)'
    APOLLO_14 = 1971, 2, 5, 'Apollo 14 (Antares)'
    APOLLO_15 = 1971, 7, 30, 'Apollo 15 (Falcon)'
    APOLLO_16 = 1972, 4, 21, 'Apollo 16 (Orion)'
    APOLLO_17 = 1972, 12, 11, 'Apollo 17 (Challenger)'
```

There are some additional caveats to be aware of:

- Enumeration types do not support named groups.
- Because an enumeration with a concrete data type requires all values to match the type, overriding the `blank label` cannot be achieved by creating a member with a value of `None`. Instead, set the `__empty__` attribute on the class:

```python
class Answer(models.IntegerChoices):
    NO = 0, _('No')
    YES = 1, _('Yes')
```

(continues on next page)
db_column

Field.db_column

The name of the database column to use for this field. If this isn’t given, Django will use the field’s name. If your database column name is an SQL reserved word, or contains characters that aren’t allowed in Python variable names—notably, the hyphen—that’s OK. Django quotes column and table names behind the scenes.

db_index

Field.db_index

If True, a database index will be created for this field.

db_tablespace

Field.db_tablespace

The name of the database tablespace to use for this field’s index, if this field is indexed. The default is the project’s DEFAULT_INDEX_TABLESPACE setting, if set, or the db_tablespace of the model, if any. If the backend doesn’t support tablespaces for indexes, this option is ignored.

default

Field.default

The default value for the field. This can be a value or a callable object. If callable it will be called every time a new object is created.

The default can’t be a mutable object (model instance, list, set, etc.), as a reference to the same instance of that object would be used as the default value in all new model instances. Instead, wrap the desired default in a callable. For example, if you want to specify a default dict for JSONField, use a function:

```python
def contact_default():
    return {"email": "to1@example.com"}

contact_info = JSONField("ContactInfo", default=contact_default)
```
1. **lambda** can’t be used for field options like `default` because they can’t be serialized by migrations. See that documentation for other caveats.

   For fields like `ForeignKey` that map to model instances, defaults should be the value of the field they reference (pk unless `to_field` is set) instead of model instances.

   The default value is used when new model instances are created and a value isn’t provided for the field. When the field is a primary key, the default is also used when the field is set to `None`.

2. **editable**

   Field `editable`

   If `False`, the field will not be displayed in the admin or any other `ModelForm`. They are also skipped during model validation. Default is `True`.

3. **error_messages**

   Field `error_messages`

   The `error_messages` argument lets you override the default messages that the field will raise. Pass in a dictionary with keys matching the error messages you want to override.

   Error message keys include `null`, `blank`, `invalid`, `invalid_choice`, `unique`, and `unique_for_date`. Additional error message keys are specified for each field in the Field types section below.

   These error messages often don’t propagate to forms. See Considerations regarding model’s error_messages.

4. **help_text**

   Field `help_text`

   Extra “help” text to be displayed with the form widget. It’s useful for documentation even if your field isn’t used on a form.

   Note that this value is not HTML-escaped in automatically-generated forms. This lets you include HTML in `help_text` if you so desire. For example:

   ```
   help_text="Please use the following format: <em>YYYY-MM-DD</em>.
   ```

   Alternatively you can use plain text and `django.utils.html.escape()` to escape any HTML special characters. Ensure that you escape any help text that may come from untrusted users to avoid a cross-site scripting attack.
primary_key

Field: primary_key

If True, this field is the primary key for the model.

If you don’t specify primary_key=True for any field in your model, Django will automatically add a field to hold the primary key, so you don’t need to set primary_key=True on any of your fields unless you want to override the default primary-key behavior. The type of auto-created primary key fields can be specified per app in AppConfig.default_auto_field or globally in the DEFAULT_AUTO_FIELD setting. For more, see Automatic primary key fields.

primary_key=True implies null=False and unique=True. Only one primary key is allowed on an object.

The primary key field is read-only. If you change the value of the primary key on an existing object and then save it, a new object will be created alongside the old one.

unique

Field: unique

If True, this field must be unique throughout the table.

This is enforced at the database level and by model validation. If you try to save a model with a duplicate value in a unique field, a django.db.IntegrityError will be raised by the model’s save() method.

This option is valid on all field types except ManyToManyField and OneToOneField.

Note that when unique is True, you don’t need to specify db_index, because unique implies the creation of an index.

unique_for_date

Field: unique_for_date

Set this to the name of a DateField or DateTimeField to require that this field be unique for the value of the date field.

For example, if you have a field title that has unique_for_date="pub_date", then Django wouldn’t allow the entry of two records with the same title and pub_date.

Note that if you set this to point to a DateTimeField, only the date portion of the field will be considered. Besides, when USE_TZ is True, the check will be performed in the current time zone at the time the object gets saved.

This is enforced by Model.validate_unique() during model validation but not at the database level. If any unique_for_date constraint involves fields that are not part of a ModelForm (for example, if one of the...
fields is listed in exclude or has editable=False), Model.validate_unique() will skip validation for that particular constraint.

unique_for_month

Field.unique_for_month

Like unique_for_date, but requires the field to be unique with respect to the month.

unique_for_year

Field.unique_for_year

Like unique_for_date and unique_for_month.

verbose_name

Field.verbose_name

A human-readable name for the field. If the verbose name isn’t given, Django will automatically create it using the field’s attribute name, converting underscores to spaces. See Verbose field names.

validators

Field.validators

A list of validators to run for this field. See the validators documentation for more information.

Registering and fetching lookups

Field implements the lookup registration API. The API can be used to customize which lookups are available for a field class, and how lookups are fetched from a field.

Field types

AutoField

class AutoField(**options)

An IntegerField that automatically increments according to available IDs. You usually won’t need to use this directly; a primary key field will automatically be added to your model if you don’t specify otherwise. See Automatic primary key fields.
BigAutoField

```python
class BigAutoField(**options)
```

A 64-bit integer, much like an `AutoField` except that it is guaranteed to fit numbers from 1 to 9223372036854775807.

BigIntegerField

```python
class BigIntegerField(**options)
```

A 64-bit integer, much like an `IntegerField` except that it is guaranteed to fit numbers from -9223372036854775808 to 9223372036854775807. The default form widget for this field is a `NumberInput`.

BinaryField

```python
class BinaryField(max_length=None, **options)
```

A field to store raw binary data. It can be assigned `bytes`, `bytearray`, or `memoryview`.

By default, `BinaryField` sets `editable` to `False`, in which case it can’t be included in a `ModelForm`.

`BinaryField.max_length`

Optional. The maximum length (in bytes) of the field. The maximum length is enforced in Django’s validation using `MaxLengthValidator`.

Abusing BinaryField

Although you might think about storing files in the database, consider that it is bad design in 99% of the cases. This field is not a replacement for proper static files handling.

BooleanField

```python
class BooleanField(**options)
```

A true/false field.

The default form widget for this field is `CheckboxInput`, or `NullBooleanSelect` if `null=True`.

The default value of `BooleanField` is `None` when `Field.default` isn’t defined.
CharField

class CharField(max_length=None, **options)

A string field, for small- to large-sized strings.
For large amounts of text, use TextField.
The default form widget for this field is a TextInput.

CharField has the following extra arguments:

CharField.max_length

Required. The maximum length (in characters) of the field. The max_length is enforced at the database level and in Django’s validation using MaxLengthValidator.

Note: If you are writing an application that must be portable to multiple database backends, you should be aware that there are restrictions on max_length for some backends. Refer to the database backend notes for details.

CharField.db_collation

Optional. The database collation name of the field.

Note: Collation names are not standardized. As such, this will not be portable across multiple database backends.

Oracle

Oracle supports collations only when the MAX_STRING_SIZE database initialization parameter is set to EXTENDED.

DateField

class DateField(auto_now=False, auto_now_add=False, **options)

A date, represented in Python by a datetime.date instance. Has a few extra, optional arguments:

DateField.auto_now

Automatically set the field to now every time the object is saved. Useful for “last-modified” timestamps. Note that the current date is always used; it’s not just a default value that you can override.
The field is only automatically updated when calling `Model.save()`. The field isn’t updated when making updates to other fields in other ways such as `QuerySet.update()`, though you can specify a custom value for the field in an update like that.

**DateField.auto_now_add**

Automatically set the field to now when the object is first created. Useful for creation of timestamps. Note that the current date is always used; it’s not just a default value that you can override. So even if you set a value for this field when creating the object, it will be ignored. If you want to be able to modify this field, set the following instead of `auto_now_add=True`:

- For `DateField`: `default=date.today` - from `datetime.date.today()`
- For `DateTimeField`: `default=timezone.now` - from `django.utils.timezone.now()`

The default form widget for this field is a `DateInput`. The admin adds a JavaScript calendar, and a shortcut for “Today”. Includes an additional `invalid_date` error message key.

The options `auto_now_add`, `auto_now`, and `default` are mutually exclusive. Any combination of these options will result in an error.

---

**Note:** As currently implemented, setting `auto_now` or `auto_now_add` to `True` will cause the field to have `editable=False` and `blank=True` set.

---

**Note:** The `auto_now` and `auto_now_add` options will always use the date in the `default timezone` at the moment of creation or update. If you need something different, you may want to consider using your own callable default or overriding `save()` instead of using `auto_now` or `auto_now_add`; or using a `DateTimeField` instead of a `DateField` and deciding how to handle the conversion from datetime to date at display time.

---

**DateTimeField**

```python
class DateTimeField(auto_now=False, auto_now_add=False, **options)
```

A date and time, represented in Python by a `datetime.datetime` instance. Takes the same extra arguments as `DateField`.

The default form widget for this field is a single `DateTimeInput`. The admin uses two separate `TextInput` widgets with JavaScript shortcuts.
**DecimalField**

```python
class DecimalField(max_digits=None, decimal_places=None, **options)
```

A fixed-precision decimal number, represented in Python by a `Decimal` instance. It validates the input using `DecimalValidator`.

Has the following required arguments:

- **max_digits**
  - The maximum number of digits allowed in the number. Note that this number must be greater than or equal to `decimal_places`.

- **decimal_places**
  - The number of decimal places to store with the number.

For example, to store numbers up to `999.99` with a resolution of 2 decimal places, you’d use:

```python
models.DecimalField(..., max_digits=5, decimal_places=2)
```

And to store numbers up to approximately one billion with a resolution of 10 decimal places:

```python
models.DecimalField(..., max_digits=19, decimal_places=10)
```

The default form widget for this field is a `NumberInput` when `localize` is `False` or `TextInput` otherwise.

*Note: For more information about the differences between the `FloatField` and `DecimalField` classes, please see `FloatField vs. DecimalField`. You should also be aware of SQLite limitations of decimal fields.*

**DurationField**

```python
class DurationField(**options)
```

A field for storing periods of time - modeled in Python by `timedelta`. When used on PostgreSQL, the data type used is an `interval` and on Oracle the data type is `INTERVAL DAY(9) TO SECOND(6)`. Otherwise a `bigint` of microseconds is used.

*Note: Arithmetic with `DurationField` works in most cases. However on all databases other than PostgreSQL, comparing the value of a `DurationField` to arithmetic on `DateTimeField` instances will not work as expected.*
**EmailField**

```python
class EmailField(max_length=254, **options)
```

A `CharField` that checks that the value is a valid email address using `EmailValidator`.

**FileField**

```python
class FileField(upload_to='', storage=None, max_length=100, **options)
```

A file-upload field.

---

**Note:** The `primary_key` argument isn’t supported and will raise an error if used.

Has the following optional arguments:

**FileField.upload_to**

This attribute provides a way of setting the upload directory and file name, and can be set in two ways. In both cases, the value is passed to the `Storage.save()` method.

If you specify a string value or a `Path`, it may contain `strftime()` formatting, which will be replaced by the date/time of the file upload (so that uploaded files don’t fill up the given directory). For example:

```python
class MyModel(models.Model):
    # file will be uploaded to MEDIA_ROOT/uploads
    upload = models.FileField(upload_to='uploads/
    # or...
    # file will be saved to MEDIA_ROOT/uploads/2015/01/30
    upload = models.FileField(upload_to='uploads/%Y/%m/%d/
```

If you are using the default `FileSystemStorage`, the string value will be appended to your `MEDIA_ROOT` path to form the location on the local filesystem where uploaded files will be stored. If you are using a different storage, check that storage’s documentation to see how it handles `upload_to`.

`upload_to` may also be a callable, such as a function. This will be called to obtain the upload path, including the filename. This callable must accept two arguments and return a Unix-style path (with forward slashes) to be passed along to the storage system. The two arguments are:
### FileField

A storage object, or a callable which returns a storage object. This handles the storage and retrieval of your files. See Managing files for details on how to provide this object.

The default form widget for this field is a `ClearableFileInput`.

Using a `FileField` or an `ImageField` (see below) in a model takes a few steps:

1. In your settings file, you’ll need to define `MEDIA_ROOT` as the full path to a directory where you’d like Django to store uploaded files. (For performance, these files are not stored in the database.) Define `MEDIA_URL` as the base public URL of that directory. Make sure that this directory is writable by the web server’s user account.

2. Add the `FileField` or `ImageField` to your model, defining the `upload_to` option to specify a subdirectory of `MEDIA_ROOT` to use for uploaded files.

3. All that will be stored in your database is a path to the file (relative to `MEDIA_ROOT`). You’ll most likely want to use the convenience `url` attribute provided by Django. For example, if your `ImageField` is called `mug_shot`, you can get the absolute path to your image in a template with `{% object.mug_shot.url %}`.

For example, say your `MEDIA_ROOT` is set to `'/home/media'`, and `upload_to` is set to `photos/%Y/%m/%d'`. The `'%Y/%m/%d'` part of `upload_to` is `strftime()` formatting; `'%Y'` is the four-digit year, `'%m'` is the two-digit month and `'%d'` is the two-digit day. If you upload a file on Jan. 15, 2007, it will be saved in the directory `/home/media/photos/2007/01/15`.

If you wanted to retrieve the uploaded file’s on-disk filename, or the file’s size, you could use the `name` attribute:

```python
# name attribute

mug_shot = object.mug_shot.name
print(mug_shot)  # /home/media/photos/2007/01/15/mug_shot.jpg
print(object.mug_shot.size)  # 245678
```

---

**Arguments**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>instance</td>
<td>Instance of the model where the <code>FileField</code> is defined. More specifically, this is the particular instance where the current file is being attached. In most cases, this object will not have been saved to the database yet, so if it uses the default <code>AutoField</code>, it might not yet have a value for its primary key field.</td>
</tr>
<tr>
<td>filename</td>
<td>Filename that was originally given to the file. This may or may not be taken into account when determining the final destination path.</td>
</tr>
</tbody>
</table>

---

**Example**

```python
def user_directory_path(instance, filename):
    # file will be uploaded to MEDIA_ROOT/user_<id>/<filename>
    return 'user_{0}/({1})'.format(instance.user.id, filename)

class MyModel(models.Model):
    upload = models.FileField(upload_to=user_directory_path)
```
and size attributes respectively; for more information on the available attributes and methods, see the File class reference and the Managing files topic guide.

Note: The file is saved as part of saving the model in the database, so the actual file name used on disk cannot be relied on until after the model has been saved.

The uploaded file’s relative URL can be obtained using the url attribute. Internally, this calls the url() method of the underlying Storage class.

Note that whenever you deal with uploaded files, you should pay close attention to where you’re uploading them and what type of files they are, to avoid security holes. Validate all uploaded files so that you’re sure the files are what you think they are. For example, if you blindly let somebody upload files, without validation, to a directory that’s within your web server’s document root, then somebody could upload a CGI or PHP script and execute that script by visiting its URL on your site. Don’t allow that.

Also note that even an uploaded HTML file, since it can be executed by the browser (though not by the server), can pose security threats that are equivalent to XSS or CSRF attacks.

FileField instances are created in your database as varchar columns with a default max length of 100 characters. As with other fields, you can change the maximum length using the max_length argument.

**FileField and FieldFile**

**class FieldFile**

When you access a FileField on a model, you are given an instance of FieldFile as a proxy for accessing the underlying file.

The API of FieldFile mirrors that of File, with one key difference: The object wrapped by the class is not necessarily a wrapper around Python’s built-in file object. Instead, it is a wrapper around the result of the Storage.open() method, which may be a File object, or it may be a custom storage’s implementation of the File API.

In addition to the API inherited from File such as read() and write(), FieldFile includes several methods that can be used to interact with the underlying file:

Warning: Two methods of this class, save() and delete(), default to saving the model object of the associated FieldFile in the database.

**FieldFile.name**

The name of the file including the relative path from the root of the Storage of the associated FileField.
FieldFile.path
A read-only property to access the file’s local filesystem path by calling the `path()` method of the underlying `Storage` class.

FieldFile.size
The result of the underlying `Storage.size()` method.

FieldFile.url
A read-only property to access the file’s relative URL by calling the `url()` method of the underlying `Storage` class.

FieldFile.open(mode='rb')
Opens or reopens the file associated with this instance in the specified mode. Unlike the standard Python `open()` method, it doesn’t return a file descriptor.

Since the underlying file is opened implicitly when accessing it, it may be unnecessary to call this method except to reset the pointer to the underlying file or to change the mode.

FieldFile.close()
Behaves like the standard Python `file.close()` method and closes the file associated with this instance.

FieldFile.save(name, content, save=True)
This method takes a filename and file contents and passes them to the storage class for the field, then associates the stored file with the model field. If you want to manually associate file data with `FileField` instances on your model, the `save()` method is used to persist that file data.

Takes two required arguments: `name` which is the name of the file, and `content` which is an object containing the file’s contents. The optional `save` argument controls whether or not the model instance is saved after the file associated with this field has been altered. Defaults to `True`.

Note that the `content` argument should be an instance of `django.core.files.File`, not Python’s built-in file object. You can construct a `File` from an existing Python file object like this:

```python
from django.core.files import File
# Open an existing file using Python's built-in open()
f = open('/path/to/hello.world')
myfile = File(f)
```

Or you can construct one from a Python string like this:

```python
from django.core.files.base import ContentFile
myfile = ContentFile("hello world")
```

For more information, see Managing files.
FieldFile.delete(save=True)

Deletes the file associated with this instance and clears all attributes on the field. Note: This method will close the file if it happens to be open when delete() is called.

The optional save argument controls whether or not the model instance is saved after the file associated with this field has been deleted. Defaults to True.

Note that when a model is deleted, related files are not deleted. If you need to cleanup orphaned files, you’ll need to handle it yourself (for instance, with a custom management command that can be run manually or scheduled to run periodically via e.g. cron).

FilePathField

```
class FilePathField(path='', match=None, recursive=False, allow_files=True, allow_folders=False, max_length=100, **options)
```

A CharField whose choices are limited to the filenames in a certain directory on the filesystem. Has some special arguments, of which the first is required:

FilePathField.path

Required. The absolute filesystem path to a directory from which this FilePathField should get its choices. Example: "/home/images".

path may also be a callable, such as a function to dynamically set the path at runtime. Example:

```
import os
from django.conf import settings
from django.db import models

def images_path():
    return os.path.join(settings.LOCAL_FILE_DIR, 'images')

class MyModel(models.Model):
    file = models.FilePathField(path=images_path)
```

FilePathField.match

Optional. A regular expression, as a string, that FilePathField will use to filter filenames. Note that the regex will be applied to the base filename, not the full path. Example: "foo.*\.txt$", which will match a file called foo23.txt but not bar.txt or foo23.png.

FilePathFieldrecursive

Optional. Either True or False. Default is False. Specifies whether all subdirectories of path should be included
**FilePathField**. **allow_files**

Optional. Either True or False. Default is True. Specifies whether files in the specified location should be included. Either this or **allow_folders** must be True.

**FilePathField**. **allow_folders**

Optional. Either True or False. Default is False. Specifies whether folders in the specified location should be included. Either this or **allow_files** must be True.

The one potential gotcha is that **match** applies to the base filename, not the full path. So, this example:

```python
FilePathField(path="/home/images", match="foo.*", recursive=True)
```

...will match /home/images/foo.png but not /home/images/foo/bar.png because the **match** applies to the base filename (foo.png and bar.png).

**FilePathField** instances are created in your database as varchar columns with a default max length of 100 characters. As with other fields, you can change the maximum length using the **max_length** argument.

**FloatField**

```python
class FloatField(**options)
```

A floating-point number represented in Python by a float instance.

The default form widget for this field is a **NumberInput** when **localize** is False or **TextInput** otherwise.

**FloatField** vs. **DecimalField**

The **FloatField** class is sometimes mixed up with the **DecimalField** class. Although they both represent real numbers, they represent those numbers differently. **FloatField** uses Python’s float type internally, while **DecimalField** uses Python’s Decimal type. For information on the difference between the two, see Python’s documentation for the decimal module.

**GenericIPAddressField**

```python
class GenericIPAddressField(protocol='both', unpack_ipv4=False, **options)
```

An IPv4 or IPv6 address, in string format (e.g. 192.0.2.30 or 2a02:42fe::4). The default form widget for this field is a **TextInput**.

The IPv6 address normalization follows RFC 4291#section-2.2 section 2.2, including using the IPv4 format suggested in paragraph 3 of that section, like ::ffff:192.0.2.0. For example, 2001:0::0:01 would be normalized to 2001::1, and ::ffff:0a0a:0a0a to ::ffff:10.10.10.10. All characters are converted to lowercase.
GenericIPAddressField.protocol

Limits valid inputs to the specified protocol. Accepted values are ‘both’ (default), ‘IPv4’ or ‘IPv6’. Matching is case insensitive.

GenericIPAddressField.unpack_ipv4

Unpacks IPv4 mapped addresses like ::ffff:192.0.2.1. If this option is enabled that address would be unpacked to 192.0.2.1. Default is disabled. Can only be used when protocol is set to ‘both’.

If you allow for blank values, you have to allow for null values since blank values are stored as null.

ImageField

class ImageField(upload_to=None, height_field=None, width_field=None, max_length=100, **options)

Inherits all attributes and methods from FileField, but also validates that the uploaded object is a valid image.

In addition to the special attributes that are available for FileField, an ImageField also has height and width attributes.

To facilitate querying on those attributes, ImageField has the following optional arguments:

ImageField.height_field

Name of a model field which will be auto-populated with the height of the image each time the model instance is saved.

ImageField.width_field

Name of a model field which will be auto-populated with the width of the image each time the model instance is saved.

Requires the Pillow library.

ImageField instances are created in your database as varchar columns with a default max length of 100 characters. As with other fields, you can change the maximum length using the max_length argument.

The default form widget for this field is a ClearableFileInput.

IntegerField

class IntegerField(**options)

An integer. Values from −2147483648 to 2147483647 are safe in all databases supported by Django.

It uses MinValueValidator and MaxValueValidator to validate the input based on the values that the default database supports.

The default form widget for this field is a NumberInput when localize is False or TextInput otherwise.
JSONField

class JSONField(encoder=None, decoder=None, **options)

A field for storing JSON encoded data. In Python the data is represented in its Python native format: dictionaries, lists, strings, numbers, booleans and None.

JSONField is supported on MariaDB, MySQL 5.7.8+, Oracle, PostgreSQL, and SQLite (with the JSON1 extension enabled).

**JSONField.encoder**

An optional `json.JSONEncoder` subclass to serialize data types not supported by the standard JSON serializer (e.g. `datetime.datetime` or `UUID`). For example, you can use the `DjangoJSONEncoder` class.

Defaults to `json.JSONEncoder`.

**JSONField.decoder**

An optional `json.JSONDecoder` subclass to deserialize the value retrieved from the database. The value will be in the format chosen by the custom encoder (most often a string). Your deserialization may need to account for the fact that you can’t be certain of the input type. For example, you run the risk of returning a `datetime` that was actually a string that just happened to be in the same format chosen for `datetimes`.

Defaults to `json.JSONDecoder`.

If you give the field a `default`, ensure it’s an immutable object, such as a `str`, or a callable object that returns a fresh mutable object each time, such as `dict` or a function. Providing a mutable default object like `default={}` or `default=[]` shares the one object between all model instances.

To query JSONField in the database, see Querying JSONField.

---

**Indexing**

`Index` and `Field.db_index` both create a B-tree index, which isn’t particularly helpful when querying JSONField. On PostgreSQL only, you can use `GinIndex` that is better suited.

---

**PostgreSQL users**

PostgreSQL has two native JSON based data types: `json` and `jsonb`. The main difference between them is how they are stored and how they can be queried. PostgreSQL’s `json` field is stored as the original string representation of the JSON and must be decoded on the fly when queried based on keys. The `jsonb` field is stored based on the actual structure of the JSON which allows indexing. The trade-off is a small additional cost on writing to the `jsonb` field. JSONField uses `jsonb`. 
Oracle users

Oracle Database does not support storing JSON scalar values. Only JSON objects and arrays (represented in Python using `dict` and `list`) are supported.

**PositiveBigIntegerField**

```python
class PositiveBigIntegerField(**options)
```

Like a `PositiveIntegerField`, but only allows values under a certain (database-dependent) point. Values from 0 to 9223372036854775807 are safe in all databases supported by Django.

**PositiveIntegerField**

```python
class PositiveIntegerField(**options)
```

Like an `IntegerField`, but must be either positive or zero (0). Values from 0 to 2147483647 are safe in all databases supported by Django. The value 0 is accepted for backward compatibility reasons.

**PositiveSmallIntegerField**

```python
class PositiveSmallIntegerField(**options)
```

Like a `PositiveIntegerField`, but only allows values under a certain (database-dependent) point. Values from 0 to 32767 are safe in all databases supported by Django.

**SlugField**

```python
class SlugField(max_length=50, **options)
```

Slug is a newspaper term. A slug is a short label for something, containing only letters, numbers, underscores or hyphens. They’re generally used in URLs.

Like a CharField, you can specify `max_length` (read the note about database portability and `max_length` in that section, too). If `max_length` is not specified, Django will use a default length of 50.

Implies setting `Field.db_index` to True.

It is often useful to automatically prepopulate a SlugField based on the value of some other value. You can do this automatically in the admin using `prepopulated_fields`.

It uses `validate_slug` or `validate_unicode_slug` for validation.
SlugField.allow_unicode

If True, the field accepts Unicode letters in addition to ASCII letters. Defaults to False.

SmallAutoField

class SmallAutoField(**options)

Like an AutoField, but only allows values under a certain (database-dependent) limit. Values from 1 to 32767 are safe in all databases supported by Django.

SmallIntegerField

class SmallIntegerField(**options)

Like an IntegerField, but only allows values under a certain (database-dependent) point. Values from -32768 to 32767 are safe in all databases supported by Django.

TextField

class TextField(**options)

A large text field. The default form widget for this field is a Textarea.

If you specify a max_length attribute, it will be reflected in the Textarea widget of the auto-generated form field. However it is not enforced at the model or database level. Use a CharField for that.

TextField.db_collation

The database collation name of the field.

Note: Collation names are not standardized. As such, this will not be portable across multiple database backends.

Oracle

Oracle does not support collations for a TextField.
TimeField

```python
class TimeField(auto_now=False, auto_now_add=False, **options)
```

A time, represented in Python by a `datetime.time` instance. Accepts the same auto-population options as `DateField`.

The default form widget for this field is a `TimeInput`. The admin adds some JavaScript shortcuts.

URLField

```python
class URLField(max_length=200, **options)
```

A `CharField` for a URL, validated by `URLValidator`.

The default form widget for this field is a `URLInput`.

Like all `CharField` subclasses, `URLField` takes the optional `max_length` argument. If you don’t specify `max_length`, a default of 200 is used.

UUIDField

```python
class UUIDField(**options)
```

A field for storing universally unique identifiers. Uses Python’s `UUID` class. When used on PostgreSQL, this stores in a `uuid` datatype, otherwise in a `char(32)`.

Universally unique identifiers are a good alternative to `AutoField` for `primary_key`. The database will not generate the UUID for you, so it is recommended to use `default`:

```python
import uuid
from django.db import models

class MyUUIDModel(models.Model):
    id = models.UUIDField(primary_key=True, default=uuid.uuid4, editable=False)
    # other fields
```

Note that a callable (with the parentheses omitted) is passed to `default`, not an instance of UUID.

Lookups on PostgreSQL

Using `iexact`, `contains`, `icontains`, `startswith`, `istartswith`, `endswith`, or `iendswith` lookups on PostgreSQL don’t work for values without hyphens, because PostgreSQL stores them in a hyphenated uuid datatype type.
Relationship fields

Django also defines a set of fields that represent relations.

ForeignKey

class ForeignKey(to, on_delete, **options)

A many-to-one relationship. Requires two positional arguments: the class to which the model is related and the on_delete option.

To create a recursive relationship—an object that has a many-to-one relationship with itself—use models.ForeignKey('self', on_delete=models.CASCADE).

If you need to create a relationship on a model that has not yet been defined, you can use the name of the model, rather than the model object itself:

from django.db import models
class Car(models.Model):
    manufacturer = models.ForeignKey(
        'Manufacturer',
        on_delete=models.CASCADE,
    )
    # ...

class Manufacturer(models.Model):
    # ...
    pass

Relationships defined this way on abstract models are resolved when the model is subclassed as a concrete model and are not relative to the abstract model’s app_label:

Listing 11: products/models.py

from django.db import models
class AbstractCar(models.Model):
    manufacturer = models.ForeignKey('Manufacturer', on_delete=models.CASCADE)

    class Meta:
        abstract = True
from django.db import models
from products.models import AbstractCar

class Manufacturer(models.Model):
    pass

class Car(AbstractCar):
    pass

# Car.manufacturer will point to 'production.Manufacturer' here.

To refer to models defined in another application, you can explicitly specify a model with the full application label. For example, if the Manufacturer model above is defined in another application called production, you’d need to use:

class Car(models.Model):
    manufacturer = models.ForeignKey(
        'production.Manufacturer',
        on_delete=models.CASCADE,
    )

This sort of reference, called a lazy relationship, can be useful when resolving circular import dependencies between two applications.

A database index is automatically created on the ForeignKey. You can disable this by setting `db_index` to `False`. You may want to avoid the overhead of an index if you are creating a foreign key for consistency rather than joins, or if you will be creating an alternative index like a partial or multiple column index.

**Database Representation**

Behind the scenes, Django appends ".id" to the field name to create its database column name. In the above example, the database table for the Car model will have a manufacturer_id column. (You can change this explicitly by specifying `db_column`) However, your code should never have to deal with the database column name, unless you write custom SQL. You’ll always deal with the field names of your model object.
Arguments

ForeignKey accepts other arguments that define the details of how the relation works.

ForeignKey.on_delete

When an object referenced by a ForeignKey is deleted, Django will emulate the behavior of the SQL constraint specified by the on_delete argument. For example, if you have a nullable ForeignKey and you want it to be set null when the referenced object is deleted:

```python
user = models.ForeignKey(
    User,
    models.SET_NULL,
    blank=True,
    null=True,
)
```

on_delete doesn’t create an SQL constraint in the database. Support for database-level cascade options may be implemented later.

The possible values for on_delete are found in django.db.models:

- **CASCADE**
  
  Cascade deletes. Django emulates the behavior of the SQL constraint ON DELETE CASCADE and also deletes the object containing the ForeignKey.
  
  `Model.delete()` isn’t called on related models, but the pre_delete and post_delete signals are sent for all deleted objects.

- **PROTECT**
  
  Prevent deletion of the referenced object by raising ProtectedError, a subclass of django.db.IntegrityError.

- **RESTRICT**
  
  Prevent deletion of the referenced object by raising RestrictedError (a subclass of django.db.IntegrityError). Unlike PROTECT, deletion of the referenced object is allowed if it also references a different object that is being deleted in the same operation, but via a CASCADE relationship.

Consider this set of models:

```python
class Artist(models.Model):
    name = models.CharField(max_length=10)

class Album(models.Model):
    artist = models.ForeignKey(Artist, on_delete=models.CASCADE)

class Song(models.Model):
```

(continues on next page)
Artist can be deleted even if that implies deleting an Album which is referenced by a Song, because Song also references Artist itself through a cascading relationship. For example:

```python
>>> artist_one = Artist.objects.create(name='artist one')
>>> artist_two = Artist.objects.create(name='artist two')
>>> album_one = Album.objects.create(artist=artist_one)
>>> album_two = Album.objects.create(artist=artist_two)
>>> song_one = Song.objects.create(artist=artist_one, album=album_one)
>>> song_two = Song.objects.create(artist=artist_one, album=album_two)
>>> album_one.delete()
# Raises RestrictedError.
>>> artist_two.delete()
# Raises RestrictedError.
>>> artist_one.delete()
(4, {'Song': 2, 'Album': 1, 'Artist': 1})
```

- **SET_NULL**
  
  Set the `ForeignKey` null; this is only possible if `null` is True.

- **SET_DEFAULT**
  
  Set the `ForeignKey` to its default value; a default for the `ForeignKey` must be set.

- **SET()**
  
  Set the `ForeignKey` to the value passed to `SET()`, or if a callable is passed in, the result of calling it. In most cases, passing a callable will be necessary to avoid executing queries at the time your models.py is imported:

```python
from django.conf import settings
from django.contrib.auth import get_user_model
from django.db import models

def get_sentinel_user():
    return get_user_model().objects.get_or_create(username='deleted')[0]

class MyModel(models.Model):
    user = models.ForeignKey(
        settings.AUTH_USER_MODEL,
        on_delete=models.SET(get_sentinel_user),
    )
```

- **DO NOTHING**
Take no action. If your database backend enforces referential integrity, this will cause an `IntegrityError` unless you manually add an SQL ON DELETE constraint to the database field.

**ForeignKey.limit_choices_to**

Sets a limit to the available choices for this field when this field is rendered using a `ModelForm` or the admin (by default, all objects in the queryset are available to choose). Either a dictionary, a `Q` object, or a callable returning a dictionary or `Q` object can be used.

For example:

```python
staff_member = models.ForeignKey(
    User,
    on_delete=models.CASCADE,
    limit_choices_to={'is_staff': True},
)
```

causes the corresponding field on the `ModelForm` to list only `Users` that have `is_staff=True`. This may be helpful in the Django admin.

The callable form can be helpful, for instance, when used in conjunction with the Python `datetime` module to limit selections by date range. For example:

```python
def limit_pub_date_CHOICES():
    return {'pub_date__lte': datetime.date.today()}

limit_choices_to = limit_pub_date_CHOICES
```

If `limit_choices_to` is or returns a `Q` object, which is useful for complex queries, then it will only have an effect on the choices available in the admin when the field is not listed in `raw_id_fields` in the `ModelAdmin` for the model.

Note: If a callable is used for `limit_choices_to`, it will be invoked every time a new form is instantiated. It may also be invoked when a model is validated, for example by management commands or the admin. The admin constructs querysets to validate its form inputs in various edge cases multiple times, so there is a possibility your callable may be invoked several times.

**ForeignKey.related_name**

The name to use for the relation from the related object back to this one. It’s also the default value for `related_query_name` (the name to use for the reverse filter name from the target model). See the related objects documentation for a full explanation and example. Note that you must set this value when defining relations on abstract models; and when you do so some special syntax is available.

If you’d prefer Django not to create a backwards relation, set `related_name` to `'+'` or end it with `'+'`. For example, this will ensure that the `User` model won’t have a backwards relation to this model:
ForeignKey.related_query_name

The name to use for the reverse filter name from the target model. It defaults to the value of related_name or default_related_name if set, otherwise it defaults to the name of the model:

```python
# Declare the ForeignKey with related_query_name
class Tag(models.Model):
    article = models.ForeignKey(
        Article,
        on_delete=models.CASCADE,
        related_name="tags",
        related_query_name="tag",
    )
    name = models.CharField(max_length=255)

# That's now the name of the reverse filter
Article.objects.filter(tag__name="important")
```

Like related_name, related_query_name supports app label and class interpolation via some special syntax.

ForeignKey.to_field

The field on the related object that the relation is to. By default, Django uses the primary key of the related object. If you reference a different field, that field must have unique=True.

ForeignKey.db_constraint

Controls whether or not a constraint should be created in the database for this foreign key. The default is True, and that’s almost certainly what you want; setting this to False can be very bad for data integrity. That said, here are some scenarios where you might want to do this:

- You have legacy data that is not valid.
- You’re sharding your database.

If this is set to False, accessing a related object that doesn’t exist will raise its DoesNotExist exception.

ForeignKey.swappable

Controls the migration framework’s reaction if this ForeignKey is pointing at a swappable model. If it is True - the default - then if the ForeignKey is pointing at a model which matches the current value of settings.AUTH_USER_MODEL (or another swappable model setting) the relationship will be stored in the migration using a reference to the setting, not to the model directly.
You only want to override this to be False if you are sure your model should always point toward the swapped-in model - for example, if it is a profile model designed specifically for your custom user model.

Setting it to False does not mean you can reference a swappable model even if it is swapped out - False means that the migrations made with this ForeignKey will always reference the exact model you specify (so it will fail hard if the user tries to run with a User model you don’t support, for example).

If in doubt, leave it to its default of True.

ManyToManyField

class ManyToManyField(to, **options)

A many-to-many relationship. Requires a positional argument: the class to which the model is related, which works exactly the same as it does for ForeignKey, including recursive and lazy relationships.

Related objects can be added, removed, or created with the field’s RelatedManager.

Database Representation

Behind the scenes, Django creates an intermediary join table to represent the many-to-many relationship. By default, this table name is generated using the name of the many-to-many field and the name of the table for the model that contains it. Since some databases don’t support table names above a certain length, these table names will be automatically truncated and a uniqueness hash will be used, e.g. author_books_9cdf. You can manually provide the name of the join table using the db_table option.

Arguments

ManyToManyField accepts an extra set of arguments – all optional – that control how the relationship functions.

ManyToManyField.related_name

Same as ForeignKey.related_name.

ManyToManyField.related_query_name

Same as ForeignKey.related_query_name.

ManyToManyField.limit_choices_to

Same as ForeignKey.limit_choices_to.

ManyToManyField.symmetrical

Only used in the definition of ManyToManyFields on self. Consider the following model:
from django.db import models

class Person(models.Model):
    friends = models.ManyToManyField("self")

When Django processes this model, it identifies that it has a ManyToManyField on itself, and as a result, it doesn’t add a person_set attribute to the Person class. Instead, the ManyToManyField is assumed to be symmetrical—that is, if I am your friend, then you are my friend.

If you do not want symmetry in many-to-many relationships with self, set symmetrical to False. This will force Django to add the descriptor for the reverse relationship, allowing ManyToManyField relationships to be non-symmetrical.

ManyToManyField.through

Django will automatically generate a table to manage many-to-many relationships. However, if you want to manually specify the intermediary table, you can use the through option to specify the Django model that represents the intermediate table that you want to use.

The most common use for this option is when you want to associate extra data with a many-to-many relationship.

Note: If you don’t want multiple associations between the same instances, add a UniqueConstraint including the from and to fields. Django’s automatically generated many-to-many tables include such a constraint.

Note: Recursive relationships using an intermediary model can’t determine the reverse accessor names, as they would be the same. You need to set a related_name to at least one of them. If you’d prefer Django not to create a backwards relation, set related_name to ‘+’.

If you don’t specify an explicit through model, there is still an implicit through model class you can use to directly access the table created to hold the association. It has three fields to link the models.

If the source and target models differ, the following fields are generated:

- id: the primary key of the relation.
- <containing_model>_id: the id of the model that declares the ManyToManyField.
- <other_model>_id: the id of the model that the ManyToManyField points to.

If the ManyToManyField points from and to the same model, the following fields are generated:

- id: the primary key of the relation.
- from_<model>_id: the id of the instance which points at the model (i.e. the source instance).
• to_<model>_id: the id of the instance to which the relationship points (i.e. the target model instance).

This class can be used to query associated records for a given model instance like a normal model:

```python
Model.m2mfield.through.objects.all()
```

**ManyToManyField.through_fields**

Only used when a custom intermediary model is specified. Django will normally determine which fields of the intermediary model to use in order to establish a many-to-many relationship automatically. However, consider the following models:

```python
from django.db import models

class Person(models.Model):
    name = models.CharField(max_length=50)

class Group(models.Model):
    name = models.CharField(max_length=128)
    members = models.ManyToManyField(
        Person,
        through='Membership',
        through_fields=('group', 'person'),
    )

class Membership(models.Model):
    group = models.ForeignKey(Group, on_delete=models.CASCADE)
    person = models.ForeignKey(Person, on_delete=models.CASCADE)
    inviter = models.ForeignKey(
        Person,
        on_delete=models.CASCADE,
        related_name="membership_invites",
    )
    invite_reason = models.CharField(max_length=64)
```

`Membership` has two foreign keys to `Person` (person and inviter), which makes the relationship ambiguous and Django can’t know which one to use. In this case, you must explicitly specify which foreign keys Django should use using `through_fields`, as in the example above.

`through_fields` accepts a 2-tuple (‘field1’, ‘field2’), where `field1` is the name of the foreign key to the model the `ManyToManyField` is defined on (group in this case), and `field2` the name of the foreign key to the target model (person in this case).

When you have more than one foreign key on an intermediary model to any (or even both) of the models participating in a many-to-many relationship, you must specify `through_fields`. This also applies to recursive relationships when an intermediary model is used and there are more than two foreign keys.
to the model, or you want to explicitly specify which two Django should use.

**ManyToManyField.db_table**

The name of the table to create for storing the many-to-many data. If this is not provided, Django will assume a default name based upon the names of: the table for the model defining the relationship and the name of the field itself.

**ManyToManyField.db_constraint**

Controls whether or not constraints should be created in the database for the foreign keys in the intermediary table. The default is True, and that’s almost certainly what you want; setting this to False can be very bad for data integrity. That said, here are some scenarios where you might want to do this:

- You have legacy data that is not valid.
- You’re sharding your database.

It is an error to pass both `db_constraint` and `through`.

**ManyToManyField.swappable**

Controls the migration framework’s reaction if this `ManyToManyField` is pointing at a swappable model. If it is True - the default - then if the `ManyToManyField` is pointing at a model which matches the current value of `settings.AUTH_USER_MODEL` (or another swappable model setting) the relationship will be stored in the migration using a reference to the setting, not to the model directly.

You only want to override this to be False if you are sure your model should always point toward the swapped-in model - for example, if it is a profile model designed specifically for your custom user model.

If in doubt, leave it to its default of True.

*ManyToOneField* does not support *validators.*

*null* has no effect since there is no way to require a relationship at the database level.

**OneToOneField**

**class OneToOneField**(to, on_delete, parent_link=False, **options)**

A one-to-one relationship. Conceptually, this is similar to a `ForeignKey` with `unique=True`, but the “reverse” side of the relation will directly return a single object.

This is most useful as the primary key of a model which “extends” another model in some way; *Multi-table inheritance* is implemented by adding an implicit one-to-one relation from the child model to the parent model, for example.

One positional argument is required: the class to which the model will be related. This works exactly the same as it does for `ForeignKey`, including all the options regarding *recursive* and *lazy* relationships.
If you do not specify the `related_name` argument for the `OneToOneField`, Django will use the lowercase name of the current model as default value.

With the following example:

```python
from django.conf import settings
from django.db import models

class MySpecialUser(models.Model):
    user = models.OneToOneField(
        settings.AUTH_USER_MODEL,
        on_delete=models.CASCADE,
    )
    supervisor = models.OneToOneField(
        settings.AUTH_USER_MODEL,
        on_delete=models.CASCADE,
        related_name='supervisor_of',
    )
```

your resulting User model will have the following attributes:

```python
>>> user = User.objects.get(pk=1)
>>> hasattr(user, 'myspecialuser')
True
>>> hasattr(user, 'supervisor_of')
True
```

A `RelatedObjectDoesNotExist` exception is raised when accessing the reverse relationship if an entry in the related table doesn’t exist. This is a subclass of the target model’s `Model.DoesNotExist` exception. For example, if a user doesn’t have a supervisor designated by `MySpecialUser`:

```python
>>> user.supervisor_of
Traceback (most recent call last):
  ...
RelatedObjectDoesNotExist: User has no supervisor_of.
```

Additionally, `OneToOneField` accepts all of the extra arguments accepted by `ForeignKey`, plus one extra argument:

`OneToOneField.parent_link`

When `True` and used in a model which inherits from another `concrete model`, indicates that this field should be used as the link back to the parent class, rather than the extra `OneToOneField` which would normally be implicitly created by subclassing.

See One-to-one relationships for usage examples of `OneToOneField`. 

1572 Chapter 6. API Reference
Field API reference

class Field

Field is an abstract class that represents a database table column. Django uses fields to create the
database table (\texttt{db\_type()}), to map Python types to database (\texttt{get\_prep\_value()}) and vice-versa
(\texttt{from\_db\_value()}).

A field is thus a fundamental piece in different Django APIs, notably, \texttt{models} and \texttt{querysets}.

In models, a field is instantiated as a class attribute and represents a particular table column, see \texttt{Models}.
It has attributes such as \texttt{null} and \texttt{unique}, and methods that Django uses to map the field value to
database-specific values.

A Field is a subclass of \texttt{RegisterLookupMixin} and thus both \texttt{Transform} and \texttt{Lookup} can be registered
on it to be used in \texttt{QuerySets} (e.g. \texttt{field\_name\_\_exact="foo"}). All built-in lookups are registered by
default.

All of Django’s built-in fields, such as \texttt{CharField}, are particular implementations of Field. If you
need a custom field, you can either subclass any of the built-in fields or write a \texttt{Field} from scratch. In
either case, see \texttt{How to create custom model fields}.

description

A verbose description of the field, e.g. for the \texttt{django.contrib.admindocs} application.

The description can be of the form:

\begin{verbatim}
    description = _("String (up to %(max_length)s)"")
\end{verbatim}

where the arguments are interpolated from the field’s \texttt{__dict__}.

descriptor_class

A class implementing the descriptor protocol that is instantiated and assigned to the model in-
stance attribute. The constructor must accept a single argument, the Field instance. Overriding
this class attribute allows for customizing the get and set behavior.

To map a Field to a database-specific type, Django exposes several methods:

get\_internal\_type()

Returns a string naming this field for backend specific purposes. By default, it returns the class
name.

See \texttt{Emulating built-in field types} for usage in custom fields.

db\_type\((\texttt{connection})\)

Returns the database column data type for the Field, taking into account the \texttt{connection}.

See \texttt{Custom database types} for usage in custom fields.
rel_db_type(connection)

Returns the database column data type for fields such as ForeignKey and OneToOneField that point to the Field, taking into account the connection.

See Custom database types for usage in custom fields.

There are three main situations where Django needs to interact with the database backend and fields:

• when it queries the database (Python value -> database backend value)
• when it loads data from the database (database backend value -> Python value)
• when it saves to the database (Python value -> database backend value)

When querying, get_db_prep_value() and get_prep_value() are used:

get_prep_value(value)

value is the current value of the model’s attribute, and the method should return data in a format that has been prepared for use as a parameter in a query.

See Converting Python objects to query values for usage.

get_db_prep_value(value, connection, prepared=False)

Converts value to a backend-specific value. By default it returns value if prepared=True and get_prep_value() if is False.

See Converting query values to database values for usage.

When loading data, from_db_value() is used:

from_db_value(value, expression, connection)

Converts a value as returned by the database to a Python object. It is the reverse of get_prep_value().

This method is not used for most built-in fields as the database backend already returns the correct Python type, or the backend itself does the conversion.

expression is the same as self.

See Converting values to Python objects for usage.

Note: For performance reasons, from_db_value is not implemented as a no-op on fields which do not require it (all Django fields). Consequently you may not call super in your definition.

When saving, pre_save() and get_db_prep_save() are used:

get_db_prep_save(value, connection)

Same as the get_db_prep_value(), but called when the field value must be saved to the database.
By default returns get_db_prep_value().
pre_save(model_instance, add)

Method called prior to get_db_prep_save() to prepare the value before being saved (e.g. for DateField.auto_now).

model_instance is the instance this field belongs to and add is whether the instance is being saved to the database for the first time.

It should return the value of the appropriate attribute from model_instance for this field. The attribute name is in self.attname (this is set up by Field).

See Preprocessing values before saving for usage.

Fields often receive their values as a different type, either from serialization or from forms.

to_python(value)

Converts the value into the correct Python object. It acts as the reverse of value_to_string(), and is also called in clean().

See Converting values to Python objects for usage.

Besides saving to the database, the field also needs to know how to serialize its value:

value_from_object(obj)

Returns the field’s value for the given model instance.

This method is often used by value_to_string().

value_to_string(obj)

Converts obj to a string. Used to serialize the value of the field.

See Converting field data for serialization for usage.

When using model forms, the Field needs to know which form field it should be represented by:

formfield(form_class=None, choices_form_class=None, **kwargs)

Returns the default django.forms.Field of this field for ModelForm.

By default, if both form_class and choices_form_class are None, it uses CharField. If the field has choices and choices_form_class isn’t specified, it uses TypedChoiceField.

See Specifying the form field for a model field for usage.

decompose()

Returns a 4-tuple with enough information to recreate the field:

1. The name of the field on the model.
2. The import path of the field (e.g. "django.db.models.IntegerField"). This should be the most portable version, so less specific may be better.
3. A list of positional arguments.
4. A dict of keyword arguments.
This method must be added to fields prior to 1.7 to migrate its data using Migrations.

### 6.16.2 Field attribute reference

Every Field instance contains several attributes that allow introspecting its behavior. Use these attributes instead of `isinstance` checks when you need to write code that depends on a field’s functionality. These attributes can be used together with the Model._meta API to narrow down a search for specific field types. Custom model fields should implement these flags.

#### Attributes for fields

**Field.auto_created**

Boolean flag that indicates if the field was automatically created, such as the OneToOneField used by model inheritance.

**Field.concrete**

Boolean flag that indicates if the field has a database column associated with it.

**Field.hidden**

Boolean flag that indicates if a field is used to back another non-hidden field’s functionality (e.g. the content_type and object_id fields that make up a GenericForeignKey). The hidden flag is used to distinguish what constitutes the public subset of fields on the model from all the fields on the model.

---

Note: `Options.get_fields()` excludes hidden fields by default. Pass in `include_hidden=True` to return hidden fields in the results.

---

**Field.is_relation**

Boolean flag that indicates if a field contains references to one or more other models for its functionality (e.g. ForeignKey, ManyToManyField, OneToOneField, etc.).

**Field.model**

Returns the model on which the field is defined. If a field is defined on a superclass of a model, `model` will refer to the superclass, not the class of the instance.
Attributes for fields with relations

These attributes are used to query for the cardinality and other details of a relation. These attributes are present on all fields; however, they will only have boolean values (rather than None) if the field is a relation type (Field.is_relation=True).

Field.many_to_many

   Boolean flag that is True if the field has a many-to-many relation; False otherwise. The only field included with Django where this is True is ManyToManyField.

Field.many_to_one

   Boolean flag that is True if the field has a many-to-one relation, such as a ForeignKey; False otherwise.

Field.one_to_many

   Boolean flag that is True if the field has a one-to-many relation, such as a GenericRelation or the reverse of a ForeignKey; False otherwise.

Field.one_to_one

   Boolean flag that is True if the field has a one-to-one relation, such as a OneToOneField; False otherwise.

Field.related_model

   Points to the model the field relates to. For example, Author in ForeignKey(Author, on_delete=models.CASCADE). The related_model for a GenericForeignKey is always None.

6.16.3 Model index reference

Index classes ease creating database indexes. They can be added using the Meta.indexes option. This document explains the API references of Index which includes the index options.

Referencing built-in indexes

Indexes are defined in django.db.models.indexes, but for convenience they’re imported into django.db.models. The standard convention is to use from django.db import models and refer to the indexes as models.<IndexClass>.
Index options

class Index(*expressions, fields=(), name=None, db_tablespace=None, opclasses=(), condition=None, include=None)

Creates an index (B-Tree) in the database.

expressions

Index.expressions

Positional argument *expressions allows creating functional indexes on expressions and database functions.

For example:

```
Index(Lower('title').desc(), 'pub_date', name='lower_title_date_idx')
```

creates an index on the lowercased value of the title field in descending order and the pub_date field in the default ascending order.

Another example:

```
Index(F('height') * F('weight'), Round('weight'), name='calc_idx')
```

creates an index on the result of multiplying fields height and weight and the weight rounded to the nearest integer.

Index.name is required when using *expressions.

Restrictions on Oracle

Oracle requires functions referenced in an index to be marked as DETERMINISTIC. Django doesn’t validate this but Oracle will error. This means that functions such as Random() aren’t accepted.

Restrictions on PostgreSQL

PostgreSQL requires functions and operators referenced in an index to be marked as IMMUTABLE. Django doesn’t validate this but PostgreSQL will error. This means that functions such as Concat() aren’t accepted.

MySQL and MariaDB

Functional indexes are ignored with MySQL < 8.0.13 and MariaDB as neither supports them.
**fields**

Index.fields

A list or tuple of the name of the fields on which the index is desired.

By default, indexes are created with an ascending order for each column. To define an index with a descending order for a column, add a hyphen before the field’s name.

For example `Index(fields=['headline', '-pub_date'])` would create SQL with (headline, pub_date DESC).

---

**MySQL and MariaDB**

Index ordering isn’t supported on MySQL < 8.0.1 and MariaDB < 10.8. In that case, a descending index is created as a normal index.

---

**name**

Index.name

The name of the index. If name isn’t provided Django will auto-generate a name. For compatibility with different databases, index names cannot be longer than 30 characters and shouldn’t start with a number (0-9) or underscore (_).

---

Partial indexes in abstract base classes

You must always specify a unique name for an index. As such, you cannot normally specify a partial index on an abstract base class, since the `Meta.indexes` option is inherited by subclasses, with exactly the same values for the attributes (including name) each time. To work around name collisions, part of the name may contain '%(app_label)s' and '%(class)s', which are replaced, respectively, by the lowercased app label and class name of the concrete model. For example `Index(fields=['title'], name='%(app_label)s_%(class)s_title_index')`.

---

**db_tablespace**

Index.db_tablespace

The name of the database tablespace to use for this index. For single field indexes, if db_tablespace isn’t provided, the index is created in the db_tablespace of the field.
If `Field.db_tablespace` isn’t specified (or if the index uses multiple fields), the index is created in tablespace specified in the `db_tablespace` option inside the model’s class `Meta`. If neither of those tablespaces are set, the index is created in the same tablespace as the table.

See also:

For a list of PostgreSQL-specific indexes, see `django.contrib.postgres.indexes`.

**opclasses**

**Index.opclasses**

The names of the PostgreSQL operator classes to use for this index. If you require a custom operator class, you must provide one for each field in the index.

For example, `GinIndex(name='json_index', fields=['jsonfield'], opclasses=['jsonb_path_ops'])` creates a gin index on `jsonfield` using `jsonb_path_ops`.

`opclasses` are ignored for databases besides PostgreSQL.

`Index.name` is required when using `opclasses`.

**condition**

**Index.condition**

If the table is very large and your queries mostly target a subset of rows, it may be useful to restrict an index to that subset. Specify a condition as a `Q`. For example, `condition=Q(pages__gt=400)` indexes records with more than 400 pages.

`Index.name` is required when using `condition`.

---

**Restrictions on PostgreSQL**

PostgreSQL requires functions referenced in the condition to be marked as IMMUTABLE. Django doesn’t validate this but PostgreSQL will error. This means that functions such as `Date functions` and `Concat` aren’t accepted. If you store dates in `DateTimeField`, comparison to `datetime` objects may require the `tzinfo` argument to be provided because otherwise the comparison could result in a mutable function due to the casting Django does for `lookups`.

---

**Restrictions on SQLite**

SQLite imposes restrictions on how a partial index can be constructed.
Oracle

Oracle does not support partial indexes. Instead, partial indexes can be emulated by using functional indexes together with `Case` expressions.

MySQL and MariaDB

The `condition` argument is ignored with MySQL and MariaDB as neither supports conditional indexes.

`include`

`Index.include`

A list or tuple of the names of the fields to be included in the covering index as non-key columns. This allows index-only scans to be used for queries that select only included fields (`include`) and filter only by indexed fields (`fields`).

For example:

```python
Index(name='covering_index', fields=['headline'], include=['pub_date'])
```

will allow filtering on `headline`, also selecting `pub_date`, while fetching data only from the index.

Using `include` will produce a smaller index than using a multiple column index but with the drawback that non-key columns can not be used for sorting or filtering.

`include` is ignored for databases besides PostgreSQL.

`Index.name` is required when using `include`.

See the PostgreSQL documentation for more details about covering indexes.

Restrictions on PostgreSQL

PostgreSQL supports covering B-Tree and `GiST indexes`. PostgreSQL 14+ also supports covering `SP-GiST indexes`.

Support for covering SP-GiST indexes with PostgreSQL 14+ was added.
6.16.4 Constraints reference

The classes defined in this module create database constraints. They are added in the model `Meta.constraints` option.

Referencing built-in constraints

Constraints are defined in `django.db.models.constraints`, but for convenience they’re imported into `django.db.models`. The standard convention is to use `from django.db import models` and refer to the constraints as `models.<Foo>Constraint`.

Constraints in abstract base classes

You must always specify a unique name for the constraint. As such, you cannot normally specify a constraint on an abstract base class, since the `Meta.constraints` option is inherited by subclasses, with exactly the same values for the attributes (including `name`) each time. To work around name collisions, part of the name may contain '%(app_label)s' and '%(class)s', which are replaced, respectively, by the lowercased app label and class name of the concrete model. For example `CheckConstraint(check=Q(age__gte=18), name='%s_%s_is_adult')`.

Validation of Constraints

Constraints are checked during the model validation.

In older versions, constraints were not checked during model validation.

BaseConstraint

```python
class BaseConstraint(name, violation_error_message=None)

Base class for all constraints. Subclasses must implement `constraint_sql()`, `create_sql()`, `remove_sql()` and `validate()` methods.
```

All constraints have the following parameters in common:
name

BaseConstraint.name

The name of the constraint. You must always specify a unique name for the constraint.

violation_error_message

BaseConstraint violation_error_message

The error message used when ValidationError is raised during model validation. Defaults to "Constraint "%(name)s" is violated."

validate()

BaseConstraint validate(model, instance, exclude=None, using=DEFAULT_DB_ALIAS)

Validates that the constraint, defined on model, is respected on the instance. This will do a query on the database to ensure that the constraint is respected. If fields in the exclude list are needed to validate the constraint, the constraint is ignored.

Raise a ValidationError if the constraint is violated.

This method must be implemented by a subclass.

CheckConstraint

class CheckConstraint(*, check, name, violation_error_message=None)

    Creates a check constraint in the database.

check

CheckConstraint.check

A Q object or boolean Expression that specifies the check you want the constraint to enforce.

For example, CheckConstraint(check=Q(age__gte=18), name='age_gte_18') ensures the age field is never less than 18.

The violation_error_message argument was added.
UniqueConstraint

class UniqueConstraint(*expressions, fields=(), name=None, condition=None, deferrable=None, include=None, opclasses=(), violation_error_message=None)

    Creates a unique constraint in the database.

expressions

UniqueConstraint.expressions

Positional argument *expressions allows creating functional unique constraints on expressions and database functions.

For example:

```
UniqueConstraint(Lower('name').desc(), 'category', name='unique_lower_name_category')
```

creates a unique constraint on the lowercased value of the name field in descending order and the category field in the default ascending order.

Functional unique constraints have the same database restrictions as Index.expressions.

fields

UniqueConstraint.fields

A list of field names that specifies the unique set of columns you want the constraint to enforce.

For example, `UniqueConstraint(fields=['room', 'date'], name='unique_booking')` ensures each room can only be booked once for each date.

condition

UniqueConstraint.condition

A Q object that specifies the condition you want the constraint to enforce.

For example:

```
UniqueConstraint(fields=['user'], condition=Q(status='DRAFT'), name='unique_draft_user')
```

ensures that each user only has one draft.

These conditions have the same database restrictions as Index.condition.
deferrable

UniqueConstraint.deferrable

Set this parameter to create a deferrable unique constraint. Accepted values are `Deferrable.DEFERRED` or `Deferrable.IMMEDIATE`. For example:

```python
from django.db.models import Deferrable, UniqueConstraint

UniqueConstraint(
    name='unique_order',
    fields=['order'],
    deferrable=Deferrable.DEFERRED,
)
```

By default constraints are not deferred. A deferred constraint will not be enforced until the end of the transaction. An immediate constraint will be enforced immediately after every command.

MySQL, MariaDB, and SQLite.

Deferrable unique constraints are ignored on MySQL, MariaDB, and SQLite as neither supports them.

---

Warning: Deferred unique constraints may lead to a performance penalty.

include

UniqueConstraint.include

A list or tuple of the names of the fields to be included in the covering unique index as non-key columns. This allows index-only scans to be used for queries that select only included fields (`include`) and filter only by unique fields (`fields`).

For example:

```python
UniqueConstraint(name='unique_booking', fields=['room', 'date'], include=['full_name'])
```

will allow filtering on `room` and `date`, also selecting `full_name`, while fetching data only from the index.

`include` is supported only on PostgreSQL.

Non-key columns have the same database restrictions as `Index.include`.
opclasses

UniqueConstraint.opclasses

The names of the PostgreSQL operator classes to use for this unique index. If you require a custom operator class, you must provide one for each field in the index.

For example:

```python
UniqueConstraint(name='unique_username', fields=['username'], opclasses=['varchar_pattern_ops'])
```

creates a unique index on `username` using `varchar_pattern_ops`.

`opclasses` are ignored for databases besides PostgreSQL.

violation_error_message

UniqueConstraint.violation_error_message

The error message used when `ValidationError` is raised during model validation. Defaults to `BaseConstraint.violation_error_message`.

This message is not used for `UniqueConstraints` with `fields` and without a condition. Such `UniqueConstraints` show the same message as constraints defined with `Field.unique` or in `Meta.unique_together`.

6.16.5 Model _meta API

class Options

The model _meta API is at the core of the Django ORM. It enables other parts of the system such as lookups, queries, forms, and the admin to understand the capabilities of each model. The API is accessible through the _meta attribute of each model class, which is an instance of an `django.db.models.options.Options` object.

Methods that it provides can be used to:

- Retrieve all field instances of a model
- Retrieve a single field instance of a model by name
Field access API

Retrieving a single field instance of a model by name

Options.get_field(field_name)

Returns the field instance given a name of a field.

field_name can be the name of a field on the model, a field on an abstract or inherited model, or a field defined on another model that points to the model. In the latter case, the field_name will be (in order of preference) the related_query_name set by the user, the related_name set by the user, or the name automatically generated by Django.

Hidden fields cannot be retrieved by name.

If a field with the given name is not found a FieldDoesNotExist exception will be raised.

```python
>>> from django.contrib.auth.models import User

# A field on the model
>>> User._meta.get_field('username')
<django.db.models.fields.CharField: username>

# A field from another model that has a relation with the current model
>>> User._meta.get_field('logentry')
<ManyToOneRel: admin.logentry>

# A non existent field
>>> User._meta.get_field('does_not_exist')
FieldDoesNotExist: User has no field named 'does_not_exist'
```

Retrieving all field instances of a model

Options.get_fields(include_parents=True, include_hidden=False)

Returns a tuple of fields associated with a model. get_fields() accepts two parameters that can be used to control which fields are returned:

include_parents

True by default. Recursively includes fields defined on parent classes. If set to False, get_fields() will only search for fields declared directly on the current model. Fields from models that directly inherit from abstract models or proxy classes are considered to be local, not on the parent.
include_hidden

False by default. If set to True, get_fields() will include fields that are used to back other field’s functionality. This will also include any fields that have a related_name (such as ManyToManyField, or ForeignKey) that start with a “+”.

```python
>>> from django.contrib.auth.models import User
>>> User._meta.get_fields()
(<ManyToOneRel: admin.logentry>,
 <django.db.models.fields.AutoField: id>,
 <django.db.models.fields.CharField: password>,
 <django.db.models.fields.DateTimeField: last_login>,
 <django.db.models.fields.BooleanField: is_superuser>,
 <django.db.models.fields.CharField: username>,
 <django.db.models.fields.CharField: first_name>,
 <django.db.models.fields.CharField: last_name>,
 <django.db.models.fields.EmailField: email>,
 <django.db.models.fields[BooleanField: is_staff>,
 <django.db.models.fields[BooleanField: is_active>,
 <django.db.models.fields.DateTimeField: date_joined>,
 <django.db.models.fields.related.ManyToManyField: groups>,
 <django.db.models.fields.related.ManyToManyField: user_permissions>)

# Also include hidden fields.
>>> User._meta.get_fields(include_hidden=True)
(<ManyToOneRel: auth.user_groups>,
 <ManyToOneRel: auth.user_user_permissions>,
 <ManyToOneRel: admin.logentry>,
 <django.db.models.fields.AutoField: id>,
 <django.db.models.fields.CharField: password>,
 <django.db.models.fields.DateTimeField: last_login>,
 <django.db.models.fields[BooleanField: is_staff>,
 <django.db.models.fields[BooleanField: is_active>,
 <django.db.models.fields.DateTimeField: date_joined>,
 <django.db.models.fields.related.ManyToManyField: groups>,
 <django.db.models.fields.related.ManyToManyField: user_permissions>)
```
6.16.6 Related objects reference

class RelatedManager

A “related manager” is a manager used in a one-to-many or many-to-many related context. This happens in two cases:

- The “other side” of a ForeignKey relation. That is:

```python
from django.db import models

class Blog(models.Model):
    # ...
    pass

class Entry(models.Model):
    blog = models.ForeignKey(Blog, on_delete=models.CASCADE, null=True)
```

In the above example, the methods below will be available on the manager blog.entry_set.

- Both sides of a ManyToManyField relation:

```python
class Topping(models.Model):
    # ...
    pass

class Pizza(models.Model):
    toppings = models.ManyToManyField(Topping)
```

In this example, the methods below will be available both on topping.pizza_set and on pizza.toppings.

`add(*objs, bulk=True, through_defaults=None)`

Adds the specified model objects to the related object set.

Example:

```python
>>> b = Blog.objects.get(id=1)
>>> e = Entry.objects.get(id=234)
>>> b.entry_set.add(e) # Associates Entry e with Blog b.
```

In the example above, in the case of a ForeignKey relationship, `QuerySet.update()` is used to perform the update. This requires the objects to already be saved.

You can use the `bulk=False` argument to instead have the related manager perform the update by calling `e.save()`.

Using `add()` with a many-to-many relationship, however, will not call any `save()` methods (the `bulk` argument doesn’t exist), but rather create the relationships using `QuerySet.bulk_create()`.
If you need to execute some custom logic when a relationship is created, listen to the `m2m_changed` signal, which will trigger `pre_add` and `post_add` actions.

Using `add()` on a relation that already exists won’t duplicate the relation, but it will still trigger signals.

For many-to-many relationships `add()` accepts either model instances or field values, normally primary keys, as the `*objs` argument.

Use the `through_defaults` argument to specify values for the new intermediate model instance(s), if needed. You can use callables as values in the `through_defaults` dictionary and they will be evaluated once before creating any intermediate instance(s).

```python
create(through_defaults=None, **kwargs)
```

Creates a new object, saves it and puts it in the related object set. Returns the newly created object:

```python
>>> b = Blog.objects.get(id=1)
>>> e = b.entry_set.create(
...     headline='Hello',
...     body_text='Hi',
...     pub_date=datetime.date(2005, 1, 1)
... )

# No need to call e.save() at this point -- it's already been saved.
```

This is equivalent to (but simpler than):

```python
>>> b = Blog.objects.get(id=1)
>>> e = Entry(
...     blog=b,
...     headline='Hello',
...     body_text='Hi',
...     pub_date=datetime.date(2005, 1, 1)
... )

>>> e.save(force_insert=True)
```

Note that there’s no need to specify the keyword argument of the model that defines the relationship. In the above example, we don’t pass the parameter `blog` to `create()`. Django figures out that the new `Entry` object’s `blog` field should be set to `b`.

Use the `through_defaults` argument to specify values for the new intermediate model instance, if needed. You can use callables as values in the `through_defaults` dictionary.

```python
remove(*objs, bulk=True)
```

Removes the specified model objects from the related object set:
Similar to `add()`, `e.save()` is called in the example above to perform the update. Using `remove()` with a many-to-many relationship, however, will delete the relationships using `QuerySet.delete()` which means no model `save()` methods are called; listen to the `m2m_changed` signal if you wish to execute custom code when a relationship is deleted.

For many-to-many relationships `remove()` accepts either model instances or field values, normally primary keys, as the `*objs` argument.

For `ForeignKey` objects, this method only exists if `null=True`. If the related field can’t be set to `None` (NULL), then an object can’t be removed from a relation without being added to another. In the above example, removing `e` from `b.entry_set()` is equivalent to doing `e.blog = None`, and because the `blog ForeignKey` doesn’t have `null=True`, this is invalid.

For `ForeignKey` objects, this method accepts a `bulk` argument to control how to perform the operation. If `True` (the default), `QuerySet.update()` is used. If `bulk=False`, the `save()` method of each individual model instance is called instead. This triggers the `pre_save` and `post_save` signals and comes at the expense of performance.

For many-to-many relationships, the `bulk` keyword argument doesn’t exist.

**clear(bulk=True)**

Removes all objects from the related object set:

```python
>>> b = Blog.objects.get(id=1)
>>> b.entry_set.clear()
```

Note this doesn’t delete the related objects—it just disassociates them.

Just like `remove()`, `clear()` is only available on `ForeignKeys` where `null=True` and it also accepts the `bulk` keyword argument.

For many-to-many relationships, the `bulk` keyword argument doesn’t exist.

**set(objs, bulk=True, clear=False, through_defaults=None)**

Replace the set of related objects:

```python
>>> new_list = [obj1, obj2, obj3]
>>> e.related_set.set(new_list)
```

This method accepts a `clear` argument to control how to perform the operation. If `False` (the default), the elements missing from the new set are removed using `remove()` and only the new ones are added. If `clear=True`, the `clear()` method is called instead and the whole set is added at once.
For `ForeignKey` objects, the `bulk` argument is passed on to `add()` and `remove()`.

For many-to-many relationships, the `bulk` keyword argument doesn’t exist.

Note that since `set()` is a compound operation, it is subject to race conditions. For instance, new objects may be added to the database in between the call to `clear()` and the call to `add()`.

For many-to-many relationships `set()` accepts a list of either model instances or field values, normally primary keys, as the `objs` argument.

Use the `through_defaults` argument to specify values for the new intermediate model instance(s), if needed. You can use callables as values in the `through_defaults` dictionary and they will be evaluated once before creating any intermediate instance(s).

---

Note: Note that `add()`, `create()`, `remove()`, `clear()`, and `set()` all apply database changes immediately for all types of related fields. In other words, there is no need to call `save()` on either end of the relationship.

If you use `prefetch_related()`, the `add()`, `remove()`, `clear()`, and `set()` methods clear the prefetched cache.

---

### 6.16.7 Model class reference

This document covers features of the `Model` class. For more information about models, see the complete list of Model reference guides.

#### Attributes

**DoesNotExist**

`exception Model.DoesNotExist`

This exception is raised by the ORM when an expected object is not found. For example, `QuerySet.get()` will raise it when no object is found for the given lookups.

Django provides a `DoesNotExist` exception as an attribute of each model class to identify the class of object that could not be found, allowing you to catch exceptions for a particular model class. The exception is a subclass of `django.core.exceptions.ObjectDoesNotExist`. 
MultipleObjectsReturned

exception Model.MultipleObjectsReturned

This exception is raised by `QuerySet.get()` when multiple objects are found for the given lookups.

Django provides a `MultipleObjectsReturned` exception as an attribute of each model class to identify the class of object for which multiple objects were found, allowing you to catch exceptions for a particular model class. The exception is a subclass of `django.core.exceptions.MultipleObjectsReturned`.

objects

Model.objects

Each non-abstract `Model` class must have a `Manager` instance added to it. Django ensures that in your model class you have at least a default `Manager` specified. If you don’t add your own `Manager`, Django will add an attribute `objects` containing default `Manager` instance. If you add your own `Manager` instance attribute, the default one does not appear. Consider the following example:

```python
from django.db import models

class Person(models.Model):
    # Add manager with another name
    people = models.Manager()
```

For more details on model managers see Managers and Retrieving objects.

6.16.8 Model Meta options

This document explains all the possible metadata options that you can give your model in its internal `class Meta`.

Available Meta options

abstract

Options.abstract

  If abstract = True, this model will be an abstract base class.
app_label

Options.app_label

If a model is defined outside of an application in INSTALLED_APPS, it must declare which app it belongs to:

```
app_label = 'myapp'
```

If you want to represent a model with the format app_label.object_name or app_label.model_name you can use model._meta.label or model._meta.label_lower respectively.

base_manager_name

Options.base_manager_name

The attribute name of the manager, for example, 'objects', to use for the model’s _base_manager.

db_table

Options.db_table

The name of the database table to use for the model:

```
db_table = 'music_album'
```

Table names

To save you time, Django automatically derives the name of the database table from the name of your model class and the app that contains it. A model’s database table name is constructed by joining the model’s “app label” – the name you used in manage.py startapp – to the model’s class name, with an underscore between them.

For example, if you have an app bookstore (as created by manage.py startapp bookstore), a model defined as class Book will have a database table named bookstore_book.

To override the database table name, use the db_table parameter in class Meta.

If your database table name is an SQL reserved word, or contains characters that aren’t allowed in Python variable names – notably, the hyphen – that’s OK. Django quotes column and table names behind the scenes.

Use lowercase table names for MariaDB and MySQL

It is strongly advised that you use lowercase table names when you override the table name via db_table, particularly if you are using the MySQL backend. See the MySQL notes for more details.
Table name quoting for Oracle

In order to meet the 30-char limitation Oracle has on table names, and match the usual conventions for Oracle databases, Django may shorten table names and turn them all-uppercase. To prevent such transformations, use a quoted name as the value for \texttt{db\_table}:

\begin{verbatim}
   db_table = '"name\_left\_in\_lowercase"
\end{verbatim}

Such quoted names can also be used with Django’s other supported database backends; except for Oracle, however, the quotes have no effect. See the Oracle notes for more details.

\texttt{db\_tablespace}

\textbf{Options.} \texttt{db\_tablespace}

The name of the database tablespace to use for this model. The default is the project’s \texttt{DEFAULT\_TABLESPACE} setting, if set. If the backend doesn’t support tablespaces, this option is ignored.

\texttt{default\_manager\_name}

\textbf{Options.} \texttt{default\_manager\_name}

The name of the manager to use for the model’s \texttt{\_default\_manager}.

\texttt{default\_related\_name}

\textbf{Options.} \texttt{default\_related\_name}

The name that will be used by default for the relation from a related object back to this one. The default is \texttt{\textless\textless model\_name\textgreater\_set}.

This option also sets \texttt{related\_query\_name}.

As the reverse name for a field should be unique, be careful if you intend to subclass your model. To work around name collisions, part of the name should contain ‘\%(app\_label)s’ and ‘\%\textless model\_name\textgreater\_s’, which are replaced respectively by the name of the application the model is in, and the name of the model, both lowercased. See the paragraph on related names for abstract models.
get_latest_by

Options.get_latest_by

The name of a field or a list of field names in the model, typically `DateField`, `DateTimeField`, or `IntegerField`. This specifies the default field(s) to use in your model Manager’s `latest()` and `earliest()` methods.

Example:

```python
# Latest by ascending order_date.
get_latest_by = "order_date"

# Latest by priority descending, order_date ascending.
get_latest_by = ['-priority', 'order_date']
```

See the `latest()` docs for more.

managed

Options.managed

Defaults to True, meaning Django will create the appropriate database tables in `migrate` or as part of migrations and remove them as part of a `flush` management command. That is, Django manages the database tables’ lifecycles.

If False, no database table creation, modification, or deletion operations will be performed for this model. This is useful if the model represents an existing table or a database view that has been created by some other means. This is the only difference when `managed=False`. All other aspects of model handling are exactly the same as normal. This includes

1. Adding an automatic primary key field to the model if you don’t declare it. To avoid confusion for later code readers, it’s recommended to specify all the columns from the database table you are modeling when using unmanaged models.

2. If a model with `managed=False` contains a `ManyToManyField` that points to another unmanaged model, then the intermediary table for the many-to-many join will also not be created. However, the intermediary table between one managed and one unmanaged model will be created.

If you need to change this default behavior, create the intermediary table as an explicit model (with `managed` set as needed) and use the `ManyToManyField.through` attribute to make the relation use your custom model.

For tests involving models with `managed=False`, it’s up to you to ensure the correct tables are created as part of the test setup.

If you’re interested in changing the Python-level behavior of a model class, you could use `managed=False` and create a copy of an existing model. However, there’s a better approach for that
situation: Proxy models.

order_with_respect_to

Options.order_with_respect_to

Makes this object orderable with respect to the given field, usually a ForeignKey. This can be used to make related objects orderable with respect to a parent object. For example, if an Answer relates to a Question object, and a question has more than one answer, and the order of answers matters, you’d do this:

```python
from django.db import models

class Question(models.Model):
    text = models.TextField()
    # ...

class Answer(models.Model):
    question = models.ForeignKey(Question, on_delete=models.CASCADE)
    # ...

class Meta:
    order_with_respect_to = 'question'
```

When order_with_respect_to is set, two additional methods are provided to retrieve and to set the order of the related objects: get_RELATED_order() and set_RELATED_order(), where RELATED is the lowercased model name. For example, assuming that a Question object has multiple related Answer objects, the list returned contains the primary keys of the related Answer objects:

```python
>>> question = Question.objects.get(id=1)
>>> question.get_answer_order()
[1, 2, 3]
```

The order of a Question object’s related Answer objects can be set by passing in a list of Answer primary keys:

```python
>>> question.set_answer_order([3, 1, 2])
```

The related objects also get two methods, get_next_in_order() and get_previous_in_order(), which can be used to access those objects in their proper order. Assuming the Answer objects are ordered by id:

```python
>>> answer = Answer.objects.get(id=2)
>>> answer.get_next_in_order()
```
**order_with_respect_to** implicitly sets the **ordering** option

Internally, **order_with_respect_to** adds an additional field/database column named `_order` and sets the model’s **ordering** option to this field. Consequently, **order_with_respect_to** and **ordering** cannot be used together, and the ordering added by **order_with_respect_to** will apply whenever you obtain a list of objects of this model.

### Changing **order_with_respect_to**

Because **order_with_respect_to** adds a new database column, be sure to make and apply the appropriate migrations if you add or change **order_with_respect_to** after your initial `migrate`.

**ordering**

#### Options.**ordering**

The default ordering for the object, for use when obtaining lists of objects:

```python
ordering = ['-order_date']
```

This is a tuple or list of strings and/or query expressions. Each string is a field name with an optional “-” prefix, which indicates descending order. Fields without a leading “-” will be ordered ascending. Use the string “?” to order randomly.

For example, to order by a `pub_date` field ascending, use this:

```python
ordering = ['pub_date']
```

To order by `pub_date` descending, use this:

```python
ordering = ['-pub_date']
```

To order by `pub_date` descending, then by `author` ascending, use this:

```python
ordering = ['-pub_date', 'author']
```

You can also use **query expressions**. To order by `author` ascending and make null values sort last, use this:
```python
from django.db.models import F
ordering = [F('author').asc(nulls_last=True)]
```

Warning: Ordering is not a free operation. Each field you add to the ordering incurs a cost to your database. Each foreign key you add will implicitly include all of its default orderings as well.

If a query doesn’t have an ordering specified, results are returned from the database in an unspecified order. A particular ordering is guaranteed only when ordering by a set of fields that uniquely identify each object in the results. For example, if a name field isn’t unique, ordering by it won’t guarantee objects with the same name always appear in the same order.

### permissions

**Options: permissions**

Extra permissions to enter into the permissions table when creating this object. Add, change, delete, and view permissions are automatically created for each model. This example specifies an extra permission, `can_deliver_pizzas`:

```python
permissions = [('can_deliver_pizzas', 'Can deliver pizzas')]
```

This is a list or tuple of 2-tuples in the format `(permission_code, human_readable_permission_name)`.

### default_permissions

**Options: default_permissions**

Defaults to (`add`, `change`, `delete`, `view`). You may customize this list, for example, by setting this to an empty list if your app doesn’t require any of the default permissions. It must be specified on the model before the model is created by `migrate` in order to prevent any omitted permissions from being created.
proxy

Options.proxy

If proxy = True, a model which subclasses another model will be treated as a proxy model.

required_db_features

Options.required_db_features

List of database features that the current connection should have so that the model is considered during the migration phase. For example, if you set this list to ['gis_enabled'], the model will only be synchronized on GIS-enabled databases. It’s also useful to skip some models when testing with several database backends. Avoid relations between models that may or may not be created as the ORM doesn’t handle this.

required_db_vendor

Options.required_db_vendor

Name of a supported database vendor that this model is specific to. Current built-in vendor names are: sqlite, postgresql, mysql, oracle. If this attribute is not empty and the current connection vendor doesn’t match it, the model will not be synchronized.

select_on_save

Options.select_on_save

Determines if Django will use the pre-1.6 django.db.models.Model.save() algorithm. The old algorithm uses SELECT to determine if there is an existing row to be updated. The new algorithm tries an UPDATE directly. In some rare cases the UPDATE of an existing row isn’t visible to Django. An example is the PostgreSQL ON UPDATE trigger which returns NULL. In such cases the new algorithm will end up doing an INSERT even when a row exists in the database.

Usually there is no need to set this attribute. The default is False.

See django.db.models.Model.save() for more about the old and new saving algorithm.
indexes

Options.indexes

A list of indexes that you want to define on the model:

```python
from django.db import models

class Customer(models.Model):
    first_name = models.CharField(max_length=100)
    last_name = models.CharField(max_length=100)

    class Meta:
        indexes = [
            models.Index(fields=['last_name', 'first_name']),
            models.Index(fields=['first_name'], name='first_name_idx'),
        ]
```

unique_together

Options.unique_together

Use UniqueConstraint with the constraints option instead.

UniqueConstraint provides more functionality than unique_together. unique_together may be deprecated in the future.

Sets of field names that, taken together, must be unique:

```python
unique_together = [['driver', 'restaurant']]
```

This is a list of lists that must be unique when considered together. It’s used in the Django admin and is enforced at the database level (i.e., the appropriate UNIQUE statements are included in the CREATE TABLE statement).

For convenience, unique_together can be a single list when dealing with a single set of fields:

```python
unique_together = ['driver', 'restaurant']
```

A ManyToManyField cannot be included in unique_together. (It’s not clear what that would even mean!) If you need to validate uniqueness related to a ManyToManyField, try using a signal or an explicit through model.

The ValidationError raised during model validation when the constraint is violated has the unique_together error code.
index_together

Options.index_together

Use the indexes option instead.

The newer indexes option provides more functionality than index_together. index_together may be deprecated in the future.

Sets of field names that, taken together, are indexed:

```python
index_together = [
    ['pub_date', 'deadline'],
]
```

This list of fields will be indexed together (i.e. the appropriate CREATE INDEX statement will be issued.)

For convenience, index_together can be a single list when dealing with a single set of fields:

```python
index_together = ['pub_date', 'deadline']
```

constraints

Options.constraints

A list of constraints that you want to define on the model:

```python
from django.db import models

class Customer(models.Model):
    age = models.IntegerField()

    class Meta:
        constraints = [
            models.CheckConstraint(check=models.Q(age__gte=18), name='age_gte_18'),
        ]
```
verbose_name

Options.verbose_name

A human-readable name for the object, singular:

```
verbose_name = "pizza"
```

If this isn’t given, Django will use a munged version of the class name: CamelCase becomes camel case.

verbose_name_plural

Options.verbose_nameplural

The plural name for the object:

```
verbose_name_plural = "stories"
```

If this isn’t given, Django will use verbose_name + "s".

Read-only Meta attributes

label

Options.label

Representation of the object, returns app_label.object_name, e.g. 'polls.Question'.

label_lower

Options.label_lower

Representation of the model, returns app_label.model_name, e.g. 'polls.question'.

6.16.9 Model instance reference

This document describes the details of the Model API. It builds on the material presented in the model and database query guides, so you’ll probably want to read and understand those documents before reading this one.

Throughout this reference we’ll use the example blog models presented in the database query guide.
Creating objects

To create a new instance of a model, instantiate it like any other Python class:

```
class Model(**kwargs)
```

The keyword arguments are the names of the fields you’ve defined on your model. Note that instantiating a model in no way touches your database; for that, you need to `save()`.

Note: You may be tempted to customize the model by overriding the `__init__` method. If you do so, however, take care not to change the calling signature as any change may prevent the model instance from being saved. Rather than overriding `__init__`, try using one of these approaches:

1. Add a classmethod on the model class:

   ```python
   from django.db import models
   
   class Book(models.Model):
       title = models.CharField(max_length=100)

   @classmethod
   def create(cls, title):
       book = cls(title=title)
       # do something with the book
       return book

   book = Book.create("Pride and Prejudice")
   ```

2. Add a method on a custom manager (usually preferred):

   ```python
   class BookManager(models.Manager):
       def create_book(self, title):
           book = self.create(title=title)
           # do something with the book
           return book

   class Book(models.Model):
       title = models.CharField(max_length=100)

   objects = BookManager()

   book = Book.objects.create_book("Pride and Prejudice")
   ```
Customizing model loading

```python
from django.db.models import DEFERRED

@classmethod
def from_db(cls, db, field_names, values):
    # Default implementation of from_db() (subject to change and could
    # be replaced with super()).
    if len(values) != len(cls._meta.concrete_fields):
        values = list(values)
        values.reverse()
        values = [
            values.pop() if f.attname in field_names else DEFERRED
            for f in cls._meta.concrete_fields
        ]
    instance = cls(*values)
    instance._state.adding = False
    instance._state.db = db
    # customization to store the original field values on the instance
    instance._loaded_values = dict(zip(field_names, (value for value in values if value is not DEFERRED)))
    return instance

def save(self, *args, **kwargs):
    # Check how the current values differ from ._loaded_values. For example,
    # prevent changing the creator_id of the model. (This example doesn't
    # support cases where 'creator_id' is deferred).
    if not self._state.adding and (self.creator_id != self._loaded_values['creator_id']):
```

(continues on next page)
raise ValueError("Updating the value of creator isn't allowed")
super().save(*args, **kwargs)

The example above shows a full `from_db()` implementation to clarify how that is done. In this case it would be possible to use a `super()` call in the `from_db()` method.

### Refreshing objects from database

If you delete a field from a model instance, accessing it again reloads the value from the database:

```python
>>> obj = MyModel.objects.first()
>>> del obj.field
>>> obj.field  # Loads the field from the database
```

`Model.refresh_from_db(using=None, fields=None)`

If you need to reload a model’s values from the database, you can use the `refresh_from_db()` method. When this method is called without arguments the following is done:

1. All non-deferred fields of the model are updated to the values currently present in the database.
2. Any cached relations are cleared from the reloaded instance.

Only fields of the model are reloaded from the database. Other database-dependent values such as annotations aren’t reloaded. Any `@cached_property` attributes aren’t cleared either.

The reloading happens from the database the instance was loaded from, or from the default database if the instance wasn’t loaded from the database. The `using` argument can be used to force the database used for reloading.

It is possible to force the set of fields to be loaded by using the `fields` argument.

For example, to test that an `update()` call resulted in the expected update, you could write a test similar to this:

```python
def test_update_result(self):
    obj = MyModel.objects.create(val=1)
    MyModel.objects.filter(pk=obj.pk).update(val=F('val') + 1)
    # At this point obj.val is still 1, but the value in the database
    # was updated to 2. The object's updated value needs to be reloaded
    # from the database.
    obj.refresh_from_db()
    self.assertEqual(obj.val, 2)
```

Note that when deferred fields are accessed, the loading of the deferred field’s value happens through this method. Thus it is possible to customize the way deferred loading happens. The example below shows how one can reload all of the instance’s fields when a deferred field is reloaded:
class ExampleModel(models.Model):
    def refresh_from_db(self, using=None, fields=None, **kwargs):
        # fields contains the name of the deferred field to be
        # loaded.
        if fields is not None:
            fields = set(fields)
            deferred_fields = self.get_deferred_fields()
            # If any deferred field is going to be loaded
            if fields.intersection(deferred_fields):
                # then load all of them
                fields = fields.union(deferred_fields)
            super().refresh_from_db(using, fields, **kwargs)

Model.get_deferred_fields()

A helper method that returns a set containing the attribute names of all those fields that are currently deferred for this model.

**Validating objects**

There are four steps involved in validating a model:

1. Validate the model fields - `Model.clean_fields()`
2. Validate the model as a whole - `Model.clean()`
3. Validate the field uniqueness - `Model.validate_unique()`
4. Validate the constraints - `Model.validate_constraints()`

All four steps are performed when you call a model’s `full_clean()` method.

When you use a `ModelForm`, the call to `is_valid()` will perform these validation steps for all the fields that are included on the form. See the `ModelForm documentation` for more information. You should only need to call a model’s `full_clean()` method if you plan to handle validation errors yourself, or if you have excluded fields from the `ModelForm` that require validation.

In older versions, constraints were not checked during the model validation.

`Model.full_clean`(exclude=None, validate_unique=True, validate_constraints=True)

This method calls `Model.clean_fields()`, `Model.clean()`, `Model.validate_unique()` (if `validate_unique` is True), and `Model.validate_constraints()` (if `validate_constraints` is True) in that order and raises a `ValidationError` that has a `message_dict` attribute containing errors from all four stages.

The optional `exclude` argument can be used to provide a set of field names that can be excluded from validation and cleaning. `ModelForm` uses this argument to exclude fields that aren’t present on your form from being validated since any errors raised could not be corrected by the user.
Note that `full_clean()` will not be called automatically when you call your model’s `save()` method. You’ll need to call it manually when you want to run one-step model validation for your own manually created models. For example:

```python
from django.core.exceptions import ValidationError
try:
    article.full_clean()
except ValidationError as e:
    # Do something based on the errors contained in e.message_dict.
    # Display them to a user, or handle them programmatically.
    pass
```

The first step `full_clean()` performs is to clean each individual field.

The `validate_constraints` argument was added.

An `exclude` value is now converted to a `set` rather than a `list`.

`Model.clean_fields(exclude=None)`

This method will validate all fields on your model. The optional `exclude` argument lets you provide a `set` of field names to exclude from validation. It will raise a `ValidationError` if any fields fail validation.

The second step `full_clean()` performs is to call `Model.clean()`. This method should be overridden to perform custom validation on your model.

`Model.clean()`

This method should be used to provide custom model validation, and to modify attributes on your model if desired. For instance, you could use it to automatically provide a value for a field, or to do validation that requires access to more than a single field:

```python
import datetime
from django.core.exceptions import ValidationError
from django.db import models
from django.utils.translation import gettext_lazy as _

class Article(models.Model):
    ...
    def clean(self):
        # Don't allow draft entries to have a pub_date.
        if self.status == 'draft' and self.pub_date is not None:
            raise ValidationError(_('Draft entries may not have a publication date.'))
        # Set the pub_date for published items if it hasn't been set already.
        if self.status == 'published' and self.pub_date is None:
            self.pub_date = datetime.date.today()
```
Note, however, that like `Model.full_clean()`, a model’s `clean()` method is not invoked when you call your model’s `save()` method.

In the above example, the `ValidationError` exception raised by `Model.clean()` was instantiated with a string, so it will be stored in a special error dictionary key, `NON_FIELD_ERRORS`. This key is used for errors that are tied to the entire model instead of to a specific field:

```python
from django.core.exceptions import NON_FIELD_ERRORS, ValidationError
try:
    article.full_clean()
except ValidationError as e:
    non_field_errors = e.message_dict[NON_FIELD_ERRORS]
```

To assign exceptions to a specific field, instantiate the `ValidationError` with a dictionary, where the keys are the field names. We could update the previous example to assign the error to the `pub_date` field:

```python
class Article(models.Model):
    ...
    def clean(self):
        # Don't allow draft entries to have a pub_date.
        if self.status == 'draft' and self.pub_date is not None:
            raise ValidationError({'pub_date': _('Draft entries may not have a publication date.')})
    ...
```

If you detect errors in multiple fields during `Model.clean()`, you can also pass a dictionary mapping field names to errors:

```
raise ValidationError({
    'title': ValidationError(_('Missing title.'), code='required'),
    'pub_date': ValidationError(_('Invalid date.'), code='invalid'),
})
```

Then, `full_clean()` will check unique constraints on your model.

**How to raise field-specific validation errors if those fields don’t appear in a ModelForm**

You can’t raise validation errors in `Model.clean()` for fields that don’t appear in a model form (a form may limit its fields using `Meta.fields` or `Meta.exclude`). Doing so will raise a `ValueError` because the validation error won’t be able to be associated with the excluded field.

To work around this dilemma, instead override `Model.clean_fields()` as it receives the list of fields that are excluded from validation. For example:
class Article(models.Model):
    ...
    def clean_fields(self, exclude=None):
        super().clean_fields(exclude=exclude)
        if self.status == 'draft' and self.pub_date is not None:
            if exclude and 'status' in exclude:
                raise ValidationError(_(  
                    'Draft entries may not have a publication date.'  
                ))
            else:
                raise ValidationError({
                    'status': _(
                        'Set status to draft if there is not a '  
                        'publication date.'  
                    ),
                })

Model.validate_unique(exclude=None)

This method is similar to clean_fields(), but validates uniqueness constraints defined via Field.unique, Field.unique_for_date, Field.unique_for_month, Field.unique_for_year, or Meta.unique_together on your model instead of individual field values. The optional exclude argument allows you to provide a set of field names to exclude from validation. It will raise a ValidationError if any fields fail validation.

UniqueConstraints defined in the Meta.constraints are validated by Model.validate_constraints().

Note that if you provide an exclude argument to validate_unique(), any unique_together constraint involving one of the fields you provided will not be checked.

Finally, full_clean() will check any other constraints on your model.

In older versions, UniqueConstraints were validated by validate_unique().

Model.validate_constraints(exclude=None)

This method validates all constraints defined in Meta.constraints. The optional exclude argument allows you to provide a set of field names to exclude from validation. It will raise a ValidationError if any constraints fail validation.
**Saving objects**

To save an object back to the database, call `save()`:

```python
Model.save(force_insert=False, force_update=False, using=DEFAULT_DB_ALIAS, update_fields=None)
```

For details on using the `force_insert` and `force_update` arguments, see Forcing an INSERT or UPDATE. Details about the `update_fields` argument can be found in the Specifying which fields to save section.

If you want customized saving behavior, you can override this `save()` method. See Overriding predefined model methods for more details.

The model save process also has some subtleties; see the sections below.

**Auto-incrementing primary keys**

If a model has an `AutoField` — an auto-incrementing primary key — then that auto-incremented value will be calculated and saved as an attribute on your object the first time you call `save()`:

```python
>>> b2 = Blog(name='Cheddar Talk', tagline='Thoughts on cheese. ')
>>> b2.id  # Returns None, because b2 doesn't have an ID yet.
>>> b2.save()
>>> b2.id  # Returns the ID of your new object.
```

There’s no way to tell what the value of an ID will be before you call `save()`, because that value is calculated by your database, not by Django.

For convenience, each model has an `AutoField` named `id` by default unless you explicitly specify `primary_key=True` on a field in your model. See the documentation for `AutoField` for more details.

**The pk property**

`Model.pk`

Regardless of whether you define a primary key field yourself, or let Django supply one for you, each model will have a property called `pk`. It behaves like a normal attribute on the model, but is actually an alias for whichever attribute is the primary key field for the model. You can read and set this value, just as you would for any other attribute, and it will update the correct field in the model.
Explicitly specifying auto-primary-key values

If a model has an AutoField but you want to define a new object’s ID explicitly when saving, define it explicitly before saving, rather than relying on the auto-assignment of the ID:

```python
>>> b3 = Blog(id=3, name='Cheddar Talk', tagline='Thoughts on cheese.')
>>> b3.id    # Returns 3.
>>> b3.save()
>>> b3.id    # Returns 3.
```

If you assign auto-primary-key values manually, make sure not to use an already-existing primary-key value! If you create a new object with an explicit primary-key value that already exists in the database, Django will assume you’re changing the existing record rather than creating a new one.

Given the above 'Cheddar Talk' blog example, this example would override the previous record in the database:

```python
b4 = Blog(id=3, name='Not Cheddar', tagline='Anything but cheese.')
b4.save()  # Overrides the previous blog with ID=3!
```

See How Django knows to UPDATE vs. INSERT, below, for the reason this happens.

Explicitly specifying auto-primary-key values is mostly useful for bulk-saving objects, when you’re confident you won’t have primary-key collision.

If you’re using PostgreSQL, the sequence associated with the primary key might need to be updated; see Manually-specifying values of auto-incrementing primary keys.

What happens when you save?

When you save an object, Django performs the following steps:

1. Emit a pre-save signal. The `pre_save` signal is sent, allowing any functions listening for that signal to do something.

2. Preprocess the data. Each field’s `pre_save()` method is called to perform any automated data modification that’s needed. For example, the date/time fields override `pre_save()` to implement `auto_now_add` and `auto_now`.

3. Prepare the data for the database. Each field’s `get_db_prep_save()` method is asked to provide its current value in a data type that can be written to the database.

Most fields don’t require data preparation. Simple data types, such as integers and strings, are ‘ready to write’ as a Python object. However, more complex data types often require some modification.

For example, `DateField` fields use a Python `datetime` object to store data. Databases don’t store `datetime` objects, so the field value must be converted into an ISO-compliant date string for insertion.
into the database.

4. Insert the data into the database. The preprocessed, prepared data is composed into an SQL statement for insertion into the database.

5. Emit a post-save signal. The `post_save` signal is sent, allowing any functions listening for that signal to do something.

**How Django knows to UPDATE vs. INSERT**

You may have noticed Django database objects use the same `save()` method for creating and changing objects. Django abstracts the need to use `INSERT` or `UPDATE` SQL statements. Specifically, when you call `save()` and the object’s primary key attribute does not define a `default`, Django follows this algorithm:

- If the object’s primary key attribute is set to a value that evaluates to `True` (i.e., a value other than `None` or the empty string), Django executes an `UPDATE`.

- If the object’s primary key attribute is not set or if the `UPDATE` didn’t update anything (e.g., if primary key is set to a value that doesn’t exist in the database), Django executes an `INSERT`.

If the object’s primary key attribute defines a `default` then Django executes an `UPDATE` if it is an existing model instance and primary key is set to a value that exists in the database. Otherwise, Django executes an `INSERT`.

The one gotcha here is that you should be careful not to specify a primary-key value explicitly when saving new objects, if you cannot guarantee the primary-key value is unused. For more on this nuance, see Explicitly specifying auto-primary-key values above and Forcing an INSERT or UPDATE below.

In Django 1.5 and earlier, Django did a `SELECT` when the primary key attribute was set. If the `SELECT` found a row, then Django did an `UPDATE`, otherwise it did an `INSERT`. The old algorithm results in one more query in the `UPDATE` case. There are some rare cases where the database doesn’t report that a row was updated even if the database contains a row for the object’s primary key value. An example is the PostgreSQL `ON UPDATE` trigger which returns NULL. In such cases it is possible to revert to the old algorithm by setting the `select_on_save` option to `True`.

**Forcing an INSERT or UPDATE**

In some rare circumstances, it’s necessary to be able to force the `save()` method to perform an SQL `INSERT` and not fall back to doing an `UPDATE`. Or vice-versa: update, if possible, but not insert a new row. In these cases you can pass the `force_insert=True` or `force_update=True` parameters to the `save()` method. Passing both parameters is an error: you cannot both insert and update at the same time!

It should be very rare that you’ll need to use these parameters. Django will almost always do the right thing and trying to override that will lead to errors that are difficult to track down. This feature is for advanced use only.

Using `update_fields` will force an update similarly to `force_update`. 

6.16. Models
Updating attributes based on existing fields

Sometimes you’ll need to perform a simple arithmetic task on a field, such as incrementing or decrementing the current value. One way of achieving this is doing the arithmetic in Python like:

```python
>>> product = Product.objects.get(name='Venezuelan Beaver Cheese')
>>> product.number_sold += 1
>>> product.save()
```

If the old `number_sold` value retrieved from the database was 10, then the value of 11 will be written back to the database.

The process can be made robust, avoiding a race condition, as well as slightly faster by expressing the update relative to the original field value, rather than as an explicit assignment of a new value. Django provides *F expressions* for performing this kind of relative update. Using *F expressions*, the previous example is expressed as:

```python
>>> from django.db.models import F
>>> product = Product.objects.get(name='Venezuelan Beaver Cheese')
>>> product.number_sold = F('number_sold') + 1
>>> product.save()
```

For more details, see the documentation on *F expressions* and their use in update queries.

Specifying which fields to save

If `save()` is passed a list of field names in keyword argument `update_fields`, only the fields named in that list will be updated. This may be desirable if you want to update just one or a few fields on an object. There will be a slight performance benefit from preventing all of the model fields from being updated in the database. For example:

```python
product.name = 'Name changed again'
product.save(update_fields=['name'])
```

The `update_fields` argument can be any iterable containing strings. An empty `update_fields` iterable will skip the save. A value of `None` will perform an update on all fields.

Specifying `update_fields` will force an update.

When saving a model fetched through deferred model loading (`only()` or `defer()`) only the fields loaded from the DB will get updated. In effect there is an automatic `update_fields` in this case. If you assign or change any deferred field value, the field will be added to the updated fields.
Deleting objects

Model.delete(using=DEFAULT_DB_ALIAS, keep_parents=False)

Issues an SQL DELETE for the object. This only deletes the object in the database; the Python instance will still exist and will still have data in its fields. This method returns the number of objects deleted and a dictionary with the number of deletions per object type.

For more details, including how to delete objects in bulk, see Deleting objects.

If you want customized deletion behavior, you can override the delete() method. See Overriding predefined model methods for more details.

Sometimes with multi-table inheritance you may want to delete only a child model’s data. Specifying keep_parents=True will keep the parent model’s data.

Pickling objects

When you pickle a model, its current state is pickled. When you unpickle it, it’ll contain the model instance at the moment it was pickled, rather than the data that’s currently in the database.

You can’t share pickles between versions

Pickles of models are only valid for the version of Django that was used to generate them. If you generate a pickle using Django version N, there is no guarantee that pickle will be readable with Django version N+1. Pickles should not be used as part of a long-term archival strategy.

Since pickle compatibility errors can be difficult to diagnose, such as silently corrupted objects, a 
RuntimeWarning is raised when you try to unpickle a model in a Django version that is different than the one in which it was pickled.

Other model instance methods

A few object methods have special purposes.

__str__()  

Model.__str__()  

The __str__() method is called whenever you call str() on an object. Django uses str(obj) in a number of places. Most notably, to display an object in the Django admin site and as the value inserted into a template when it displays an object. Thus, you should always return a nice, human-readable representation of the model from the __str__() method.
For example:

```python
from django.db import models

class Person(models.Model):
    first_name = models.CharField(max_length=50)
    last_name = models.CharField(max_length=50)

    def __str__(self):
        return '%s %s' % (self.first_name, self.last_name)

__eq__()  
Model.__eq__()

The equality method is defined such that instances with the same primary key value and the same concrete
```

class MyModel(models.Model):
    id = models.AutoField(primary_key=True)

class MyProxyModel(MyModel):
    class Meta:
        proxy = True

class MultitableInherited(MyModel):
    pass

# Primary keys compared
MyModel(id=1) == MyModel(id=1)
MyModel(id=1) != MyModel(id=2)
# Primary keys are None
MyModel(id=None) != MyModel(id=None)
# Same instance
instance = MyModel(id=None)
instance == instance
# Proxy model
MyModel(id=1) == MyProxyModel(id=1)
```
# Multi-table inheritance

```python
MyModel(id=1) != MultitableInherited(id=1)
```

__hash__()

Model.__hash__()

The __hash__() method is based on the instance’s primary key value. It is effectively hash(obj.pk). If the instance doesn’t have a primary key value then a TypeError will be raised (otherwise the __hash__() method would return different values before and after the instance is saved, but changing the __hash__() value of an instance is forbidden in Python.

get_absolute_url()

Model.get_absolute_url()

Define a get_absolute_url() method to tell Django how to calculate the canonical URL for an object. To callers, this method should appear to return a string that can be used to refer to the object over HTTP.

For example:

```python
def get_absolute_url(self):
    return f"/people/%i/" % self.id
```

While this code is correct and simple, it may not be the most portable way to to write this kind of method. The reverse() function is usually the best approach.

For example:

```python
def get_absolute_url(self):
    from django.urls import reverse
    return reverse('people-detail', kwargs={'pk': self.pk})
```

One place Django uses get_absolute_url() is in the admin app. If an object defines this method, the object-editing page will have a “View on site” link that will jump you directly to the object’s public view, as given by get_absolute_url().

Similarly, a couple of other bits of Django, such as the syndication feed framework, use get_absolute_url() when it is defined. If it makes sense for your model’s instances to each have a unique URL, you should define get_absolute_url().
Warning: You should avoid building the URL from unvalidated user input, in order to reduce possibilities of link or redirect poisoning:

```python
def get_absolute_url(self):
    return '/%s/' % self.name
```

If `self.name` is '/example.com' this returns '/example.com/' which, in turn, is a valid schema relative URL but not the expected '/%2Fexample.com/'.

It’s good practice to use `get_absolute_url()` in templates, instead of hard-coding your objects’ URLs. For example, this template code is bad:

```html
<!-- BAD template code. Avoid! -->
<a href="/people/{{ object.id }}/">{{ object.name }}</a>
```

This template code is much better:

```html
<a href="{{ object.get_absolute_url }}">{{ object.name }}</a>
```

The logic here is that if you change the URL structure of your objects, even for something small like correcting a spelling error, you don’t want to have to track down every place that the URL might be created. Specify it once, in `get_absolute_url()` and have all your other code call that one place.

Note: The string you return from `get_absolute_url()` must contain only ASCII characters (required by the URI specification, RFC 2396#section-2) and be URL-encoded, if necessary.

Code and templates calling `get_absolute_url()` should be able to use the result directly without any further processing. You may wish to use the `django.utils.encoding.iri_to_uri()` function to help with this if you are using strings containing characters outside the ASCII range.

### Extra instance methods

In addition to `save()`, `delete()`, a model object might have some of the following methods:

```python
Model.get_FOO_display()
```

For every field that has `choices` set, the object will have a `get_FOO_display()` method, where `FOO` is the name of the field. This method returns the “human-readable” value of the field.

For example:

```python
from django.db import models

class Person(models.Model):
```

(continues on next page)
SHIRT_SIZES = (
    ('S', 'Small'),
    ('M', 'Medium'),
    ('L', 'Large'),
)
name = models.CharField(max_length=60)
shirt_size = models.CharField(max_length=2, choices=SHIRT_SIZES)

>>> p = Person(name="Fred Flintstone", shirt_size="L")
>>> p.save()
>>> p.shirt_size
'L'
>>> p.get_shirt_size_display()
'Large'

Model.get_next_by_FOO(**kwargs)

Model.get_previous_by_FOO(**kwargs)

For every DateField and DateTimeField that does not have null=True, the object will have get_next_by_FOO() and get_previous_by_FOO() methods, where FOO is the name of the field. This returns the next and previous object with respect to the date field, raising a DoesNotExist exception when appropriate.

Both of these methods will perform their queries using the default manager for the model. If you need to emulate filtering used by a custom manager, or want to perform one-off custom filtering, both methods also accept optional keyword arguments, which should be in the format described in Field lookups.

Note that in the case of identical date values, these methods will use the primary key as a tie-breaker. This guarantees that no records are skipped or duplicated. That also means you cannot use those methods on unsaved objects.

Overriding extra instance methods

In most cases overriding or inheriting get_FOO_display(), get_next_by_FOO(), and get_previous_by_FOO() should work as expected. Since they are added by the metaclass however, it is not practical to account for all possible inheritance structures. In more complex cases you should override Field.contribute_to_class() to set the methods you need.
Other attributes

_state

Model._state

The _state attribute refers to a ModelState object that tracks the lifecycle of the model instance.

The ModelState object has two attributes: adding, a flag which is True if the model has not been saved to the database yet, and db, a string referring to the database alias the instance was loaded from or saved to.

Newly instantiated instances have adding=True and db=None, since they are yet to be saved. Instances fetched from a QuerySet will have adding=False and db set to the alias of the associated database.

6.16.10 QuerySet API reference

This document describes the details of the QuerySet API. It builds on the material presented in the model and database query guides, so you’ll probably want to read and understand those documents before reading this one.

Throughout this reference we’ll use the example blog models presented in the database query guide.

When QuerySets are evaluated

Internally, a QuerySet can be constructed, filtered, sliced, and generally passed around without actually hitting the database. No database activity actually occurs until you do something to evaluate the queryset.

You can evaluate a QuerySet in the following ways:

- Iteration. A QuerySet is iterable, and it executes its database query the first time you iterate over it. For example, this will print the headline of all entries in the database:

```python
for e in Entry.objects.all():
    print(e.headline)
```

Note: Don’t use this if all you want to do is determine if at least one result exists. It’s more efficient to use exists().

- Asynchronous iteration. A QuerySet can also be iterated over using async for:

```python
async for e in Entry.objects.all():
    results.append(e)
```

Both synchronous and asynchronous iterators of QuerySets share the same underlying cache.

Support for asynchronous iteration was added.
• Slicing. As explained in Limiting QuerySets, a QuerySet can be sliced, using Python’s array-slicing syntax. Slicing an unevaluated QuerySet usually returns another unevaluated QuerySet, but Django will execute the database query if you use the “step” parameter of slice syntax, and will return a list. Slicing a QuerySet that has been evaluated also returns a list.

Also note that even though slicing an unevaluated QuerySet returns another unevaluated QuerySet, modifying it further (e.g., adding more filters, or modifying ordering) is not allowed, since that does not translate well into SQL and it would not have a clear meaning either.

• Pickling/Caching. See the following section for details of what is involved when pickling QuerySets. The important thing for the purposes of this section is that the results are read from the database.

• repr(). A QuerySet is evaluated when you call repr() on it. This is for convenience in the Python interactive interpreter, so you can immediately see your results when using the API interactively.

• len(). A QuerySet is evaluated when you call len() on it. This, as you might expect, returns the length of the result list.

Note: If you only need to determine the number of records in the set (and don’t need the actual objects), it’s much more efficient to handle a count at the database level using SQL’s SELECT COUNT(*). Django provides a count() method for precisely this reason.

• list(). Force evaluation of a QuerySet by calling list() on it. For example:

```python
entry_list = list(Entry.objects.all())
```

• bool(). Testing a QuerySet in a boolean context, such as using bool(), or, and or an if statement, will cause the query to be executed. If there is at least one result, the QuerySet is True, otherwise False. For example:

```python
if Entry.objects.filter(headline="Test"):
    print("There is at least one Entry with the headline Test")
```

Note: If you only want to determine if at least one result exists (and don’t need the actual objects), it’s more efficient to use exists().

### Pickling QuerySets

If you pickle a QuerySet, this will force all the results to be loaded into memory prior to pickling. Pickling is usually used as a precursor to caching and when the cached queryset is reloaded, you want the results to already be present and ready for use (reading from the database can take some time, defeating the purpose of caching). This means that when you unpickle a QuerySet, it contains the results at the moment it was pickled, rather than the results that are currently in the database.

If you only want to pickle the necessary information to recreate the QuerySet from the database at a later time, pickle the query attribute of the QuerySet. You can then recreate the original QuerySet (without any results loaded) using some code like this:
The `query` attribute is an opaque object. It represents the internals of the query construction and is not part of the public API. However, it is safe (and fully supported) to pickle and unpickle the attribute’s contents as described here.

Restrictions on `QuerySet.values_list()`

If you recreate `QuerySet.values_list()` using the pickled `query` attribute, it will be converted to `QuerySet.values()`:

```python
>>> import pickle
>>> qs = Blog.objects.values_list('id', 'name')
>>> qs
<QuerySet [(1, 'Beatles Blog')]>  # Not pickleable
>>> reloaded_qs = Blog.objects.all()
>>> reloaded_qs.query = pickle.loads(pickle.dumps(qs.query))
>>> reloaded_qs
<QuerySet [{'id': 1, 'name': 'Beatles Blog'}]>
```

You can’t share pickles between versions

Pickles of `QuerySets` are only valid for the version of Django that was used to generate them. If you generate a pickle using Django version N, there is no guarantee that pickle will be readable with Django version N+1. Pickles should not be used as part of a long-term archival strategy.

Since pickle compatibility errors can be difficult to diagnose, such as silently corrupted objects, a `RuntimeWarning` is raised when you try to unpickle a queryset in a Django version that is different than the one in which it was pickled.

**QuerySet API**

Here’s the formal declaration of a `QuerySet`:

```python
class QuerySet(model=None, query=None, using=None, hints=None)
```

Usually when you’ll interact with a `QuerySet` you’ll use it by chaining filters. To make this work, most `QuerySet` methods return new querysets. These methods are covered in detail later in this section.

The `QuerySet` class has the following public attributes you can use for introspection:
ordered

True if the QuerySet is ordered — i.e. has an order_by() clause or a default ordering on the model.
False otherwise.

db

The database that will be used if this query is executed now.

---

Note: The query parameter to QuerySet exists so that specialized query subclasses can reconstruct internal query state. The value of the parameter is an opaque representation of that query state and is not part of a public API.

---

Methods that return new QuerySets

Django provides a range of QuerySet refinement methods that modify either the types of results returned by the QuerySet or the way its SQL query is executed.

---

Note: These methods do not run database queries, therefore they are safe to run in asynchronous code, and do not have separate asynchronous versions.

---

filter()

filter(*args, **kwargs)

Returns a new QuerySet containing objects that match the given lookup parameters.

The lookup parameters (**kwargs) should be in the format described in Field lookups below. Multiple parameters are joined via AND in the underlying SQL statement.

If you need to execute more complex queries (for example, queries with OR statements), you can use Q objects(*args).

exclude()

exclude(*args, **kwargs)

Returns a new QuerySet containing objects that do not match the given lookup parameters.

The lookup parameters (**kwargs) should be in the format described in Field lookups below. Multiple parameters are joined via AND in the underlying SQL statement, and the whole thing is enclosed in a NOT().

This example excludes all entries whose pub_date is later than 2005-1-3 AND whose headline is “Hello”:
Entry.objects.exclude(pub_date__gt=datetime.date(2005, 1, 3), headline='Hello')

In SQL terms, that evaluates to:

```
SELECT ... 
WHERE NOT (pub_date > '2005-1-3' AND headline = 'Hello')
```

This example excludes all entries whose `pub_date` is later than 2005-1-3 OR whose headline is “Hello”:

Entry.objects.exclude(pub_date__gt=datetime.date(2005, 1, 3)).exclude(headline='Hello')

In SQL terms, that evaluates to:

```
SELECT ... 
WHERE NOT pub_date > '2005-1-3' 
AND NOT headline = 'Hello'
```

Note the second example is more restrictive.

If you need to execute more complex queries (for example, queries with OR statements), you can use `Q` objects.

```python
annotate()
```

```python
annotate(*args, **kwargs)
```

Annotates each object in the QuerySet with the provided list of query expressions. An expression may be a simple value, a reference to a field on the model (or any related models), or an aggregate expression (averages, sums, etc.) that has been computed over the objects that are related to the objects in the QuerySet.

Each argument to annotate() is an annotation that will be added to each object in the QuerySet that is returned.

The aggregation functions that are provided by Django are described in Aggregation Functions below.

Annotations specified using keyword arguments will use the keyword as the alias for the annotation. Anonymous arguments will have an alias generated for them based upon the name of the aggregate function and the model field that is being aggregated. Only aggregate expressions that reference a single field can be anonymous arguments. Everything else must be a keyword argument.

For example, if you were manipulating a list of blogs, you may want to determine how many entries have been made in each blog:

```python
>>> from django.db.models import Count
>>> q = Blog.objects.annotate(Count('entry'))
# The name of the first blog
```
The `Blog` model doesn’t define an `entry__count` attribute by itself, but by using a keyword argument to specify the aggregate function, you can control the name of the annotation:

```python
>>> q = Blog.objects.annotate(number_of_entries=Count('entry'))
# The number of entries on the first blog, using the name provided
>>> q[0].number_of_entries
42
```

For an in-depth discussion of aggregation, see the topic guide on Aggregation.

`alias()`

`alias(*args, **kwargs)`

Same as `annotate()`, but instead of annotating objects in the `QuerySet`, saves the expression for later reuse with other `QuerySet` methods. This is useful when the result of the expression itself is not needed but it is used for filtering, ordering, or as a part of a complex expression. Not selecting the unused value removes redundant work from the database which should result in better performance.

For example, if you want to find blogs with more than 5 entries, but are not interested in the exact number of entries, you could do this:

```python
>>> from django.db.models import Count
>>> blogs = Blog.objects.alias(entries=Count('entry')).filter(entries__gt=5)
```

`alias()` can be used in conjunction with `annotate()`, `exclude()`, `filter()`, `order_by()`, and `update()`. To use aliased expression with other methods (e.g. `aggregate()`), you must promote it to an annotation:

```python
Blog.objects.alias(entries=Count('entry')).annotate(
    entries=F('entries'),
).aggregate(Sum('entries'))
```

`filter()` and `order_by()` can take expressions directly, but expression construction and usage often does not happen in the same place (for example, QuerySet method creates expressions, for later use in views). `alias()` allows building complex expressions incrementally, possibly spanning multiple methods and modules, refer to the expression parts by their aliases and only use `annotate()` for the final result.
order_by()

order_by(*fields)

By default, results returned by a QuerySet are ordered by the ordering tuple given by the ordering option in the model’s Meta. You can override this on a per-QuerySet basis by using the order_by method.

Example:

Entry.objects.filter(pub_date__year=2005).order_by('^-pub_date', 'headline')

The result above will be ordered by pub_date descending, then by headline ascending. The negative sign in front of "^-pub_date" indicates descending order. Ascending order is implied. To order randomly, use "?", like so:

Entry.objects.order_by('?')

Note: order_by('?') queries may be expensive and slow, depending on the database backend you’re using.

To order by a field in a different model, use the same syntax as when you are querying across model relations. That is, the name of the field, followed by a double underscore (__), followed by the name of the field in the new model, and so on for as many models as you want to join. For example:

Entry.objects.order_by('blog__name', 'headline')

If you try to order by a field that is a relation to another model, Django will use the default ordering on the related model, or order by the related model’s primary key if there is no Meta.ordering specified. For example, since the Blog model has no default ordering specified:

Entry.objects.order_by('blog')

...is identical to:

Entry.objects.order_by('blog__id')

If Blog had ordering = ['name'], then the first queryset would be identical to:

Entry.objects.order_by('blog__name')

You can also order by query expressions by calling asc() or desc() on the expression:

Entry.objects.order_by(Coalesce('summary', 'headline').desc())

asc() and desc() have arguments (nulls_first and nulls_last) that control how null values are sorted.

Be cautious when ordering by fields in related models if you are also using distinct(). See the note in distinct() for an explanation of how related model ordering can change the expected results.
Note: It is permissible to specify a multi-valued field to order the results by (for example, a `ManyToManyField` field, or the reverse relation of a `ForeignKey` field).

Consider this case:

```python
class Event(Model):
    parent = models.ForeignKey(
        'self',
        on_delete=models.CASCADE,
        related_name='children',
    )
    date = models.DateField()

Event.objects.order_by('children__date')
```

Here, there could potentially be multiple ordering data for each `Event`; each `Event` with multiple `children` will be returned multiple times into the new `QuerySet` that `order_by()` creates. In other words, using `order_by()` on the `QuerySet` could return more items than you were working on to begin with - which is probably neither expected nor useful.

Thus, take care when using multi-valued field to order the results. If you can be sure that there will only be one ordering piece of data for each of the items you’re ordering, this approach should not present problems. If not, make sure the results are what you expect.

There’s no way to specify whether ordering should be case sensitive. With respect to case-sensitivity, Django will order results however your database backend normally orders them.

You can order by a field converted to lowercase with `Lower` which will achieve case-consistent ordering:

```python
Entry.objects.order_by(Lower('headline').desc())
```

If you don’t want any ordering to be applied to a query, not even the default ordering, call `order_by()` with no parameters.

You can tell if a query is ordered or not by checking the `QuerySet.ordered` attribute, which will be `True` if the `QuerySet` has been ordered in any way.

Each `order_by()` call will clear any previous ordering. For example, this query will be ordered by `pub_date` and not `headline`:

```python
Entry.objects.order_by('headline').order_by('pub_date')
```

Warning: Ordering is not a free operation. Each field you add to the ordering incurs a cost to your database. Each foreign key you add will implicitly include all of its default orderings as well.
If a query doesn’t have an ordering specified, results are returned from the database in an unspecified order. A particular ordering is guaranteed only when ordering by a set of fields that uniquely identify each object in the results. For example, if a name field isn’t unique, ordering by it won’t guarantee objects with the same name always appear in the same order.

reverse()

reverse()

Use the reverse() method to reverse the order in which a queryset’s elements are returned. Calling reverse() a second time restores the ordering back to the normal direction.

To retrieve the “last” five items in a queryset, you could do this:

```
my_queryset.reverse()[5]
```

Note that this is not quite the same as slicing from the end of a sequence in Python. The above example will return the last item first, then the penultimate item and so on. If we had a Python sequence and looked at `seq[-5:]`, we would see the fifth-last item first. Django doesn’t support that mode of access (slicing from the end), because it’s not possible to do it efficiently in SQL.

Also, note that reverse() should generally only be called on a QuerySet which has a defined ordering (e.g., when querying against a model which defines a default ordering, or when using order_by()). If no such ordering is defined for a given QuerySet, calling reverse() on it has no real effect (the ordering was undefined prior to calling reverse(), and will remain undefined afterward).

distinct()

distinct(*fields)

Returns a new QuerySet that uses SELECT DISTINCT in its SQL query. This eliminates duplicate rows from the query results.

By default, a QuerySet will not eliminate duplicate rows. In practice, this is rarely a problem, because simple queries such as `Blog.objects.all()` don’t introduce the possibility of duplicate result rows. However, if your query spans multiple tables, it’s possible to get duplicate results when a QuerySet is evaluated. That’s when you’d use distinct().

Note: Any fields used in an order_by() call are included in the SQL SELECT columns. This can sometimes lead to unexpected results when used in conjunction with distinct(). If you order by fields from a related model, those fields will be added to the selected columns and they may make otherwise duplicate rows appear
to be distinct. Since the extra columns don’t appear in the returned results (they are only there to support ordering), it sometimes looks like non-distinct results are being returned.

Similarly, if you use a `values()` query to restrict the columns selected, the columns used in any `order_by()` (or default model ordering) will still be involved and may affect uniqueness of the results.

The moral here is that if you are using `distinct()` be careful about ordering by related models. Similarly, when using `distinct()` and `values()` together, be careful when ordering by fields not in the `values()` call.

On PostgreSQL only, you can pass positional arguments (`*fields`) in order to specify the names of fields to which the `DISTINCT` should apply. This translates to a `SELECT DISTINCT ON` SQL query. Here’s the difference. For a normal `distinct()` call, the database compares each field in each row when determining which rows are distinct. For a `distinct()` call with specified field names, the database will only compare the specified field names.

Note: When you specify field names, you must provide an `order_by()` in the `QuerySet`, and the fields in `order_by()` must start with the fields in `distinct()`, in the same order.

For example, `SELECT DISTINCT ON (a)` gives you the first row for each value in column `a`. If you don’t specify an order, you’ll get some arbitrary row.

Examples (those after the first will only work on PostgreSQL):

```python
>>> Author.objects.distinct()
[...]

>>> Entry.objects.order_by('pub_date').distinct('pub_date')
[...]

>>> Entry.objects.order_by('blog').distinct('blog')
[...]

>>> Entry.objects.order_by('author', 'pub_date').distinct('author', 'pub_date')
[...]

>>> Entry.objects.order_by('blog__name', 'mod_date').distinct('blog__name', 'mod_date')
[...]

>>> Entry.objects.order_by('author', 'pub_date').distinct('author')
[...]
```

Note: Keep in mind that `order_by()` uses any default related model ordering that has been defined. You might have to explicitly order by the relation `_id` or referenced field to make sure the `DISTINCT ON` ex-
pressions match those at the beginning of the ORDER BY clause. For example, if the Blog model defined an ordering by name:

```python
Entry.objects.order_by('blog').distinct('blog')
```

...wouldn’t work because the query would be ordered by blog__name thus mismatching the DISTINCT ON expression. You’d have to explicitly order by the relation _id field (blog_id in this case) or the referenced one (blog__pk) to make sure both expressions match.

values()

values(*fields, **expressions)

Returns a QuerySet that returns dictionaries, rather than model instances, when used as an iterable.

Each of those dictionaries represents an object, with the keys corresponding to the attribute names of model objects.

This example compares the dictionaries of values() with the normal model objects:

```python
# This list contains a Blog object.
>>> Blog.objects.filter(name__startswith='Beatles')
<QuerySet [<Blog: Beatles Blog>]> # This list contains a dictionary.
>>> Blog.objects.filter(name__startswith='Beatles').values()
<QuerySet [{'id': 1, 'name': 'Beatles Blog', 'tagline': 'All the latest Beatles news.'}]>
```

The values() method takes optional positional arguments, *fields, which specify field names to which the SELECT should be limited. If you specify the fields, each dictionary will contain only the field keys/values for the fields you specify. If you don’t specify the fields, each dictionary will contain a key and value for every field in the database table.

Example:

```python
>>> Blog.objects.values()
<QuerySet [{id': 1, 'name': 'Beatles Blog', 'tagline': 'All the latest Beatles news.'}]>
>>> Blog.objects.values('id', 'name')
<QuerySet [{id': 1, 'name': 'Beatles Blog'}]>
```

The values() method also takes optional keyword arguments, **expressions, which are passed through to annotate():
You can use built-in and custom lookups in ordering. For example:

```python
>>> from django.db.models.functions import Lower
>>> Blog.objects.values(lower_name=Lower('name'))
<QuerySet [{'lower_name': 'beatles blog'}]>
```

An aggregate within a `values()` clause is applied before other arguments within the same `values()` clause. If you need to group by another value, add it to an earlier `values()` clause instead. For example:

```python
>>> from django.db.models import Count
>>> Blog.objects.values('entry__authors', entries=Count('entry'))
<QuerySet [{'entry__authors': 1, 'entries': 20}, {'entry__authors': 1, 'entries': 13}]>
>>> Blog.objects.values('entry__authors').annotate(entries=Count('entry'))
<QuerySet [{'entry__authors': 1, 'entries': 33}]>
```

A few subtleties that are worth mentioning:

- If you have a field called `foo` that is a `ForeignKey`, the default `values()` call will return a dictionary key called `foo_id`, since this is the name of the hidden model attribute that stores the actual value (the `foo` attribute refers to the related model). When you are calling `values()` and passing in field names, you can pass in either `foo` or `foo_id` and you will get back the same thing (the dictionary key will match the field name you passed in).

  For example:

  ```python
  >>> Entry.objects.values()
  <QuerySet [{'blog_id': 1, 'headline': 'First Entry', ...}, ...]>
  >>> Entry.objects.values('blog')
  <QuerySet [{'blog': 1}, ...]>
  >>> Entry.objects.values('blog_id')
  <QuerySet [{'blog_id': 1}, ...]>
  ```

- When using `values()` together with `distinct()`, be aware that ordering can affect the results. See the note in `distinct()` for details.

- If you use a `values()` clause after an `extra()` call, any fields defined by a `select` argument in the `extra()` must be explicitly included in the `values()` call. Any `extra()` call made after a `values()` call will have its extra selected fields ignored.
• Calling `only()` and `defer()` after `values()` doesn’t make sense, so doing so will raise a `TypeError`.

• Combining transforms and aggregates requires the use of two `annotate()` calls, either explicitly or as keyword arguments to `values()`. As above, if the transform has been registered on the relevant field type the first `annotate()` can be omitted, thus the following examples are equivalent:

```python
>>> from django.db.models import CharField, Count
>>> from django.db.models.functions import Lower
>>> CharField.register_lookup(Lower)
>>> Blog.objects.values('entry__authors__name__lower').annotate(entries=Count('entry'))
<QuerySet [{'entry__authors__name__lower': 'test author', 'entries': 33}]>
>>> Blog.objects.values(
...     entry__authors__name__lower=Lower('entry__authors__name')
... ).annotate(entries=Count('entry'))
<QuerySet [{'entry__authors__name__lower': 'test author', 'entries': 33}]>
>>> Blog.objects.annotate(
...     entry__authors__name__lower=Lower('entry__authors__name')
... ).values('entry__authors__name__lower').annotate(entries=Count('entry'))
<QuerySet [{'entry__authors__name__lower': 'test author', 'entries': 33}]>
```

It is useful when you know you’re only going to need values from a small number of the available fields and you won’t need the functionality of a model instance object. It’s more efficient to select only the fields you need to use.

Finally, note that you can call `filter()`, `order_by()`, etc. after the `values()` call, that means that these two calls are identical:

```python
Blog.objects.values().order_by('id')
Blog.objects.order_by('id').values()
```

The people who made Django prefer to put all the SQL-affecting methods first, followed (optionally) by any output-affecting methods (such as `values()`), but it doesn’t really matter. This is your chance to really flaunt your individualism.

You can also refer to fields on related models with reverse relations through `OneToOneField`, `ForeignKey` and `ManyToManyField` attributes:

```python
>>> Blog.objects.values('name', 'entry__headline')
<QuerySet [{'name': 'My blog', 'entry__headline': 'An entry'},
{'name': 'My blog', 'entry__headline': 'Another entry'}, ...]
```

Warning: Because `ManyToManyField` attributes and reverse relations can have multiple related rows, including these can have a multiplier effect on the size of your result set. This will be especially pronounced if you include multiple such fields in your `values()` query, in which case all possible combinations will
values_list()

values_list(*fields, flat=False, named=False)

This is similar to values() except that instead of returning dictionaries, it returns tuples when iterated over. Each tuple contains the value from the respective field or expression passed into the values_list() call — so the first item is the first field, etc. For example:

```python
>>> Entry.objects.values_list('id', 'headline')
<QuerySet [(1, 'First entry'), ...]>
```

If you only pass in a single field, you can also pass in the flat parameter. If True, this will mean the returned results are single values, rather than one-tuples. An example should make the difference clearer:

```python
>>> Entry.objects.values_list('id').order_by('id')
<QuerySet[(1,), (2,), (3,), ...]>

>>> Entry.objects.values_list('id', flat=True).order_by('id')
<QuerySet [1, 2, 3, ...]>
```

It is an error to pass in flat when there is more than one field.

You can pass named=True to get results as a namedtuple():

```python
>>> Entry.objects.values_list('id', 'headline', named=True)
<QuerySet [Row(id=1, headline='First entry'), ...]>
```

Using a named tuple may make use of the results more readable, at the expense of a small performance penalty for transforming the results into a named tuple.

If you don’t pass any values to values_list(), it will return all the fields in the model, in the order they were declared.

A common need is to get a specific field value of a certain model instance. To achieve that, use values_list() followed by a get() call:

```python
>>> Entry.objects.values_list('headline', flat=True).get(pk=1)
'First entry'
```
values() and values_list() are both intended as optimizations for a specific use case: retrieving a subset of data without the overhead of creating a model instance. This metaphor falls apart when dealing with many-to-many and other multivalued relations (such as the one-to-many relation of a reverse foreign key) because the “one row, one object” assumption doesn’t hold.

For example, notice the behavior when querying across a ManyToManyField:

```python
>>> Author.objects.values_list('name', 'entry__headline')
<QuerySet [('Noam Chomsky', 'Impressions of Gaza'),
('George Orwell', 'Why Socialists Do Not Believe in Fun'),
('George Orwell', 'In Defence of English Cooking'),
('Don Quixote', None)]>
```

Authors with multiple entries appear multiple times and authors without any entries have `None` for the entry headline.

Similarly, when querying a reverse foreign key, `None` appears for entries not having any author:

```python
>>> Entry.objects.values_list('authors')
<QuerySet [('Noam Chomsky',), ('George Orwell',), (None,)]>
```

dates()

dates(field, kind, order='ASC')

Returns a QuerySet that evaluates to a list of `datetime.date` objects representing all available dates of a particular kind within the contents of the QuerySet.

field should be the name of a DateField of your model. kind should be either "year", "month", "week", or "day". Each `datetime.date` object in the result list is “truncated” to the given type.

- "year" returns a list of all distinct year values for the field.
- "month" returns a list of all distinct year/month values for the field.
- "week" returns a list of all distinct year/week values for the field. All dates will be a Monday.
- "day" returns a list of all distinct year/month/day values for the field.

order, which defaults to 'ASC', should be either 'ASC' or 'DESC'. This specifies how to order the results.

Examples:

```python
>>> Entry.objects.dates('pub_date', 'year')
[datetime.date(2005, 1, 1)]
>>> Entry.objects.dates('pub_date', 'month')
[datetime.date(2005, 2, 1), datetime.date(2005, 3, 1)]
>>> Entry.objects.dates('pub_date', 'week')
```
Entry.objects.dates('pub_date', 'day')

Entry.objects.dates('pub_date', 'day', order='DESC')

Entry.objects.filter(headline__contains='Lennon').dates('pub_date', 'day')

```
[datetime.date(2005, 2, 14), datetime.date(2005, 3, 14)]
```

```
[datetime.date(2005, 2, 20), datetime.date(2005, 3, 20)]
```

```
[datetime.date(2005, 3, 20), datetime.date(2005, 2, 20)]
```

```
[datetime.date(2005, 3, 20)]
```

**datetimes()**

**datetimes(field_name, kind, order='ASC', tzinfo=None, is_dst=None)**

Returns a QuerySet that evaluates to a list of `datetime.datetime` objects representing all available dates of a particular kind within the contents of the QuerySet.

*field_name* should be the name of a DateTimeField of your model.

*kind* should be either "year", "month", "week", "day", "hour", "minute", or "second". Each `datetime.datetime` object in the result list is “truncated” to the given *type*.

*order*, which defaults to 'ASC', should be either 'ASC' or 'DESC'. This specifies how to order the results.

*tzinfo* defines the time zone to which datetimes are converted prior to truncation. Indeed, a given datetime has different representations depending on the time zone in use. This parameter must be a `datetime.tzinfo` object. If it’s None, Django uses the current time zone. It has no effect when USE_TZ is False.

*is_dst* indicates whether or not pytz should interpret nonexistent and ambiguous datetimes in daylight saving time. By default (when is_dst=None), pytz raises an exception for such datetimes.

Deprecated since version 4.0: The *is_dst* parameter is deprecated and will be removed in Django 5.0.

---

**Note:** This function performs time zone conversions directly in the database. As a consequence, your database must be able to interpret the value of `tzinfo.tzname(None)`. This translates into the following requirements:

- **SQLite:** no requirements. Conversions are performed in Python.
- **PostgreSQL:** no requirements (see Time Zones).
- **Oracle:** no requirements (see Choosing a Time Zone File).
- **MySQL:** load the time zone tables with `mysql_tzinfo_to_sql`.

---
Calling `none()` will create a queryset that never returns any objects and no query will be executed when accessing the results. A `qs.none()` queryset is an instance of `EmptyQuerySet`.

Examples:

```python
>>> Entry.objects.none()
<QuerySet []>
>>> from django.db.models.query import EmptyQuerySet
>>> isinstance(Entry.objects.none(), EmptyQuerySet)
True
```

`all()`

`all()`

Returns a copy of the current `QuerySet` (or `QuerySet` subclass). This can be useful in situations where you might want to pass in either a model manager or a `QuerySet` and do further filtering on the result. After calling `all()` on either object, you’ll definitely have a `QuerySet` to work with.

When a `QuerySet` is evaluated, it typically caches its results. If the data in the database might have changed since a `QuerySet` was evaluated, you can get updated results for the same query by calling `all()` on a previously evaluated `QuerySet`.

`union()`

`union(*other_qs, all=False)`

Uses SQL’s UNION operator to combine the results of two or more `QuerySets`. For example:

```python
>>> qs1.union(qs2, qs3)
```

The UNION operator selects only distinct values by default. To allow duplicate values, use the `all=True` argument.

`union()`, `intersection()`, and `difference()` return model instances of the type of the first `QuerySet` even if the arguments are `QuerySets` of other models. Passing different models works as long as the SELECT list is the same in all `QuerySets` (at least the types, the names don’t matter as long as the types are in the same order). In such cases, you must use the column names from the first `QuerySet` in `QuerySet` methods applied to the resulting `QuerySet`. For example:
>>> qs1 = Author.objects.values_list('name')
>>> qs2 = Entry.objects.values_list('headline')
>>> qs1.union(qs2).order_by('name')

In addition, only LIMIT, OFFSET, COUNT(*), ORDER BY, and specifying columns (i.e. slicing, count(), exists(), order_by(), and values()/values_list()) are allowed on the resulting QuerySet. Further, databases place restrictions on what operations are allowed in the combined queries. For example, most databases don’t allow LIMIT or OFFSET in the combined queries.

intersection()

intersection(*other_qs)

Uses SQL’s INTERSECT operator to return the shared elements of two or more QuerySets. For example:

>>> qs1.intersection(qs2, qs3)

See union() for some restrictions.

difference()

difference(*other_qs)

Uses SQL’s EXCEPT operator to keep only elements present in the QuerySet but not in some other QuerySets. For example:

>>> qs1.difference(qs2, qs3)

See union() for some restrictions.

select_related()

select_related(*fields)

Returns a QuerySet that will “follow” foreign-key relationships, selecting additional related-object data when it executes its query. This is a performance booster which results in a single more complex query but means later use of foreign-key relationships won’t require database queries.

The following examples illustrate the difference between plain lookups and select_related() lookups. Here’s standard lookup:
# Hits the database.
e = Entry.objects.get(id=5)

# Hits the database again to get the related Blog object.
b = e.blog

And here’s `select_related` lookup:

# Hits the database.
e = Entry.objects.select_related('blog').get(id=5)

# Doesn’t hit the database, because e.blog has been prepopulated
# in the previous query.
b = e.blog

You can use `select_related()` with any queryset of objects:

```python
from django.utils import timezone

# Find all the blogs with entries scheduled to be published in the future.
blogs = set()

for e in Entry.objects.filter(pub_date__gt=timezone.now()).select_related('blog'):
    # Without select_related(), this would make a database query for each
    # loop iteration in order to fetch the related blog for each entry.
    blogs.add(e.blog)
```

The order of `filter()` and `select_related()` chaining isn’t important. These querysets are equivalent:

```python
Entry.objects.filter(pub_date__gt=timezone.now()).select_related('blog')
Entry.objects.select_related('blog').filter(pub_date__gt=timezone.now())
```

You can follow foreign keys in a similar way to querying them. If you have the following models:

```python
from django.db import models

class City(models.Model):
    # ...
    pass

class Person(models.Model):
    # ...
    hometown = models.ForeignKey(
        City,
        on_delete=models.SET_NULL,
```

(continues on next page)
... then a call to `Book.objects.select_related('author__hometown').get(id=4)` will cache the related `Person` and the related `City`:

```python
# Hits the database with joins to the author and hometown tables.
b = Book.objects.select_related('author__hometown').get(id=4)
p = b.author  # Doesn't hit the database.
c = p.hometown  # Doesn't hit the database.

# Without select_related()...
b = Book.objects.get(id=4)  # Hits the database.
p = b.author  # Hits the database.
c = p.hometown  # Hits the database.
```

You can refer to any `ForeignKey` or `OneToOneField` relation in the list of fields passed to `select_related()`. You can also refer to the reverse direction of a `OneToOneField` in the list of fields passed to `select_related`—that is, you can traverse a `OneToOneField` back to the object on which the field is defined. Instead of specifying the field name, use the `related_name` for the field on the related object.

There may be some situations where you wish to call `select_related()` with a lot of related objects, or where you don’t know all of the relations. In these cases it is possible to call `select_related()` with no arguments. This will follow all non-null foreign keys it can find - nullable foreign keys must be specified. This is not recommended in most cases as it is likely to make the underlying query more complex, and return more data, than is actually needed.

If you need to clear the list of related fields added by past calls of `select_related` on a QuerySet, you can pass `None` as a parameter:

```python
>>> without_relations = queryset.select_related(None)
```

Chaining `select_related` calls works in a similar way to other methods - that is that `select_related('foo', 'bar')` is equivalent to `select_related('foo').select_related('bar').`
prefetch_related()

prefetch_related(*lookups)

Returns a QuerySet that will automatically retrieve, in a single batch, related objects for each of the specified lookups.

This has a similar purpose to select_related, in that both are designed to stop the deluge of database queries that is caused by accessing related objects, but the strategy is quite different.

select_related works by creating an SQL join and including the fields of the related object in the SELECT statement. For this reason, select_related gets the related objects in the same database query. However, to avoid the much larger result set that would result from joining across a ‘many’ relationship, select_related is limited to single-valued relationships - foreign key and one-to-one.

prefetch_related, on the other hand, does a separate lookup for each relationship, and does the ‘joining’ in Python. This allows it to prefetch many-to-many and many-to-one objects, which cannot be done using select_related, in addition to the foreign key and one-to-one relationships that are supported by select_related. It also supports prefetching of GenericRelation and GenericForeignKey, however, it must be restricted to a homogeneous set of results. For example, prefetching objects referenced by a GenericForeignKey is only supported if the query is restricted to one ContentType.

For example, suppose you have these models:

```python
from django.db import models

class Topping(models.Model):
    name = models.CharField(max_length=30)

class Pizza(models.Model):
    name = models.CharField(max_length=50)
    toppings = models.ManyToManyField(Topping)

    def __str__(self):
        return "%s (%s)" % (self.name,
                           ", ".join(topping.name for topping in self.toppings.all()),
                           )
```

and run:

```python
>>> Pizza.objects.all()
["Hawaiian (ham, pineapple)", "Seafood (prawns, smoked salmon)"
```

The problem with this is that every time Pizza.__str__() asks for self.toppings.all() it has to query the database, so Pizza.objects.all() will run a query on the Toppings table for every item in the Pizza QuerySet.
We can reduce to just two queries using `prefetch_related`:

```python
>>> Pizza.objects.prefetch_related('toppings')
```

This implies a `self.toppings.all()` for each Pizza; now each time `self.toppings.all()` is called, instead of having to go to the database for the items, it will find them in a prefetched `QuerySet` cache that was populated in a single query.

That is, all the relevant toppings will have been fetched in a single query, and used to make `QuerySets` that have a pre-filled cache of the relevant results; these `QuerySets` are then used in the `self.toppings.all()` calls.

The additional queries in `prefetch_related()` are executed after the `QuerySet` has begun to be evaluated and the primary query has been executed.

If you have an iterable of model instances, you can prefetch related attributes on those instances using the `prefetch_related_objects()` function.

Note that the result cache of the primary `QuerySet` and all specified related objects will then be fully loaded into memory. This changes the typical behavior of `QuerySets`, which normally try to avoid loading all objects into memory before they are needed, even after a query has been executed in the database.

---

Note: Remember that, as always with `QuerySets`, any subsequent chained methods which imply a different database query will ignore previously cached results, and retrieve data using a fresh database query. So, if you write the following:

```python
>>> pizzas = Pizza.objects.prefetch_related('toppings')
>>> [list(pizza.toppings.filter(spicy=True)) for pizza in pizzas]
```

...then the fact that `pizza.toppings.all()` has been prefetched will not help you. The `prefetch_related('toppings')` implied `pizza.toppings.all()`, but `pizza.toppings.filter()` is a new and different query. The prefetched cache can’t help here; in fact it hurts performance, since you have done a database query that you haven’t used. So use this feature with caution!

Also, if you call the database-altering methods `add()`, `remove()`, `clear()` or `set()`, on related managers, any prefetched cache for the relation will be cleared.

You can also use the normal join syntax to do related fields of related fields. Suppose we have an additional model to the example above:

```python
class Restaurant(models.Model):
    pizzas = models.ManyToManyField(Pizza, related_name='restaurants')
    best_pizza = models.ForeignKey(Pizza, related_name='championed_by', on_delete=models.CASCADE)
```

The following are all legal:
This will prefetch all pizzas belonging to restaurants, and all toppings belonging to those pizzas. This will result in a total of 3 database queries - one for the restaurants, one for the pizzas, and one for the toppings.

```
>>> Restaurant.objects.prefetch_related('pizzas__toppings')
```

This will fetch the best pizza and all the toppings for the best pizza for each restaurant. This will be done in 3 database queries - one for the restaurants, one for the ‘best pizzas’, and one for the toppings.

The `best_pizza` relationship could also be fetched using `select_related` to reduce the query count to 2:

```
>>> Restaurant.objects.select_related('best_pizza').prefetch_related('best_pizza__toppings')
```

Since the prefetch is executed after the main query (which includes the joins needed by `select_related`), it is able to detect that the `best_pizza` objects have already been fetched, and it will skip fetching them again.

Chaining `prefetch_related` calls will accumulate the lookups that are prefetched. To clear any `prefetch_related` behavior, pass `None` as a parameter:

```
>>> non_prefetched = qs.prefetch_related(None)
```

One difference to note when using `prefetch_related` is that objects created by a query can be shared between the different objects that they are related to i.e. a single Python model instance can appear at more than one point in the tree of objects that are returned. This will normally happen with foreign key relationships. Typically this behavior will not be a problem, and will in fact save both memory and CPU time.

While `prefetch_related` supports prefetching `GenericForeignKey` relationships, the number of queries will depend on the data. Since a `GenericForeignKey` can reference data in multiple tables, one query per table referenced is needed, rather than one query for all the items. There could be additional queries on the `ContentType` table if the relevant rows have not already been fetched.

`prefetch_related` in most cases will be implemented using an SQL query that uses the ‘IN’ operator. This means that for a large `QuerySet` a large ‘IN’ clause could be generated, which, depending on the database, might have performance problems of its own when it comes to parsing or executing the SQL query. Always profile for your use case!

If you use `iterator()` to run the query, `prefetch_related()` calls will only be observed if a value for `chunk_size` is provided.

You can use the `Prefetch` object to further control the prefetch operation.

In its simplest form `Prefetch` is equivalent to the traditional string based lookups:
You can provide a custom queryset with the optional `queryset` argument. This can be used to change the default ordering of the queryset:

```python
>>> Restaurant.objects.prefetch_related(
    ...
    Prefetch('pizzas__toppings', queryset=Toppings.objects.order_by('name'))
```

Or to call `select_related()` when applicable to reduce the number of queries even further:

```python
>>> Pizza.objects.prefetch_related(
    ...
    Prefetch('restaurants', queryset=Restaurant.objects.select_related('best_pizza'))
```

You can also assign the prefetched result to a custom attribute with the optional `to_attr` argument. The result will be stored directly in a list.

This allows prefetching the same relation multiple times with a different QuerySet; for instance:

```python
>>> vegetarian_pizzas = Pizza.objects.filter(vegetarian=True)
>>> Restaurant.objects.prefetch_related(
    ...
    Prefetch('pizzas', to_attr='menu'),
    ...
    Prefetch('pizzas', queryset=vegetarian_pizzas, to_attr='vegetarian_menu'))
```

Lookups created with custom `to_attr` can still be traversed as usual by other lookups:

```python
>>> vegetarian_pizzas = Pizza.objects.filter(vegetarian=True)
>>> Restaurant.objects.prefetch_related(
    ...
    Prefetch('pizzas', queryset=vegetarian_pizzas, to_attr='vegetarian_menu'),
    ...'vegetarian_menu__toppings')
```

Using `to_attr` is recommended when filtering down the prefetch result as it is less ambiguous than storing a filtered result in the related manager’s cache:

```python
>>> queryset = Pizza.objects.filter(vegetarian=True)
    ...
>>> # Recommended:
>>> restaurants = Restaurant.objects.prefetch_related(
    ...
    Prefetch('pizzas', queryset=queryset, to_attr='vegetarian_pizzas'))
>>> vegetarian_pizzas = restaurants[0].vegetarian_pizzas
>>> ...
>>> # Not recommended:
>>> restaurants = Restaurant.objects.prefetch_related(
    ...
    Prefetch('pizzas', queryset=queryset))
>>> vegetarian_pizzas = restaurants[0].pizzas.all()
```

Custom prefetching also works with single related relations like forward ForeignKey or OneToOneField. Generally you’ll want to use `select_related()` for these relations, but there are a number of cases where prefetching with a custom QuerySet is useful:
* You want to use a QuerySet that performs further prefetching on related models.
* You want to prefetch only a subset of the related objects.
* You want to use performance optimization techniques like *deferred fields*:

```python
>>> queryset = Pizza.objects.only('name')
>>> restaurants = Restaurant.objects.prefetch_related(
    ...   Prefetch('best_pizza', queryset=queryset))
```

When using multiple databases, Prefetch will respect your choice of database. If the inner query does not specify a database, it will use the database selected by the outer query. All of the following are valid:

```python
>>> # Both inner and outer queries will use the 'replica' database
>>> Restaurant.objects.prefetch_related('pizzas__toppings').using('replica')
>>> Restaurant.objects.prefetch_related(
    ...   Prefetch('pizzas__toppings'),
    ... ).using('replica')
>>> # Inner will use the 'replica' database; outer will use 'default' database
>>> Restaurant.objects.prefetch_related(
    ...   Prefetch('pizzas__toppings', queryset=Toppings.objects.using('replica')),
    ... )
>>> # Inner will use 'replica' database; outer will use 'cold-storage' database
>>> Restaurant.objects.prefetch_related(
    ...   Prefetch('pizzas__toppings', queryset=Toppings.objects.using('replica')),
    ... ).using('cold-storage')
```

Note: The ordering of lookups matters.

Take the following examples:

```python
>>> prefetch_related('pizzas__toppings', 'pizzas')
```

This works even though it’s unordered because 'pizzas__toppings' already contains all the needed information, therefore the second argument 'pizzas' is actually redundant.

```python
>>> prefetch_related('pizzas__toppings', Prefetch('pizzas', queryset=Pizza.objects.all()))
```

This will raise a ValueError because of the attempt to redefine the queryset of a previously seen lookup. Note that an implicit queryset was created to traverse 'pizzas' as part of the 'pizzas__toppings' lookup.

```python
>>> prefetch_related('pizza_list__toppings', Prefetch('pizzas', to_attr='pizza_list'))
```
This will trigger an `AttributeError` because 'pizza_list' doesn’t exist yet when 'pizza_list__toppings' is being processed.

This consideration is not limited to the use of `Prefetch` objects. Some advanced techniques may require that the lookups be performed in a specific order to avoid creating extra queries; therefore it’s recommended to always carefully order `prefetch_related` arguments.

```python
extra()
```

`extra(select=None, where=None, params=None, tables=None, order_by=None, select_params=None)`

Sometimes, the Django query syntax by itself can’t easily express a complex `WHERE` clause. For these edge cases, Django provides the `extra()` QuerySet modifier—a hook for injecting specific clauses into the SQL generated by a QuerySet.

Use this method as a last resort

This is an old API that we aim to deprecate at some point in the future. Use it only if you cannot express your query using other queryset methods. If you do need to use it, please file a ticket using the `QuerySet.extra` keyword with your use case (please check the list of existing tickets first) so that we can enhance the QuerySet API to allow removing `extra()`. We are no longer improving or fixing bugs for this method.

For example, this use of `extra()`:

```python
>>> qs.extra(  
...     select={'val': "select col from sometable where othercol = %s"},  
...     select_params=(someparam,),  
... )
```

is equivalent to:

```python
>>> qs.annotate(val=RawSQL("select col from sometable where othercol = %s", (someparam,)))
```

The main benefit of using `RawSQL` is that you can set `output_field` if needed. The main downside is that if you refer to some table alias of the queryset in the raw SQL, then it is possible that Django might change that alias (for example, when the queryset is used as a subquery in yet another query).

Warning: You should be very careful whenever you use `extra()`. Every time you use it, you should escape any parameters that the user can control by using `params` in order to protect against SQL injection attacks.

---

6.16. Models
You also must not quote placeholders in the SQL string. This example is vulnerable to SQL injection because of the quotes around %s:

```sql
SELECT col FROM sometable WHERE othercol = '%s'  # unsafe!
```

You can read more about how Django’s SQL injection protection works.

By definition, these extra lookups may not be portable to different database engines (because you’re explicitly writing SQL code) and violate the DRY principle, so you should avoid them if possible.

Specify one or more of `params`, `select`, `where` or `tables`. None of the arguments is required, but you should use at least one of them.

- **select**

  The `select` argument lets you put extra fields in the SELECT clause. It should be a dictionary mapping attribute names to SQL clauses to use to calculate that attribute.

  Example:

  ```python
  Entry.objects.extra(select={'is_recent': "pub_date > '2006-01-01'"})
  ```

  As a result, each `Entry` object will have an extra attribute, `is_recent`, a boolean representing whether the entry’s `pub_date` is greater than Jan. 1, 2006.

  Django inserts the given SQL snippet directly into the SELECT statement, so the resulting SQL of the above example would be something like:

  ```sql
  SELECT blog_entry.*, (pub_date > '2006-01-01') AS is_recent
  FROM blog_entry;
  ```

  The next example is more advanced; it does a subquery to give each resulting `Blog` object an `entry_count` attribute, an integer count of associated `Entry` objects:

  ```python
  Blog.objects.extra(
      select={
        'entry_count': 'SELECT COUNT(*) FROM blog_entry WHERE blog_entry.blog_id = blog_blog.id',
      },
  )
  ```

  In this particular case, we’re exploiting the fact that the query will already contain the `blog_blog` table in its FROM clause.

  The resulting SQL of the above example would be:
SELECT blog_blog.*, (SELECT COUNT(*) FROM blog_entry WHERE blog_entry.blog_id = blog_blog.id) AS entry_count
FROM blog_blog;

Note that the parentheses required by most database engines around subqueries are not required in Django’s `select` clauses. Also note that some database backends, such as some MySQL versions, don’t support subqueries.

In some rare cases, you might wish to pass parameters to the SQL fragments in `extra(select=...)`. For this purpose, use the `select_params` parameter.

This will work, for example:

```python
Blog.objects.extra(
    select={'a': '%s', 'b': '%s'},
    select_params=('one', 'two'),
)
```

If you need to use a literal `%s` inside your select string, use the sequence `%%s`.

- **where / tables**

You can define explicit SQL `WHERE` clauses —perhaps to perform non-explicit joins—by using `where`. You can manually add tables to the SQL `FROM` clause by using `tables`.

`where` and `tables` both take a list of strings. All `where` parameters are “AND” ed to any other search criteria.

Example:

```python
Entry.objects.extra(where=["foo='a' OR bar = 'a'", "baz = 'a'"])
```

... translates (roughly) into the following SQL:

```
SELECT * FROM blog_entry WHERE (foo='a' OR bar='a') AND (baz='a')
```

Be careful when using the `tables` parameter if you’re specifying tables that are already used in the query. When you add extra tables via the `tables` parameter, Django assumes you want that table included an extra time, if it is already included. That creates a problem, since the table name will then be given an alias. If a table appears multiple times in an SQL statement, the second and subsequent occurrences must use aliases so the database can tell them apart. If you’re referring to the extra table you added in the extra `where` parameter this is going to cause errors.

Normally you’ll only be adding extra tables that don’t already appear in the query. However, if the case outlined above does occur, there are a few solutions. First, see if you can get by without including the extra table and use the one already in the query. If that isn’t possible, put your `extra()` call at the front of the queryset construction so that your table is the first use of that table. Finally, if all else
fails, look at the query produced and rewrite your `where` addition to use the alias given to your extra table. The alias will be the same each time you construct the queryset in the same way, so you can rely upon the alias name to not change.

- **order_by**

  If you need to order the resulting queryset using some of the new fields or tables you have included via `extra()` use the `order_by` parameter to `extra()` and pass in a sequence of strings. These strings should either be model fields (as in the normal `order_by()` method on querysets), of the form `table_name.column_name` or an alias for a column that you specified in the `select` parameter to `extra()`.

  For example:

  ```
  q = Entry.objects.extra(select={'is_recent': "pub_date > '2006-01-01'"})
  q = q.extra(order_by=['-is_recent'])
  ```

  This would sort all the items for which `is_recent` is true to the front of the result set (True sorts before False in a descending ordering).

  This shows, by the way, that you can make multiple calls to `extra()` and it will behave as you expect (adding new constraints each time).

- **params**

  The `where` parameter described above may use standard Python database string placeholders — `%s` to indicate parameters the database engine should automatically quote. The `params` argument is a list of any extra parameters to be substituted.

  Example:

  ```
  Entry.objects.extra(where=['headline=%s'], params=['Lennon'])
  ```

  Always use `params` instead of embedding values directly into `where` because `params` will ensure values are quoted correctly according to your particular backend. For example, quotes will be escaped correctly.

  Bad:

  ```
  Entry.objects.extra(where=['headline='Lennon''])
  ```

  Good:

  ```
  Entry.objects.extra(where=['headline=%s'], params=['Lennon'])
  ```

  Warning: If you are performing queries on MySQL, note that MySQL’s silent type coercion may cause unexpected results when mixing types. If you query on a string type column, but with an integer value, MySQL will coerce the types of all values in the table to an integer before performing the comparison.
For example, if your table contains the values ‘abc’, 'def' and you query for WHERE mycolumn=0, both rows will match. To prevent this, perform the correct typecasting before using the value in a query.

defer()

defer(*fields)

In some complex data-modeling situations, your models might contain a lot of fields, some of which could contain a lot of data (for example, text fields), or require expensive processing to convert them to Python objects. If you are using the results of a queryset in some situation where you don’t know if you need those particular fields when you initially fetch the data, you can tell Django not to retrieve them from the database. This is done by passing the names of the fields to not load to `defer()`:

```python
Entry.objects.defer("headline", "body")
```

A queryset that has deferred fields will still return model instances. Each deferred field will be retrieved from the database if you access that field (one at a time, not all the deferred fields at once).

Note: Deferred fields will not lazy-load like this from asynchronous code. Instead, you will get a `SynchronousOnlyOperation` exception. If you are writing asynchronous code, you should not try to access any fields that you `defer()`.

You can make multiple calls to `defer()`. Each call adds new fields to the deferred set:

```python
# Defers both the body and headline fields.
Entry.objects.defer("body").filter(rating=5).defer("headline")
```

The order in which fields are added to the deferred set does not matter. Calling `defer()` with a field name that has already been deferred is harmless (the field will still be deferred).

You can defer loading of fields in related models (if the related models are loading via `select_related()`) by using the standard double-underscore notation to separate related fields:

```python
Blog.objects.select_related().defer("entry__headline", "entry__body")
```

If you want to clear the set of deferred fields, pass `None` as a parameter to `defer()`:

```python
# Load all fields immediately.
my_queryset.defer(None)
```

Some fields in a model won’t be deferred, even if you ask for them. You can never defer the loading of the primary key. If you are using `select_related()` to retrieve related models, you shouldn’t defer the loading
of the field that connects from the primary model to the related one, doing so will result in an error.

Note: The `defer()` method (and its cousin, `only()`, below) are only for advanced use-cases. They provide an optimization for when you have analyzed your queries closely and understand exactly what information you need and have measured that the difference between returning the fields you need and the full set of fields for the model will be significant.

Even if you think you are in the advanced use-case situation, only use “defer()” when you cannot, at queryset load time, determine if you will need the extra fields or not. If you are frequently loading and using a particular subset of your data, the best choice you can make is to normalize your models and put the non-loaded data into a separate model (and database table). If the columns must stay in the one table for some reason, create a model with `Meta.managed = False` (see the `managed attribute` documentation) containing just the fields you normally need to load and use that where you might otherwise call `defer()`. This makes your code more explicit to the reader, is slightly faster and consumes a little less memory in the Python process.

For example, both of these models use the same underlying database table:

```python
class CommonlyUsedModel(models.Model):
    f1 = models.CharField(max_length=10)
    
    class Meta:
        managed = False
        db_table = 'app_largetable'

class ManagedModel(models.Model):
    f1 = models.CharField(max_length=10)
    f2 = models.CharField(max_length=10)
    
    class Meta:
        db_table = 'app_largetable'

# Two equivalent QuerySets:
CommonlyUsedModel.objects.all()
ManagedModel.objects.defer('f2')
```

If many fields need to be duplicated in the unmanaged model, it may be best to create an abstract model with the shared fields and then have the unmanaged and managed models inherit from the abstract model.

Note: When calling `save()` for instances with deferred fields, only the loaded fields will be saved. See `save()` for more details.
only() only(*fields)

The only() method is more or less the opposite of defer(). You call it with the fields that should not be deferred when retrieving a model. If you have a model where almost all the fields need to be deferred, using only() to specify the complementary set of fields can result in simpler code.

Suppose you have a model with fields name, age and biography. The following two querysets are the same, in terms of deferred fields:

```python
Person.objects.defer("age", "biography")
Person.objects.only("name")
```

Whenever you call only() it replaces the set of fields to load immediately. The method’s name is mnemonic: only those fields are loaded immediately; the remainder are deferred. Thus, successive calls to only() result in only the final fields being considered:

```python
# This will defer all fields except the headline.
Entry.objects.only("body", "rating").only("headline")
```

Since defer() acts incrementally (adding fields to the deferred list), you can combine calls to only() and defer() and things will behave logically:

```python
# Final result is that everything except "headline" is deferred.
Entry.objects.only("headline", "body").defer("body")

# Final result loads headline and body immediately (only() replaces any
# existing set of fields).
Entry.objects.defer("body").only("headline", "body")
```

All of the cautions in the note for the defer() documentation apply to only() as well. Use it cautiously and only after exhausting your other options.

Using only() and omitting a field requested using select_related() is an error as well.

As with defer(), you cannot access the non-loaded fields from asynchronous code and expect them to load. Instead, you will get a SynchronousOnlyOperation exception. Ensure that all fields you might access are in your only() call.

---

Note: When calling save() for instances with deferred fields, only the loaded fields will be saved. See save() for more details.
using()

using(alias)

This method is for controlling which database the QuerySet will be evaluated against if you are using more than one database. The only argument this method takes is the alias of a database, as defined in `DATABASES`.

For example:

```python
# queries the database with the 'default' alias.
>>> Entry.objects.all()

# queries the database with the 'backup' alias
>>> Entry.objects.using('backup')
```

select_for_update()

**select_for_update**(nowait=False, skip_locked=False, of=(), no_key=False)

Returns a queryset that will lock rows until the end of the transaction, generating a `SELECT ... FOR UPDATE` SQL statement on supported databases.

For example:

```python
from django.db import transaction

entries = Entry.objects.select_for_update().filter(author=request.user)
with transaction.atomic():
    for entry in entries:
        ...
```

When the queryset is evaluated (for `entry in entries` in this case), all matched entries will be locked until the end of the transaction block, meaning that other transactions will be prevented from changing or acquiring locks on them.

Usually, if another transaction has already acquired a lock on one of the selected rows, the query will block until the lock is released. If this is not the behavior you want, call `select_for_update(nowait=True)`. This will make the call non-blocking. If a conflicting lock is already acquired by another transaction, `DatabaseError` will be raised when the queryset is evaluated. You can also ignore locked rows by using `select_for_update(skip_locked=True)` instead. The `nowait` and `skip_locked` are mutually exclusive and attempts to call `select_for_update()` with both options enabled will result in a `ValueError`.

By default, `select_for_update()` locks all rows that are selected by the query. For example, rows of related objects specified in `select_related()` are locked in addition to rows of the queryset’s model. If this isn’t desired, specify the related objects you want to lock in `select_for_update(of=(...))` using the same fields syntax as `select_related()`. Use the value `self` to refer to the queryset’s model.
Lock parents models in `select_for_update(of=...)`  

If you want to lock parents models when using multi-table inheritance, you must specify parent link fields (by default `<parent_model_name>_ptr`) in the of argument. For example:

```python
Restaurant.objects.select_for_update(of=('self', 'place_ptr'))
```

Using `select_for_update(of=...)` with specified fields

If you want to lock models and specify selected fields, e.g. using `values()`, you must select at least one field from each model in the of argument. Models without selected fields will not be locked.

On PostgreSQL only, you can pass `no_key=True` in order to acquire a weaker lock, that still allows creating rows that merely reference locked rows (through a foreign key, for example) while the lock is in place. The PostgreSQL documentation has more details about row-level lock modes.

You can’t use `select_for_update()` on nullable relations:

```python
>>> Person.objects.select_related('hometown').select_for_update()
Traceback (most recent call last):
  ...
django.db.utils.NotSupportedError: FOR UPDATE cannot be applied to the nullable side of an outer...

-join
```

To avoid that restriction, you can exclude null objects if you don’t care about them:

```python
>>> Person.objects.select_related('hometown').select_for_update().exclude(hometown=None)
<QuerySet [<Person: ...>], ...>  
```

The `postgresql`, `oracle`, and `mysql` database backends support `select_for_update()`. However, MariaDB only supports the `nowait` argument, MariaDB 10.6+ also supports the `skip_locked` argument, and MySQL 8.0.1+ supports the `nowait`, `skip_locked`, and of arguments. The `no_key` argument is only supported on PostgreSQL.

Passing `nowait=True, skip_locked=True, no_key=True, or of` to `select_for_update()` using database backends that do not support these options, such as MySQL, raises a `NotSupportedError`. This prevents code from unexpectedly blocking.

Evaluating a queryset with `select_for_update()` in autocommit mode on backends which support `SELECT ...

FOR UPDATE` is a `TransactionManagementError` error because the rows are not locked in that case. If allowed, this would facilitate data corruption and could easily be caused by calling code that expects to be run in a transaction outside of one.

---

6.16. Models 1653
Using `select_for_update()` on backends which do not support `SELECT ... FOR UPDATE` (such as SQLite) will have no effect. `SELECT ... FOR UPDATE` will not be added to the query, and an error isn’t raised if `select_for_update()` is used in autocommit mode.

Warning: Although `select_for_update()` normally fails in autocommit mode, since `TestCase` automatically wraps each test in a transaction, calling `select_for_update()` in a `TestCase` even outside an `atomic()` block will (perhaps unexpectedly) pass without raising a `TransactionManagementError`. To properly test `select_for_update()` you should use `TransactionTestCase`.

Certain expressions may not be supported

PostgreSQL doesn’t support `select_for_update()` with `Window` expressions.

```
raw()
```

```
raw(raw_query, params=(), translations=None, using=None)
```

Takes a raw SQL query, executes it, and returns a `django.db.models.query.RawQuerySet` instance. This `RawQuerySet` instance can be iterated over just like a normal `QuerySet` to provide object instances.

See the **Performing raw SQL queries** for more information.

Warning: `raw()` always triggers a new query and doesn’t account for previous filtering. As such, it should generally be called from the `Manager` or from a fresh `QuerySet` instance.

### Operators that return new QuerySets

Combined querysets must use the same model.

**AND (&)**

Combines two `QuerySets` using the SQL `AND` operator.

The following are equivalent:

```
Model.objects.filter(x=1) & Model.objects.filter(y=2)
Model.objects.filter(x=1, y=2)
from django.db.models import Q
Model.objects.filter(Q(x=1) & Q(y=2))
```
SQL equivalent:

```
SELECT ... WHERE x=1 AND y=2
```

**OR (|)**

Combines two QuerySets using the SQL OR operator.

The following are equivalent:

```python
Model.objects.filter(x=1) | Model.objects.filter(y=2)
from django.db.models import Q
Model.objects.filter(Q(x=1) | Q(y=2))
```

SQL equivalent:

```
SELECT ... WHERE x=1 OR y=2
```

| is not a commutative operation, as different (though equivalent) queries may be generated.

**XOR (^)**

Combines two QuerySets using the SQL XOR operator.

The following are equivalent:

```python
Model.objects.filter(x=1) ^ Model.objects.filter(y=2)
from django.db.models import Q
Model.objects.filter(Q(x=1) ^ Q(y=2))
```

SQL equivalent:

```
SELECT ... WHERE x=1 XOR y=2
```

Note: XOR is natively supported on MariaDB and MySQL. On other databases, x ^ y ^ ... ^ z is converted to an equivalent:

```
(x OR y OR ... OR z) AND
1=(
    (CASE WHEN x THEN 1 ELSE 0 END) +
    (CASE WHEN y THEN 1 ELSE 0 END) +
    ...
    (CASE WHEN z THEN 1 ELSE 0 END) +
)
```
Methods that do not return QuerySets

The following QuerySet methods evaluate the QuerySet and return something other than a QuerySet. 

These methods do not use a cache (see Caching and QuerySets). Rather, they query the database each time they’re called.

Because these methods evaluate the QuerySet, they are blocking calls, and so their main (synchronous) versions cannot be called from asynchronous code. For this reason, each has a corresponding asynchronous version with an a prefix - for example, rather than \texttt{get(...)} you can \texttt{await aget(...)}.

There is usually no difference in behavior apart from their asynchronous nature, but any differences are noted below next to each method.

The asynchronous versions of each method, prefixed with a was added.

\texttt{get()}

\texttt{get(*args,**kwargs)}

\texttt{aget(*args,**kwargs)}

Asynchronous version: \texttt{aget()}

Returns the object matching the given lookup parameters, which should be in the format described in Field lookups. You should use lookups that are guaranteed unique, such as the primary key or fields in a unique constraint. For example:

\begin{verbatim}
Entry.objects.get(id=1)
Entry.objects.get(Q(blog=blog) & Q(entry_number=1))
\end{verbatim}

If you expect a queryset to already return one row, you can use \texttt{get()} without any arguments to return the object for that row:

\begin{verbatim}
Entry.objects.filter(pk=1).get()
\end{verbatim}

If \texttt{get()} doesn’t find any object, it raises a \texttt{Model.DoesNotExist} exception:

\begin{verbatim}
Entry.objects.get(id=-999) # raises Entry.DoesNotExist
\end{verbatim}

If \texttt{get()} finds more than one object, it raises a \texttt{Model.MultipleObjectsReturned} exception:

\begin{verbatim}
Entry.objects.get(name='A Duplicated Name') # raises Entry.MultipleObjectsReturned
\end{verbatim}
Both these exception classes are attributes of the model class, and specific to that model. If you want to handle such exceptions from several `get()` calls for different models, you can use their generic base classes. For example, you can use `django.core.exceptions.ObjectDoesNotExist` to handle `DoesNotExist` exceptions from multiple models:

```python
from django.core.exceptions import ObjectDoesNotExist

try:
    blog = Blog.objects.get(id=1)
    entry = Entry.objects.get(blog=blog, entry_number=1)
except ObjectDoesNotExist:
    print("Either the blog or entry doesn't exist.")
```

`get()` method was added.

**create()**

`create(**kwargs)`

`acreate(*args, **kwargs)`

Asynchronous version: `acreate()`

A convenience method for creating an object and saving it all in one step. Thus:

```python
p = Person.objects.create(first_name="Bruce", last_name="Springsteen")
```

and:

```python
p = Person(first_name="Bruce", last_name="Springsteen")
p.save(force_insert=True)
```

are equivalent.

The `force_insert` parameter is documented elsewhere, but all it means is that a new object will always be created. Normally you won’t need to worry about this. However, if your model contains a manual primary key value that you set and if that value already exists in the database, a call to `create()` will fail with an `IntegrityError` since primary keys must be unique. Be prepared to handle the exception if you are using manual primary keys.

`acreate()` method was added.
get_or_create()

get_or_create(defaults=None, **kwargs)

A convenience method for looking up an object with the given kwargs (may be empty if your model has defaults for all fields), creating one if necessary.

Returns a tuple of (object, created), where object is the retrieved or created object and created is a boolean specifying whether a new object was created.

This is meant to prevent duplicate objects from being created when requests are made in parallel, and as a shortcut to boilerplatish code. For example:

```python
try:
    obj = Person.objects.get(first_name='John', last_name='Lennon')
except Person.DoesNotExist:
    obj = Person(first_name='John', last_name='Lennon', birthday=date(1940, 10, 9))
    obj.save()
```

Here, with concurrent requests, multiple attempts to save a Person with the same parameters may be made. To avoid this race condition, the above example can be rewritten using get_or_create() like so:

```python
obj, created = Person.objects.get_or_create(
    first_name='John',
    last_name='Lennon',
    defaults={'birthday': date(1940, 10, 9)},
)
```

Any keyword arguments passed to get_or_create() —except an optional one called defaults— will be used in a get() call. If an object is found, get_or_create() returns a tuple of that object and False.

Warning: This method is atomic assuming that the database enforces uniqueness of the keyword arguments (see unique or unique_together). If the fields used in the keyword arguments do not have a uniqueness constraint, concurrent calls to this method may result in multiple rows with the same parameters being inserted.

You can specify more complex conditions for the retrieved object by chaining get_or_create() with filter() and using Q objects. For example, to retrieve Robert or Bob Marley if either exists, and create the latter otherwise:
from django.db.models import Q

obj, created = Person.objects.filter(
    Q(first_name='Bob') | Q(first_name='Robert'),
).get_or_create(last_name='Marley', defaults={'first_name': 'Bob'})

If multiple objects are found, get_or_create() raises MultipleObjectsReturned. If an object is not found, get_or_create() will instantiate and save a new object, returning a tuple of the new object and True. The new object will be created roughly according to this algorithm:

```python
params = {k: v for k, v in kwargs.items() if '__' not in k}
params.update({k: v() if callable(v) else v for k, v in defaults.items()})
obj = self.model(**params)
obj.save()
```

In English, that means start with any non-‘defaults’ keyword argument that doesn’t contain a double underscore (which would indicate a non-exact lookup). Then add the contents of defaults, overriding any keys if necessary, and use the result as the keyword arguments to the model class. If there are any callables in defaults, evaluate them. As hinted at above, this is a simplification of the algorithm that is used, but it contains all the pertinent details. The internal implementation has some more error-checking than this and handles some extra edge-conditions; if you’re interested, read the code.

If you have a field named defaults and want to use it as an exact lookup in get_or_create(), use 'defaults__exact', like so:

```python
Foo.objects.get_or_create(defaults__exact='bar', defaults={'defaults': 'baz'})
```

The get_or_create() method has similar error behavior to create() when you’re using manually specified primary keys. If an object needs to be created and the key already exists in the database, an IntegrityError will be raised.

Finally, a word on using get_or_create() in Django views. Please make sure to use it only in POST requests unless you have a good reason not to. GET requests shouldn’t have any effect on data. Instead, use POST whenever a request to a page has a side effect on your data. For more, see Safe methods in the HTTP spec.

Warning: You can use get_or_create() through ManyToManyField attributes and reverse relations. In that case you will restrict the queries inside the context of that relation. That could lead you to some integrity problems if you don’t use it consistently.

Being the following models:

```python
class Chapter(models.Model):
    title = models.CharField(max_length=255, unique=True)

class Book(models.Model):
    title = models.CharField(max_length=256)
    chapters = models.ManyToManyField(Chapter)
```
You can use `get_or_create()` through Book’s chapters field, but it only fetches inside the context of that book:

```python
>>> book = Book.objects.create(title="Ulysses")
>>> book.chapters.get_or_create(title="Telemachus")
(<Chapter: Telemachus>, True)
>>> book.chapters.get_or_create(title="Telemachus")
(<Chapter: Telemachus>, False)
>>> Chapter.objects.create(title="Chapter 1")
<Chapter: Chapter 1>
>>> book.chapters.get_or_create(title="Chapter 1")
# Raises IntegrityError
```

This is happening because it’s trying to get or create “Chapter 1” through the book “Ulysses”, but it can’t do any of them: the relation can’t fetch that chapter because it isn’t related to that book, but it can’t create it either because `title` field should be unique.

`get_or_create()` method was added.

```
update_or_create()
```

```
update_or_create(defaults=None, **kwargs)
```

```
aupdate_or_create(defaults=None, **kwargs)
```

Asynchronous version: `aupdate_or_create()`

A convenience method for updating an object with the given `kwargs`, creating a new one if necessary. The `defaults` is a dictionary of (field, value) pairs used to update the object. The values in `defaults` can be callables.

Returns a tuple of `(object, created)`, where `object` is the created or updated object and `created` is a boolean specifying whether a new object was created.

The `update_or_create` method tries to fetch an object from database based on the given `kwargs`. If a match is found, it updates the fields passed in the `defaults` dictionary.

This is meant as a shortcut to boilerplatish code. For example:

```python
defaults = {"first_name": 'Bob'}
try:
    obj = Person.objects.get(first_name='John', last_name='Lennon')
    for key, value in defaults.items():
        setattr(obj, key, value)
    obj.save()
except Person.DoesNotExist:
```

(continues on next page)
new_values = {'first_name': 'John', 'last_name': 'Lennon'}
new_values.update(defaults)
obj = Person(**new_values)
obj.save()

This pattern gets quite unwieldy as the number of fields in a model goes up. The above example can be rewritten using update_or_create() like so:

```
obj, created = Person.objects.update_or_create(
    first_name='John', last_name='Lennon',
    defaults={'first_name': 'Bob'},
)
```

For a detailed description of how names passed in kwargs are resolved, see get_or_create().

As described above in get_or_create(), this method is prone to a race-condition which can result in multiple rows being inserted simultaneously if uniqueness is not enforced at the database level.

Like get_or_create() and create(), if you’re using manually specified primary keys and an object needs to be created but the key already exists in the database, an IntegrityError is raised.

The update_or_create() method was added.

bulk_create()

bulk_create(objs, batch_size=None, ignore_conflicts=False, update_conflicts=False, update_fields=None, unique_fields=None)

abulk_create(objs, batch_size=None, ignore_conflicts=False, update_conflicts=False, update_fields=None, unique_fields=None)

Asynchronous version: abulk_create()

This method inserts the provided list of objects into the database in an efficient manner (generally only 1 query, no matter how many objects there are), and returns created objects as a list, in the same order as provided:

```
>>> objs = Entry.objects.bulk_create([
    ...   Entry(headline='This is a test'),
    ...   Entry(headline='This is only a test'),
    ... ])
```

This has a number of caveats though:

- The model’s save() method will not be called, and the pre_save and post_save signals will not be sent.
• It does not work with child models in a multi-table inheritance scenario.

• If the model’s primary key is an `AutoField`, the primary key attribute can only be retrieved on certain databases (currently PostgreSQL, MariaDB 10.5+, and SQLite 3.35+). On other databases, it will not be set.

• It does not work with many-to-many relationships.

• It casts `objs` to a list, which fully evaluates `objs` if it’s a generator. The cast allows inspecting all objects so that any objects with a manually set primary key can be inserted first. If you want to insert objects in batches without evaluating the entire generator at once, you can use this technique as long as the objects don’t have any manually set primary keys:

```python
from itertools import islice

batch_size = 100
objs = (Entry(headline='Test %s' % i) for i in range(1000))
while True:
    batch = list(islice(objs, batch_size))
    if not batch:
        break
    Entry.objects.bulk_create(batch, batch_size)
```

The `batch_size` parameter controls how many objects are created in a single query. The default is to create all objects in one batch, except for SQLite where the default is such that at most 999 variables per query are used.

On databases that support it (all but Oracle), setting the `ignore_conflicts` parameter to `True` tells the database to ignore failure to insert any rows that fail constraints such as duplicate unique values.

On databases that support it (all except Oracle and SQLite < 3.24), setting the `update_conflicts` parameter to `True`, tells the database to update `update_fields` when a row insertion fails on conflicts. On PostgreSQL and SQLite, in addition to `update_fields`, a list of `unique_fields` that may be in conflict must be provided.

Enabling the `ignore_conflicts` or `update_conflicts` parameter disable setting the primary key on each model instance (if the database normally support it).

```
Warning: On MySQL and MariaDB, setting the ignore_conflicts parameter to True turns certain types of errors, other than duplicate key, into warnings. Even with Strict Mode. For example: invalid values or non-nullable violations. See the MySQL documentation and MariaDB documentation for more details.
```

The `update_conflicts`, `update_fields`, and `unique_fields` parameters were added to support updating fields when a row insertion fails on conflict.

`bulk_create()` method was added.
Django Documentation, Release 4.2.dev20220706084552

bulk_update()

bulk_update(objs, fields, batch_size=None)

abulk_update(objs, fields, batch_size=None)

Asynchronous version: abulk_update()

This method efficiently updates the given fields on the provided model instances, generally with one query, and returns the number of objects updated:

```python
>>> objs = [
    ... Entry.objects.create(headline='Entry 1'),
    ... Entry.objects.create(headline='Entry 2'),
    ...]
>>> objs[0].headline = 'This is entry 1'
>>> objs[1].headline = 'This is entry 2'
>>> Entry.objects.bulk_update(objs, ['headline'])
2
```

QuerySet.update() is used to save the changes, so this is more efficient than iterating through the list of models and calling save() on each of them, but it has a few caveats:

- You cannot update the model’s primary key.

- Each model’s save() method isn’t called, and the pre_save and post_save signals aren’t sent.

- If updating a large number of columns in a large number of rows, the SQL generated can be very large. Avoid this by specifying a suitable batch_size.

- Updating fields defined on multi-table inheritance ancestors will incur an extra query per ancestor.

- When an individual batch contains duplicates, only the first instance in that batch will result in an update.

- The number of objects updated returned by the function may be fewer than the number of objects passed in. This can be due to duplicate objects passed in which are updated in the same batch or race conditions such that objects are no longer present in the database.

The batch_size parameter controls how many objects are saved in a single query. The default is to update all objects in one batch, except for SQLite and Oracle which have restrictions on the number of variables used in a query.

abulk_update() method was added.
count()

count()

count()

Asynchronous version: acount()

Returns an integer representing the number of objects in the database matching the QuerySet.

Example:

```python
# Returns the total number of entries in the database.
Entry.objects.count()

# Returns the number of entries whose headline contains 'Lennon'
Entry.objects.filter(headline__contains='Lennon').count()
```

A count() call performs a SELECT COUNT(*) behind the scenes, so you should always use count() rather than loading all of the record into Python objects and calling len() on the result (unless you need to load the objects into memory anyway, in which case len() will be faster).

Note that if you want the number of items in a QuerySet and are also retrieving model instances from it (for example, by iterating over it), it’s probably more efficient to use len(queryset) which won’t cause an extra database query like count() would.

If the queryset has already been fully retrieved, count() will use that length rather than perform an extra database query.

acount() method was added.

in_bulk()

in_bulk(id_list=None, *, field_name='pk')

ain_bulk(id_list=None, *, field_name='pk')

Asynchronous version: ain_bulk()

Takes a list of field values (id_list) and the field_name for those values, and returns a dictionary mapping each value to an instance of the object with the given field value. No django.core.exceptions.ObjectDoesNotExist exceptions will ever be raised by in_bulk; that is, any id_list value not matching any instance will simply be ignored. If id_list isn’t provided, all objects in the queryset are returned. field_name must be a unique field or a distinct field (if there’s only one field specified in distinct()).

field_name defaults to the primary key.

Example:
If you pass `in_bulk()` an empty list, you’ll get an empty dictionary.

`in_bulk()` method was added.

**iterator()**

`iterator(chunk_size=None)`

**aiterator()**

Asynchronous version: `aiterator()`

Evaluates the QuerySet (by performing the query) and returns an iterator (see PEP 234) over the results, or an asynchronous iterator (see PEP 492) if you call its asynchronous version `aiterator()`.

A QuerySet typically caches its results internally so that repeated evaluations do not result in additional queries. In contrast, `iterator()` will read results directly, without doing any caching at the QuerySet level (internally, the default iterator calls `iterator()` and caches the return value). For a QuerySet which returns a large number of objects that you only need to access once, this can result in better performance and a significant reduction in memory.

Note that using `iterator()` on a QuerySet which has already been evaluated will force it to evaluate again, repeating the query.

`iterator()` is compatible with previous calls to `prefetch_related()` as long as `chunk_size` is given. Larger values will necessitate fewer queries to accomplish the prefetching at the cost of greater memory usage.

---

**Notes:**

- `aiterator()` is not compatible with previous calls to `prefetch_related()`.

On some databases (e.g. Oracle, SQLite), the maximum number of terms in an SQL IN clause might be limited. Hence values below this limit should be used. (In particular, when prefetching across two or more relations, a
chunk_size should be small enough that the anticipated number of results for each prefetched relation still falls below the limit.)

So long as the QuerySet does not prefetch any related objects, providing no value for chunk_size will result in Django using an implicit default of 2000.

Depending on the database backend, query results will either be loaded all at once or streamed from the database using server-side cursors.

Support for prefetching related objects was added to iterator().

aiterator() method was added.

Deprecated since version 4.1: Using iterator() on a queryset that prefetches related objects without providing the chunk_size is deprecated. In Django 5.0, an exception will be raise.

**With server-side cursors**

Oracle and PostgreSQL use server-side cursors to stream results from the database without loading the entire result set into memory.

The Oracle database driver always uses server-side cursors.

With server-side cursors, the chunk_size parameter specifies the number of results to cache at the database driver level. Fetching bigger chunks diminishes the number of round trips between the database driver and the database, at the expense of memory.

On PostgreSQL, server-side cursors will only be used when the DISABLE_SERVER_SIDE_CURSORS setting is False. Read Transaction pooling and server-side cursors if you’re using a connection pooler configured in transaction pooling mode. When server-side cursors are disabled, the behavior is the same as databases that don’t support server-side cursors.

**Without server-side cursors**

MySQL doesn’t support streaming results, hence the Python database driver loads the entire result set into memory. The result set is then transformed into Python row objects by the database adapter using the fetchmany() method defined in PEP 249.

SQLite can fetch results in batches using fetchmany(), but since SQLite doesn’t provide isolation between queries within a connection, be careful when writing to the table being iterated over. See Isolation when using QuerySet.iterator() for more information.

The chunk_size parameter controls the size of batches Django retrieves from the database driver. Larger batches decrease the overhead of communicating with the database driver at the expense of a slight increase in memory consumption.

So long as the QuerySet does not prefetch any related objects, providing no value for chunk_size will result in Django using an implicit default of 2000, a value derived from a calculation on the psycopg mailing list:
Assuming rows of 10-20 columns with a mix of textual and numeric data, 2000 is going to fetch less than 100KB of data, which seems a good compromise between the number of rows transferred and the data discarded if the loop is exited early.

```python
latest()
```

```python
latest(*fields)
```

```python
alatest(*fields)
```

Asynchronous version: `alatest()`

Returns the latest object in the table based on the given field(s).

This example returns the latest `Entry` in the table, according to the `pub_date` field:

```python
Entry.objects.latest('pub_date')
```

You can also choose the latest based on several fields. For example, to select the `Entry` with the earliest `expire_date` when two entries have the same `pub_date`:

```python
Entry.objects.latest('pub_date', '-expire_date')
```

The negative sign in `-expire_date` means to sort `expire_date` in descending order. Since `latest()` gets the last result, the `Entry` with the earliest `expire_date` is selected.

If your model’s `Meta` specifies `get_latest_by`, you can omit any arguments to `earliest()` or `latest()`. The fields specified in `get_latest_by` will be used by default.

Like `get()`, `earliest()` and `latest()` raise `DoesNotExist` if there is no object with the given parameters.

Note that `earliest()` and `latest()` exist purely for convenience and readability.

---

`earliest()` and `latest()` may return instances with null dates.

Since ordering is delegated to the database, results on fields that allow null values may be ordered differently if you use different databases. For example, PostgreSQL and MySQL sort null values as if they are higher than non-null values, while SQLite does the opposite.

You may want to filter out null values:

```python
Entry.objects.filter(pub_date__isnull=False).latest('pub_date')
```

`alatest()` method was added.
earliest()

earliest(*fields)

asynchronous version: earliest()

Works otherwise like latest() except the direction is changed.

asynchronous version: earliest() method was added.

first()

asynchronous version: afirst()

Returns the first object matched by the queryset, or None if there is no matching object. If the QuerySet has no ordering defined, then the queryset is automatically ordered by the primary key. This can affect aggregation results as described in Interaction with order_by().

Example:

```
p = Article.objects.order_by('title', 'pub_date').first()
```

Note that first() is a convenience method, the following code sample is equivalent to the above example:

```
try:
    p = Article.objects.order_by('title', 'pub_date')[0]
except IndexError:
    p = None
```

asynchronous version: afirst() method was added.

last()

last()

asynchronous version: alast()

Works like first(), but returns the last object in the queryset.

asynchronous version: alast() method was added.
aggregate()

aggregate(*args, **kwargs)
aaggregate(*args, **kwargs)

Asynchronous version: aaggregate()

Returns a dictionary of aggregate values (averages, sums, etc.) calculated over the QuerySet. Each argument to aggregate() specifies a value that will be included in the dictionary that is returned.

The aggregation functions that are provided by Django are described in Aggregation Functions below. Since aggregates are also query expressions, you may combine aggregates with other aggregates or values to create complex aggregates.

Aggregates specified using keyword arguments will use the keyword as the name for the annotation. Anonymous arguments will have a name generated for them based upon the name of the aggregate function and the model field that is being aggregated. Complex aggregates cannot use anonymous arguments and must specify a keyword argument as an alias.

For example, when you are working with blog entries, you may want to know the number of authors that have contributed blog entries:

```python
>>> from django.db.models import Count
>>> q = Blog.objects.aggregate(Count('entry'))
{'entry__count': 16}
```

By using a keyword argument to specify the aggregate function, you can control the name of the aggregation value that is returned:

```python
>>> q = Blog.objects.aggregate(number_of_entries=Count('entry'))
{'number_of_entries': 16}
```

For an in-depth discussion of aggregation, see the topic guide on Aggregation.

aaggregate() method was added.

exists()

exists()
aexists()

Asynchronous version: aexists()

Returns True if the QuerySet contains any results, and False if not. This tries to perform the query in the simplest and fastest way possible, but it does execute nearly the same query as a normal QuerySet query.
exists() is useful for searches relating to the existence of any objects in a QuerySet, particularly in the context of a large QuerySet.

To find whether a queryset contains any items:

```python
if some_queryset.exists():
    print("There is at least one object in some_queryset")
```

Which will be faster than:

```python
if some_queryset:
    print("There is at least one object in some_queryset")
```

... but not by a large degree (hence needing a large queryset for efficiency gains).

Additionally, if a some_queryset has not yet been evaluated, but you know that it will be at some point, then using some_queryset.exists() will do more overall work (one query for the existence check plus an extra one to later retrieve the results) than using bool(some_queryset), which retrieves the results and then checks if any were returned.

aexists() method was added.

contains()

contains(obj)

acontains(obj)

Asynchronous version: acontains()

Returns True if the QuerySet contains obj, and False if not. This tries to perform the query in the simplest and fastest way possible.

contains() is useful for checking an object membership in a QuerySet, particularly in the context of a large QuerySet.

To check whether a queryset contains a specific item:

```python
if some_queryset.contains(obj):
    print('Entry contained in queryset')
```

This will be faster than the following which requires evaluating and iterating through the entire queryset:

```python
if obj in some_queryset:
    print('Entry contained in queryset')
```
Like `exists()`, if `some_queryset` has not yet been evaluated, but you know that it will be at some point, then using `some_queryset.contains(obj)` will make an additional database query, generally resulting in slower overall performance.

A `contains()` method was added.

**update()**

**update(**kwargs**)

**aupdate(**kwargs**)

Asynchronous version: `aupdate()`

Performs an SQL update query for the specified fields, and returns the number of rows matched (which may not be equal to the number of rows updated if some rows already have the new value).

For example, to turn comments off for all blog entries published in 2010, you could do this:

```python
>>> Entry.objects.filter(pub_date__year=2010).update(comments_on=False)
```

(This assumes your `Entry` model has fields `pub_date` and `comments_on`.)

You can update multiple fields — there’s no limit on how many. For example, here we update the `comments_on` and `headline` fields:

```python
>>> Entry.objects.filter(pub_date__year=2010).update(comments_on=False, headline='This is old')
```

The `update()` method is applied instantly, and the only restriction on the `QuerySet` that is updated is that it can only update columns in the model’s main table, not on related models. You can’t do this, for example:

```python
>>> Entry.objects.update(blog_name='foo')  # Won’t work!
```

Filtering based on related fields is still possible, though:

```python
>>> Entry.objects.filter(blog__id=1).update(comments_on=True)
```

You cannot call `update()` on a `QuerySet` that has had a slice taken or can otherwise no longer be filtered.

The `update()` method returns the number of affected rows:

```python
>>> Entry.objects.filter(id=64).update(comments_on=True)
1

>>> Entry.objects.filter(slug='nonexistent-slug').update(comments_on=True)
0
```

(continues on next page)
If you’re just updating a record and don’t need to do anything with the model object, the most efficient approach is to call `update()`, rather than loading the model object into memory. For example, instead of doing this:

```python
e = Entry.objects.get(id=10)
e.comments_on = False
e.save()
```

...do this:

```python
Entry.objects.filter(id=10).update(comments_on=False)
```

Using `update()` also prevents a race condition wherein something might change in your database in the short period of time between loading the object and calling `save()`.

Finally, realize that `update()` does an update at the SQL level and, thus, does not call any `save()` methods on your models, nor does it emit the `pre_save` or `post_save` signals (which are a consequence of calling `Model.save()`). If you want to update a bunch of records for a model that has a custom `save()` method, loop over them and call `save()`, like this:

```python
for e in Entry.objects.filter(pub_date__year=2010):
    e.comments_on = False
    e.save()
```

`update()` method was added.

**Ordered queryset**

Chaining `order_by()` with `update()` is supported only on MariaDB and MySQL, and is ignored for different databases. This is useful for updating a unique field in the order that is specified without conflicts. For example:

```python
Entry.objects.order_by('-number').update(number=F('number') + 1)
```

Note: `order_by()` clause will be ignored if it contains annotations, inherited fields, or lookups spanning relations.
delete()

Asynchronous version: adelete()

Performs an SQL delete query on all rows in the QuerySet and returns the number of objects deleted and a dictionary with the number of deletions per object type.

The delete() is applied instantly. You cannot call delete() on a QuerySet that has had a slice taken or can otherwise no longer be filtered.

For example, to delete all the entries in a particular blog:

```python
>>> b = Blog.objects.get(pk=1)

# Delete all the entries belonging to this Blog.
>>> Entry.objects.filter(blog=b).delete()
(4, {'blog.Entry': 2, 'blog.Entry_authors': 2})
```

By default, Django’s ForeignKey emulates the SQL constraint ON DELETE CASCADE—in other words, any objects with foreign keys pointing at the objects to be deleted will be deleted along with them. For example:

```python
>>> blogs = Blog.objects.all()

# This will delete all Blogs and all of their Entry objects.
>>> blogs.delete()
(5, {'blog.Blog': 1, 'blog.Entry': 2, 'blog.Entry_authors': 2})
```

This cascade behavior is customizable via the on_delete argument to the ForeignKey.

The delete() method does a bulk delete and does not call any delete() methods on your models. It does, however, emit the pre_delete and post_delete signals for all deleted objects (including cascaded deletions). Django needs to fetch objects into memory to send signals and handle cascades. However, if there are no cascades and no signals, then Django may take a fast-path and delete objects without fetching into memory. For large deletes this can result in significantly reduced memory usage. The amount of executed queries can be reduced, too.

ForeignKeys which are set to on_delete DO NOTHING do not prevent taking the fast-path in deletion.

Note that the queries generated in object deletion is an implementation detail subject to change.

adelete() method was added.
as_manager()

classmethod as_manager()

Class method that returns an instance of Manager with a copy of the QuerySet’s methods. See Creating a manager with QuerySet methods for more details.

Note that unlike the other entries in this section, this does not have an asynchronous variant as it does not execute a query.

explain()

explain(format=None, **options)

eexplain(format=None, **options)

Asynchronous version: aexplain()

Returns a string of the QuerySet’s execution plan, which details how the database would execute the query, including any indexes or joins that would be used. Knowing these details may help you improve the performance of slow queries.

For example, when using PostgreSQL:

```python
>>> print(Blog.objects.filter(title='My Blog').explain())
Seq Scan on blog (cost=0.00..35.50 rows=10 width=12)
  Filter: (title = 'My Blog'::bpchar)
```

The output differs significantly between databases.

explain() is supported by all built-in database backends except Oracle because an implementation there isn’t straightforward.

The format parameter changes the output format from the databases’ s default, which is usually text-based. PostgreSQL supports 'TEXT', 'JSON', 'YAML', and 'XML' formats. MariaDB and MySQL support 'TEXT' (also called 'TRADITIONAL') and 'JSON' formats. MySQL 8.0.16+ also supports an improved 'TREE' format, which is similar to PostgreSQL’s 'TEXT' output and is used by default, if supported.

Some databases accept flags that can return more information about the query. Pass these flags as keyword arguments. For example, when using PostgreSQL:

```python
>>> print(Blog.objects.filter(title='My Blog').explain(verbose=True, analyze=True))
Seq Scan on public.blog (cost=0.00..35.50 rows=10 width=12) (actual time=0.004..0.004 rows=10, loops=1)
  Output: id, title
  Filter: (blog.title = 'My Blog'::bpchar)
```

(continues on next page)
On some databases, flags may cause the query to be executed which could have adverse effects on your database. For example, the `ANALYZE` flag supported by MariaDB, MySQL 8.0.18+, and PostgreSQL could result in changes to data if there are triggers or if a function is called, even for a `SELECT` query.

The `aexplain()` method was added.

**Field lookups**

Field lookups are how you specify the meat of an SQL `WHERE` clause. They’re specified as keyword arguments to the `QuerySet` methods `filter()`, `exclude()` and `get()`.

For an introduction, see models and database queries documentation.

Django’s built-in lookups are listed below. It is also possible to write custom lookups for model fields.

As a convenience when no lookup type is provided (like in `Entry.objects.get(id=14)`) the lookup type is assumed to be *exact*.

**exact**

Exact match. If the value provided for comparison is `None`, it will be interpreted as an SQL `NULL` (see `isnull` for more details).

Examples:

```
Entry.objects.get(id__exact=14)
Entry.objects.get(id__exact=None)
```

SQL equivalents:

```
SELECT ... WHERE id = 14;
SELECT ... WHERE id IS NULL;
```

**MySQL comparisons**

In MySQL, a database table’s “collation” setting determines whether `exact` comparisons are case-sensitive. This is a database setting, not a Django setting. It’s possible to configure your MySQL tables to use case-sensitive comparisons, but some trade-offs are involved. For more information about this, see the `collation section` in the `databases` documentation.
**iexact**

Case-insensitive exact match. If the value provided for comparison is `None`, it will be interpreted as an SQL NULL (see `isnull` for more details).

Example:

```python
Blog.objects.get(name__iexact='beatles blog')
Blog.objects.get(name__iexact=None)
```

SQL equivalents:

```sql
SELECT ... WHERE name ILIKE 'beatles blog';
SELECT ... WHERE name IS NULL;
```

Note the first query will match 'Beatles Blog', 'beatles blog', 'BeAtLes BlOg', etc.

**contains**

Case-sensitive containment test.

Example:

```python
Entry.objects.get(headline__contains='Lennon')
```

SQL equivalent:

```sql
SELECT ... WHERE headline LIKE '%Lennon%';
```

Note this will match the headline 'Lennon honored today' but not 'lennon honored today'.

**SQLite users**

SQLite doesn’t support case-sensitive LIKE statements; `contains` acts like `icontains` for SQLite. See the database note for more information.
icontains

Case-insensitive containment test.

Example:

```python
Entry.objects.get(headline__icontains='Lennon')
```

SQL equivalent:

```sql
SELECT ... WHERE headline ILIKE '%Lennon%';
```

SQLite users

When using the SQLite backend and non-ASCII strings, bear in mind the database note about string comparisons.

in

In a given iterable; often a list, tuple, or queryset. It’s not a common use case, but strings (being iterables) are accepted.

Examples:

```python
Entry.objects.filter(id__in=[1, 3, 4])
Entry.objects.filter(headline__in='abc')
```

SQL equivalents:

```sql
SELECT ... WHERE id IN (1, 3, 4);
SELECT ... WHERE headline IN ('a', 'b', 'c');
```

You can also use a queryset to dynamically evaluate the list of values instead of providing a list of literal values:

```python
inner_qs = Blog.objects.filter(name__contains='Cheddar')
entries = Entry.objects.filter(blog__in=inner_qs)
```

This queryset will be evaluated as subselect statement:

```sql
SELECT ... WHERE blog.id IN (SELECT id FROM ... WHERE NAME LIKE '%Cheddar%')
```

If you pass in a QuerySet resulting from `values()` or `values_list()` as the value to an `__in` lookup, you need to ensure you are only extracting one field in the result. For example, this will work (filtering on the
blog names):

```python
inner_qs = Blog.objects.filter(name__contains='Ch').values('name')
entries = Entry.objects.filter(blog__name__in=inner_qs)
```

This example will raise an exception, since the inner query is trying to extract two field values, where only one is expected:

```python
# Bad code! Will raise a TypeError.
inner_qs = Blog.objects.filter(name__contains='Ch').values('name', 'id')
entries = Entry.objects.filter(blog__name__in=inner_qs)
```

Performance considerations

Be cautious about using nested queries and understand your database server’s performance characteristics (if in doubt, benchmark!). Some database backends, most notably MySQL, don’t optimize nested queries very well. It is more efficient, in those cases, to extract a list of values and then pass that into the second query. That is, execute two queries instead of one:

```python
values = Blog.objects.filter(name__contains='Cheddar').values_list('pk', flat=True)
entries = Entry.objects.filter(blog__in=list(values))
```

Note the `list()` call around the Blog QuerySet to force execution of the first query. Without it, a nested query would be executed, because *QuerySets are lazy.*

### gt

Greater than.

Example:

```python
Entry.objects.filter(id__gt=4)
```

SQL equivalent:

```
SELECT ... WHERE id > 4;
```
gte

Greater than or equal to.

lt

Less than.

lte

Less than or equal to.

startswith

Case-sensitive starts-with.

Example:

```
Entry.objects.filter(headline__startswith='Lennon')
```

SQL equivalent:

```
SELECT ... WHERE headline LIKE 'Lennon%';
```

SQLite doesn’t support case-sensitive LIKE statements; `startswith` acts like `istartswith` for SQLite.

istartswith

Case-insensitive starts-with.

Example:

```
Entry.objects.filter(headline__istartswith='Lennon')
```

SQL equivalent:

```
SELECT ... WHERE headline ILIKE 'Lennon%';
```

SQLite users

When using the SQLite backend and non-ASCII strings, bear in mind the database note about string comparisons.
**endswith**

Case-sensitive ends-with.

Example:

```python
Entry.objects.filter(headline__endswith='Lennon')
```

SQL equivalent:

```sql
SELECT ... WHERE headline LIKE '%Lennon';
```

SQLite users

SQLite doesn’t support case-sensitive LIKE statements; `endswith` acts like `iendswith` for SQLite. Refer to the database note documentation for more.

**iendswith**

Case-insensitive ends-with.

Example:

```python
Entry.objects.filter(headline__iendswith='Lennon')
```

SQL equivalent:

```sql
SELECT ... WHERE headline ILIKE '%Lennon'
```

SQLite users

When using the SQLite backend and non-ASCII strings, bear in mind the database note about string comparisons.
range

Range test (inclusive).

Example:

```python
import datetime
start_date = datetime.date(2005, 1, 1)
end_date = datetime.date(2005, 3, 31)
Entry.objects.filter(pub_date__range=(start_date, end_date))
```

SQL equivalent:

```sql
SELECT ... WHERE pub_date BETWEEN '2005-01-01' and '2005-03-31';
```

You can use `range` anywhere you can use `BETWEEN` in SQL—for dates, numbers and even characters.

Warning: Filtering a DateTimeField with dates won’t include items on the last day, because the bounds are interpreted as “0am on the given date”. If `pub_date` was a DateTimeField, the above expression would be turned into this SQL:

```sql
SELECT ... WHERE pub_date BETWEEN '2005-01-01 00:00:00' and '2005-03-31 00:00:00';
```

Generally speaking, you can’t mix dates and datetimes.

date

For datetime fields, casts the value as date. Allows chaining additional field lookups. Takes a date value.

Example:

```python
Entry.objects.filter(pub_date__date=datetime.date(2005, 1, 1))
Entry.objects.filter(pub_date__date__gt=datetime.date(2005, 1, 1))
```

(No equivalent SQL code fragment is included for this lookup because implementation of the relevant query varies among different database engines.)

When `USE_TZ` is `True`, fields are converted to the current time zone before filtering. This requires time zone definitions in the database.
**year**

For date and datetime fields, an exact year match. Allows chaining additional field lookups. Takes an integer year.

Example:

```python
Entry.objects.filter(pub_date__year=2005)
Entry.objects.filter(pub_date__year__gte=2005)
```

SQL equivalent:

```sql
SELECT ... WHERE pub_date BETWEEN '2005-01-01' AND '2005-12-31';
SELECT ... WHERE pub_date >= '2005-01-01';
```

(The exact SQL syntax varies for each database engine.)

When `USE_TZ` is `True`, datetime fields are converted to the current time zone before filtering. This requires time zone definitions in the database.

**iso_year**

For date and datetime fields, an exact ISO 8601 week-numbering year match. Allows chaining additional field lookups. Takes an integer year.

Example:

```python
Entry.objects.filter(pub_date__iso_year=2005)
Entry.objects.filter(pub_date__iso_year__gte=2005)
```

(The exact SQL syntax varies for each database engine.)

When `USE_TZ` is `True`, datetime fields are converted to the current time zone before filtering. This requires time zone definitions in the database.

**month**

For date and datetime fields, an exact month match. Allows chaining additional field lookups. Takes an integer 1 (January) through 12 (December).

Example:

```python
Entry.objects.filter(pub_date__month=12)
Entry.objects.filter(pub_date__month__gte=6)
```

SQL equivalent:
(The exact SQL syntax varies for each database engine.)

When `USE_TZ` is `True`, datetime fields are converted to the current time zone before filtering. This requires time zone definitions in the database.

**day**

For date and datetime fields, an exact day match. Allows chaining additional field lookups. Takes an integer day.

Example:

```python
Entry.objects.filter(pub_date__day=3)
Entry.objects.filter(pub_date__day__gte=3)
```

SQL equivalent:

```sql
SELECT ... WHERE EXTRACT('day' FROM pub_date) = '3';
SELECT ... WHERE EXTRACT('day' FROM pub_date) >= '3';
```

(No equivalent SQL code fragment is included for this lookup because implementation of the relevant query varies among different database engines.)

When `USE_TZ` is `True`, datetime fields are converted to the current time zone before filtering. This requires time zone definitions in the database.

**week**

For date and datetime fields, return the week number (1-52 or 53) according to ISO-8601, i.e., weeks start on a Monday and the first week contains the year’s first Thursday.

Example:

```python
Entry.objects.filter(pub_date__week=52)
Entry.objects.filter(pub_date__week__gte=32, pub_date__week__lte=38)
```

(No equivalent SQL code fragment is included for this lookup because implementation of the relevant query varies among different database engines.)

When `USE_TZ` is `True`, datetime fields are converted to the current time zone before filtering. This requires time zone definitions in the database.
**week_day**

For date and datetime fields, a ‘day of the week’ match. Allows chaining additional field lookups.

Takes an integer value representing the day of week from 1 (Sunday) to 7 (Saturday).

Example:

```python
Entry.objects.filter(pub_date__week_day=2)
Entry.objects.filter(pub_date__week_day__gte=2)
```

(No equivalent SQL code fragment is included for this lookup because implementation of the relevant query varies among different database engines.)

Note this will match any record with a `pub_date` that falls on a Monday (day 2 of the week), regardless of the month or year in which it occurs. Week days are indexed with day 1 being Sunday and day 7 being Saturday.

When `USE_TZ` is `True`, datetime fields are converted to the current time zone before filtering. This requires time zone definitions in the database.

**iso_week_day**

For date and datetime fields, an exact ISO 8601 day of the week match. Allows chaining additional field lookups.

Takes an integer value representing the day of the week from 1 (Monday) to 7 (Sunday).

Example:

```python
Entry.objects.filter(pub_date__iso_week_day=1)
Entry.objects.filter(pub_date__iso_week_day__gte=1)
```

(No equivalent SQL code fragment is included for this lookup because implementation of the relevant query varies among different database engines.)

Note this will match any record with a `pub_date` that falls on a Monday (day 1 of the week), regardless of the month or year in which it occurs. Week days are indexed with day 1 being Monday and day 7 being Sunday.

When `USE_TZ` is `True`, datetime fields are converted to the current time zone before filtering. This requires time zone definitions in the database.
**quarter**

For date and datetime fields, a ‘quarter of the year’ match. Allows chaining additional field lookups. Takes an integer value between 1 and 4 representing the quarter of the year.

Example to retrieve entries in the second quarter (April 1 to June 30):

```python
Entry.objects.filter(pub_date__quarter=2)
```

(No equivalent SQL code fragment is included for this lookup because implementation of the relevant query varies among different database engines.)

When `USE_TZ` is True, datetime fields are converted to the current time zone before filtering. This requires time zone definitions in the database.

**time**

For datetime fields, casts the value as time. Allows chaining additional field lookups. Takes a `datetime.time` value.

Example:

```python
Entry.objects.filter(pub_date__time=datetime.time(14, 30))
Entry.objects.filter(pub_date__time__range=(datetime.time(8), datetime.time(17)))
```

(No equivalent SQL code fragment is included for this lookup because implementation of the relevant query varies among different database engines.)

When `USE_TZ` is True, fields are converted to the current time zone before filtering. This requires time zone definitions in the database.

**hour**

For datetime and time fields, an exact hour match. Allows chaining additional field lookups. Takes an integer between 0 and 23.

Example:

```python
Event.objects.filter(timestamp__hour=23)
Event.objects.filter(time__hour=5)
Event.objects.filter(timestamp__hour__gte=12)
```

SQL equivalent:
SELECT ... WHERE EXTRACT('hour' FROM timestamp) = '23';
SELECT ... WHERE EXTRACT('hour' FROM time) = '5';
SELECT ... WHERE EXTRACT('hour' FROM timestamp) >= '12';

(The exact SQL syntax varies for each database engine.)

When `USE_TZ` is True, datetime fields are converted to the current time zone before filtering. This requires time zone definitions in the database.

**minute**

For datetime and time fields, an exact minute match. Allows chaining additional field lookups. Takes an integer between 0 and 59.

Example:

```python
Event.objects.filter(timestamp__minute=29)
Event.objects.filter(time__minute=46)
Event.objects.filter(timestamp__minute__gte=29)
```

SQL equivalent:

```sql
SELECT ... WHERE EXTRACT('minute' FROM timestamp) = '29';
SELECT ... WHERE EXTRACT('minute' FROM time) = '46';
SELECT ... WHERE EXTRACT('minute' FROM timestamp) >= '29';
```

(The exact SQL syntax varies for each database engine.)

When `USE_TZ` is True, datetime fields are converted to the current time zone before filtering. This requires time zone definitions in the database.

**second**

For datetime and time fields, an exact second match. Allows chaining additional field lookups. Takes an integer between 0 and 59.

Example:

```python
Event.objects.filter(timestamp__second=31)
Event.objects.filter(time__second=2)
Event.objects.filter(timestamp__second__gte=31)
```

SQL equivalent:
SELECT ... WHERE EXTRACT('second' FROM timestamp) = '31';
SELECT ... WHERE EXTRACT('second' FROM time) = '2';
SELECT ... WHERE EXTRACT('second' FROM timestamp) >= '31';

(The exact SQL syntax varies for each database engine.)

When `USE_TZ` is `True`, datetime fields are converted to the current time zone before filtering. This requires time zone definitions in the database.

**isnull**

Takes either `True` or `False`, which correspond to SQL queries of `IS NULL` and `IS NOT NULL`, respectively.

Example:

```python
Entry.objects.filter(pub_date__isnull=True)
```

SQL equivalent:

```sql
SELECT ... WHERE pub_date IS NULL;
```

**regex**

Case-sensitive regular expression match.

The regular expression syntax is that of the database backend in use. In the case of SQLite, which has no built-in regular expression support, this feature is provided by a (Python) user-defined `REGEXP` function, and the regular expression syntax is therefore that of Python’s `re` module.

Example:

```python
Entry.objects.get(title__regex=r'^(An?|The) +')
```

SQL equivalents:

```sql
SELECT ... WHERE title REGEXP BINARY `^(An?|The) +`; -- MySQL
SELECT ... WHERE REGEXP_LIKE(title, `^(An?|The) +`, 'c'); -- Oracle
SELECT ... WHERE title ~ '^(An?|The) +'; -- PostgreSQL
SELECT ... WHERE title REGEXP `^(An?|The) +`; -- SQLite
```

Using raw strings (e.g., `r'foo'` instead of `'foo'`) for passing in the regular expression syntax is recommended.
iregex

Case-insensitive regular expression match.

Example:

```python
Entry.objects.get(title__iregex=r'^(an?|the) +')
```

SQL equivalents:

```sql
SELECT ... WHERE title REGEXP '^(an?|the) +'; -- MySQL
SELECT ... WHERE REGEXP_LIKE(title, '^(an?|the) +', 'i'); -- Oracle
SELECT ... WHERE title ~~ '^(an?|the) +'; -- PostgreSQL
SELECT ... WHERE title REGEXP '(?i)^(an?|the) +'; -- SQLite
```

### Aggregation functions

Django provides the following aggregation functions in the `django.db.models` module. For details on how to use these aggregate functions, see the topic guide on aggregation. See the `Aggregate` documentation to learn how to create your aggregates.

Warning:SQLite can’t handle aggregation on date/time fields out of the box. This is because there are no native date/time fields in SQLite and Django currently emulates these features using a text field. Attempts to use aggregation on date/time fields in SQLite will raise `NotSupportedError`.

Note

Aggregation functions return `None` when used with an empty `QuerySet`. For example, the `Sum` aggregation function returns `None` instead of 0 if the `QuerySet` contains no entries. To return another value instead, pass a value to the `default` argument. An exception is `Count`, which does return 0 if the `QuerySet` is empty. `Count` does not support the `default` argument.

All aggregates have the following parameters in common:
expressions

Strings that reference fields on the model, transforms of the field, or query expressions.

output_field

An optional argument that represents the model field of the return value.

Note: When combining multiple field types, Django can only determine the output_field if all fields are of the same type. Otherwise, you must provide the output_field yourself.

filter

An optional Q object that’s used to filter the rows that are aggregated.

See Conditional aggregation and Filtering on annotations for example usage.

default

An optional argument that allows specifying a value to use as a default value when the queryset (or grouping) contains no entries.

**extra

Keyword arguments that can provide extra context for the SQL generated by the aggregate.

Avg

class Avg(expression, output_field=None, distinct=False, filter=None, default=None, **extra)

Returns the mean value of the given expression, which must be numeric unless you specify a different output_field.

- Default alias: <field>__avg
- Return type: float if input is int, otherwise same as input field, or output_field if supplied

distinct

Optional. If distinct=True, Avg returns the mean value of unique values. This is the SQL equivalent of AVG(DISTINCT <field>). The default value is False.
Count

class Count(expression, distinct=False, filter=None, **extra)

Returns the number of objects that are related through the provided expression.

- Default alias: `<field>__count`
- Return type: int

**distinct**

Optional. If `distinct=True`, the count will only include unique instances. This is the SQL equivalent of `COUNT(DISTINCT <field>)`. The default value is False.

Note: The default argument is not supported.

Max

class Max(expression, output_field=None, filter=None, default=None, **extra)

Returns the maximum value of the given expression.

- Default alias: `<field>__max`
- Return type: same as input field, or `output_field` if supplied

Min

class Min(expression, output_field=None, filter=None, default=None, **extra)

Returns the minimum value of the given expression.

- Default alias: `<field>__min`
- Return type: same as input field, or `output_field` if supplied

StdDev

class StdDev(expression, output_field=None, sample=False, filter=None, default=None, **extra)

Returns the standard deviation of the data in the provided expression.

- Default alias: `<field>__stddev`
- Return type: `float` if input is `int`, otherwise same as input field, or `output_field` if supplied
Optional. By default, StdDev returns the population standard deviation. However, if `sample=True`, the return value will be the sample standard deviation.

### Sum

```python
class Sum(expression, output_field=None, distinct=False, filter=None, default=None, **extra)
```

Computes the sum of all values of the given expression.

- Default alias: `<field>__sum`
- Return type: same as input field, or `output_field` if supplied

### Variance

```python
class Variance(expression, output_field=None, sample=False, filter=None, default=None, **extra)
```

Returns the variance of the data in the provided expression.

- Default alias: `<field>__variance`
- Return type: `float` if input is `int`, otherwise same as input field, or `output_field` if supplied

Optional. By default, Variance returns the population variance. However, if `sample=True`, the return value will be the sample variance.

### Query-related tools

This section provides reference material for query-related tools not documented elsewhere.

#### Q() objects

```python
class Q
```

A `Q()` object represents an SQL condition that can be used in database-related operations. It’s similar to how an `F()` object represents the value of a model field or annotation. They make it possible to define and reuse conditions, and combine them using operators such as `| (OR), & (AND), and ^ (XOR). See Complex lookups with Q objects.

Support for the `^ (XOR)` operator was added.
Prefetch() objects

class Prefetch(lookup, queryset=None, to_attr=None)

The Prefetch() object can be used to control the operation of prefetch_related(). The lookup argument describes the relations to follow and works the same as the string based lookups passed to prefetch_related(). For example:

```python
>>> from django.db.models import Prefetch
>>> Question.objects.prefetch_related(Prefetch('choice_set')).get().choice_set.all()
<QuerySet [<Choice: Not much>, <Choice: The sky>, <Choice: Just hacking again>]>  # This will only execute two queries regardless of the number of Question # and Choice objects.
>>> Question.objects.prefetch_related(Prefetch('choice_set'))
<QuerySet [<Question: What's up?>]>
```

The queryset argument supplies a base QuerySet for the given lookup. This is useful to further filter down the prefetch operation, or to call select_related() from the prefetched relation, hence reducing the number of queries even further:

```python
>>> voted_choices = Choice.objects.filter(votes__gt=0)
>>> voted_choices
<QuerySet [<Choice: The sky]>>
>>> prefetch = Prefetch('choice_set', queryset=voted_choices)
>>> Question.objects.prefetch_related(prefetch).get().choice_set.all()
<QuerySet [<Choice: The sky]>>
```

The to_attr argument sets the result of the prefetch operation to a custom attribute:

```python
>>> prefetch = Prefetch('choice_set', queryset=voted_choices, to_attr='voted_choices')
>>> Question.objects.prefetch_related(prefetch).get().voted_choices
[<Choice: The sky>]
>>> Question.objects.prefetch_related(prefetch).get().choice_set.all()
<QuerySet [<Choice: Not much>, <Choice: The sky>, <Choice: Just hacking again>]>
```

Note: When using to_attr the prefetched result is stored in a list. This can provide a significant speed improvement over traditional prefetch_related calls which store the cached result within a QuerySet instance.
**prefetch_related_objects()**

**prefetch_related_objects**(model_instances, *related_lookups)

Prefetches the given lookups on an iterable of model instances. This is useful in code that receives a list of model instances as opposed to a QuerySet; for example, when fetching models from a cache or instantiating them manually.

Pass an iterable of model instances (must all be of the same class) and the lookups or *Prefetch* objects you want to prefetch for. For example:

```python
>>> from django.db.models import prefetch_related_objects
>>> restaurants = fetch_top_restaurants_from_cache()  # A list of Restaurants
>>> prefetch_related_objects(restaurants, 'pizzas__toppings')
```

When using multiple databases with **prefetch_related_objects**, the prefetch query will use the database associated with the model instance. This can be overridden by using a custom queryset in a related lookup.

**FilteredRelation() objects**

**class FilteredRelation**(relation_name, *, condition=Q())

  **relation_name**
  
  The name of the field on which you’d like to filter the relation.

  **condition**
  
  A *Q* object to control the filtering.

*FilteredRelation* is used with **annotate()** to create an **ON** clause when a **JOIN** is performed. It doesn’t act on the default relationship but on the annotation name (pizzas_vegetarian in example below).

For example, to find restaurants that have vegetarian pizzas with 'mozzarella' in the name:

```python
>>> from django.db.models import FilteredRelation, Q
>>> Restaurant.objects.annotate(  
...    pizzas_vegetarian=FilteredRelation(  
...      'pizzas', condition=Q(pizzas__vegetarian=True),  
...    ),  
...  ).filter(pizzas_vegetarian__name__icontains='mozzarella')
```

If there are a large number of pizzas, this queryset performs better than:

```python
>>> Restaurant.objects.filter(  
...    pizzas__vegetarian=True,  
...    pizzas__name__icontains='mozzarella',  
...  )
```
because the filtering in the **WHERE** clause of the first queryset will only operate on vegetarian pizzas.

**FilteredRelation** doesn’t support:
- `QuerySet.only()` and `prefetch_related()`.
- A `GenericForeignKey` inherited from a parent model.

### 6.16.11 Lookup API reference

This document has the API references of lookups, the Django API for building the **WHERE** clause of a database query. To learn how to use lookups, see **Making queries**; to learn how to create new lookups, see **How to write custom lookups**.

The lookup API has two components: a `RegisterLookupMixin` class that registers lookups, and the Query Expression API, a set of methods that a class has to implement to be registrable as a lookup.

Django has two base classes that follow the query expression API and from where all Django builtin lookups are derived:
- **Lookup**: to lookup a field (e.g. the `exact` of `field_name__exact`)
- **Transform**: to transform a field

A lookup expression consists of three parts:
- Fields part (e.g. `Book.objects.filter(author__best_friends__first_name...`);
- Transforms part (may be omitted) (e.g. `%lower%first3chars%reversed`);
- A lookup (e.g. `%icontains`) that, if omitted, defaults to `%exact`.

### Registration API

Django uses `RegisterLookupMixin` to give a class the interface to register lookups on itself. The two prominent examples are `Field`, the base class of all model fields, and `Transform`, the base class of all Django transforms.

```python
class lookups.RegisterLookupMixin

A mixin that implements the lookup API on a class.

classmethod register_lookup(lookup, lookup_name=None)

Registers a new lookup in the class. For example `DateField.register_lookup(YearExact)` will register `YearExact` lookup on `DateField`. It overrides a lookup that already exists with the same name. `lookup_name` will be used for this lookup if provided, otherwise `lookup.lookup_name` will be used.
```
get_lookup(lookup_name)

Returns the Lookup named lookup_name registered in the class. The default implementation looks recursively on all parent classes and checks if any has a registered lookup named lookup_name, returning the first match.

get_lookups()

Returns a dictionary of each lookup name registered in the class mapped to the Lookup class.

get_transform(transform_name)

Returns a Transform named transform_name. The default implementation looks recursively on all parent classes to check if any has the registered transform named transform_name, returning the first match.

For a class to be a lookup, it must follow the Query Expression API. Lookup and Transform naturally follow this API.

**The Query Expression API**

The query expression API is a common set of methods that classes define to be usable in query expressions to translate themselves into SQL expressions. Direct field references, aggregates, and Transform are examples that follow this API. A class is said to follow the query expression API when it implements the following methods:

as_sql(compiler, connection)

Generates the SQL fragment for the expression. Returns a tuple (sql, params), where sql is the SQL string, and params is the list or tuple of query parameters. The compiler is an SQLCompiler object, which has a compile() method that can be used to compile other expressions. The connection is the connection used to execute the query.

Calling expression.as_sql() is usually incorrect - instead compiler.compile(expression) should be used. The compiler.compile() method will take care of calling vendor-specific methods of the expression.

Custom keyword arguments may be defined on this method if it’s likely that as_vendorname() methods or subclasses will need to supply data to override the generation of the SQL string. See Func.as_sql() for example usage.

as_vendorname(compiler, connection)

Works like as_sql() method. When an expression is compiled by compiler.compile(), Django will first try to call as_vendorname(), where vendorname is the vendor name of the backend used for executing the query. The vendorname is one of postgresql, oracle, sqlite, or mysql for Django’s built-in backends.

get_lookup(lookup_name)

Must return the lookup named lookup_name. For instance, by returning self.output_field.
get_lookup(lookup_name).
get_transform(transform_name)

Must return the lookup named transform_name. For instance, by returning self.output_field.

output_field

Defines the type of class returned by the get_lookup() method. It must be a Field instance.

Transform reference

class Transform

A Transform is a generic class to implement field transformations. A prominent example is __year that transforms a DateField into a IntegerField.

The notation to use a Transform in a lookup expression is <expression>__<transformation> (e.g. date__year).

This class follows the Query Expression API, which implies that you can use <expression>__<transform1>__<transform2>. It’s a specialized Func() expression that only accepts one argument. It can also be used on the right hand side of a filter or directly as an annotation.

bilateral

A boolean indicating whether this transformation should apply to both lhs and rhs. Bilateral transformations will be applied to rhs in the same order as they appear in the lookup expression. By default it is set to False. For example usage, see How to write custom lookups.

lhs

The left-hand side - what is being transformed. It must follow the Query Expression API.

lookup_name

The name of the lookup, used for identifying it on parsing query expressions. It cannot contain the string "__".

output_field

Defines the class this transformation outputs. It must be a Field instance. By default is the same as its lhs.output_field.
Lookup reference

class Lookup

A Lookup is a generic class to implement lookups. A lookup is a query expression with a left-hand side, \texttt{lhs}; a right-hand side, \texttt{rhs}; and a \texttt{lookup\_name} that is used to produce a boolean comparison between \texttt{lhs} and \texttt{rhs} such as \texttt{lhs in rhs} or \texttt{lhs > rhs}.

The primary notation to use a lookup in an expression is \texttt{<lhs> \textunderscore<lookup\_name>=<rhs>}. Lookups can also be used directly in \texttt{QuerySet} filters:

```
Book.objects.filter(LessThan(F('word\_count'), 7500))
```

...or annotations:

```
Book.objects.annotate(is\_short\_story=LessThan(F('word\_count'), 7500))
```

\texttt{lhs}

The left-hand side - what is being looked up. The object typically follows the \texttt{Query Expression API}. It may also be a plain value.

\texttt{rhs}

The right-hand side - what \texttt{lhs} is being compared against. It can be a plain value, or something that compiles into SQL, typically an \texttt{F()} object or a \texttt{QuerySet}.

\texttt{lookup\_name}

The name of this lookup, used to identify it on parsing query expressions. It cannot contain the string "\textunderscore".

\texttt{process\_lhs}\texttt{(compiler, connection, lhs=None)}

Returns a tuple \texttt{(lhs\_string, lhs\_params)}, as returned by \texttt{compiler.compile(lhs)}. This method can be overridden to tune how the \texttt{lhs} is processed.

\texttt{compiler} is an \texttt{SQLCompiler} object, to be used like \texttt{compiler.compile(lhs)} for compiling \texttt{lhs}. The connection can be used for compiling vendor specific SQL. If \texttt{lhs} is not \texttt{None}, use it as the processed \texttt{lhs} instead of \texttt{self.lhs}.

\texttt{process\_rhs}\texttt{(compiler, connection)}

Behaves the same way as \texttt{process\_lhs()}, for the right-hand side.
6.16.12 Query Expressions

Query expressions describe a value or a computation that can be used as part of an update, create, filter, order by, annotation, or aggregate. When an expression outputs a boolean value, it may be used directly in filters. There are a number of built-in expressions (documented below) that can be used to help you write queries. Expressions can be combined, or in some cases nested, to form more complex computations.

Supported arithmetic

Django supports negation, addition, subtraction, multiplication, division, modulo arithmetic, and the power operator on query expressions, using Python constants, variables, and even other expressions.

Some examples

```python
from django.db.models import Count, F, Value
from django.db.models.functions import Length, Upper
from django.db.models.lookups import GreaterThan

# Find companies that have more employees than chairs.
Company.objects.filter(num_employees__gt=F('num_chairs'))

# Find companies that have at least twice as many employees as chairs. Both the querysets below are equivalent.
Company.objects.filter(num_employees__gt=F('num_chairs') * 2)
Company.objects.filter(
    num_employees__gt=F('num_chairs') + F('num_chairs'))

# How many chairs are needed for each company to seat all employees?
>>> company = Company.objects.filter(
    ... num_employees__gt=F('num_chairs')).annotate(
    ... chairs_needed=F('num_employees') - F('num_chairs')).first()
>>> company.num_employees
120
>>> company.num_chairs
50
>>> company.chairs_needed
70

# Create a new company using expressions.
>>> company = Company.objects.create(name='Google', ticker=Upper(Value('goog')))
# Be sure to refresh it if you need to access the field.
>>> company.refresh_from_db()
>>> company.ticker
```

(continues on next page)
# Annotate models with an aggregated value. Both forms below are equivalent.

```python
Company.objects.annotate(num_products=Count('products'))
Company.objects.annotate(num_products=Count(F('products')))  
```

# Aggregates can contain complex computations also

```python
Company.objects.annotate(num_offerings=Count(F('products') + F('services')))  
```

# Expressions can also be used in order_by(), either directly

```python
Company.objects.order_by(Length('name').asc())
Company.objects.order_by(Length('name').desc())  
```

# or using the double underscore lookup syntax.

```python
from django.db.models import CharField
from django.db.models.functions import Length
CharField.register_lookup(Length)
Company.objects.order_by('name__length')  
```

# Boolean expression can be used directly in filters.

```python
from django.db.models import Exists
Company.objects.filter(
    Exists(Employee.objects.filter(company=OuterRef('pk'), salary__gt=10))  
)
```

# Lookup expressions can also be used directly in filters

```python
Company.objects.filter(GreaterThan(F('num_employees'), F('num_chairs')))  
```

# or annotations.

```python
Company.objects.annotate(
    need_chairs=GreaterThan(F('num_employees'), F('num_chairs')),)  
```

## Built-in Expressions

Note: These expressions are defined in `django.db.models.expressions` and `django.db.models.aggregates`, but for convenience they’re available and usually imported from `django.db.models`
F() expressions

class F

An F() object represents the value of a model field, transformed value of a model field, or annotated column. It makes it possible to refer to model field values and perform database operations using them without actually having to pull them out of the database into Python memory.

Instead, Django uses the F() object to generate an SQL expression that describes the required operation at the database level.

Let’s try this with an example. Normally, one might do something like this:

```python
# Tintin filed a news story!
reporter = Reporters.objects.get(name='Tintin')
reporter.stories_filed += 1
reporter.save()
```

Here, we have pulled the value of `reporter.stories_filed` from the database into memory and manipulated it using familiar Python operators, and then saved the object back to the database. But instead we could also have done:

```python
from django.db.models import F

reporter = Reporters.objects.get(name='Tintin')
reporter.stories_filed = F('stories_filed') + 1
reporter.save()
```

Although `reporter.stories_filed = F('stories_filed') + 1` looks like a normal Python assignment of value to an instance attribute, in fact it’s an SQL construct describing an operation on the database.

When Django encounters an instance of F(), it overrides the standard Python operators to create an encapsulated SQL expression; in this case, one which instructs the database to increment the database field represented by `reporter.stories_filed`.

Whatever value is or was on `reporter.stories_filed`, Python never gets to know about it - it is dealt with entirely by the database. All Python does, through Django’s F() class, is create the SQL syntax to refer to the field and describe the operation.

To access the new value saved this way, the object must be reloaded:

```python
reporter = Reporters.objects.get(pk=reporter.pk)
# Or, more succinctly:
reporter.refresh_from_db()
```

As well as being used in operations on single instances as above, F() can be used on QuerySets of object instances, with update(). This reduces the two queries we were using above - the get() and the save() - to
just one:

```python
reporter = Reporters.objects.filter(name='Tintin')
reporter.update(stories Filed=F('stories Filed') + 1)
```

We can also use `update()` to increment the field value on multiple objects - which could be very much faster than pulling them all into Python from the database, looping over them, incrementing the field value of each one, and saving each one back to the database:

```python
Reporter.objects.update(stories Filed=F('stories Filed') + 1)
```

F() therefore can offer performance advantages by:

- getting the database, rather than Python, to do work
- reducing the number of queries some operations require

**Avoiding race conditions using F()**

Another useful benefit of F() is that having the database - rather than Python - update a field’s value avoids a race condition.

If two Python threads execute the code in the first example above, one thread could retrieve, increment, and save a field’s value after the other has retrieved it from the database. The value that the second thread saves will be based on the original value; the work of the first thread will be lost.

If the database is responsible for updating the field, the process is more robust: it will only ever update the field based on the value of the field in the database when the `save()` or `update()` is executed, rather than based on its value when the instance was retrieved.

**F() assignments persist after Model.save()**

F() objects assigned to model fields persist after saving the model instance and will be applied on each `save()`. For example:

```python
reporter = Reporters.objects.get(name='Tintin')
reporter.stories Filed = F('stories Filed') + 1
reporter.save()

reporter.name = 'Tintin Jr.'
reporter.save()
```

`stories Filed` will be updated twice in this case. If it’s initially 1, the final value will be 3. This persistence can be avoided by reloading the model object after saving it, for example, by using `refresh_from_db()`.
Using **F()** in filters

**F()** is also very useful in **QuerySet** filters, where they make it possible to filter a set of objects against criteria based on their field values, rather than on Python values.

This is documented in using **F() expressions in queries**.

Using **F()** with annotations

**F()** can be used to create dynamic fields on your models by combining different fields with arithmetic:

```python
company = Company.objects.annotate(
    chairs_needed=F('num_employees') - F('num_chairs'))
```

If the fields that you’re combining are of different types you’ll need to tell Django what kind of field will be returned. Since **F()** does not directly support `output_field` you will need to wrap the expression with `ExpressionWrapper`:

```python
from django.db.models import DateTimeField, ExpressionWrapper, F

Ticket.objects.annotate(
    expires=ExpressionWrapper(
        F('active_at') + F('duration'), output_field=DateTimeField()))
```

When referencing relational fields such as **ForeignKey**, **F()** returns the primary key value rather than a model instance:

```python
>>> car = Company.objects.annotate(built_by=F('manufacturer'))[0]
>>> car.manufacturer
<Manufacturer: Toyota>
>>> car.built_by
3
```

Using **F()** to sort null values

Use **F()** and the `nulls_first` or `nulls_last` keyword argument to `Expression.asc()` or `desc()` to control the ordering of a field’s null values. By default, the ordering depends on your database.

For example, to sort companies that haven’t been contacted (**last_contacted** is null) after companies that have been contacted:

```python
from django.db.models import F
Company.objects.order_by(F('last_contacted').desc(nulls_last=True))
```
**Func() expressions**

*Func()* expressions are the base type of all expressions that involve database functions like `COALESCE` and `LOWER`, or aggregates like `SUM`. They can be used directly:

```python
from django.db.models import F, Func

queryset.annotate(field_lower=Func(F('field'), function='LOWER'))
```

or they can be used to build a library of database functions:

```python
class Lower(Func):
    function = 'LOWER'

queryset.annotate(field_lower=Lower('field'))
```

But both cases will result in a queryset where each model is annotated with an extra attribute `field_lower` produced, roughly, from the following SQL:

```sql
SELECT ...
    LOWER("db_table"."field") as "field_lower"
```

See [Database Functions](#) for a list of built-in database functions.

The *Func* API is as follows:

```python
class Func(*expressions, **extra)

    function
    A class attribute describing the function that will be generated. Specifically, the *function* will be interpolated as the *function* placeholder within *template*. Defaults to *None*.

    template
    A class attribute, as a format string, that describes the SQL that is generated for this function. Defaults to '%(function)s(%(expressions)s)'.

    If you’re constructing SQL like `strftime('%W', 'date')` and need a literal `%` character in the query, quadruple it `%%%%` in the *template* attribute because the string is interpolated twice: once during the template interpolation in *as_sql()* and once in the SQL interpolation with the query parameters in the database cursor.

    arg_joiner
    A class attribute that denotes the character used to join the list of *expressions* together. Defaults to ',', '.
```
arity

A class attribute that denotes the number of arguments the function accepts. If this attribute is
set and the function is called with a different number of expressions, TypeError will be raised.
Defaults to None.

```
    as_sql(compiler, connection, function=None, template=None, arg_joiner=None, **extra_context)
```

Generates the SQL fragment for the database function. Returns a tuple (sql, params), where
sql is the SQL string, and params is the list or tuple of query parameters.

The as_vendor() methods should use the function, template, arg_joiner, and any other
**extra_context parameters to customize the SQL as needed. For example:

```
Listing 13: django/db/models/functions.py
```

```python
class ConcatPair(Func):
    ...
    function = 'CONCAT'
    ...

    def as_mysql(self, compiler, connection, **extra_context):
        return super().as_sql(
            compiler, connection,
            function='CONCAT_WS',
            template='%(function)s(%%(expressions)s)',
            **extra_context
        )
```

To avoid an SQL injection vulnerability, extra_context must not contain untrusted user input as
these values are interpolated into the SQL string rather than passed as query parameters, where
the database driver would escape them.

The *expressions argument is a list of positional expressions that the function will be applied to. The
expressions will be converted to strings, joined together with arg_joiner, and then interpolated into the
template as the expressions placeholder.

Positional arguments can be expressions or Python values. Strings are assumed to be column references and
will be wrapped in F() expressions while other values will be wrapped in Value() expressions.

The **extra kwars are key=value pairs that can be interpolated into the template attribute. To avoid an
SQL injection vulnerability, extra must not contain untrusted user input as these values are interpolated
into the SQL string rather than passed as query parameters, where the database driver would escape them.

The function, template, and arg_joiner keywords can be used to replace the attributes of the same name
without having to define your own class. output_field can be used to define the expected return type.
Aggregate() expressions

An aggregate expression is a special case of a Func() expression that informs the query that a GROUP BY clause is required. All of the aggregate functions, like Sum() and Count(), inherit from Aggregate().

Since Aggregates are expressions and wrap expressions, you can represent some complex computations:

```
from django.db.models import Count

Company.objects.annotate(
    managers_required=(Count('num_employees') / 4) + Count('num_managers'))
```

The Aggregate API is as follows:

```python
class Aggregate(*expressions, output_field=None, distinct=False, filter=None, default=None, **extra)
    template
        A class attribute, as a format string, that describes the SQL that is generated for this aggregate. Defaults to '%(function)s%(distinct)s%(expressions)s'.
    function
        A class attribute describing the aggregate function that will be generated. Specifically, the function will be interpolated as the function placeholder within template. Defaults to None.
    window_compatible
        Defaults to True since most aggregate functions can be used as the source expression in Window.
    allow_distinct
        A class attribute determining whether or not this aggregate function allows passing a distinct keyword argument. If set to False (default), TypeError is raised if distinct=True is passed.
    empty_result_set_value
        Defaults to None since most aggregate functions result in NULL when applied to an empty result set.
```

The expressions positional arguments can include expressions, transforms of the model field, or the names of model fields. They will be converted to a string and used as the expressions placeholder within the template.

The output_field argument requires a model field instance, like IntegerField() or BooleanField(), into which Django will load the value after it’s retrieved from the database. Usually no arguments are needed when instantiating the model field as any arguments relating to data validation (max_length, max_digits, etc.) will not be enforced on the expression’s output value.

Note that output_field is only required when Django is unable to determine what field type the result should be. Complex expressions that mix field types should define the desired output_field. For example, adding an IntegerField() and a FloatField() together should probably have output_field=FloatField() defined.
The `distinct` argument determines whether or not the aggregate function should be invoked for each distinct value of `expressions` (or set of values, for multiple `expressions`). The argument is only supported on aggregates that have `allow_distinct` set to True.

The `filter` argument takes a `Q` object that’s used to filter the rows that are aggregated. See Conditional aggregation and Filtering on annotations for example usage.

The `default` argument takes a value that will be passed along with the aggregate to Coalesce. This is useful for specifying a value to be returned other than None when the queryset (or grouping) contains no entries.

The **extra** kwargs are key=value pairs that can be interpolated into the `template` attribute.

### Creating your own Aggregate Functions

You can create your own aggregate functions, too. At a minimum, you need to define `function`, but you can also completely customize the SQL that is generated. Here’s a brief example:

```python
from django.db.models import Aggregate

class Sum(Aggregate):
    # Supports SUM(ALL field).
    function = 'SUM'
    template = '%(function)s%(all_values)s%(expressions)s'
    allow_distinct = False

    def __init__(self, expression, all_values=False, **extra):
        super().__init__(expression,
                         all_values='ALL ' if all_values else '',
                         **extra)
```

#### Value() expressions

```python
class Value(value, output_field=None)
```

A `Value()` object represents the smallest possible component of an expression: a simple value. When you need to represent the value of an integer, boolean, or string within an expression, you can wrap that value within a `Value()`.

You will rarely need to use `Value()` directly. When you write the expression `F('field') + 1`, Django implicitly wraps the 1 in a `Value()`, allowing simple values to be used in more complex expressions. You will need to use `Value()` when you want to pass a string to an expression. Most expressions interpret a string argument as the name of a field, like `Lower('name')`. 
The `value` argument describes the value to be included in the expression, such as 1, `True`, or `None`. Django knows how to convert these Python values into their corresponding database type.

The `output_field` argument should be a model field instance, like `IntegerField()` or `BooleanField()`, into which Django will load the value after it’s retrieved from the database. Usually no arguments are needed when instantiating the model field as any arguments relating to data validation (e.g., `max_length`, `max_digits`, etc.) will not be enforced on the expression’s output value. If no `output_field` is specified it will be tentatively inferred from the type of the provided `value`, if possible. For example, passing an instance of `datetime.datetime` as `value` would default `output_field` to `DateTimeField`.

### ExpressionWrapper() expressions

```python
class ExpressionWrapper(expression, output_field)
```

`ExpressionWrapper` surrounds another expression and provides access to properties, such as `output_field`, that may not be available on other expressions. `ExpressionWrapper` is necessary when using arithmetic on `F()` expressions with different types as described in Using F() with annotations.

### Conditional expressions

Conditional expressions allow you to use `if ... elif ... else` logic in queries. Django natively supports SQL `CASE` expressions. For more details see Conditional Expressions.

### Subquery() expressions

```python
class Subquery(queryset, output_field=None)
```

You can add an explicit subquery to a `QuerySet` using the `Subquery` expression.

For example, to annotate each post with the email address of the author of the newest comment on that post:

```python
>>> from django.db.models import OuterRef, Subquery
>>> newest = Comment.objects.filter(post=OuterRef('pk')).order_by('-created_at')
>>> Post.objects.annotate(newest_commenter_email=Subquery(newest.values('email')[:1]))
```

On PostgreSQL, the SQL looks like:

```sql
SELECT "post"."id", (SELECT U0."email" FROM "comment" U0 WHERE U0."post_id" = ("post"."id") ORDER BY U0."created_at" DESC LIMIT 1) AS "newest_commenter_email" FROM "post"
```
Note: The examples in this section are designed to show how to force Django to execute a subquery. In some cases it may be possible to write an equivalent queryset that performs the same task more clearly or efficiently.

Referencing columns from the outer queryset

class OuterRef(field)

Use OuterRef when a queryset in a Subquery needs to refer to a field from the outer query or its transform. It acts like an $F$ expression except that the check to see if it refers to a valid field isn’t made until the outer queryset is resolved.

Instances of OuterRef may be used in conjunction with nested instances of Subquery to refer to a containing queryset that isn’t the immediate parent. For example, this queryset would need to be within a nested pair of Subquery instances to resolve correctly:

```python
>>> Book.objects.filter(author=OuterRef(OuterRef('pk')))
```

Limiting a subquery to a single column

There are times when a single column must be returned from a Subquery, for instance, to use a Subquery as the target of an `__in` lookup. To return all comments for posts published within the last day:

```python
>>> from datetime import timedelta
>>> from django.utils import timezone
>>> one_day_ago = timezone.now() - timedelta(days=1)
>>> posts = Post.objects.filter(published_at__gte=one_day_ago)
>>> Comment.objects.filter(post__in=Subquery(posts.values('pk')))
```

In this case, the subquery must use `values()` to return only a single column: the primary key of the post.

Limiting the subquery to a single row

To prevent a subquery from returning multiple rows, a slice `[1:1]` of the queryset is used:

```python
>>> subquery = Subquery(newest.values('email')[1:1])
>>> Post.objects.annotate(newest_commenter_email=subquery)
```

In this case, the subquery must only return a single column and a single row: the email address of the most recently created comment.
(Using `get()` instead of a slice would fail because the `OuterRef` cannot be resolved until the queryset is used within a Subquery.)

**Exists() subqueries**

```python
>>> from django.db.models import Exists, OuterRef
>>> from datetime import timedelta
>>> from django.utils import timezone
>>> one_day_ago = timezone.now() - timedelta(days=1)
>>> recent_comments = Comment.objects.filter(...
...    post=OuterRef('pk'),
...    created_at__gte=one_day_ago,
...)
>>> Post.objects.annotate(recent_comment=Exists(recent_comments))
```

On PostgreSQL, the SQL looks like:

```sql
SELECT "post"."id", "post"."published_at", EXISTS(
    SELECT (1) as "a"
    FROM "comment" U0
    WHERE (U0."created_at" >= YYYY-MM-DD HH:MM:SS AND
    U0."post_id" = "post"."id")
    LIMIT 1
) AS "recent_comment" FROM "post"
```

It’s unnecessary to force `Exists` to refer to a single column, since the columns are discarded and a boolean result is returned. Similarly, since ordering is unimportant within an SQL EXISTS subquery and would only degrade performance, it’s automatically removed.

You can query using NOT EXISTS with `~Exists()`.
Filtering on a Subquery() or Exists() expressions

Subquery() that returns a boolean value and Exists() may be used as a condition in *When* expressions, or to directly filter a queryset:

```python
>>> recent_comments = Comment.objects.filter(...). # From above
>>> Post.objects.filter(Exists(recent_comments))
```

This will ensure that the subquery will not be added to the SELECT columns, which may result in a better performance.

Using aggregates within a Subquery expression

Aggregates may be used within a Subquery, but they require a specific combination of `filter()`, `values()`, and `annotate()` to get the subquery grouping correct.

Assuming both models have a `length` field, to find posts where the post length is greater than the total length of all combined comments:

```python
>>> from django.db.models import OuterRef, Subquery, Sum
>>> comments = Comment.objects.filter(post=OuterRef('pk')).order_by().values('post')
>>> total_comments = comments.annotate(total=Sum('length')).values('total')
>>> Post.objects.filter(length__gt=Subquery(total_comments))
```

The initial `filter(...)` limits the subquery to the relevant parameters. `order_by()` removes the default `ordering` (if any) on the `Comment` model. `values('post')` aggregates comments by `Post`. Finally, `annotate(...)` performs the aggregation. The order in which these queryset methods are applied is important. In this case, since the subquery must be limited to a single column, `values('total')` is required.

This is the only way to perform an aggregation within a Subquery, as using `aggregate()` attempts to evaluate the queryset (and if there is an `OuterRef`, this will not be possible to resolve).

Raw SQL expressions

```python
class RawSQL(sql, params, output_field=None)
```

Sometimes database expressions can’t easily express a complex WHERE clause. In these edge cases, use the RawSQL expression. For example:

```python
>>> from django.db.models.expressions import RawSQL
>>> queryset.annotate(val=RawSQL("select col from sometable where othercol = %s", (param,)))
```

These extra lookups may not be portable to different database engines (because you’re explicitly writing SQL code) and violate the DRY principle, so you should avoid them if possible.
RawSQL expressions can also be used as the target of \texttt{__in} filters:

```python
>>> queryset.filter(id__in=RawSQL("select id from sometable where col = \%s\", (param,)))
```

Warning: To protect against SQL injection attacks, you must escape any parameters that the user can control by using \texttt{params}. \texttt{params} is a required argument to force you to acknowledge that you’re not interpolating your SQL with user-provided data.

You also must not quote placeholders in the SQL string. This example is vulnerable to SQL injection because of the quotes around \texttt{\%s}:

```python
RawSQL("select col from sometable where othercol = \'\%s\'\") # unsafe!
```

You can read more about how Django’s SQL injection protection works.

**Window functions**

Window functions provide a way to apply functions on partitions. Unlike a normal aggregation function which computes a final result for each set defined by the group by, window functions operate on frames and partitions, and compute the result for each row.

You can specify multiple windows in the same query which in Django ORM would be equivalent to including multiple expressions in a \texttt{QuerySet.annotate()} call. The ORM doesn’t make use of named windows, instead they are part of the selected columns.

```python
class Window(expression, partition_by=None, order_by=None, frame=None, output_field=None)
```

- **filterable**
  
  Defaults to \texttt{False}. The SQL standard disallows referencing window functions in the \texttt{WHERE} clause and Django raises an exception when constructing a \texttt{QuerySet} that would do that.

- **template**
  
  Defaults to \texttt{\%(expression)s OVER \%(window)s\'). If only the \texttt{expression} argument is provided, the window clause will be blank.

The \texttt{Window} class is the main expression for an \texttt{OVER} clause.

The \texttt{expression} argument is either a \texttt{window function}, an \texttt{aggregate function}, or an expression that’s compatible in a window clause.

The \texttt{partition_by} argument accepts an expression or a sequence of expressions (column names should be wrapped in an \texttt{F}-object) that control the partitioning of the rows. Partitioning narrows which rows are used to compute the result set.

The \texttt{output_field} is specified either as an argument or by the expression.
The `order_by` argument accepts an expression on which you can call `asc()` and `desc()`, a string of a field name (with an optional "-" prefix which indicates descending order), or a tuple or list of strings and/or expressions. The ordering controls the order in which the expression is applied. For example, if you sum over the rows in a partition, the first result is the value of the first row, the second is the sum of first and second row.

The `frame` parameter specifies which other rows that should be used in the computation. See Frames for details.

Support for `order_by` by field name references was added.

For example, to annotate each movie with the average rating for the movies by the same studio in the same genre and release year:

```python
>>> from django.db.models import Avg, F, Window
>>> Movie.objects.annotate(
    avg_rating=Window(
        expression=Avg('rating'),
        partition_by=[F('studio'), F('genre')],
        order_by='released__year',
    ),
)
```

This allows you to check if a movie is rated better or worse than its peers.

You may want to apply multiple expressions over the same window, i.e., the same partition and frame. For example, you could modify the previous example to also include the best and worst rating in each movie’s group (same studio, genre, and release year) by using three window functions in the same query. The partition and ordering from the previous example is extracted into a dictionary to reduce repetition:

```python
>>> from django.db.models import Avg, F, Max, Min, Window
>>> window = {
    'partition_by': [F('studio'), F('genre')],
    'order_by': 'released__year',
}
>>> Movie.objects.annotate(
    avg_rating=Window(
        expression=Avg('rating'), **window,
    ),
    best=Window(
        expression=Max('rating'), **window,
    ),
    worst=Window(
        expression=Min('rating'), **window,
    ),
)
```
Among Django’s built-in database backends, MySQL 8.0.2+, PostgreSQL, and Oracle support window expressions. Support for different window expression features varies among the different databases. For example, the options in `asc()` and `desc()` may not be supported. Consult the documentation for your database as needed.

**Frames**

For a window frame, you can choose either a range-based sequence of rows or an ordinary sequence of rows.

```python
class ValueRange(start=None, end=None):
    frame_type = 'RANGE'
    This attribute is set to 'RANGE'.

    PostgreSQL has limited support for ValueRange and only supports use of the standard start and end points, such as CURRENT ROW and UNBOUNDED FOLLOWING.

class RowRange(start=None, end=None):
    frame_type = 'ROWS'
    This attribute is set to 'ROWS'.
```

Both classes return SQL with the template:

```
%(frame_type)s BETWEEN %(start)s AND %(end)s
```

Frames narrow the rows that are used for computing the result. They shift from some start point to some specified end point. Frames can be used with and without partitions, but it’s often a good idea to specify an ordering of the window to ensure a deterministic result. In a frame, a peer in a frame is a row with an equivalent value, or all rows if an ordering clause isn’t present.

The default starting point for a frame is UNBOUNDED PRECEDING which is the first row of the partition. The end point is always explicitly included in the SQL generated by the ORM and is by default UNBOUNDED FOLLOWING. The default frame includes all rows from the partition to the last row in the set.

The accepted values for the `start` and `end` arguments are `None`, an integer, or zero. A negative integer for `start` results in `N preceding`, while `None` yields UNBOUNDED PRECEDING. For both `start` and `end`, zero will return CURRENT ROW. Positive integers are accepted for `end`.

There’s a difference in what CURRENT ROW includes. When specified in ROWS mode, the frame starts or ends with the current row. When specified in RANGE mode, the frame starts or ends at the first or last peer according to the ordering clause. Thus, RANGE CURRENT ROW evaluates the expression for rows which have the same value specified by the ordering. Because the template includes both the `start` and `end` points, this may be expressed with:
ValueRange(start=0, end=0)

If a movie’s “peers” are described as movies released by the same studio in the same genre in the same year, this RowRange example annotates each movie with the average rating of a movie’s two prior and two following peers:

```python
>>> from django.db.models import Avg, F, RowRange, Window
>>> Movie.objects.annotate(
    avg_rating=Window(expression=Avg('rating'),
                      partition_by=[F('studio'), F('genre')],
                      order_by='released__year',
                      frame=RowRange(start=-2, end=2),
            ),
)
```

If the database supports it, you can specify the start and end points based on values of an expression in the partition. If the `released` field of the `Movie` model stores the release month of each movie, this ValueRange example annotates each movie with the average rating of a movie’s peers released between twelve months before and twelve months after the each movie:

```python
>>> from django.db.models import Avg, F, ValueRange, Window
>>> Movie.objects.annotate(
    avg_rating=Window(expression=Avg('rating'),
                      partition_by=[F('studio'), F('genre')],
                      order_by='released__year',
                      frame=ValueRange(start=-12, end=12),
            ),
)
```

**Technical Information**

Below you’ll find technical implementation details that may be useful to library authors. The technical API and examples below will help with creating generic query expressions that can extend the built-in functionality that Django provides.
Expression API

Query expressions implement the query expression API, but also expose a number of extra methods and attributes listed below. All query expressions must inherit from `Expression()` or a relevant subclass.

When a query expression wraps another expression, it is responsible for calling the appropriate methods on the wrapped expression.

class Expression

    contains_aggregate
        Tells Django that this expression contains an aggregate and that a GROUP BY clause needs to be added to the query.

    contains_over_clause
        Tells Django that this expression contains a Window expression. It’s used, for example, to disallow window function expressions in queries that modify data.

    filterable
        Tells Django that this expression can be referenced in `QuerySet.filter()`. Defaults to True.

    window_compatible
        Tells Django that this expression can be used as the source expression in `Window`. Defaults to False.

    empty_result_set_value
        Tells Django which value should be returned when the expression is used to apply a function over an empty result set. Defaults to `NotImplemented` which forces the expression to be computed on the database.

    resolve_expression(query=None, allow_joins=True, reuse=None, summarize=False, for_save=False)
        Provides the chance to do any preprocessing or validation of the expression before it’s added to the query. `resolve_expression()` must also be called on any nested expressions. A `copy()` of `self` should be returned with any necessary transformations.

        `query` is the backend query implementation.

        `allow_joins` is a boolean that allows or denies the use of joins in the query.

        `reuse` is a set of reusable joins for multi-join scenarios.

        `summarize` is a boolean that, when True, signals that the query being computed is a terminal aggregate query.

        `for_save` is a boolean that, when True, signals that the query being executed is performing a create or update.
get_source_expressions()

Returns an ordered list of inner expressions. For example:

```python
>>> Sum(F('foo')).get_source_expressions()
[F('foo')]
```

set_source_expressions(expressions)

Takes a list of expressions and stores them such that get_source_expressions() can return them.

relabeled_clone(change_map)

Returns a clone (copy) of self, with any column aliases relabeled. Column aliases are renamed when subqueries are created. relabeled_clone() should also be called on any nested expressions and assigned to the clone.

change_map is a dictionary mapping old aliases to new aliases.

Example:

```python
def relabeled_clone(self, change_map):
    clone = copy.copy(self)
    clone.expression = self.expression.relabeled_clone(change_map)
    return clone
```

convert_value(value, expression, connection)

A hook allowing the expression to coerce value into a more appropriate type.

expression is the same as self.

get_group_by_cols(alias=None)

Responsible for returning the list of columns references by this expression. get_group_by_cols() should be called on any nested expressions. F() objects, in particular, hold a reference to a column. The alias parameter will be None unless the expression has been annotated and is used for grouping.

asc(nulls_first=None, nulls_last=None)

Returns the expression ready to be sorted in ascending order.

nulls_first and nulls_last define how null values are sorted. See Using F() to sort null values for example usage.

In older versions, nulls_first and nulls_last defaulted to False.

Deprecated since version 4.1: Passing nulls_first=False or nulls_last=False to asc() is deprecated. Use None instead.

desc(nulls_first=None, nulls_last=None)

Returns the expression ready to be sorted in descending order.
nulls_first and nulls_last define how null values are sorted. See Using F() to sort null values for example usage.

In older versions, nulls_first and nulls_last defaulted to False.

Deprecated since version 4.1: Passing nulls_first=False or nulls_last=False to desc() is deprecated. Use None instead.

reverse_ordering()

Returns self with any modifications required to reverse the sort order within an order_by call. As an example, an expression implementing NULLS LAST would change its value to be NULLS FIRST. Modifications are only required for expressions that implement sort order like OrderBy. This method is called when reverse() is called on a queryset.

Writing your own Query Expressions

You can write your own query expression classes that use, and can integrate with, other query expressions. Let’s step through an example by writing an implementation of the COALESCE SQL function, without using the built-in Func() expressions.

The COALESCE SQL function is defined as taking a list of columns or values. It will return the first column or value that isn’t NULL.

We’ll start by defining the template to be used for SQL generation and an __init__() method to set some attributes:

```python
import copy
from django.db.models import Expression

class Coalesce(Expression):
    template = 'COALESCE( %(expressions)s )'

    def __init__(self, expressions, output_field):
        super().__init__(output_field=output_field)
        if len(expressions) < 2:
            raise ValueError('expressions must have at least 2 elements')
        for expression in expressions:
            if not hasattr(expression, 'resolve_expression'):
                raise TypeError('%r is not an Expression' % expression)
        self.expressions = expressions
```

We do some basic validation on the parameters, including requiring at least 2 columns or values, and ensuring they are expressions. We are requiring output_field here so that Django knows what kind of model field to assign the eventual result to.

Now we implement the preprocessing and validation. Since we do not have any of our own validation at this
point, we delegate to the nested expressions:

```python
def resolve_expression(self, query=None, allow_joins=True, reuse=None, summarize=False, for_=False, save=False):
    c = self.copy()
    c.is_summary = summarize
    for pos, expression in enumerate(self.expressions):
        c.expressions[pos] = expression.resolve_expression(query, allow_joins, reuse, summarize,
        for_, save)
    return c
```

Next, we write the method responsible for generating the SQL:

```python
def as_sql(self, compiler, connection, template=None):
    sql_expressions, sql_params = [], []
    for expression in self.expressions:
        sql, params = compiler.compile(expression)
        sql_expressions.append(sql)
        sql_params.extend(params)
    template = template or self.template
    data = {'expressions': ','.join(sql_expressions)}
    return template % data, sql_params

def as_oracle(self, compiler, connection):
    """
    Example of vendor specific handling (Oracle in this case).
    Let's make the function name lowercase.
    """
    return self.as_sql(compiler, connection, template='coalesce( %(expressions)s )')
```

`as_sql()` methods can support custom keyword arguments, allowing `as_vendorname()` methods to override data used to generate the SQL string. Using `as_sql()` keyword arguments for customization is preferable to mutating `self` within `as_vendorname()` methods as the latter can lead to errors when running on different database backends. If your class relies on class attributes to define data, consider allowing overrides in your `as_sql()` method.

We generate the SQL for each of the `expressions` by using the `compiler.compile()` method, and join the result together with commas. Then the template is filled out with our data and the SQL and parameters are returned.

We’ve also defined a custom implementation that is specific to the Oracle backend. The `as_oracle()` function will be called instead of `as_sql()` if the Oracle backend is in use.

Finally, we implement the rest of the methods that allow our query expression to play nice with other query expressions:
def get_source_expressions(self):
    return self.expressions

def set_source_expressions(self, expressions):
    self.expressions = expressions

Let’s see how it works:

```python
>>> from django.db.models import F, Value, CharField
>>> qs = Company.objects.annotate(
...    tagline=Coalesce([
...        F('motto'),
...        F('ticker_name'),
...        F('description'),
...        Value('No Tagline')
...    ], output_field=CharField()))

>>> for c in qs:
...    print("%s: %s" % (c.name, c.tagline))
...  
Google: Do No Evil
Apple: AAPL
Yahoo: Internet Company
Django Software Foundation: No Tagline
```

### Avoiding SQL injection

Since a `Func`’s keyword arguments for `__init__` (**extra**) and `as_sql` (**extra_context**) are interpolated into the SQL string rather than passed as query parameters (where the database driver would escape them), they must not contain untrusted user input.

For example, if `substring` is user-provided, this function is vulnerable to SQL injection:

```python
from django.db.models import Func

class Position(Func):
    function = 'POSITION'
    template = "%(function)s('%(substring)s' in %(expressions)s)"

    def __init__(self, expression, substring):
        # substring=substring is an SQL injection vulnerability!
        super().__init__(expression, substring=substring)
```

This function generates an SQL string without any parameters. Since `substring` is passed to `super().__init__()` as a keyword argument, it’s interpolated into the SQL string before the query is sent to the database.
Here’s a corrected rewrite:

```python
class Position(Func):
    function = 'POSITION'
    arg_joiner = ' IN '

    def __init__(self, expression, substring):
        super().__init__(substring, expression)
```

With `substring` instead passed as a positional argument, it’ll be passed as a parameter in the database query.

**Adding support in third-party database backends**

If you’re using a database backend that uses a different SQL syntax for a certain function, you can add support for it by monkey patching a new method onto the function’s class.

Let’s say we’re writing a backend for Microsoft’s SQL Server which uses the SQL `LEN` instead of `LENGTH` for the `Length` function. We’ll monkey patch a new method called `as_sqlserver()` onto the `Length` class:

```python
from django.db.models.functions import Length

def sqlserver_length(self, compiler, connection):
    return self.as_sql(compiler, connection, function='LEN')

Length.as_sqlserver = sqlserver_length
```

You can also customize the SQL using the `template` parameter of `as_sql()`.

We use `as_sqlserver()` because `django.db.connection.vendor` returns `sqlserver` for the backend.

Third-party backends can register their functions in the top level `__init__.py` file of the backend package or in a top level `expressions.py` file (or package) that is imported from the top level `__init__.py`.

For user projects wishing to patch the backend that they’re using, this code should live in an ` AppConfig.ready()` method.
6.16.13 Conditional Expressions

Conditional expressions let you use if ... elif ... else logic within filters, annotations, aggregations, and updates. A conditional expression evaluates a series of conditions for each row of a table and returns the matching result expression. Conditional expressions can also be combined and nested like other expressions.

The conditional expression classes

We’ll be using the following model in the subsequent examples:

```python
from django.db import models

class Client(models.Model):
    REGULAR = 'R'
    GOLD = 'G'
    PLATINUM = 'P'
    ACCOUNT_TYPE_CHOICES = [
        (REGULAR, 'Regular'),
        (GOLD, 'Gold'),
        (PLATINUM, 'Platinum'),
    ]
    name = models.CharField(max_length=50)
    registered_on = models.DateField()
    account_type = models.CharField(
        max_length=1,
        choices=ACCOUNT_TYPE_CHOICES,
        default=REGULAR,
    )
```

A `When()` object is used to encapsulate a condition and its result for use in the conditional expression. Using a `When()` object is similar to using the `filter()` method. The condition can be specified using field lookups, `Q` objects, or `Expression` objects that have an `output_field` that is a `BooleanField`. The result is provided using the `then` keyword.

Some examples:

```python
>>> from django.db.models import F, Q, When

>>> # String arguments refer to fields; the following two examples are equivalent:
>>> When(account_type=Client.GOLD, then='name')
```

(continues on next page)
Keep in mind that each of these values can be an expression.

Note: Since the `then` keyword argument is reserved for the result of the `When()`, there is a potential conflict if a `Model` has a field named `then`. This can be resolved in two ways:

```python
>>> When(then__exact=0, then=1)
>>> When(Q(then=0), then=1)
```

Case

class Case(*cases, **extra)

A `Case()` expression is like the `if ... elif ... else` statement in Python. Each condition in the provided `When()` objects is evaluated in order, until one evaluates to a truthfull value. The `result` expression from the matching `When()` object is returned.

An example:
>>> from datetime import date, timedelta
>>> from django.db.models import Case, Value, When

>>> Client.objects.create(
...     name='Jane Doe',
...     account_type=Client.REGULAR,
...     registered_on=date.today() - timedelta(days=36))

>>> Client.objects.create(
...     name='James Smith',
...     account_type=Client.GOLD,
...     registered_on=date.today() - timedelta(days=6))

>>> Client.objects.create(
...     name='Jack Black',
...     account_type=Client.PLATINUM,
...     registered_on=date.today() - timedelta(days=10 * 365))

>>> # Get the discount for each Client based on the account type

>>> Client.objects.annotate(
...     discount=Case(
...         When(account_type=Client.GOLD, then=Value('5%')),
...         When(account_type=Client.PLATINUM, then=Value('10%')),
...         default=Value('0%'),
...     ),
... ).values_list('name', 'discount')
<QuerySet [('Jane Doe', '0%'), ('James Smith', '5%'), ('Jack Black', '10%')]>
Note: Remember that the conditions are evaluated in order, so in the above example we get the correct result even though the second condition matches both Jane Doe and Jack Black. This works just like an \texttt{if} \ldots \texttt{elif} \ldots \texttt{else} statement in Python.

\texttt{Case()} also works in a \texttt{filter()} clause. For example, to find gold clients that registered more than a month ago and platinum clients that registered more than a year ago:

```python
>>> a_month_ago = date.today() - timedelta(days=30)
>>> a_year_ago = date.today() - timedelta(days=365)

>>> Client.objects.filter(  
...     registered_on__lte=Case(  
...         When(account_type=Client.GOLD, then=a_month_ago),  
...         When(account_type=Client.PLATINUM, then=a_year_ago),  
...     ),  
... ).values_list('name', 'account_type')
<QuerySet [('Jack Black', 'P')]
```

\textbf{Advanced queries}

Conditional expressions can be used in annotations, aggregations, filters, lookups, and updates. They can also be combined and nested with other expressions. This allows you to make powerful conditional queries.

\textbf{Conditional update}

Let’s say we want to change the \texttt{account\_type} for our clients to match their registration dates. We can do this using a conditional expression and the \texttt{update()} method:

```python
>>> a_month_ago = date.today() - timedelta(days=30)
>>> a_year_ago = date.today() - timedelta(days=365)

>>> # Update the account\_type for each Client from the registration date

>>> Client.objects.update(  
...     account_type=Case(  
...         When(registered_on__lte=a_year_ago,  
...             then=Value(Client.PLATINUM)),  
...         When(registered_on__lte=a_month_ago,  
...             then=Value(Client.GOLD)),  
...         default=Value(Client.REGULAR)  
...     ),  
... )

>>> Client.objects.values_list('name', 'account_type')
<QuerySet [('Jane Doe', 'G'), ('James Smith', 'R'), ('Jack Black', 'P')]
```
Conditional aggregation

What if we want to find out how many clients there are for each account_type? We can use the filter argument of `aggregate` functions to achieve this:

```python
>>> # Create some more Clients first so we can have something to count
>>> Client.objects.create(
...     name='Jean Grey',
...     account_type=Client.REGULAR,
...     registered_on=date.today())
>>> Client.objects.create(
...     name='James Bond',
...     account_type=Client.PLATINUM,
...     registered_on=date.today())
>>> Client.objects.create(
...     name='Jane Porter',
...     account_type=Client.PLATINUM,
...     registered_on=date.today())
>>> # Get counts for each value of account_type
>>> from django.db.models import Count
>>> Client.objects.aggregate(
...     regular=Count('pk', filter=Q(account_type=Client.REGULAR)),
...     gold=Count('pk', filter=Q(account_type=Client.GOLD)),
...     platinum=Count('pk', filter=Q(account_type=Client.PLATINUM)),
... )
{'regular': 2, 'gold': 1, 'platinum': 3}
```

This aggregate produces a query with the SQL 2003 `FILTER WHERE` syntax on databases that support it:

```sql
SELECT count('id') FILTER (WHERE account_type=1) as regular,
       count('id') FILTER (WHERE account_type=2) as gold,
       count('id') FILTER (WHERE account_type=3) as platinum
FROM clients;
```

On other databases, this is emulated using a `CASE` statement:

```sql
SELECT count(CASE WHEN account_type=1 THEN id ELSE null END) as regular,
       count(CASE WHEN account_type=2 THEN id ELSE null END) as gold,
       count(CASE WHEN account_type=3 THEN id ELSE null END) as platinum
FROM clients;
```

The two SQL statements are functionally equivalent but the more explicit `FILTER` may perform better.
Conditional filter

When a conditional expression returns a boolean value, it is possible to use it directly in filters. This means that it will not be added to the SELECT columns, but you can still use it to filter results:

```python
>>> non_unique_account_type = Client.objects.filter(
    ...     account_type=OuterRef('account_type'),
    ... ).exclude(pk=OuterRef('pk')).values('pk')
```

In SQL terms, that evaluates to:

```sql
SELECT ...
FROM client c0
WHERE NOT EXISTS (  
    SELECT c1.id  
    FROM client c1  
    WHERE c1.account_type = c0.account_type AND NOT c1.id = c0.id  
)
```

### 6.16.14 Database Functions

The classes documented below provide a way for users to use functions provided by the underlying database as annotations, aggregations, or filters in Django. Functions are also expressions, so they can be used and combined with other expressions like aggregate functions.

We’ll be using the following model in examples of each function:

```python
class Author(models.Model):
    name = models.CharField(max_length=50)
    age = models.PositiveIntegerField(null=True, blank=True)
    alias = models.CharField(max_length=50, null=True, blank=True)
    goes_by = models.CharField(max_length=50, null=True, blank=True)
```

We don’t usually recommend allowing `null=True` for `CharField` since this allows the field to have two “empty values”, but it’s important for the `Coalesce` example below.
Comparison and conversion functions

Cast

class Cast(expression, output_field)

Forces the result type of expression to be the one from output_field.

Usage example:

```python
>>> from django.db.models import FloatField
>>> from django.db.models.functions import Cast
>>> Author.objects.create(age=25, name='Margaret Smith')
>>> author = Author.objects.annotate(...    age_as_float=Cast('age', output_field=FloatField()),...).get()
>>> print(author.age_as_float)
25.0
```

Coalesce

class Coalesce(*expressions, **extra)

Accepts a list of at least two field names or expressions and returns the first non-null value (note that an empty string is not considered a null value). Each argument must be of a similar type, so mixing text and numbers will result in a database error.

Usage examples:

```python
>>> # Get a screen name from least to most public
>>> from django.db.models import Sum
>>> from django.db.models.functions import Coalesce
>>> Author.objects.create(name='Margaret Smith', goes_by='Maggie')
>>> author = Author.objects.annotate(...    screen_name=Coalesce('alias', 'goes_by', 'name')).get()
>>> print(author.screen_name)
Maggie

>>> # Prevent an aggregate Sum() from returning None
>>> # The aggregate default argument uses Coalesce() under the hood.
>>> aggregated = Author.objects.aggregate(...    combined_age=Sum('age'),
    ...    combined_age_default=Sum('age', default=0),
    ...    combined_age_coalesce=Coalesce(Sum('age'), 0),
    ...)
```
>>> print(aggregated['combined_age'])
None
>>> print(aggregated['combined_age_default'])
0
>>> print(aggregated['combined_age_coalesce'])
0

Warning: A Python value passed to Coalesce on MySQL may be converted to an incorrect type unless explicitly cast to the correct database type:

```python
>>> from django.db.models import DateTimeField
>>> from django.db.models.functions import Cast, Coalesce
>>> from django.utils import timezone
>>> now = timezone.now()
>>> Coalesce('updated', Cast(now, DateTimeField()))
```

Collate

class Collate(expression, collation)

Takes an expression and a collation name to query against.

For example, to filter case-insensitively in SQLite:

```python
>>> Author.objects.filter(name=Collate(Value('john'), 'nocase'))
<QuerySet [<Author: John>, <Author: john]>>
```

It can also be used when ordering, for example with PostgreSQL:

```python
>>> Author.objects.order_by(Collate('name', 'et-x-icu'))
<QuerySet [<Author: Ursula>, <Author: Veronika>, <Author: Ülle]>>
```

Greatest

class Greatest(*expressions, **extra)

Accepts a list of at least two field names or expressions and returns the greatest value. Each argument must be of a similar type, so mixing text and numbers will result in a database error.

Usage example:
class Blog(models.Model):
    body = models.TextField()
    modified = models.DateTimeField(auto_now=True)

class Comment(models.Model):
    body = models.TextField()
    modified = models.DateTimeField(auto_now=True)
    blog = models.ForeignKey(Blog, on_delete=models.CASCADE)

>>> from django.db.models.functions import Greatest
>>> blog = Blog.objects.create(body='Greatest is the best.')
>>> comment = Comment.objects.create(body='No, Least is better.', blog=blog)
>>> comments = Comment.objects.annotate(last_updated=Greatest('modified', 'blog__modified'))
>>> annotated_comment = comments.get()

annotated_comment.last_updated will be the most recent of blog.modified and comment.modified.

Warning: The behavior of Greatest when one or more expression may be null varies between
databases:

- PostgreSQL: Greatest will return the largest non-null expression, or null if all expressions are
  null.
- SQLite, Oracle, and MySQL: If any expression is null, Greatest will return null.

The PostgreSQL behavior can be emulated using Coalesce if you know a sensible minimum value to
provide as a default.

JSONObject

class JSONObject(**fields)

Takes a list of key-value pairs and returns a JSON object containing those pairs.

Usage example:

```python
>>> from django.db.models import F
>>> from django.db.models.functions import JSONObject, Lower
>>> Author.objects.create(name='Margaret Smith', alias='msmith', age=25)
>>> author = Author.objects.annotate(json_object=JSONObject(
...     name=Lower('name'),
...     alias='alias',
...     age=F('age') * 2,
... )).get()
```

(continues on next page)
>>> author.json_object
{'name': 'margaret smith', 'alias': 'msmith', 'age': 50}

Least

class Least(*expressions, **extra)

Accepts a list of at least two field names or expressions and returns the least value. Each argument must be of a similar type, so mixing text and numbers will result in a database error.

Warning: The behavior of Least when one or more expression may be null varies between databases:

- PostgreSQL: Least will return the smallest non-null expression, or null if all expressions are null.
- SQLite, Oracle, and MySQL: If any expression is null, Least will return null.

The PostgreSQL behavior can be emulated using Coalesce if you know a sensible maximum value to provide as a default.

NullIf

class NullIf(expression1, expression2)

Accepts two expressions and returns None if they are equal, otherwise returns expression1.

Caveats on Oracle

Due to an Oracle convention, this function returns the empty string instead of None when the expressions are of type CharField.

Passing Value(None) to expression1 is prohibited on Oracle since Oracle doesn’t accept NULL as the first argument.

Date functions

We’ll be using the following model in examples of each function:

class Experiment(models.Model):
    start_datetime = models.DateTimeField()
    start_date = models.DateField(null=True, blank=True)
    start_time = models.TimeField(null=True, blank=True)
end_datetime = models.DateTimeField(null=True, blank=True)
end_date = models.DateField(null=True, blank=True)
end_time = models.TimeField(null=True, blank=True)

Extract

class Extract(expression, lookup_name=None, tzinfo=None, **extra)

Extracts a component of a date as a number.

Takes an expression representing a DateField, DateTimeField, TimeField, or DurationField and a lookup_name, and returns the part of the date referenced by lookup_name as an IntegerField. Django usually uses the databases’ extract function, so you may use any lookup_name that your database supports. A tzinfo subclass, usually provided by zoneinfo, can be passed to extract a value in a specific timezone.

Given the datetime 2015-06-15 23:30:01.000321+00:00, the built-in lookup_names return:

- “year”: 2015
- “iso_year”: 2015
- “quarter”: 2
- “month”: 6
- “day”: 15
- “week”: 25
- “week_day”: 2
- “iso_week_day”: 1
- “hour”: 23
- “minute”: 30
- “second”: 1

If a different timezone like Australia/Melbourne is active in Django, then the datetime is converted to the timezone before the value is extracted. The timezone offset for Melbourne in the example date above is +10:00. The values returned when this timezone is active will be the same as above except for:

- “day”: 16
- “week_day”: 3
- “iso_week_day”: 2
- “hour”: 9
### week\_day values

The **week\_day** lookup\_type is calculated differently from most databases and from Python’s standard functions. This function will return 1 for Sunday, 2 for Monday, through 7 for Saturday.

The equivalent calculation in Python is:

```python
>>> from datetime import datetime
dt = datetime(2015, 6, 15)
>>> (dt.isoweekday() % 7) + 1
2
```

### week values

The **week** lookup\_type is calculated based on ISO-8601, i.e., a week starts on a Monday. The first week of a year is the one that contains the year’s first Thursday, i.e. the first week has the majority (four or more) of its days in the year. The value returned is in the range 1 to 52 or 53.

Each lookup\_name above has a corresponding Extract subclass (listed below) that should typically be used instead of the more verbose equivalent, e.g. use `ExtractYear(...)` rather than `Extract(..., lookup\_name='year')`.

Usage example:

```python
>>> from datetime import datetime
>>> from django.db.models.functions import Extract
>>> start = datetime(2015, 6, 15)
>>> end = datetime(2015, 7, 2)
>>> Experiment.objects.create(
...     start_datetime=start, start_date=start.date(),
...     end_datetime=end, end_date=end.date())
>>> # Add the experiment start year as a field in the QuerySet.
>>> experiment = Experiment.objects.annotate(
...     start_year=Extract('start_datetime', 'year')).get()
>>> experiment.start_year
2015
>>> # How many experiments completed in the same year in which they started?
>>> Experiment.objects.filter(
...     start_datetime__year=Extract('end_datetime', 'year')).count()
1
```
**DateField extracts**

```python
class ExtractYear(expression, tzinfo=None, **extra)
    lookup_name = 'year'
class ExtractIsoYear(expression, tzinfo=None, **extra)
    Returns the ISO-8601 week-numbering year.
    lookup_name = 'iso_year'
class ExtractMonth(expression, tzinfo=None, **extra)
    lookup_name = 'month'
class ExtractDay(expression, tzinfo=None, **extra)
    lookup_name = 'day'
class ExtractWeekDay(expression, tzinfo=None, **extra)
    lookup_name = 'week_day'
class ExtractIsoWeekDay(expression, tzinfo=None, **extra)
    Returns the ISO-8601 weekday with day 1 being Monday and day 7 being Sunday.
    lookup_name = 'iso_week_day'
class ExtractWeek(expression, tzinfo=None, **extra)
    lookup_name = 'week'
class ExtractQuarter(expression, tzinfo=None, **extra)
    lookup_name = 'quarter'
```

These are logically equivalent to `Extract('date_field', lookup_name)`. Each class is also a `Transform` registered on `DateField` and `DateTimeField` as `__(lookup_name)`, e.g. `__year`.

Since `DateField`s don’t have a time component, only `Extract` subclasses that deal with date-parts can be used with `DateField`:

```python
>>> from datetime import datetime, timezone
>>> from django.db.models.functions import (...
...     ExtractDay, ExtractMonth, ExtractQuarter, ExtractWeek,
...     ExtractIsoWeekDay, ExtractWeekDay, ExtractIsoYear, ExtractYear,
... )
>>> start_2015 = datetime(2015, 6, 15, 23, 30, 1, tzinfo=timezone.utc)
>>> end_2015 = datetime(2015, 6, 16, 13, 11, 27, tzinfo=timezone.utc)
```
>>> Experiment.objects.create(
...   start_datetime=start_2015, start_date=start_2015.date(),
...   end_datetime=end_2015, end_date=end_2015.date())
>>> Experiment.objects.annotate(
...   year=ExtractYear('start_date'),
...   isoyear=ExtractIsoYear('start_date'),
...   quarter=ExtractQuarter('start_date'),
...   month=ExtractMonth('start_date'),
...   week=ExtractWeek('start_date'),
...   day=ExtractDay('start_date'),
...   weekday=ExtractWeekDay('start_date'),
...   isoweekday=ExtractIsoWeekDay('start_date'),
...   ).values(
...     'year', 'isoyear', 'quarter', 'month', 'week', 'day', 'weekday',
...     'isoweekday',
...   ).get(end_date__year=ExtractYear('start_date'))
{'year': 2015, 'isoyear': 2015, 'quarter': 2, 'month': 6, 'week': 25,
 'day': 15, 'weekday': 2, 'isoweekday': 1}

**DateTimeField extracts**

In addition to the following, all extracts for `DateField` listed above may also be used on `DateTimeField`.

class `ExtractHour` (expression, tzinfo=None, **extra)

    lookup_name = 'hour'

class `ExtractMinute` (expression, tzinfo=None, **extra)

    lookup_name = 'minute'

class `ExtractSecond` (expression, tzinfo=None, **extra)

    lookup_name = 'second'

These are logically equivalent to `Extract('datetime_field', lookup_name)`. Each class is also a `Transform` registered on `DateTimeField` as `__`(lookup_name), e.g. `__minute`.

**DateTimeField examples**:

```python
>>> from datetime import datetime, timezone
>>> from django.db.models.functions import (  
...   ExtractDay, ExtractHour, ExtractMinute, ExtractMonth,  
...   ExtractQuarter, ExtractSecond, ExtractWeek, ExtractIsoWeekDay,  
...   ExtractWeekDay, ExtractIsoYear, ExtractYear,  
```
...)

```python
>>> start_2015 = datetime(2015, 6, 15, 23, 30, 1, tzinfo=timezone.utc)
>>> end_2015 = datetime(2015, 6, 16, 13, 11, 27, tzinfo=timezone.utc)
>>> Experiment.objects.create(
...   start_datetime=start_2015, start_date=start_2015.date(),
...   end_datetime=end_2015, end_date=end_2015.date())
>>> Experiment.objects.annotate(
...   year=ExtractYear('start_datetime'),
...   isoyear=ExtractIsoYear('start_datetime'),
...   quarter=ExtractQuarter('start_datetime'),
...   month=ExtractMonth('start_datetime'),
...   week=ExtractWeek('start_datetime'),
...   day=ExtractDay('start_datetime'),
...   weekday=ExtractWeekDay('start_datetime'),
...   isoweekday=ExtractIsoWeekDay('start_datetime'),
...   hour=ExtractHour('start_datetime'),
...   minute=ExtractMinute('start_datetime'),
...   second=ExtractSecond('start_datetime'),
... ).values('year', 'isoyear', 'month', 'week', 'day',
... 'weekday', 'isoweekday', 'hour', 'minute', 'second',
... ).get(end_datetime__year=ExtractYear('start_datetime'))
{'year': 2015, 'isoyear': 2015, 'quarter': 2, 'month': 6, 'week': 25, 'day': 15, 'weekday': 2, 'isoweekday': 1, 'hour': 23, 'minute': 30, 'second': 1}
```

When `USE_TZ` is True then datetimes are stored in the database in UTC. If a different timezone is active in Django, the datetime is converted to that timezone before the value is extracted. The example below converts to the Melbourne timezone (UTC +10:00), which changes the day, weekday, and hour values that are returned:

```python
>>> from django.utils import timezone
>>> import zoneinfo
>>> melb = zoneinfo.ZoneInfo('Australia/Melbourne')  # UTC+10:00
>>> with timezone.override(melb):
...   Experiment.objects.annotate(
...     day=ExtractDay('start_datetime'),
...     weekday=ExtractWeekDay('start_datetime'),
...     isoweekday=ExtractIsoWeekDay('start_datetime'),
...     hour=ExtractHour('start_datetime'),
...   ).values('day', 'weekday', 'isoweekday', 'hour').get(
...     end_datetime__year=ExtractYear('start_datetime'),
...   )
{'day': 16, 'weekday': 3, 'isoweekday': 2, 'hour': 9}
```
Explicitly passing the timezone to the `Extract` function behaves in the same way, and takes priority over an active timezone:

```python
>>> import zoneinfo
>>> melb = zoneinfo.ZoneInfo('Australia/Melbourne')
>>> Experiment.objects.annotate(
...    day=ExtractDay('start_datetime', tzinfo=melb),
...    weekday=ExtractWeekDay('start_datetime', tzinfo=melb),
...    isoweekday=ExtractIsoWeekDay('start_datetime', tzinfo=melb),
...    hour=ExtractHour('start_datetime', tzinfo=melb),
...    end_datetime__year=ExtractYear('start_datetime'),
...).values('day', 'weekday', 'isoweekday', 'hour')
{'day': 16, 'weekday': 3, 'isoweekday': 2, 'hour': 9}
```

### Now

**class Now**

Returns the database server’s current date and time when the query is executed, typically using the SQL `CURRENT_TIMESTAMP`.

Usage example:

```python
>>> from django.db.models.functions import Now
>>> Article.objects.filter(published__lte=Now())
<QuerySet [<Article: How to Django>]>```

### PostgreSQL considerations

On PostgreSQL, the SQL `CURRENT_TIMESTAMP` returns the time that the current transaction started. Therefore for cross-database compatibility, `Now()` uses `STATEMENT_TIMESTAMP` instead. If you need the transaction timestamp, use `django.contrib.postgres.functions.TransactionNow`.

### Trunc

**class Trunc**(expression, kind, output_field=None, tzinfo=None, is_dst=None, **extra)

Truncates a date up to a significant component.

When you only care if something happened in a particular year, hour, or day, but not the exact second, then `Trunc` (and its subclasses) can be useful to filter or aggregate your data. For example, you can use `Trunc` to calculate the number of sales per day.
Trunc takes a single expression, representing a DateField, TimeField, or DateTimeField, a kind representing a date or time part, and an output_field that’s either DateTimeField(), TimeField(), or DateField(). It returns a datetime, date, or time depending on output_field, with fields up to kind set to their minimum value. If output_field is omitted, it will default to the output_field of expression. A tzinfo subclass, usually provided by zoneinfo, can be passed to truncate a value in a specific timezone.

Deprecated since version 4.0: The is_dst parameter indicates whether or not pytz should interpret nonexistent and ambiguous datetimes in daylight saving time. By default (when is_dst=\texttt{None}), pytz raises an exception for such datetimes.

The is_dst parameter is deprecated and will be removed in Django 5.0.

Given the datetime \texttt{2015-06-15 14:30:50.000321+00:00}, the built-in kinds return:

- “year” : 2015-01-01 00:00:00+00:00
- “quarter” : 2015-04-01 00:00:00+00:00
- “month” : 2015-06-01 00:00:00+00:00
- “week” : 2015-06-15 00:00:00+00:00
- “day” : 2015-06-15 00:00:00+00:00
- “hour” : 2015-06-15 14:00:00+00:00
- “minute” : 2015-06-15 14:30:00+00:00
- “second” : 2015-06-15 14:30:50+00:00

If a different timezone like Australia/Melbourne is active in Django, then the datetime is converted to the new timezone before the value is truncated. The timezone offset for Melbourne in the example date above is +10:00. The values returned when this timezone is active will be:

- “year” : 2015-01-01 00:00:00+11:00
- “quarter” : 2015-04-01 00:00:00+10:00
- “month” : 2015-06-01 00:00:00+10:00
- “week” : 2015-06-16 00:00:00+10:00
- “day” : 2015-06-16 00:00:00+10:00
- “hour” : 2015-06-16 00:00:00+10:00
- “minute” : 2015-06-16 00:30:00+10:00
- “second” : 2015-06-16 00:30:50+10:00

The year has an offset of +11:00 because the result transitioned into daylight saving time.

Each kind above has a corresponding Trunc subclass (listed below) that should typically be used instead of the more verbose equivalent, e.g. use \texttt{TruncYear(...) } rather than \texttt{Trunc(..., kind='year')}. 

6.16. Models 1737
The subclasses are all defined as transforms, but they aren’t registered with any fields, because the lookup names are already reserved by the `Extract` subclasses.

Usage example:

```python
>>> from datetime import datetime
>>> from django.db.models import Count, DateTimeField
>>> from django.db.models.functions import Trunc
>>> Experiment.objects.create(start_datetime=datetime(2015, 6, 15, 14, 30, 50, 321))
>>> Experiment.objects.create(start_datetime=datetime(2015, 6, 15, 14, 40, 2, 123))
>>> experiments_per_day = Experiment.objects.annotate(
...     start_day=Trunc('start_datetime', 'day', output_field=DateTimeField())
... ).values('start_day').annotate(experiments=Count('id'))
>>> for exp in experiments_per_day:
...     print(exp['start_day'], exp['experiments'])
...     2015-06-15 00:00:00 2
2015-12-25 00:00:00 1
>>> experiments = Experiment.objects.annotate(
...     start_day=Trunc('start_datetime', 'day', output_field=DateTimeField())
... ).filter(start_day=datetime(2015, 6, 15))
>>> for exp in experiments:
...     print(exp.start_datetime)
...     2015-06-15 14:30:50.000321
2015-06-15 14:40:02.000123
```

**DateField truncation**

```python
class TruncYear(expression, output_field=None, tzinfo=None, is_dst=None, **extra)
    kind = 'year'
class TruncMonth(expression, output_field=None, tzinfo=None, is_dst=None, **extra)
    kind = 'month'
class TruncWeek(expression, output_field=None, tzinfo=None, is_dst=None, **extra)
    Truncates to midnight on the Monday of the week.
    kind = 'week'
class TruncQuarter(expression, output_field=None, tzinfo=None, is_dst=None, **extra)
```
kind = 'quarter'

Deprecated since version 4.0: The is_dst parameter is deprecated and will be removed in Django 5.0.

These are logically equivalent to \texttt{Trunc('date\_field', kind)}. They truncate all parts of the date up to \texttt{kind} which allows grouping or filtering dates with less precision. \texttt{expression} can have an \texttt{output\_field} of either \texttt{DateField} or \texttt{DateTimeField}.

Since \texttt{DateField} don’t have a time component, only \texttt{Trunc} subclasses that deal with date-parts can be used with \texttt{DateField}:

```python
>>> from datetime import datetime, timezone
>>> from django.db.models import Count
>>> from django.db.models.functions import TruncMonth, TruncYear
>>> start1 = datetime(2014, 6, 15, 14, 30, 50, 321, tzinfo=timezone.utc)
>>> start2 = datetime(2015, 6, 15, 14, 40, 2, 123, tzinfo=timezone.utc)
>>> start3 = datetime(2015, 12, 31, 17, 5, 27, 999, tzinfo=timezone.utc)
>>> Experiment.objects.create(start_datetime=start1, start_date=start1.date())
>>> Experiment.objects.create(start_datetime=start2, start_date=start2.date())
>>> Experiment.objects.create(start_datetime=start3, start_date=start3.date())
>>> experiments_per_year = Experiment.objects.annotate(
...     year=TruncYear('start\_date')).values('year').annotate(
...     experiments=Count('id'))
>>> for exp in experiments_per_year:
...     print(exp['year'], exp['experiments'])
...     2014-01-01 1
...     2015-01-01 2

>>> import zoneinfo

>>> melb = zoneinfo.ZoneInfo('Australia/Melbourne')
>>> experiments_per_month = Experiment.objects.annotate(
...     month=TruncMonth('start\_datetime', tzinfo=melb)).values('month').annotate(
...     experiments=Count('id'))
>>> for exp in experiments_per_month:
...     print(exp['month'], exp['experiments'])
...     2015-06-01 00:00:00+10:00 1
...     2016-01-01 00:00:00+11:00 1
...     2014-06-01 00:00:00+10:00 1
```
**DateTimeField truncation**

```python
class TruncDate(expression, tzinfo=None, **extra):
    lookup_name = 'date'
    output_field = DateField()
```

TruncDate casts `expression` to a date rather than using the built-in SQL truncate function. It’s also registered as a transform on `DateTimeField` as `_date`.

```python
class TruncTime(expression, tzinfo=None, **extra):
    lookup_name = 'time'
    output_field = TimeField()
```

TruncTime casts `expression` to a time rather than using the built-in SQL truncate function. It’s also registered as a transform on `DateTimeField` as `_time`.

```python
class TruncDay(expression, output_field=None, tzinfo=None, is_dst=None, **extra)
    kind = 'day'
```

```python
class TruncHour(expression, output_field=None, tzinfo=None, is_dst=None, **extra)
    kind = 'hour'
```

```python
class TruncMinute(expression, output_field=None, tzinfo=None, is_dst=None, **extra)
    kind = 'minute'
```

```python
class TruncSecond(expression, output_field=None, tzinfo=None, is_dst=None, **extra)
    kind = 'second'
```

Deprecated since version 4.0: The `is_dst` parameter is deprecated and will be removed in Django 5.0.

These are logically equivalent to `Trunc('datetime_field', kind)`. They truncate all parts of the date up to `kind` and allow grouping or filtering datetimes with less precision. `expression` must have an `output_field` of `DateTimeField`.

Usage example:

```python
>>> from datetime import date, datetime, timezone
>>> from django.db.models import Count
>>> from django.db.models.functions import TruncDate, TruncDay, TruncHour, TruncMinute, TruncSecond,
...     ...     ... import zoneinfo
```

(continues on next page)
>>> start1 = datetime(2014, 6, 15, 14, 30, 50, 321, tzinfo=timezone.utc)
>>> Experiment.objects.create(start_datetime=start1, start_date=start1.date())
>>> melb = timezone.ZoneInfo('Australia/Melbourne')
>>> Experiment.objects.annotate(
...     date=TruncDate('start_datetime'),
...     day=TruncDay('start_datetime', tzinfo=melb),
...     hour=TruncHour('start_datetime', tzinfo=melb),
...     minute=TruncMinute('start_datetime'),
...     second=TruncSecond('start_datetime'),
... ).values('date', 'day', 'hour', 'minute', 'second').get()
{'date': datetime.date(2014, 6, 15),
 'day': datetime.datetime(2014, 6, 16, 0, 0, tzinfo=zoneinfo.ZoneInfo('Australia/Melbourne')),
 'hour': datetime.datetime(2014, 6, 16, 0, 0, tzinfo=zoneinfo.ZoneInfo('Australia/Melbourne')),
 'minute': 'minute': datetime.datetime(2014, 6, 15, 14, 30, tzinfo=zoneinfo.ZoneInfo('UTC')),
 'second': datetime.datetime(2014, 6, 15, 14, 30, 50, tzinfo=zoneinfo.ZoneInfo('UTC'))
}

**TimeField truncation**

```python

class TruncHour(expression, output_field=None, tzinfo=None, is_dst=None, **extra)
    kind = 'hour'

class TruncMinute(expression, output_field=None, tzinfo=None, is_dst=None, **extra)
    kind = 'minute'

class TruncSecond(expression, output_field=None, tzinfo=None, is_dst=None, **extra)
    kind = 'second'
```

Deprecated since version 4.0: The is_dst parameter is deprecated and will be removed in Django 5.0.

These are logically equivalent to `Trunc('time_field', kind)`. They truncate all parts of the time up to kind which allows grouping or filtering times with less precision. expression can have an output_field of either TimeField or DateTimeField.

Since TimeFields don’t have a date component, only Trunc subclasses that deal with time-parts can be used with TimeField:

```python
>>> from datetime import datetime, timezone
>>> from django.db.models import Count, TimeField
>>> from django.db.models.functions import TruncHour
>>> start1 = datetime(2014, 6, 15, 14, 30, 50, 321, tzinfo=timezone.utc)
>>> start2 = datetime(2014, 6, 15, 14, 40, 2, 123, tzinfo=timezone.utc)
```
>>> start3 = datetime(2015, 12, 31, 17, 5, 27, 999, tzinfo=timezone.utc)
>>> Experiment.objects.create(start_datetime=start1, start_time=start1.time())
>>> Experiment.objects.create(start_datetime=start2, start_time=start2.time())
>>> Experiment.objects.create(start_datetime=start3, start_time=start3.time())

>>> experiments_per_hour = Experiment.objects.annotate(
...     hour=TruncHour('start_datetime', output_field=TimeField()),
... ).values('hour').annotate(experiments=Count('id'))

>>> for exp in experiments_per_hour:
...     print(exp['hour'], exp['experiments'])

... 14:00:00 2
17:00:00 1

>>> import zoneinfo
>>> melb = zoneinfo.ZoneInfo('Australia/Melbourne')

>>> experiments_per_hour = Experiment.objects.annotate(
...     hour=TruncHour('start_datetime', tzinfo=melb),
... ).values('hour').annotate(experiments=Count('id'))

>>> for exp in experiments_per_hour:
...     print(exp['hour'], exp['experiments'])

... 2014-06-16 00:00:00+10:00 2
2016-01-01 04:00:00+11:00 1

Math Functions

We’ll be using the following model in math function examples:

class Vector(models.Model):
    x = models.FloatField()
    y = models.FloatField()

Abs

class Abs(expression, **extra)

Returns the absolute value of a numeric field or expression.

Usage example:

>>> from django.db.models.functions import Abs

>>> Vector.objects.create(x=-0.5, y=1.1)
It can also be registered as a transform. For example:

```
>>> from django.db.models import FloatField
>>> from django.db.models.functions import Abs
>>> floatField.register_lookup(Abs)

# Get vectors inside the unit cube
>>> vectors = Vector.objects.filter(x__abs__lt=1, y__abs__lt=1)
```

**ACos**

class ACos(expression, **extra)

Returns the arccosine of a numeric field or expression. The expression value must be within the range -1 to 1.

Usage example:

```
>>> from django.db.models.functions import ACos

# Get vectors whose arccosine is less than 1
>>> vectors = Vector.objects.filter(x__acos__lt=1, y__acos__lt=1)
```

**ASin**

class ASin(expression, **extra)

Returns the arcsine of a numeric field or expression. The expression value must be in the range -1 to 1.

Usage example:
>>> from django.db.models.functions import ASin
>>> Vector.objects.create(x=0, y=1)
>>> vector = Vector.objects.annotate(x_asin=ASin('x'), y_asin=ASin('y')).get()
>>> vector.x_asin, vector.y_asin
(0.0, 1.5707963267948966)

It can also be registered as a transform. For example:

```python
>>> from django.db.models import FloatField
>>> from django.db.models.functions import ASin
>>> FloatField.register_lookup(ASin)
>>> # Get vectors whose arcsine is less than 1
>>> vectors = Vector.objects.filter(x__asin__lt=1, y__asin__lt=1)
```

**ATan**

class ATan(expression, **extra)

Returns the arctangent of a numeric field or expression.

Usage example:

```python
>>> from django.db.models.functions import ATan
>>> Vector.objects.create(x=3.12, y=6.987)
>>> vector = Vector.objects.annotate(x_atan=ATan('x'), y_atan=ATan('y')).get()
>>> vector.x_atan, vector.y_atan
(1.2606282660069106, 1.428638798133829)
```

It can also be registered as a transform. For example:

```python
>>> from django.db.models import FloatField
>>> from django.db.models.functions import ATan
>>> FloatField.register_lookup(ATan)
>>> # Get vectors whose arctangent is less than 2
>>> vectors = Vector.objects.filter(x__atan__lt=2, y__atan__lt=2)
```
ATan2

class ATan2(expression1, expression2, **extra)

Returns the arctangent of \( \frac{\text{expression1}}{\text{expression2}} \).

Usage example:

```python
>>> from django.db.models.functions import ATan2
>>> Vector.objects.create(x=2.5, y=1.9)
>>> vector = Vector.objects.annotate(atan2=ATan2('x', 'y')).get()
>>> vector.atan2
0.9209258773829491
```

Ceil

class Ceil(expression, **extra)

Returns the smallest integer greater than or equal to a numeric field or expression.

Usage example:

```python
>>> from django.db.models.functions import Ceil
>>> Vector.objects.create(x=3.12, y=7.0)
>>> vector = Vector.objects.annotate(x_ceil=Ceil('x'), y_ceil=Ceil('y')).get()
>>> vector.x_ceil, vector.y_ceil
(4.0, 7.0)
```

It can also be registered as a transform. For example:

```python
>>> from django.db.models import FloatField
>>> from django.db.models.functions import Ceil
>>> FloatField.register_lookup(Ceil)
>>> # Get vectors whose ceil is less than 10
>>> vectors = Vector.objects.filter(x__ceil__lt=10, y__ceil__lt=10)
```

Cos

class Cos(expression, **extra)

Returns the cosine of a numeric field or expression.

Usage example:
>>> from django.db.models.functions import Cos
>>> Vector.objects.create(x=-8.0, y=3.1415926)
>>> vector = Vector.objects.annotate(x_cos=Cos('x'), y_cos=Cos('y')).get()
>>> vector.x, vector.y
(-0.14550003380861354, -0.9999999999999986)

It can also be registered as a transform. For example:

>>> from django.db.models import FloatField
>>> from django.db.models.functions import Cos
>>> FloatField.register_lookup(Cos)
>>> # Get vectors whose cosine is less than 0.5
>>> vectors = Vector.objects.filter(x__cos__lt=0.5, y__cos__lt=0.5)

Cot

class Cot(expression, **extra)

Returns the cotangent of a numeric field or expression.

Usage example:

>>> from django.db.models.functions import Cot
>>> Vector.objects.create(x=12.0, y=1.0)
>>> vector = Vector.objects.annotate(x_cot=Cot('x'), y_cot=Cot('y')).get()
>>> vector.x_cot, vector.y_cot
(-1.5726734063976826, 0.642092615934331)

It can also be registered as a transform. For example:

>>> from django.db.models import FloatField
>>> from django.db.models.functions import Cot
>>> FloatField.register_lookup(Cot)
>>> # Get vectors whose cotangent is less than 1
>>> vectors = Vector.objects.filter(x__cot__lt=1, y__cot__lt=1)
Degrees

```
class Degrees(expression, **extra)
```

Converts a numeric field or expression from radians to degrees.

Usage example:

```python
>>> from django.db.models.functions import Degrees
>>> Vector.objects.create(x=-1.57, y=3.14)
>>> vector = Vector.objects.annotate(x_d=Degrees('x'), y_d=Degrees('y')).get()
>>> vector.x_d, vector.y_d
(-89.95437383553924, 179.9087476710785)
```

It can also be registered as a transform. For example:

```python
>>> from django.db.models import FloatField
>>> from django.db.models.functions import Degrees
>>> FloatField.register_lookup(Degrees)
>>> # Get vectors whose degrees are less than 360
>>> vectors = Vector.objects.filter(x__degrees__lt=360, y__degrees__lt=360)
```

Exp

```
class Exp(expression, **extra)
```

Returns the value of e (the natural logarithm base) raised to the power of a numeric field or expression.

Usage example:

```python
>>> from django.db.models.functions import Exp
>>> Vector.objects.create(x=5.4, y=-2.0)
>>> vector = Vector.objects.annotate(x_exp=Exp('x'), y_exp=Exp('y')).get()
>>> vector.x_exp, vector.y_exp
(221.40641620418717, 0.1353352832366127)
```

It can also be registered as a transform. For example:

```python
>>> from django.db.models import FloatField
>>> from django.db.models.functions import Exp
>>> FloatField.register_lookup(Exp)
>>> # Get vectors whose exp() is greater than 10
>>> vectors = Vector.objects.filter(x__exp__gt=10, y__exp__gt=10)
```
Floor

class Floor(expression, **extra)

Returns the largest integer value not greater than a numeric field or expression.

Usage example:

```python
>>> from django.db.models.functions import Floor
>>> Vector.objects.create(x=5.4, y=-2.3)
>>> vector = Vector.objects.annotate(x_floor=Floor('x'), y_floor=Floor('y')).get()
>>> vector.x_floor, vector.y_floor
(5.0, -3.0)
```

It can also be registered as a transform. For example:

```python
>>> from django.db.models import FloatField
>>> from django.db.models.functions import Floor
>>> FloatField.register_lookup(Floor)
>>> # Get vectors whose floor() is greater than 10
>>> vectors = Vector.objects.filter(x__floor__gt=10, y__floor__gt=10)
```

Ln

class Ln(expression, **extra)

Returns the natural logarithm a numeric field or expression.

Usage example:

```python
>>> from django.db.models.functions import Ln
>>> Vector.objects.create(x=5.4, y=233.0)
>>> vector = Vector.objects.annotate(x_ln=Ln('x'), y_ln=Ln('y')).get()
>>> vector.x_ln, vector.y_ln
(1.6863989535702288, 5.4510384535657)
```

It can also be registered as a transform. For example:

```python
>>> from django.db.models import FloatField
>>> from django.db.models.functions import Ln
>>> FloatField.register_lookup(Ln)
>>> # Get vectors whose value greater than e
>>> vectors = Vector.objects.filter(x__ln__gt=1, y__ln__gt=1)
```
Log

**class Log**(expression1, expression2, **extra)**

Accepts two numeric fields or expressions and returns the logarithm of the first to base of the second.

Usage example:

```python
>>> from django.db.models.functions import Log
>>> Vector.objects.create(x=2.0, y=4.0)
>>> vector = Vector.objects.annotate(log=Log('x', 'y')).get()
>>> vector.log
2.0
```

Mod

**class Mod**(expression1, expression2, **extra)**

Accepts two numeric fields or expressions and returns the remainder of the first divided by the second (modulo operation).

Usage example:

```python
>>> from django.db.models.functions import Mod
>>> Vector.objects.create(x=5.4, y=2.3)
>>> vector = Vector.objects.annotate(mod=Mod('x', 'y')).get()
>>> vector.mod
0.8
```

Pi

**class Pi**(**extra)**

Returns the value of the mathematical constant \( \pi \).

Power

**class Power**(expression1, expression2, **extra)**

Accepts two numeric fields or expressions and returns the value of the first raised to the power of the second.

Usage example:
from django.db.models.functions import Power
Vector.objects.create(x=2, y=-2)
vector = Vector.objects.annotate(power=Power('x', 'y')).get()
vector.power
0.25

Radians

class Radians(expression, **extra)

Converts a numeric field or expression from degrees to radians.

Usage example:

from django.db.models.functions import Radians
Vector.objects.create(x=-90, y=180)
vector = Vector.objects.annotate(x_r=Radians('x'), y_r=Radians('y')).get()
vector.x_r, vector.y_r
(-1.5707963267948966, 3.141592653589793)

It can also be registered as a transform. For example:

from django.db.models import FloatField
from django.db.models.functions import Radians
FloatField.register_lookup(Radians)
# Get vectors whose radians are less than 1
vectors = Vector.objects.filter(x__radians__lt=1, y__radians__lt=1)

Random

class Random(**extra)

Returns a random value in the range 0.0 ≤ x < 1.0.

Round

class Round(expression, precision=0, **extra)

 Rounds a numeric field or expression to precision (must be an integer) decimal places. By default, it rounds to the nearest integer. Whether half values are rounded up or down depends on the database.

Usage example:
It can also be registered as a transform. For example:

```python
>>> from django.db.models.functions import Round
>>> from django.db.models import FloatField
>>> FloatField.register_lookup(Round)
>>> # Get vectors whose round() is less than 20
>>> vectors = Vector.objects.filter(x__round__lt=20, y__round__lt=20)
```

### Sign

class **Sign**(expression, **extra)

Returns the sign (-1, 0, 1) of a numeric field or expression.

Usage example:

```python
>>> from django.db.models.functions import Sign
>>> Vector.objects.create(x=5.4, y=-2.3)
>>> vector = Vector.objects.annotate(x_sign=Sign('x'), y_sign=Sign('y')).get()
>>> vector.x_sign, vector.y_sign
(1, -1)
```

It can also be registered as a transform. For example:

```python
>>> from django.db.models import FloatField
>>> from django.db.models.functions import Sign
>>> FloatField.register_lookup(Sign)
>>> # Get vectors whose signs of components are less than 0.
>>> vectors = Vector.objects.filter(x__sign__lt=0, y__sign__lt=0)
```
Sin

class Sin(expression, **extra)

Returns the sine of a numeric field or expression.

Usage example:

```python
>>> from django.db.models.functions import Sin
>>> Vector.objects.create(x=5.4, y=-2.3)
>>> vector = Vector.objects.annotate(x_sin=Sin('x'), y_sin=Sin('y')).get()
>>> vector.x_sin, vector.y_sin
(-0.7727644875559871, -0.7457052121767203)
```

It can also be registered as a transform. For example:

```python
>>> from django.db.models import FloatField
>>> from django.db.models.functions import Sin
>>> FloatField.register_lookup(Sin)
>>> # Get vectors whose sin() is less than 0
>>> vectors = Vector.objects.filter(x__sin__lt=0, y__sin__lt=0)
```

Sqrt

class Sqrt(expression, **extra)

Returns the square root of a nonnegative numeric field or expression.

Usage example:

```python
>>> from django.db.models.functions import Sqrt
>>> Vector.objects.create(x=4.0, y=12.0)
>>> vector = Vector.objects.annotate(x_sqrt=Sqrt('x'), y_sqrt=Sqrt('y')).get()
>>> vector.x_sqrt, vector.y_sqrt
(2.0, 3.46410)
```

It can also be registered as a transform. For example:

```python
>>> from django.db.models import FloatField
>>> from django.db.models.functions import Sqrt
>>> FloatField.register_lookup(Sqrt)
>>> # Get vectors whose sqrt() is less than 5
>>> vectors = Vector.objects.filter(x__sqrt__lt=5, y__sqrt__lt=5)
```
Tan

class Tan(expression, **extra)

Returns the tangent of a numeric field or expression.

Usage example:

```python
>>> from django.db.models.functions import Tan
>>> Vector.objects.create(x=0, y=12)
>>> vector = Vector.objects.annotate(x_tan=Tan('x'), y_tan=Tan('y')).get()
>>> vector.x_tan, vector.y_tan
(0.0, -0.6358599286615808)
```

It can also be registered as a transform. For example:

```python
>>> from django.db.models import FloatField
>>> from django.db.models.functions import Tan
>>> FloatField.register_lookup(Tan)
>>> # Get vectors whose tangent is less than 0
>>> vectors = Vector.objects.filter(x__tan__lt=0, y__tan__lt=0)
```

Text functions

Chr

class Chr(expression, **extra)

Accepts a numeric field or expression and returns the text representation of the expression as a single character. It works the same as Python’s `chr()` function.

Like Length, it can be registered as a transform on IntegerField. The default lookup name is chr.

Usage example:

```python
>>> from django.db.models.functions import Chr
>>> Author.objects.create(name='Margaret Smith')
>>> author = Author.objects.filter(name__startswith=Chr(ord('M'))).get()
>>> print(author.name)
Margaret Smith
```
Concat

class Concat(*expressions, **extra)

Accepts a list of at least two text fields or expressions and returns the concatenated text. Each argument must be of a text or char type. If you want to concatenate a TextField() with a CharField(), then be sure to tell Django that the output_field should be a TextField(). Specifying an output_field is also required when concatenating a Value as in the example below.

This function will never have a null result. On backends where a null argument results in the entire expression being null, Django will ensure that each null part is converted to an empty string first.

Usage example:

```python
>>> # Get the display name as “name (goes_by)”
>>> from django.db.models import CharField, Value as V
>>> from django.db.models.functions import Concat
>>> Author.objects.create(name='Margaret Smith', goes_by='Maggie')
>>> author = Author.objects.annotate(
...     screen_name=Concat(...
...         'name', V('('), 'goes_by', V(')'),
...         output_field=CharField()
...     ).get()
>>> print(author.screen_name)
Margaret Smith (Maggie)
```

Left

class Left(expression, length, **extra)

Returns the first length characters of the given text field or expression.

Usage example:

```python
>>> from django.db.models.functions import Left
>>> Author.objects.create(name='Margaret Smith')
>>> author = Author.objects.annotate(first_initial=Left('name', 1)).get()
>>> print(author.first_initial)
M
```
Length

class Length(expression, **extra)

Accepts a single text field or expression and returns the number of characters the value has. If the expression is null, then the length will also be null.

Usage example:

```python
>>> # Get the length of the name and goes_by fields
>>> from django.db.models.functions import Length
>>> Author.objects.create(name='Margaret Smith')
>>> author = Author.objects.annotate(
...     name_length=Length('name'),
...     goes_by_length=Length('goes_by')).get()
>>> print(author.name_length, author.goes_by_length)
(14, None)
```

It can also be registered as a transform. For example:

```python
>>> from django.db.models import CharField
>>> from django.db.models.functions import Length
>>> CharField.register_lookup(Length)
>>> # Get authors whose name is longer than 7 characters
>>> authors = Author.objects.filter(name__length__gt=7)
```

Lower

class Lower(expression, **extra)

Accepts a single text field or expression and returns the lowercase representation.

It can also be registered as a transform as described in Length.

Usage example:

```python
>>> from django.db.models.functions import Lower
>>> Author.objects.create(name='Margaret Smith')
>>> author = Author.objects.annotate(name_lower=Lower('name')).get()
>>> print(author.name_lower)
margaret smith
```
LPad

class LPad(expression, length, fill_text=Value(' '), **extra)

Returns the value of the given text field or expression padded on the left side with fill_text so that the resulting value is length characters long. The default fill_text is a space.

Usage example:

```python
>>> from django.db.models import Value
>>> from django.db.models.functions import LPad
>>> Author.objects.create(name='John', alias='j')
>>> Author.objects.update(name=LPad('name', 8, Value('abc')))
1
>>> print(Author.objects.get(alias='j').name)
abcaJohn
```

LTrim

class LTrim(expression, **extra)

Similar to Trim, but removes only leading spaces.

MD5

class MD5(expression, **extra)

Accepts a single text field or expression and returns the MD5 hash of the string.

It can also be registered as a transform as described in Length.

Usage example:

```python
>>> from django.db.models.functions import MD5
>>> Author.objects.create(name='Margaret Smith')
>>> author = Author.objects.annotate(name_md5=MD5('name')).get()
>>> print(author.name_md5)
749fb689816b2db85f5b169c2055b247
```
Ord

class Ord(expression, **extra)

Accepts a single text field or expression and returns the Unicode code point value for the first character of that expression. It works similar to Python’s `ord()` function, but an exception isn’t raised if the expression is more than one character long.

It can also be registered as a transform as described in Length. The default lookup name is `ord`.

Usage example:

```python
>>> from django.db.models.functions import Ord
>>> Author.objects.create(name='Margaret Smith')
>>> author = Author.objects.annotate(name_code_point=Ord('name')).get()
>>> print(author.name_code_point)
77
```

Repeat

class Repeat(expression, number, **extra)

Returns the value of the given text field or expression repeated `number` times.

Usage example:

```python
>>> from django.db.models.functions import Repeat
>>> Author.objects.create(name='John', alias='j')
>>> Author.objects.update(name=Repeat('name', 3))
1
>>> print(Author.objects.get(alias='j').name)
JohnJohnJohn
```

Replace

class Replace(expression, text, replacement=Value(‘’), **extra)

Replaces all occurrences of `text` with `replacement` in `expression`. The default replacement text is the empty string. The arguments to the function are case-sensitive.

Usage example:

```python
>>> from django.db.models import Value
>>> from django.db.models.functions import Replace
>>> Author.objects.create(name='Margaret Johnson')
```

(continues on next page)
Reverse

class Reverse(expression, **extra)

Accepts a single text field or expression and returns the characters of that expression in reverse order. It can also be registered as a transform as described in \textit{Length}. The default lookup name is \texttt{reverse}.

Usage example:

```python
>>> from django.db.models.functions import Reverse
>>> Author.objects.create(name='Margaret Smith')
>>> author = Author.objects.annotate(backward=Reverse('name')).get()
>>> print(author.backward)
htimS teragraM
```

Right

class Right(expression, length, **extra)

Returns the last \texttt{length} characters of the given text field or expression.

Usage example:

```python
>>> from django.db.models.functions import Right
>>> Author.objects.create(name='Margaret Smith')
>>> author = Author.objects.annotate(last_letter=Right('name', 1)).get()
>>> print(author.last_letter)
h
```
RPad

```python
class RPad(expression, length, fill_text=Value(' '), **extra)
```

Similar to `LPad`, but pads on the right side.

RTrim

```python
class RTrim(expression, **extra)
```

Similar to `Trim`, but removes only trailing spaces.

SHA1, SHA224, SHA256, SHA384, and SHA512

```python
class SHA1(expression, **extra)
class SHA224(expression, **extra)
class SHA256(expression, **extra)
class SHA384(expression, **extra)
class SHA512(expression, **extra)
```

Accepts a single text field or expression and returns the particular hash of the string.

They can also be registered as transforms as described in `Length`.

Usage example:

```python
>>> from django.db.models.functions import SHA1
>>> Author.objects.create(name='Margaret Smith')
>>> author = Author.objects.annotate(name_sha1=SHA1('name')).get()
>>> print(author.name_sha1)
b87efd8a6c991c390be5a68e8a7945a7851c7e5c
```

PostgreSQL

The `pgcrypto extension` must be installed. You can use the `CryptoExtension` migration operation to install it.

Oracle

Oracle doesn’t support the SHA224 function.
class StrIndex(string, substring, **extra)

Returns a positive integer corresponding to the 1-indexed position of the first occurrence of substring inside string, or 0 if substring is not found.

Usage example:

```python
>>> from django.db.models import Value as V
>>> from django.db.models.functions import StrIndex
>>> Author.objects.create(name='Margaret Smith')
>>> Author.objects.create(name='Smith, Margaret')
>>> Author.objects.create(name='Margaret Jackson')
>>> Author.objects.filter(name='Margaret Jackson').annotate(
...     smith_index=StrIndex('name', V('Smith'))
... ).get().smith_index
0
>>> authors = Author.objects.annotate(
...     smith_index=StrIndex('name', V('Smith'))
... ).filter(smith_index__gt=0)
<QuerySet [<Author: Margaret Smith>, <Author: Smith, Margaret>]>  
```

Warning: In MySQL, a database table’s collation determines whether string comparisons (such as the expression and substring of this function) are case-sensitive. Comparisons are case-insensitive by default.

class Substr(expression, pos, length=None, **extra)

Returns a substring of length length from the field or expression starting at position pos. The position is 1-indexed, so the position must be greater than 0. If length is None, then the rest of the string will be returned.

Usage example:

```python
>>> # Set the alias to the first 5 characters of the name as lowercase
>>> from django.db.models.functions import Lower, Substr
>>> Author.objects.create(name='Margaret Smith')
>>> Author.objects.update(alias=Lower(Substr('name', 1, 5)))
1
>>> print(Author.objects.get(name='Margaret Smith').alias)
marga
```
Trim

class Trim(expression, **extra)

Returns the value of the given text field or expression with leading and trailing spaces removed.

Usage example:

```python
>>> from django.db.models.functions import Trim
>>> Author.objects.create(name='  John  ', alias='j')
>>> Author.objects.update(name=Trim('name'))
1
>>> print(Author.objects.get(alias='j').name)
John
```

Upper

class Upper(expression, **extra)

Accepts a single text field or expression and returns the uppercase representation.

It can also be registered as a transform as described in `Length`.

Usage example:

```python
>>> from django.db.models.functions import Upper
>>> Author.objects.create(name='Margaret Smith')
>>> author = Author.objects.annotate(name_upper=Upper('name')).get()
>>> print(author.name_upper)
MARGARET SMITH
```

Window functions

There are a number of functions to use in a `Window` expression for computing the rank of elements or the `Ntile` of some rows.

CumeDist

class CumeDist(*expressions, **extra)

Calculates the cumulative distribution of a value within a window or partition. The cumulative distribution is defined as the number of rows preceding or peered with the current row divided by the total number of rows in the frame.
DenseRank

class DenseRank(*expressions, **extra)

Equivalent to Rank but does not have gaps.

FirstValue

class FirstValue(expression, **extra)

Returns the value evaluated at the row that’s the first row of the window frame, or None if no such value exists.

Lag

class Lag(expression, offset=1, default=None, **extra)

Calculates the value offset by offset, and if no row exists there, returns default.

default must have the same type as the expression, however, this is only validated by the database and not in Python.

MariaDB and default

MariaDB doesn’t support the default parameter.

LastValue

class LastValue(expression, **extra)

Comparable to FirstValue, it calculates the last value in a given frame clause.

Lead

class Lead(expression, offset=1, default=None, **extra)

Calculates the leading value in a given frame. Both offset and default are evaluated with respect to the current row.

default must have the same type as the expression, however, this is only validated by the database and not in Python.

MariaDB and default
MariaDB doesn’t support the default parameter.

### NthValue

**class NthValue(expression, nth=1, **extra)**

Computes the row relative to the offset nth (must be a positive value) within the window. Returns `None` if no row exists.

Some databases may handle a nonexistent nth-value differently. For example, Oracle returns an empty string rather than `None` for character-based expressions. Django doesn’t do any conversions in these cases.

### Ntile

**class Ntile(num_buckets=1, **extra)**

Calculates a partition for each of the rows in the frame clause, distributing numbers as evenly as possible between 1 and num_buckets. If the rows don’t divide evenly into a number of buckets, one or more buckets will be represented more frequently.

### PercentRank

**class PercentRank(*expressions, **extra)**

Computes the percentile rank of the rows in the frame clause. This computation is equivalent to evaluating:

\[
\frac{\text{rank} - 1}{\text{total rows} - 1}
\]

The following table explains the calculation for the percentile rank of a row:

<table>
<thead>
<tr>
<th>Row #</th>
<th>Value</th>
<th>Rank</th>
<th>Calculation</th>
<th>Percent Rank</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>15</td>
<td>1</td>
<td>(1-1)/(7-1)</td>
<td>0.0000</td>
</tr>
<tr>
<td>2</td>
<td>20</td>
<td>2</td>
<td>(2-1)/(7-1)</td>
<td>0.1666</td>
</tr>
<tr>
<td>3</td>
<td>20</td>
<td>2</td>
<td>(2-1)/(7-1)</td>
<td>0.1666</td>
</tr>
<tr>
<td>4</td>
<td>20</td>
<td>2</td>
<td>(2-1)/(7-1)</td>
<td>0.1666</td>
</tr>
<tr>
<td>5</td>
<td>30</td>
<td>5</td>
<td>(5-1)/(7-1)</td>
<td>0.6666</td>
</tr>
<tr>
<td>6</td>
<td>30</td>
<td>5</td>
<td>(5-1)/(7-1)</td>
<td>0.6666</td>
</tr>
<tr>
<td>7</td>
<td>40</td>
<td>7</td>
<td>(7-1)/(7-1)</td>
<td>1.0000</td>
</tr>
</tbody>
</table>

6.16. Models
Rank

class Rank(*expressions, **extra)

Comparable to RowNumber, this function ranks rows in the window. The computed rank contains gaps. Use DenseRank to compute rank without gaps.

RowNumber

class RowNumber(*expressions, **extra)

Computes the row number according to the ordering of either the frame clause or the ordering of the whole query if there is no partitioning of the window frame.

6.17 Paginator

Django provides a few classes that help you manage paginated data—that is, data that’s split across several pages, with “Previous/Next” links. These classes live in django/core/paginator.py.

For examples, see the Pagination topic guide.

6.17.1 Paginator class

class Paginator(object_list, per_page, orphans=0, allow_empty_first_page=True)

A paginator acts like a sequence of Page when using len() or iterating it directly.

Paginator.object_list

Required. A list, tuple, QuerySet, or other sliceable object with a count() or __len__() method. For consistent pagination, QuerySets should be ordered, e.g. with an order_by() clause or with a default ordering on the model.

Performance issues paginating large QuerySets

If you’re using a QuerySet with a very large number of items, requesting high page numbers might be slow on some databases, because the resulting LIMIT/OFFSET query needs to count the number of OFFSET records which takes longer as the page number gets higher.

Paginator.per_page

Required. The maximum number of items to include on a page, not including orphans (see the orphans optional argument below).
Paginator\texttt{.orphans}

Optional. Use this when you don’t want to have a last page with very few items. If the last page would normally have a number of items less than or equal to \texttt{orphans}, then those items will be added to the previous page (which becomes the last page) instead of leaving the items on a page by themselves. For example, with 23 items, \texttt{per_page=10}, and \texttt{orphans=3}, there will be two pages; the first page with 10 items and the second (and last) page with 13 items. \texttt{orphans} defaults to zero, which means pages are never combined and the last page may have one item.

Paginator\texttt{.allow_empty_first_page}

Optional. Whether or not the first page is allowed to be empty. If \texttt{False} and \texttt{object_list} is empty, then an \texttt{EmptyPage} error will be raised.

Methods

\texttt{Paginator.get_page(number)}

Returns a \texttt{Page} object with the given 1-based index, while also handling out of range and invalid page numbers.

If the page isn’t a number, it returns the first page. If the page number is negative or greater than the number of pages, it returns the last page.

Raises an \texttt{EmptyPage} exception only if you specify \texttt{Paginator(..., allow_empty_first_page=False)} and the \texttt{object_list} is empty.

\texttt{Paginator.page(number)}

Returns a \texttt{Page} object with the given 1-based index. Raises \texttt{PageNotAnInteger} if the \texttt{number} cannot be converted to an integer by calling \texttt{int()}. Raises \texttt{EmptyPage} if the given page number doesn’t exist.

\texttt{Paginator.get_elided_page_range(number, *, on_each_side=3, on_ends=2)}

Returns a 1-based list of page numbers similar to \texttt{Paginator.page_range}, but may add an ellipsis to either or both sides of the current page number when \texttt{Paginator.num_pages} is large.

The number of pages to include on each side of the current page number is determined by the \texttt{on_each_side} argument which defaults to 3.

The number of pages to include at the beginning and end of page range is determined by the \texttt{on_ends} argument which defaults to 2.

For example, with the default values for \texttt{on_each_side} and \texttt{on_ends}, if the current page is 10 and there are 50 pages, the page range will be \([1, 2, \ldots, 7, 8, 9, 10, 11, 12, 13, \ldots, 49, 50]\). This will result in pages 7, 8, and 9 to the left of and 11, 12, and 13 to the right of the current page as well as pages 1 and 2 at the start and 49 and 50 at the end.

Raises \texttt{InvalidPage} if the given page number doesn’t exist.
Attributes

Paginator.ELLIPSIS

A translatable string used as a substitute for elided page numbers in the page range returned by `get_elided_page_range()`. Default is '…'.

Paginator.count

The total number of objects, across all pages.

Note: When determining the number of objects contained in `object_list`, Paginator will first try calling `object_list.count()`. If `object_list` has no `count()` method, then Paginator will fall back to using `len(object_list)`. This allows objects, such as QuerySet, to use a more efficient `count()` method when available.

Paginator.num_pages

The total number of pages.

Paginator.page_range

A 1-based range iterator of page numbers, e.g. yielding [1, 2, 3, 4].

6.17.2 Page class

You usually won’t construct Page objects by hand—you’ll get them by iterating Paginator, or by using Paginator.page().

class Page(object_list, number, paginator)

A page acts like a sequence of Page.object_list when using len() or iterating it directly.

Methods

Page.has_next()

Returns True if there’s a next page.

Page.has_previous()

Returns True if there’s a previous page.

Page.has_other_pages()

Returns True if there’s a next or previous page.

Page.next_page_number()

Returns the next page number. Raises InvalidPage if next page doesn’t exist.
Page.previous_page_number()

Returns the previous page number. Raises InvalidPage if previous page doesn’t exist.

Page.start_index()

Returns the 1-based index of the first object on the page, relative to all of the objects in the paginator’s list. For example, when paginating a list of 5 objects with 2 objects per page, the second page’s start_index() would return 3.

Page.end_index()

Returns the 1-based index of the last object on the page, relative to all of the objects in the paginator’s list. For example, when paginating a list of 5 objects with 2 objects per page, the second page’s end_index() would return 4.

Attributes

Page.object_list

The list of objects on this page.

Page.number

The 1-based page number for this page.

Page.paginator

The associated Paginator object.

6.17.3 Exceptions

definition exception InvalidPage

A base class for exceptions raised when a paginator is passed an invalid page number.

The Paginator.page() method raises an exception if the requested page is invalid (i.e. not an integer) or contains no objects. Generally, it’s enough to catch the InvalidPage exception, but if you’d like more granularity, you can catch either of the following exceptions:

definition exception PageNotAnInteger

Raised when page() is given a value that isn’t an integer.

definition exception EmptyPage

Raised when page() is given a valid value but no objects exist on that page.

Both of the exceptions are subclasses of InvalidPage, so you can handle them both with except InvalidPage.
6.18 Request and response objects

6.18.1 Quick overview

Django uses request and response objects to pass state through the system.

When a page is requested, Django creates an HttpRequest object that contains metadata about the request. Then Django loads the appropriate view, passing the HttpRequest as the first argument to the view function. Each view is responsible for returning an HttpResponse object.

This document explains the APIs for HttpRequest and HttpResponse objects, which are defined in the django.http module.

6.18.2 HttpRequest objects

class HttpRequest

Attributes

All attributes should be considered read-only, unless stated otherwise.

HttpRequest.scheme
  A string representing the scheme of the request (http or https usually).

HttpRequest.body
  The raw HTTP request body as a bytestring. This is useful for processing data in different ways than conventional HTML forms: binary images, XML payload etc. For processing conventional form data, use HttpRequest.POST.

  You can also read from an HttpRequest using a file-like interface with HttpRequest.read() or HttpRequest.readline(). Accessing the body attribute after reading the request with either of these I/O stream methods will produce a RawPostDataException.

HttpRequest.path
  A string representing the full path to the requested page, not including the scheme, domain, or query string.

  Example: "/music/bands/the_beatles/"

HttpRequest.path_info
  Under some web server configurations, the portion of the URL after the host name is split up into a script prefix portion and a path info portion. The path_info attribute always contains the path info portion of the path, no matter what web server is being used. Using this instead of path can make your code easier to move between test and deployment servers.
For example, if the WSGIScriptAlias for your application is set to "/minfo", then path might be "/minfo/music/bands/the_beatles/" and path_info would be "/music/bands/the_beatles/".

HttpRequest.method

A string representing the HTTP method used in the request. This is guaranteed to be uppercase. For example:

```python
if request.method == 'GET':
    do_something()
elif request.method == 'POST':
    do_something_else()
```

HttpRequest.encoding

A string representing the current encoding used to decode form submission data (or None, which means the DEFAULT_CHARSET setting is used). You can write to this attribute to change the encoding used when accessing the form data. Any subsequent attribute accesses (such as reading from GET or POST) will use the new encoding value. Useful if you know the form data is not in the DEFAULT_CHARSET encoding.

HttpRequest.content_type

A string representing the MIME type of the request, parsed from the CONTENT_TYPE header.

HttpRequest.content_params

A dictionary of key/value parameters included in the CONTENT_TYPE header.

HttpRequest.GET

A dictionary-like object containing all given HTTP GET parameters. See the QueryDict documentation below.

HttpRequest.POST

A dictionary-like object containing all given HTTP POST parameters, providing that the request contains form data. See the QueryDict documentation below. If you need to access raw or non-form data posted in the request, access this through the HttpRequest.body attribute instead.

It’s possible that a request can come in via POST with an empty POST dictionary—if, say, a form is requested via the POST HTTP method but does not include form data. Therefore, you shouldn’t use if request.POST to check for use of the POST method; instead, use if request.method == "POST" (see HttpRequest.method).

POST does not include file-upload information. See FILES.

HttpRequest.COOKIES

A dictionary containing all cookies. Keys and values are strings.

HttpRequest.FILES

A dictionary-like object containing all uploaded files. Each key in FILES is the name from the <input type="file" name="">. Each value in FILES is an UploadedFile.
See Managing files for more information.

FILES will only contain data if the request method was POST and the `<form>` that posted to the request had `enctype="multipart/form-data"`. Otherwise, FILES will be a blank dictionary-like object.

HttpRequest.META

A dictionary containing all available HTTP headers. Available headers depend on the client and server, but here are some examples:

- `CONTENT_LENGTH` – The length of the request body (as a string).
- `CONTENT_TYPE` – The MIME type of the request body.
- `HTTP_ACCEPT` – Acceptable content types for the response.
- `HTTP_ACCEPT_ENCODING` – Acceptable encodings for the response.
- `HTTP_ACCEPT_LANGUAGE` – Acceptable languages for the response.
- `HTTP_HOST` – The HTTP Host header sent by the client.
- `HTTP_REFERER` – The referring page, if any.
- `HTTP_USER_AGENT` – The client’s user-agent string.
- `QUERY_STRING` – The query string, as a single (unparsed) string.
- `REMOTE_ADDR` – The IP address of the client.
- `REMOTE_HOST` – The hostname of the client.
- `REMOTE_USER` – The user authenticated by the web server, if any.
- `REQUEST_METHOD` – A string such as "GET" or "POST".
- `SERVER_NAME` – The hostname of the server.
- `SERVER_PORT` – The port of the server (as a string).

With the exception of `CONTENT_LENGTH` and `CONTENT_TYPE`, as given above, any HTTP headers in the request are converted to `META` keys by converting all characters to uppercase, replacing any hyphens with underscores and adding an `HTTP_` prefix to the name. So, for example, a header called `X-Bender` would be mapped to the `META` key `HTTP_X_BENDER`.

Note that `runserver` strips all headers with underscores in the name, so you won’t see them in `META`. This prevents header-spoofing based on ambiguity between underscores and dashes both being normalizing to underscores in WSGI environment variables. It matches the behavior of web servers like Nginx and Apache 2.4+.

HttpRequest.headers is a simpler way to access all HTTP-prefixed headers, plus `CONTENT_LENGTH` and `CONTENT_TYPE`. 
HttpRequest.headers

A case insensitive, dict-like object that provides access to all HTTP-prefixed headers (plus Content-Length and Content-Type) from the request.

The name of each header is stylized with title-casing (e.g. User-Agent) when it’s displayed. You can access headers case-insensitively:

```python
>>> request.headers
{'User-Agent': 'Mozilla/5.0 (Macintosh; Intel Mac OS X 10_12_6', ...

>>> 'User-Agent' in request.headers
True

>>> 'user-agent' in request.headers
True

>>> request.headers['User-Agent']
Mozilla/5.0 (Macintosh; Intel Mac OS X 10_12_6)

>>> request.headers['user-agent']
Mozilla/5.0 (Macintosh; Intel Mac OS X 10_12_6)

>>> request.headers.get('User-Agent')
Mozilla/5.0 (Macintosh; Intel Mac OS X 10_12_6)

>>> request.headers.get('user-agent')
Mozilla/5.0 (Macintosh; Intel Mac OS X 10_12_6)
```

For use in, for example, Django templates, headers can also be looked up using underscores in place of hyphens:

```html
{{ request.headers.user_agent }}
```

HttpRequest.resolver_match

An instance of ResolverMatch representing the resolved URL. This attribute is only set after URL resolving took place, which means it’s available in all views but not in middleware which are executed before URL resolving takes place (you can use it in process_view() though).

Attributes set by application code

Django doesn’t set these attributes itself but makes use of them if set by your application.

HttpRequest.current_app

The url template tag will use its value as the current_app argument to reverse().

HttpRequest.urlconf

This will be used as the root URLconf for the current request, overriding the ROOT_URLCONF setting. See How Django processes a request for details.
urlconf can be set to None to revert any changes made by previous middleware and return to using the \textit{ROOT\_URLCONF}.

\texttt{HttpRequest.\texttt{exception\_reporter\_filter}}

This will be used instead of \texttt{DEFAULT\_EXCEPTION\_REPORTER\_FILTER} for the current request. See Custom error reports for details.

\texttt{HttpRequest.\texttt{exception\_reporter\_class}}

This will be used instead of \texttt{DEFAULT\_EXCEPTION\_REPORTER} for the current request. See Custom error reports for details.

\textbf{Attributes set by middleware}

Some of the middleware included in Django’s contrib apps set attributes on the request. If you don’t see the attribute on a request, be sure the appropriate middleware class is listed in \texttt{MIDDLEWARE}.

\texttt{HttpRequest.\texttt{session}}

From the \texttt{SessionMiddleware}: A readable and writable, dictionary-like object that represents the current session.

\texttt{HttpRequest.\texttt{site}}

From the \texttt{CurrentSiteMiddleware}: An instance of \texttt{Site} or \texttt{RequestSite} as returned by \texttt{get\_current\_site()} representing the current site.

\texttt{HttpRequest.\texttt{user}}

From the \texttt{AuthenticationMiddleware}: An instance of \texttt{AUTH\_USER\_MODEL} representing the currently logged-in user. If the user isn’t currently logged in, \texttt{user} will be set to an instance of \texttt{AnonymousUser}. You can tell them apart with \texttt{is\_authenticated}, like so:

```python
if request.user.is_authenticated:
    ... # Do something for logged-in users.
else:
    ... # Do something for anonymous users.
```

\textbf{Methods}

\texttt{HttpRequest.\texttt{get\_host}()}

Returns the originating host of the request using information from the \texttt{HTTP\_X\_FORWARDED\_HOST} (if \texttt{USE\_X\_FORWARDED\_HOST} is enabled) and \texttt{HTTP\_HOST} headers, in that order. If they don’t provide a value, the method uses a combination of \texttt{SERVER\_NAME} and \texttt{SERVER\_PORT} as detailed in \texttt{PEP 3333}.

Example: "127.0.0.1:8000"

Raises \texttt{django\_core\_exceptions\_DisallowedHost} if the host is not in \texttt{ALLOWED\_HOSTS} or the domain name is invalid according to \texttt{RFC 1034/1035}.
Note: The `get_host()` method fails when the host is behind multiple proxies. One solution is to use middleware to rewrite the proxy headers, as in the following example:

```python
class MultipleProxyMiddleware:
    FORWARDED_FOR_FIELDS = ['HTTP_X_FORWARDED_FOR', 'HTTP_X_FORWARDED_HOST', 'HTTP_X_FORWARDED_SERVER',
]

def __init__(self, get_response):
    self.get_response = get_response

def __call__(self, request):
    """
    Rewrites the proxy headers so that only the most recent proxy is used.
    """
    for field in self.FORWARDED_FOR_FIELDS:
        if field in request.META:
            if ',' in request.META[field]:
                parts = request.META[field].split(',')
                request.META[field] = parts[-1].strip()
    return self.get_response(request)
```

This middleware should be positioned before any other middleware that relies on the value of `get_host()`—for instance, `CommonMiddleware` or `CsrfViewMiddleware`.

**HttpRequest.get_port()**

Returns the originating port of the request using information from the `HTTP_X_FORWARDED_PORT` (if `USE_X_FORWARDED_PORT` is enabled) and `SERVER_PORT META` variables, in that order.

**HttpRequest.get_full_path()**

Returns the path, plus an appended query string, if applicable.

Example: `/music/bands/the_beatles/?print=true`

**HttpRequest.get_full_path_info()**

Like `get_full_path()`, but uses `path_info` instead of `path`.

Example: `/minfo/music/bands/the_beatles/?print=true`

**HttpRequest.build_absolute_uri**(location=None)

Returns the absolute URI form of `location`. If no location is provided, the location will be set to `request.get_full_path()`.
If the location is already an absolute URI, it will not be altered. Otherwise the absolute URI is built using the server variables available in this request. For example:

```python
>>> request.build_absolute_uri()
'https://example.com/music/bands/the_beatles/?print=true'
>>> request.build_absolute_uri('/bands/')
'https://example.com/bands/'
>>> request.build_absolute_uri('https://example2.com/bands/)
'https://example2.com/bands/'
```

Note: Mixing HTTP and HTTPS on the same site is discouraged, therefore `build_absolute_uri()` will always generate an absolute URI with the same scheme the current request has. If you need to redirect users to HTTPS, it’s best to let your web server redirect all HTTP traffic to HTTPS.

`HttpRequest.get_signed_cookie(key, default=RAISE_ERROR, salt='', max_age=None)`

Returns a cookie value for a signed cookie, or raises a `django.core.signing.BadSignature` exception if the signature is no longer valid. If you provide the `default` argument the exception will be suppressed and that default value will be returned instead.

The optional `salt` argument can be used to provide extra protection against brute force attacks on your secret key. If supplied, the `max_age` argument will be checked against the signed timestamp attached to the cookie value to ensure the cookie is not older than `max_age` seconds.

For example:

```python
>>> request.get_signed_cookie('name')
'Tony'
>>> request.get_signed_cookie('name', salt='name-salt')
'Tony' # assuming cookie was set using the same salt
>>> request.get_signed_cookie('nonexistent-cookie')
...
KeyError: 'nonexistent-cookie'
>>> request.get_signed_cookie('nonexistent-cookie', False)
False
>>> request.get_signed_cookie('cookie-that-was-tampered-with')
...
BadSignature: ...
>>> request.get_signed_cookie('name', max_age=60)
...
SignatureExpired: Signature age 1677.3839159 > 60 seconds
>>> request.get_signed_cookie('name', False, max_age=60)
False
```

See [cryptographic signing](https://docs.djangoproject.com/en/4.2/topics/http/cookies/) for more information.
HttpRequest.is_secure()

Returns True if the request is secure; that is, if it was made with HTTPS.

HttpRequest.accepts(mime_type)

Returns True if the request Accept header matches the mime_type argument:

```python
>>> request.accepts('text/html')
True
```

Most browsers send `Accept: */*` by default, so this would return True for all content types. Setting an explicit `Accept` header in API requests can be useful for returning a different content type for those consumers only. See Content negotiation example of using accepts() to return different content to API consumers.

If a response varies depending on the content of the `Accept` header and you are using some form of caching like Django’s `cache middleware`, you should decorate the view with `vary_on_headers('Accept')` so that the responses are properly cached.

HttpRequest.read(size=None)

HttpRequest.readline()

HttpRequest.readlines()

HttpRequest.__iter__()

Methods implementing a file-like interface for reading from an HttpRequest instance. This makes it possible to consume an incoming request in a streaming fashion. A common use-case would be to process a big XML payload with an iterative parser without constructing a whole XML tree in memory.

Given this standard interface, an HttpRequest instance can be passed directly to an XML parser such as ElementTree:

```python
import xml.etree.ElementTree as ET
for element in ET.iterparse(request):
    process(element)
```

## 6.18.3 QueryDict objects

class QueryDict

In an HttpRequest object, the GET and POST attributes are instances of django.http.QueryDict, a dictionary-like class customized to deal with multiple values for the same key. This is necessary because some HTML form elements, notably `<select multiple>`, pass multiple values for the same key.

The QueryDicts at request.POST and request.GET will be immutable when accessed in a normal request/response cycle. To get a mutable version you need to use `QueryDict.copy()`.

### 6.18. Request and response objects
Methods

*QueryDict* implements all the standard dictionary methods because it’s a subclass of dictionary. Exceptions are outlined here:

*QueryDict.__init__(query_string=None, mutable=False, encoding=None)*

Instantiates a *QueryDict* object based on *query_string*.

```python
>>> QueryDict('a=1&a=2&c=3')
<QueryDict: {'a': ['1', '2'], 'c': ['3']}>  
```

If *query_string* is not passed in, the resulting *QueryDict* will be empty (it will have no keys or values). Most *QueryDicts* you encounter, and in particular those at *request.POST* and *request.GET*, will be immutable. If you are instantiating one yourself, you can make it mutable by passing *mutable=True* to its *__init__()*. Strings for setting both keys and values will be converted from *encoding* to *str*. If *encoding* is not set, it defaults to *DEFAULT_CHARSET*.  

*classmethod QueryDict.fromkeys(iterable, value='', mutable=False, encoding=None)*

Creates a new *QueryDict* with keys from *iterable* and each value equal to *value*. For example:

```python
>>> QueryDict.fromkeys(['a', 'a', 'b'], value='val')
<QueryDict: {'a': ['val', 'val'], 'b': ['val']}>  
```

*QueryDict.__getitem__(key)*

Returns the value for the given key. If the key has more than one value, it returns the last value. Raises *django.utils.datastructures.MultiValueDictKeyError* if the key does not exist. (This is a subclass of Python’s standard *KeyError*, so you can stick to catching *KeyError*.)

*QueryDict.__setitem__(key, value)*

Sets the given key to [value] (a list whose single element is value). Note that this, as other dictionary functions that have side effects, can only be called on a mutable *QueryDict* (such as one that was created via *QueryDict.copy()*).

*QueryDict.__contains__(key)*

Returns *True* if the given key is set. This lets you do, e.g., if "foo" in *request.GET*.  

*QueryDict.get(key, default=None)*

Uses the same logic as *__getitem__()*, with a hook for returning a default value if the key doesn’t exist.  

*QueryDict.setdefault(key, default=None)*

Like *dict.setdefault()*, except it uses *__setitem__()* internally.
QueryDict.update(other_dict)

Takes either a QueryDict or a dictionary. Like dict.update(), except it appends to the current dictionary items rather than replacing them. For example:

```python
>>> q = QueryDict('a=1', mutable=True)
>>> q.update({'a': '2'})
>>> q.getlist('a')
['1', '2']
>>> q['a']  # returns the last
'2'
```

QueryDict.items()

Like dict.items(), except this uses the same last-value logic as __getitem__() and returns an iterator object instead of a view object. For example:

```python
>>> q = QueryDict('a=1&a=2&a=3')
>>> list(q.items())
[('a', '3')]
```

QueryDict.values()

Like dict.values(), except this uses the same last-value logic as __getitem__() and returns an iterator instead of a view object. For example:

```python
>>> q = QueryDict('a=1&a=2&a=3')
>>> list(q.values())
['3']
```

In addition, QueryDict has the following methods:

QueryDict.copy()

Returns a copy of the object using copy.deepcopy(). This copy will be mutable even if the original was not.

QueryDict.getlist(key, default=None)

Returns a list of the data with the requested key. Returns an empty list if the key doesn’t exist and default is None. It’s guaranteed to return a list unless the default value provided isn’t a list.

QueryDict.setlist(key, list_)

Sets the given key to list_ (unlike __setitem__).

QueryDict.appendlist(key, item)

Appends an item to the internal list associated with key.

QueryDict.setlistdefault(key, default_list=None)

Like setdefault(), except it takes a list of values instead of a single value.

6.18. Request and response objects
QueryDict.lists()

Like `items()` except it includes all values, as a list, for each member of the dictionary. For example:

```python
>>> q = QueryDict('a=1&a=2&a=3')
>>> q.lists()
[('a', ['1', '2', '3'])]
```

QueryDict.pop(key)

Returns a list of values for the given key and removes them from the dictionary. Raises KeyError if the key does not exist. For example:

```python
>>> q = QueryDict('a=1&a=2&a=3', mutable=True)
>>> q.pop('a')
['1', '2', '3']
```

QueryDict.popitem()

Removes an arbitrary member of the dictionary (since there’s no concept of ordering), and returns a two value tuple containing the key and a list of all values for the key. Raises KeyError when called on an empty dictionary. For example:

```python
>>> q = QueryDict('a=1&a=2&a=3', mutable=True)
>>> q.popitem()
('a', ['1', '2', '3'])
```

QueryDict.dict()

Returns a dict representation of QueryDict. For every (key, list) pair in QueryDict, dict will have (key, item), where item is one element of the list, using the same logic as `QueryDict.__getitem__()`:

```python
>>> q = QueryDict('a=1&a=3&a=5')
>>> q.dict()
{'a': '5'}
```

QueryDict.urlencode(safe=None)

Returns a string of the data in query string format. For example:

```python
>>> q = QueryDict('a=2&b=3&b=5')
>>> q.urlencode()
'a=2&b=3&b=5'
```

Use the `safe` parameter to pass characters which don’t require encoding. For example:

```python
>>> q = QueryDict(mutable=True)
>>> q['next'] = '/a&b/
```

(continues on next page)
6.18.4 HttpResponse objects

class HttpResponse

In contrast to HttpRequest objects, which are created automatically by Django, HttpResponse objects are your responsibility. Each view you write is responsible for instantiating, populating, and returning an HttpResponse.

The HttpResponse class lives in the django.http module.

Usage

Passing strings

Typical usage is to pass the contents of the page, as a string, bytestring, or memoryview, to the HttpResponse constructor:

```python
>>> from django.http import HttpResponse
>>> response = HttpResponse("Here's the text of the web page.")
>>> response = HttpResponse("Text only, please.", content_type="text/plain")
>>> response = HttpResponse(b'Bytestrings are also accepted.')
>>> response = HttpResponse(memoryview(b'Memoryview as well.'))
```

But if you want to add content incrementally, you can use response as a file-like object:

```python
>>> response = HttpResponse()
>>> response.write("<p>Here's the text of the web page.</p>"
>>> response.write("<p>Here's another paragraph.</p>"
```

Passing iterators

Finally, you can pass HttpResponse an iterator rather than strings. HttpResponse will consume the iterator immediately, store its content as a string, and discard it. Objects with a close() method such as files and generators are immediately closed.

If you need the response to be streamed from the iterator to the client, you must use the StreamingHttpResponse class instead.
Setting header fields

To set or remove a header field in your response, use `HttpResponse.headers`:

```python
>>> response = HttpResponse()
>>> response.headers['Age'] = 120
>>> del response.headers['Age']
```

You can also manipulate headers by treating your response like a dictionary:

```python
>>> response = HttpResponse()
>>> response['Age'] = 120
>>> del response['Age']
```

This proxies to `HttpResponse.headers`, and is the original interface offered by `HttpResponse`.

When using this interface, unlike a dictionary, `del` doesn’t raise `KeyError` if the header field doesn’t exist.

You can also set headers on instantiation:

```python
>>> response = HttpResponse(headers={'Age': 120})
```

For setting the `Cache-Control` and `Vary` header fields, it is recommended to use the `patch_cache_control()` and `patch_vary_headers()` methods from `django.utils.cache`, since these fields can have multiple, comma-separated values. The “patch” methods ensure that other values, e.g. added by a middleware, are not removed.

HTTP header fields cannot contain newlines. An attempt to set a header field containing a newline character (CR or LF) will raise `BadHeaderError`.

**Telling the browser to treat the response as a file attachment**

To tell the browser to treat the response as a file attachment, set the `Content-Type` and `Content-Disposition` headers. For example, this is how you might return a Microsoft Excel spreadsheet:

```python
>>> response = HttpResponse(my_data, headers={
...    'Content-Type': 'application/vnd.ms-excel',
...    'Content-Disposition': 'attachment; filename=foo.xls',
... })
```

There’s nothing Django-specific about the `Content-Disposition` header, but it’s easy to forget the syntax, so we’ve included it here.
Attributes

**HttpResponse.content**
A bytestring representing the content, encoded from a string if necessary.

**HttpResponse.headers**
A case insensitive, dict-like object that provides an interface to all HTTP headers on the response. See Setting header fields.

**HttpResponse.charset**
A string denoting the charset in which the response will be encoded. If not given at HttpResponse instantiation time, it will be extracted from `content_type` and if that is unsuccessful, the `DEFAULT_CHARSET` setting will be used.

**HttpResponse.status_code**
The HTTP status code for the response.
Unless `reason_phrase` is explicitly set, modifying the value of `status_code` outside the constructor will also modify the value of `reason_phrase`.

**HttpResponse.reason_phrase**
The HTTP reason phrase for the response. It uses the HTTP standard’s default reason phrases.
Unless explicitly set, `reason_phrase` is determined by the value of `status_code`.

**HttpResponse.streaming**
This is always False.
This attribute exists so middleware can treat streaming responses differently from regular responses.

**HttpResponse.closed**
True if the response has been closed.

Methods

**HttpResponse.__init__**(content=b'', content_type=None, status=200, reason=None, charset=None, headers=None)
Instantiates an HttpResponse object with the given page content, content type, and headers.
`content` is most commonly an iterator, bytestring, `memoryview`, or string. Other types will be converted to a bytestring by encoding their string representation. Iterators should return strings or bytestrings and those will be joined together to form the content of the response.

`content_type` is the MIME type optionally completed by a character set encoding and is used to fill the HTTP `Content-Type` header. If not specified, it is formed by 'text/html' and the `DEFAULT_CHARSET` settings, by default: "text/html; charset=utf-8".
status is the HTTP status code for the response. You can use Python’s `http.HTTPStatus` for meaningful aliases, such as `HTTPStatus.NO_CONTENT`.

reason is the HTTP response phrase. If not provided, a default phrase will be used.

charset is the charset in which the response will be encoded. If not given it will be extracted from `content_type`, and if that is unsuccessful, the `DEFAULT_CHARSET` setting will be used.

headers is a `dict` of HTTP headers for the response.

```python
HttpResponse.__setitem__(header, value)
```

Sets the given header name to the given value. Both `header` and `value` should be strings.

```python
HttpResponse.__delitem__(header)
```

Deletes the header with the given name. Fails silently if the header doesn’t exist. Case-insensitive.

```python
HttpResponse.__getitem__(header)
```

Returns the value for the given header name. Case-insensitive.

```python
HttpResponse.get(header, alternate=None)
```

Returns the value for the given header name, or an `alternate` if the header doesn’t exist.

```python
HttpResponse.has_header(header)
```

Returns `True` or `False` based on a case-insensitive check for a header with the given name.

```python
HttpResponse.items()
```

Acts like `dict.items()` for HTTP headers on the response.

```python
HttpResponse.setdefault(header, value)
```

Sets a header unless it has already been set.

```python
HttpResponse.set_cookie(key, value='', max_age=None, expires=None, path='/', domain=None, secure=False, httponly=False, samesite=None)
```

Sets a cookie. The parameters are the same as in the `Morsel` cookie object in the Python standard library.

- `max_age` should be a `timedelta` object, an integer number of seconds, or `None` (default) if the cookie should last only as long as the client’s browser session. If `expires` is not specified, it will be calculated.

Support for `timedelta` objects was added.

- `expires` should either be a string in the format "Wdy, DD-Mon-YY HH:MM:SS GMT" or a `datetime.datetime` object in UTC. If `expires` is a `datetime` object, the `max_age` will be calculated.

- Use `domain` if you want to set a cross-domain cookie. For example, `domain="example.com"` will set a cookie that is readable by the domains www.example.com, blog.example.com, etc. Otherwise, a cookie will only be readable by the domain that set it.
• Use `secure=True` if you want the cookie to be only sent to the server when a request is made with the `https` scheme.

• Use `httponly=True` if you want to prevent client-side JavaScript from having access to the cookie. `HttpOnly` is a flag included in a Set-Cookie HTTP response header. It’s part of the RFC 6265 standard for cookies and can be a useful way to mitigate the risk of a client-side script accessing the protected cookie data.

• Use `samesite='Strict'` or `samesite='Lax'` to tell the browser not to send this cookie when performing a cross-origin request. `SameSite` isn’t supported by all browsers, so it’s not a replacement for Django’s CSRF protection, but rather a defense in depth measure.

Use `samesite='None'` (string) to explicitly state that this cookie is sent with all same-site and cross-site requests.

**Warning:** RFC 6265 states that user agents should support cookies of at least 4096 bytes. For many browsers this is also the maximum size. Django will not raise an exception if there’s an attempt to store a cookie of more than 4096 bytes, but many browsers will not set the cookie correctly.

```
HttpResponse.set_signed_cookie(key, value, salt='', max_age=None, expires=None, path='/', domain=None, secure=False, httponly=False, samesite=None)
```

Like `set_cookie()`, but cryptographic signing the cookie before setting it. Use in conjunction with `HttpRequest.get_signed_cookie()`. You can use the optional `salt` argument for added key strength, but you will need to remember to pass it to the corresponding `HttpRequest.get_signed_cookie()` call.

```
HttpResponse.delete_cookie(key, path='/', domain=None, samesite=None)
```

Deletes the cookie with the given key. Fails silently if the key doesn’t exist.

Due to the way cookies work, `path` and `domain` should be the same values you used in `set_cookie()` — otherwise the cookie may not be deleted.

```
HttpResponse.close()
```

This method is called at the end of the request directly by the WSGI server.

```
HttpResponse.write(content)
```

This method makes an `HttpResponse` instance a file-like object.

```
HttpResponse.flush()
```

This method makes an `HttpResponse` instance a file-like object.

```
HttpResponse.tell()
```

This method makes an `HttpResponse` instance a file-like object.
HttpResponse.getvalue()

Returns the value of HttpResponse.content. This method makes an HttpResponse instance a stream-like object.

HttpResponse.readable()

Always False. This method makes an HttpResponse instance a stream-like object.

HttpResponse.seekable()

Always False. This method makes an HttpResponse instance a stream-like object.

HttpResponse.writable()

Always True. This method makes an HttpResponse instance a stream-like object.

HttpResponse.writelines(lines)

Writes a list of lines to the response. Line separators are not added. This method makes an HttpResponse instance a stream-like object.

HttpResponse subclasses

Django includes a number of HttpResponse subclasses that handle different types of HTTP responses. Like HttpResponse, these subclasses live in django.http.

class HttpResponseRedirect

The first argument to the constructor is required—the path to redirect to. This can be a fully qualified URL (e.g. 'https://www.yahoo.com/search/'), an absolute path with no domain (e.g. '/search/'), or even a relative path (e.g. 'search/'). In that last case, the client browser will reconstruct the full URL itself according to the current path. See HttpResponse for other optional constructor arguments. Note that this returns an HTTP status code 302.

url

This read-only attribute represents the URL the response will redirect to (equivalent to the Location response header).

class HttpResponsePermanentRedirect

Like HttpResponseRedirect, but it returns a permanent redirect (HTTP status code 301) instead of a “found” redirect (status code 302).

class HttpResponseNotModified

The constructor doesn’t take any arguments and no content should be added to this response. Use this to designate that a page hasn’t been modified since the user’s last request (status code 304).

class HttpResponseBadRequest

Acts just like HttpResponse but uses a 400 status code.
class HttpResponseNotFound
    Acts just like HttpResponse but uses a 404 status code.

class HttpResponseForbidden
    Acts just like HttpResponse but uses a 403 status code.

class HttpResponseNotAllowed
    Like HttpResponse, but uses a 405 status code. The first argument to the constructor is required: a list of permitted methods (e.g. ['GET', 'POST']).

class HttpResponseGone
    Acts just like HttpResponse but uses a 410 status code.

class HttpResponseServerError
    Acts just like HttpResponse but uses a 500 status code.

Note: If a custom subclass of HttpResponse implements a render method, Django will treat it as emulating a SimpleTemplateResponse, and the render method must itself return a valid response object.

Custom response classes

If you find yourself needing a response class that Django doesn’t provide, you can create it with the help of http.HTTPStatus. For example:

```python
from http import HTTPStatus
from django.http import HttpResponse

class HttpResponseNoContent(HttpResponse):
    status_code = HTTPStatus.NO_CONTENT
```

6.18.5 JsonResponse objects

class JsonResponse(data, encoder=DjangoJSONEncoder, safe=True, json_dumps_params=None, **kwargs)

An HttpResponse subclass that helps to create a JSON-encoded response. It inherits most behavior from its superclass with a couple differences:

Its default Content-Type header is set to application/json.

The first parameter, data, should be a dict instance. If the safe parameter is set to False (see below) it can be any JSON-serializable object.
The encoder, which defaults to \texttt{django.core.serializers.json.DjangoJSONEncoder}, will be used to serialize the data. See JSON serialization for more details about this serializer.

The \texttt{safe} boolean parameter defaults to \texttt{True}. If it’s set to \texttt{False}, any object can be passed for serialization (otherwise only \texttt{dict} instances are allowed). If \texttt{safe} is \texttt{True} and a non-\texttt{dict} object is passed as the first argument, a \texttt{TypeError} will be raised.

The \texttt{json_dumps_params} parameter is a dictionary of keyword arguments to pass to the \texttt{json.dumps()} call used to generate the response.

Usage

Typical usage could look like:

```python
>>> from django.http import JsonResponse
>>> response = JsonResponse({'foo': 'bar'})
>>> response.content
b'{"foo": "bar"}'
```

Serializing non-dictionary objects

In order to serialize objects other than \texttt{dict} you must set the \texttt{safe} parameter to \texttt{False}:

```python
>>> response = JsonResponse([1, 2, 3], safe=False)
```

Without passing \texttt{safe=False}, a \texttt{TypeError} will be raised.

Note that an API based on \texttt{dict} objects is more extensible, flexible, and makes it easier to maintain forwards compatibility. Therefore, you should avoid using non-\texttt{dict} objects in JSON-encoded response.

Warning: Before the 5th edition of ECMAScript it was possible to poison the JavaScript \texttt{Array} constructor. For this reason, Django does not allow passing non-\texttt{dict} objects to the \texttt{JsonResponse} constructor by default. However, most modern browsers implement ECMAScript 5 which removes this attack vector. Therefore it is possible to disable this security precaution.
Changing the default JSON encoder

If you need to use a different JSON encoder class you can pass the `encoder` parameter to the constructor method:

```python
>>> response = JsonResponse(data, encoder=MyJSONEncoder)
```

6.18.6 StreamingHttpResponse objects

class StreamingHttpResponse

The `StreamingHttpResponse` class is used to stream a response from Django to the browser. You might want to do this if generating the response takes too long or uses too much memory. For instance, it’s useful for generating large CSV files.

Performance considerations

Django is designed for short-lived requests. Streaming responses will tie a worker process for the entire duration of the response. This may result in poor performance.

Generally speaking, you should perform expensive tasks outside of the request-response cycle, rather than resorting to a streamed response.

The `StreamingHttpResponse` is not a subclass of `HttpResponse`, because it features a slightly different API. However, it is almost identical, with the following notable differences:

- It should be given an iterator that yields bytestrings as content.
- You cannot access its content, except by iterating the response object itself. This should only occur when the response is returned to the client.
- It has no `content` attribute. Instead, it has a `streaming_content` attribute.
- You cannot use the file-like object `tell()` or `write()` methods. Doing so will raise an exception.

`StreamingHttpResponse` should only be used in situations where it is absolutely required that the whole content isn’t iterated before transferring the data to the client. Because the content can’t be accessed, many middleware can’t function normally. For example the `ETag` and `Content-Length` headers can’t be generated for streaming responses.

The `HttpResponseBase` base class is common between `HttpResponse` and `StreamingHttpResponse`.

6.18. Request and response objects 1787
Attributes

StreamingHttpResponse.streaming_content
An iterator of the response content, bytestring encoded according to HttpResponse.charset.

StreamingHttpResponse.status_code
The HTTP status code for the response.

Unless reason_phrase is explicitly set, modifying the value of status_code outside the constructor will also modify the value of reason_phrase.

StreamingHttpResponse.reason_phrase
The HTTP reason phrase for the response. It uses the HTTP standard’s default reason phrases.

Unless explicitly set, reason_phrase is determined by the value of status_code.

StreamingHttpResponse.streaming
This is always True.

6.18.7 FileResponse objects

class FileResponse(open_file, as_attachment=False, filename='', **kwargs)

FileResponse is a subclass of StreamingHttpResponse optimized for binary files. It uses wsgi.file_wrapper if provided by the wsgi server, otherwise it streams the file out in small chunks.

If as_attachment=True, the Content-Disposition header is set to attachment, which asks the browser to offer the file to the user as a download. Otherwise, a Content-Disposition header with a value of inline (the browser default) will be set only if a filename is available.

If open_file doesn’t have a name or if the name of open_file isn’t appropriate, provide a custom file name using the filename parameter. Note that if you pass a file-like object like io.BytesIO, it’s your task to seek() it before passing it to FileResponse.

The Content-Length and Content-Type headers are automatically set when they can be guessed from contents of open_file.

FileResponse accepts any file-like object with binary content, for example a file open in binary mode like so:

```python
>>> from django.http import FileResponse
>>> response = FileResponse(open('myfile.png', 'rb'))
```

The file will be closed automatically, so don’t open it with a context manager.
Methods

FileResponse.set_headers(open_file)

   This method is automatically called during the response initialization and set various headers (Content-Length, Content-Type, and Content-Disposition) depending on open_file.

6.18.8 HttpResponseBase class

class HttpResponseBase

   The HttpResponseBase class is common to all Django responses. It should not be used to create responses directly, but it can be useful for type-checking.

6.19 SchemaEditor

class BaseDatabaseSchemaEditor

   Django’s migration system is split into two parts; the logic for calculating and storing what operations should be run (django.db.migrations), and the database abstraction layer that turns things like “create a model” or “delete a field” into SQL - which is the job of the SchemaEditor.

   It’s unlikely that you will want to interact directly with SchemaEditor as a normal developer using Django, but if you want to write your own migration system, or have more advanced needs, it’s a lot nicer than writing SQL.

   Each database backend in Django supplies its own version of SchemaEditor, and it’s always accessible via the connection.schema_editor() context manager:

   ```
   with connection.schema_editor() as schema_editor:
       schema_editor.delete_model(MyModel)
   ```

   It must be used via the context manager as this allows it to manage things like transactions and deferred SQL (like creating ForeignKey constraints).

   It exposes all possible operations as methods, that should be called in the order you wish changes to be applied. Some possible operations or types of change are not possible on all databases - for example, MyISAM does not support foreign key constraints.

   If you are writing or maintaining a third-party database backend for Django, you will need to provide a SchemaEditor implementation in order to work with Django’s migration functionality - however, as long as your database is relatively standard in its use of SQL and relational design, you should be able to subclass one of the built-in Django SchemaEditor classes and tweak the syntax a little.
6.19.1 Methods

execute()

BaseDatabaseSchemaEditor.execute(sql, params=())

Executes the SQL statement passed in, with parameters if supplied. This is a wrapper around the normal database cursors that allows capture of the SQL to a .sql file if the user wishes.

create_model()

BaseDatabaseSchemaEditor.create_model(model)

Creates a new table in the database for the provided model, along with any unique constraints or indexes it requires.

delete_model()

BaseDatabaseSchemaEditor.delete_model(model)

Drops the model’s table in the database along with any unique constraints or indexes it has.

add_index()

BaseDatabaseSchemaEditor.add_index(model, index)

Adds index to model’s table.

remove_index()

BaseDatabaseSchemaEditor.remove_index(model, index)

Removes index from model’s table.

rename_index()

BaseDatabaseSchemaEditor.rename_index(model, old_index, new_index)

Renames old_index from model’s table to new_index.
add_constraint()

BaseDatabaseSchemaEditor.add_constraint(model, constraint)

Adds constraint to model’s table.

remove_constraint()

BaseDatabaseSchemaEditor.remove_constraint(model, constraint)

Removes constraint from model’s table.

alter_unique_together()

BaseDatabaseSchemaEditor.alter_unique_together(model, old_unique_together, new_unique_together)

Changes a model’s unique_together value; this will add or remove unique constraints from the model’s table until they match the new value.

alter_index_together()

BaseDatabaseSchemaEditor.alter_index_together(model, old_index_together, new_index_together)

Changes a model’s index_together value; this will add or remove indexes from the model’s table until they match the new value.

alter_db_table()

BaseDatabaseSchemaEditor.alter_db_table(model, old_db_table, new_db_table)

Renames the model’s table from old_db_table to new_db_table.

alter_db_tablespace()

BaseDatabaseSchemaEditor.alter_db_tablespace(model, old_db_tablespace, new_db_tablespace)

Moves the model’s table from one tablespace to another.
add_field()

BaseDatabaseSchemaEditor.add_field(model, field)

Adds a column (or sometimes multiple) to the model’s table to represent the field. This will also add indexes or a unique constraint if the field has db_index=True or unique=True.

If the field is a ManyToManyField without a value for through, instead of creating a column, it will make a table to represent the relationship. If through is provided, it is a no-op.

If the field is a ForeignKey, this will also add the foreign key constraint to the column.

remove_field()

BaseDatabaseSchemaEditor.remove_field(model, field)

Removes the column(s) representing the field from the model’s table, along with any unique constraints, foreign key constraints, or indexes caused by that field.

If the field is a ManyToManyField without a value for through, it will remove the table created to track the relationship. If through is provided, it is a no-op.

alter_field()

BaseDatabaseSchemaEditor.alter_field(model, old_field, new_field, strict=False)

This transforms the field on the model from the old field to the new one. This includes changing the name of the column (the db_column attribute), changing the type of the field (if the field class changes), changing the NULL status of the field, adding or removing field-only unique constraints and indexes, changing primary key, and changing the destination of ForeignKey constraints.

The most common transformation this cannot do is transforming a ManyToManyField into a normal Field or vice-versa; Django cannot do this without losing data, and so it will refuse to do it. Instead, remove_field() and add_field() should be called separately.

If the database has the supports_combined_alters, Django will try and do as many of these in a single database call as possible; otherwise, it will issue a separate ALTER statement for each change, but will not issue ALTERs where no change is required.
6.19.2 Attributes

All attributes should be considered read-only unless stated otherwise.

connection

SchemaEditor.connection

A connection object to the database. A useful attribute of the connection is alias which can be used to determine the name of the database being accessed.

This is useful when doing data migrations for migrations with multiple databases.

6.20 Settings

- Core Settings
- Auth
- Messages
- Sessions
- Sites
- Static Files
- Core Settings Topical Index

Warning: Be careful when you override settings, especially when the default value is a non-empty list or dictionary, such as STATICFILES_FINDERS. Make sure you keep the components required by the features of Django you wish to use.

6.20.1 Core Settings

Here’s a list of settings available in Django core and their default values. Settings provided by contrib apps are listed below, followed by a topical index of the core settings. For introductory material, see the settings topic guide.
**ABSOLUTE_URL_OVERRIDES**

Default: {} (Empty dictionary)

A dictionary mapping "app_label.model_name" strings to functions that take a model object and return its URL. This is a way of inserting or overriding get_absolute_url() methods on a per-installation basis. Example:

```python
ABSOLUTE_URL_OVERRIDES = {
    'blogs.blog': lambda o: '/blogs/%s' % o.slug,
    'news.story': lambda o: '/stories/%s/%s' % (o.pub_year, o.slug),
}
```

The model name used in this setting should be all lowercase, regardless of the case of the actual model class name.

**ADMINS**

Default: [] (Empty list)

A list of all the people who get code error notifications. When DEBUG=False and AdminEmailHandler is configured in LOGGING (done by default), Django emails these people the details of exceptions raised in the request/response cycle.

Each item in the list should be a tuple of (Full name, email address). Example:

```python
[('John', 'john@example.com'), ('Mary', 'mary@example.com')]
```

**ALLOWED_HOSTS**

Default: [] (Empty list)

A list of strings representing the host/domain names that this Django site can serve. This is a security measure to prevent HTTP Host header attacks, which are possible even under many seemingly-safe web server configurations.

Values in this list can be fully qualified names (e.g. 'www.example.com'), in which case they will be matched against the request’s Host header exactly (case-insensitive, not including port). A value beginning with a period can be used as a subdomain wildcard: '.example.com' will match example.com, www.example.com, and any other subdomain of example.com. A value of '*' will match anything; in this case you are responsible to provide your own validation of the Host header (perhaps in a middleware; if so this middleware must be listed first in MIDDLEWARE).

Django also allows the fully qualified domain name (FQDN) of any entries. Some browsers include a trailing dot in the Host header which Django strips when performing host validation.
If the Host header (or X-Forwarded-Host if USE_X_FORWARDED_HOST is enabled) does not match any value in this list, the django.http.HttpRequest.get_host() method will raise SuspiciousOperation.

When DEBUG is True and ALLOWED_HOSTS is empty, the host is validated against ['.localhost', '127.0.0.1', '::1'].

ALLOWED_HOSTS is also checked when running tests.

This validation only applies via get_host(); if your code accesses the Host header directly from request.META you are bypassing this security protection.

**APPEND_SLASH**

Default: True

When set to True, if the request URL does not match any of the patterns in the URLconf and it doesn’t end in a slash, an HTTP redirect is issued to the same URL with a slash appended. Note that the redirect may cause any data submitted in a POST request to be lost.

The APPEND_SLASH setting is only used if CommonMiddleware is installed (see Middleware). See also PREPEND_WWW.

**CACHES**

Default:

```{  
    'default': {  
        'BACKEND': 'django.core.cache.backends.locmem.LocMemCache',  
    }  
}
```

A dictionary containing the settings for all caches to be used with Django. It is a nested dictionary whose contents maps cache aliases to a dictionary containing the options for an individual cache.

The CACHES setting must configure a default cache; any number of additional caches may also be specified. If you are using a cache backend other than the local memory cache, or you need to define multiple caches, other options will be required. The following cache options are available.
BACKEND

Default: '' (Empty string)

The cache backend to use. The built-in cache backends are:

- 'django.core.cache.backends.db.DatabaseCache'
- 'django.core.cache.backends.dummy.DummyCache'
- 'django.core.cache.backends.filebased.FileBasedCache'
- 'django.core.cache.backends.locmem.LocMemCache'
- 'django.core.cache.backends.memcached.PyMemcacheCache'
- 'django.core.cache.backends.memcached.PyLibMCCache'
- 'django.core.cache.backends.redis.RedisCache'

You can use a cache backend that doesn’t ship with Django by setting `BACKEND` to a fully-qualified path of a cache backend class (i.e. `mypackage.backends.whatever.WhateverCache`).

KEY_FUNCTION

A string containing a dotted path to a function (or any callable) that defines how to compose a prefix, version and key into a final cache key. The default implementation is equivalent to the function:

```python
def make_key(key, key_prefix, version):
    return ':'.join([key_prefix, str(version), key])
```

You may use any key function you want, as long as it has the same argument signature.

See the cache documentation for more information.

KEY_PREFIX

Default: '' (Empty string)

A string that will be automatically included (prepended by default) to all cache keys used by the Django server.

See the cache documentation for more information.
LOCATION

Default: '' (Empty string)

The location of the cache to use. This might be the directory for a file system cache, a host and port for a memcache server, or an identifying name for a local memory cache. e.g.:

```
CACHES = {
    'default': {
        'BACKEND': 'django.core.cache.backends.filebased.FileBasedCache',
        'LOCATION': '/var/tmp/django_cache',
    }
}
```

OPTIONS

Default: None

Extra parameters to pass to the cache backend. Available parameters vary depending on your cache backend.

Some information on available parameters can be found in the cache arguments documentation. For more information, consult your backend module’s own documentation.

TIMEOUT

Default: 300

The number of seconds before a cache entry is considered stale. If the value of this setting is None, cache entries will not expire. A value of 0 causes keys to immediately expire (effectively “don’t cache”).

VERSION

Default: 1

The default version number for cache keys generated by the Django server.

See the cache documentation for more information.
**CACHE_MIDDLEWARE_ALIAS**

Default: 'default'

The cache connection to use for the cache middleware.

**CACHE_MIDDLEWARE_KEY_PREFIX**

Default: '' (Empty string)

A string which will be prefixed to the cache keys generated by the cache middleware. This prefix is combined with the KEY_PREFIX setting; it does not replace it.

See Django’s cache framework.

**CACHE_MIDDLEWARE_SECONDS**

Default: 600

The default number of seconds to cache a page for the cache middleware.

See Django’s cache framework.

**CSRF_COOKIE_AGE**

Default: 31449600 (approximately 1 year, in seconds)

The age of CSRF cookies, in seconds.

The reason for setting a long-lived expiration time is to avoid problems in the case of a user closing a browser or bookmarking a page and then loading that page from a browser cache. Without persistent cookies, the form submission would fail in this case.

Some browsers (specifically Internet Explorer) can disallow the use of persistent cookies or can have the indexes to the cookie jar corrupted on disk, thereby causing CSRF protection checks to (sometimes intermittently) fail. Change this setting to None to use session-based CSRF cookies, which keep the cookies in-memory instead of on persistent storage.

**CSRF_COOKIE_DOMAIN**

Default: None

The domain to be used when setting the CSRF cookie. This can be useful for easily allowing cross-subdomain requests to be excluded from the normal cross site request forgery protection. It should be set to a string such as ".example.com" to allow a POST request from a form on one subdomain to be accepted by a view served from another subdomain.
Please note that the presence of this setting does not imply that Django’s CSRF protection is safe from cross-subdomain attacks by default - please see the CSRF limitations section.

**CSRF_COOKIE_HTTPONLY**

Default: False

Whether to use HttpOnly flag on the CSRF cookie. If this is set to True, client-side JavaScript will not be able to access the CSRF cookie.

Designating the CSRF cookie as HttpOnly doesn’t offer any practical protection because CSRF is only to protect against cross-domain attacks. If an attacker can read the cookie via JavaScript, they’re already on the same domain as far as the browser knows, so they can do anything they like anyway. (XSS is a much bigger hole than CSRF.)

Although the setting offers little practical benefit, it’s sometimes required by security auditors.

If you enable this and need to send the value of the CSRF token with an AJAX request, your JavaScript must pull the value from a hidden CSRF token form input instead of from the cookie.

See **SESSION_COOKIE_HTTPONLY** for details on HttpOnly.

**CSRF_COOKIE_MASKED**

Default: False

Whether to mask the CSRF cookie. See release notes for usage details.

Deprecated since version 4.1: This transitional setting is deprecated and will be removed in Django 5.0.

**CSRF_COOKIE_NAME**

Default: 'csrftoken'

The name of the cookie to use for the CSRF authentication token. This can be whatever you want (as long as it’s different from the other cookie names in your application). See Cross Site Request Forgery protection.

**CSRF_COOKIE_PATH**

Default: '/'

The path set on the CSRF cookie. This should either match the URL path of your Django installation or be a parent of that path.

This is useful if you have multiple Django instances running under the same hostname. They can use different cookie paths, and each instance will only see its own CSRF cookie.
CSRF_COOKIE_SAMESITE

Default: 'Lax'

The value of the SameSite flag on the CSRF cookie. This flag prevents the cookie from being sent in cross-site requests.

See SESSION_COOKIE_SAMESITE for details about SameSite.

CSRF_COOKIE_SECURE

Default: False

Whether to use a secure cookie for the CSRF cookie. If this is set to True, the cookie will be marked as “secure”, which means browsers may ensure that the cookie is only sent with an HTTPS connection.

CSRF_USE_SESSIONS

Default: False

Whether to store the CSRF token in the user’s session instead of in a cookie. It requires the use of django.contrib.sessions.

Storing the CSRF token in a cookie (Django’s default) is safe, but storing it in the session is common practice in other web frameworks and therefore sometimes demanded by security auditors.

Since the default error views require the CSRF token, SessionMiddleware must appear in MIDDLEWARE before any middleware that may raise an exception to trigger an error view (such as PermissionDenied) if you’re using CSRF_USE_SESSIONS. See Middleware ordering.

CSRF_FAILURE_VIEW

Default: 'django.views.csrf.csrf_failure'

A dotted path to the view function to be used when an incoming request is rejected by the CSRF protection. The function should have this signature:

```python
def csrf_failure(request, reason=None):
    ...
```

where reason is a short message (intended for developers or logging, not for end users) indicating the reason the request was rejected. It should return an HttpResponseForbidden.

django.views.csrf.csrf_failure() accepts an additional template_name parameter that defaults to '403_csrf.html'. If a template with that name exists, it will be used to render the page.
CSRF_HEADER_NAME

Default: 'HTTP_X_CSRFTOKEN'

The name of the request header used for CSRF authentication.

As with other HTTP headers in request.META, the header name received from the server is normalized by converting all characters to uppercase, replacing any hyphens with underscores, and adding an 'HTTP_' prefix to the name. For example, if your client sends a 'X-XSRF-TOKEN' header, the setting should be 'HTTP_X_XSRF_TOKEN'.

CSRF_TRUSTED_ORIGINS

Default: [] (Empty list)

A list of trusted origins for unsafe requests (e.g. POST).

For requests that include the Origin header, Django’s CSRF protection requires that header match the origin present in the Host header.

For a secure unsafe request that doesn’t include the Origin header, the request must have a Referer header that matches the origin present in the Host header.

These checks prevent, for example, a POST request from subdomain.example.com from succeeding against api.example.com. If you need cross-origin unsafe requests, continuing the example, add 'https://subdomain.example.com' to this list (and/or http://... if requests originate from an insecure page).

The setting also supports subdomains, so you could add 'https://*.example.com', for example, to allow access from all subdomains of example.com.

DATABASES

Default: {} (Empty dictionary)

A dictionary containing the settings for all databases to be used with Django. It is a nested dictionary whose contents map a database alias to a dictionary containing the options for an individual database.

The DATABASES setting must configure a default database; any number of additional databases may also be specified.

The simplest possible settings file is for a single-database setup using SQLite. This can be configured using the following:

```python
DATABASES = {
    'default': {
        'ENGINE': 'django.db.backends.sqlite3',
        'NAME': 'mydatabase',
    }
}
```

(continues on next page)
When connecting to other database backends, such as MariaDB, MySQL, Oracle, or PostgreSQL, additional connection parameters will be required. See the `ENGINE` setting below on how to specify other database types. This example is for PostgreSQL:

```python
DATABASES = {
    'default': {
        'ENGINE': 'django.db.backends.postgresql',
        'NAME': 'mydatabase',
        'USER': 'mydatabaseuser',
        'PASSWORD': 'mypassword',
        'HOST': '127.0.0.1',
        'PORT': '5432',
    }
}
```

The following inner options that may be required for more complex configurations are available:

**ATOMIC_REQUESTS**

Default: `False`

Set this to `True` to wrap each view in a transaction on this database. See Tying transactions to HTTP requests.

**AUTOCOMMIT**

Default: `True`

Set this to `False` if you want to disable Django’s transaction management and implement your own.

**ENGINE**

Default: `' '` (Empty string)

The database backend to use. The built-in database backends are:

- `'django.db.backends.postgresql'`
- `'django.db.backends.mysql'`
- `'django.db.backends.sqlite3'`
'django.db.backends.oracle'

You can use a database backend that doesn’t ship with Django by setting ENGINE to a fully-qualified path (i.e. mypackage.backends.whatever).

```
HOST

Default: '' (Empty string)

Which host to use when connecting to the database. An empty string means localhost. Not used with SQLite.

If this value starts with a forward slash (‘/’) and you’re using MySQL, MySQL will connect via a Unix socket to the specified socket. For example:

``HOST'': '/var/run/mysql'

If you’re using MySQL and this value doesn’t start with a forward slash, then this value is assumed to be the host.

If you’re using PostgreSQL, by default (empty HOST), the connection to the database is done through UNIX domain sockets (‘local’ lines in pg_hba.conf). If your UNIX domain socket is not in the standard location, use the same value of unix_socket_directory from postgresql.conf. If you want to connect through TCP sockets, set HOST to ‘localhost’ or ‘127.0.0.1’ (‘host’ lines in pg_hba.conf). On Windows, you should always define HOST, as UNIX domain sockets are not available.

```
NAME

Default: '' (Empty string)

The name of the database to use. For SQLite, it’s the full path to the database file. When specifying the path, always use forward slashes, even on Windows (e.g. C:/homes/user/mysite/sqlite3.db).

```
CONN_MAX_AGE

Default: 0

The lifetime of a database connection, as an integer of seconds. Use 0 to close database connections at the end of each request —Django’s historical behavior —and None for unlimited persistent database connections.
CONN_HEALTH_CHECKS

Default: False

If set to True, existing persistent database connections will be health checked before they are reused in each request performing database access. If the health check fails, the connection will be reestablished without failing the request when the connection is no longer usable but the database server is ready to accept and serve new connections (e.g. after database server restart closing existing connections).

OPTIONS

Default: {} (Empty dictionary)

Extra parameters to use when connecting to the database. Available parameters vary depending on your database backend.

Some information on available parameters can be found in the Database Backends documentation. For more information, consult your backend module’s own documentation.

PASSWORD

Default: '' (Empty string)

The password to use when connecting to the database. Not used with SQLite.

PORT

Default: '' (Empty string)

The port to use when connecting to the database. An empty string means the default port. Not used with SQLite.

TIME_ZONE

Default: None

A string representing the time zone for this database connection or None. This inner option of the DATABASES setting accepts the same values as the general TIME_ZONE setting.

When USE_TZ is True and this option is set, reading datetimes from the database returns aware datetimes in this time zone instead of UTC. When USE_TZ is False, it is an error to set this option.

- If the database backend doesn’t support time zones (e.g. SQLite, MySQL, Oracle), Django reads and writes datetimes in local time according to this option if it is set and in UTC if it isn’t.

Changing the connection time zone changes how datetimes are read from and written to the database.
- If Django manages the database and you don’t have a strong reason to do otherwise, you should leave this option unset. It’s best to store datetimes in UTC because it avoids ambiguous or nonexistent datetimes during daylight saving time changes. Also, receiving datetimes in UTC keeps datetime arithmetic simple — there’s no need to consider potential offset changes over a DST transition.

- If you’re connecting to a third-party database that stores datetimes in a local time rather than UTC, then you must set this option to the appropriate time zone. Likewise, if Django manages the database but third-party systems connect to the same database and expect to find datetimes in local time, then you must set this option.

  • If the database backend supports time zones (e.g., PostgreSQL), the `TIME_ZONE` option is very rarely needed. It can be changed at any time; the database takes care of converting datetimes to the desired time zone.

  Setting the time zone of the database connection may be useful for running raw SQL queries involving date/time functions provided by the database, such as `date_trunc`, because their results depend on the time zone.

  However, this has a downside: receiving all datetimes in local time makes datetime arithmetic more tricky — you must account for possible offset changes over DST transitions.

  Consider converting to local time explicitly with `AT TIME ZONE` in raw SQL queries instead of setting the `TIME_ZONE` option.

**DISABLE_SERVER_SIDE_CURSORS**

Default: `False`

Set this to `True` if you want to disable the use of server-side cursors with `QuerySet.iterator()`. Transaction pooling and server-side cursors describes the use case.

This is a PostgreSQL-specific setting.

**USER**

Default: `' ' (Empty string)`

The username to use when connecting to the database. Not used with SQLite.
TEST

Default: `{}` (Empty dictionary)

A dictionary of settings for test databases; for more details about the creation and use of test databases, see The test database.

Here’s an example with a test database configuration:

```python
DATABASES = {
    'default': {
        'ENGINE': 'django.db.backends.postgresql',
        'USER': 'mydatabaseuser',
        'NAME': 'mydatabase',
        'TEST': {
            'NAME': 'mytestdatabase',
        },
    },
}
```

The following keys in the TEST dictionary are available:

CHARSET

Default: `None`

The character set encoding used to create the test database. The value of this string is passed directly through to the database, so its format is backend-specific.

Supported by the PostgreSQL (`postgresql`) and MySQL (`mysql`) backends.

COLLATION

Default: `None`

The collation order to use when creating the test database. This value is passed directly to the backend, so its format is backend-specific.

Only supported for the `mysql` backend (see the MySQL manual for details).
DEPENDENCIES

Default: ['default'], for all databases other than default, which has no dependencies.

The creation-order dependencies of the database. See the documentation on controlling the creation order of test databases for details.

MIGRATE

Default: True

When set to False, migrations won’t run when creating the test database. This is similar to setting None as a value in MIGRATION_MODULES, but for all apps.

MIRROR

Default: None

The alias of the database that this database should mirror during testing.

This setting exists to allow for testing of primary/replica (referred to as master/slave by some databases) configurations of multiple databases. See the documentation on testing primary/replica configurations for details.

NAME

Default: None

The name of database to use when running the test suite.

If the default value (None) is used with the SQLite database engine, the tests will use a memory resident database. For all other database engines the test database will use the name 'test_' + DATABASE_NAME.

See The test database.

SERIALIZE

Boolean value to control whether or not the default test runner serializes the database into an in-memory JSON string before running tests (used to restore the database state between tests if you don’t have transactions). You can set this to False to speed up creation time if you don’t have any test classes with serialized_rollback=True.

Deprecated since version 4.0: This setting is deprecated as it can be inferred from the databases with the serialized_rollback option enabled.
**TEMPLATE**

This is a PostgreSQL-specific setting.

The name of a template (e.g. 'template0') from which to create the test database.

**CREATE_DB**

Default: True

This is an Oracle-specific setting.

If it is set to False, the test tables won’t be automatically created at the beginning of the tests or dropped at the end.

**CREATE_USER**

Default: True

This is an Oracle-specific setting.

If it is set to False, the test user won’t be automatically created at the beginning of the tests and dropped at the end.

**USER**

Default: None

This is an Oracle-specific setting.

The username to use when connecting to the Oracle database that will be used when running tests. If not provided, Django will use 'test_' + USER.

**PASSWORD**

Default: None

This is an Oracle-specific setting.

The password to use when connecting to the Oracle database that will be used when running tests. If not provided, Django will generate a random password.
**ORACLE_MANAGED_FILES**

Default: `False`

This is an Oracle-specific setting.

If set to `True`, Oracle Managed Files (OMF) tablespaces will be used. `DATAFILE` and `DATAFILE_TMP` will be ignored.

**TBLSPACE**

Default: `None`

This is an Oracle-specific setting.

The name of the tablespace that will be used when running tests. If not provided, Django will use `'test_' + USER`.

**TBLSPACE_TMP**

Default: `None`

This is an Oracle-specific setting.

The name of the temporary tablespace that will be used when running tests. If not provided, Django will use `'test_' + USER + '_temp'`.

**DATAFILE**

Default: `None`

This is an Oracle-specific setting.

The name of the datafile to use for the TBLSPACE. If not provided, Django will use `TBLSPACE + '.dbf'`.

**DATAFILE_TMP**

Default: `None`

This is an Oracle-specific setting.

The name of the datafile to use for the TBLSPACE_TMP. If not provided, Django will use `TBLSPACE_TMP + '.dbf'`. 
**DATAFILE_MAXSIZE**

Default: '500M'

This is an Oracle-specific setting.

The maximum size that the DATAFILE is allowed to grow to.

**DATAFILE_TMP_MAXSIZE**

Default: '500M'

This is an Oracle-specific setting.

The maximum size that the DATAFILE_TMP is allowed to grow to.

**DATAFILE_SIZE**

Default: '50M'

This is an Oracle-specific setting.

The initial size of the DATAFILE.

**DATAFILE_TMP_SIZE**

Default: '50M'

This is an Oracle-specific setting.

The initial size of the DATAFILE_TMP.

**DATAFILE_EXTSIZE**

Default: '25M'

This is an Oracle-specific setting.

The amount by which the DATAFILE is extended when more space is required.
DATAFILE_TMP_EXTSIZE

Default: '25M'

This is an Oracle-specific setting.
The amount by which the DATAFILE_TMP is extended when more space is required.

DATA_UPLOAD_MAX_MEMORY_SIZE

Default: 2621440 (i.e. 2.5 MB).

The maximum size in bytes that a request body may be before a SuspiciousOperation (RequestDataTooBig) is raised. The check is done when accessing request.body or request.POST and is calculated against the total request size excluding any file upload data. You can set this to None to disable the check. Applications that are expected to receive unusually large form posts should tune this setting.

The amount of request data is correlated to the amount of memory needed to process the request and populate the GET and POST dictionaries. Large requests could be used as a denial-of-service attack vector if left unchecked. Since web servers don’t typically perform deep request inspection, it’s not possible to perform a similar check at that level.

See also FILE_UPLOAD_MAX_MEMORY_SIZE.

DATA_UPLOAD_MAX_NUMBER_FIELDS

Default: 1000

The maximum number of parameters that may be received via GET or POST before a SuspiciousOperation (TooManyFields) is raised. You can set this to None to disable the check. Applications that are expected to receive an unusually large number of form fields should tune this setting.

The number of request parameters is correlated to the amount of time needed to process the request and populate the GET and POST dictionaries. Large requests could be used as a denial-of-service attack vector if left unchecked. Since web servers don’t typically perform deep request inspection, it’s not possible to perform a similar check at that level.
DATABASE_ROUTERS

Default: [] (Empty list)

The list of routers that will be used to determine which database to use when performing a database query. See the documentation on automatic database routing in multi database configurations.

DATE_FORMAT

Default: 'N j, Y' (e.g. Feb. 4, 2003)

The default formatting to use for displaying date fields in any part of the system. Note that if USE_L10N is set to True, then the locale-dictated format has higher precedence and will be applied instead. See allowed date format strings.

See also DATETIME_FORMAT, TIME_FORMAT and SHORT_DATE_FORMAT.

DATE_INPUT_FORMATS

Default:

```
[
    '%Y-%m-%d', # '2006-10-25'
    '%m/%d/%Y', # '10/25/2006'
    '%m/%d/%y', # '10/25/06'
    '%b %d %Y', # 'Oct 25 2006'
    '%b %d, %Y', # 'Oct 25, 2006'
    '%d %b %Y', # '25 Oct 2006'
    '%d %b, %Y', # '25 Oct, 2006'
    '%B %d, %Y', # 'October 25 2006'
    '%B %d %Y', # 'October 25, 2006'
    '%d %B %Y', # '25 October 2006'
    '%d %B, %Y', # '25 October, 2006'
]
```

A list of formats that will be accepted when inputting data on a date field. Formats will be tried in order, using the first valid one. Note that these format strings use Python’s datetime module syntax, not the format strings from the date template filter.

When USE_L10N is True, the locale-dictated format has higher precedence and will be applied instead.

See also DATETIME_INPUT_FORMATS and TIME_INPUT_FORMATS.
DATETIME_FORMAT

Default: 'N j, Y, P' (e.g. Feb. 4, 2003, 4 p.m.)

The default formatting to use for displaying datetime fields in any part of the system. Note that if USE_L10N is set to True, then the locale-dictated format has higher precedence and will be applied instead. See allowed date format strings.

See also DATE_FORMAT, TIME_FORMAT and SHORT_DATETIME_FORMAT.

DATETIME_INPUT_FORMATS

Default:

```
['%Y-%m-%d %H:%M:%S',         # '2006-10-25 14:30:59'
 '%Y-%m-%d %H:%M:%S.%f',      # '2006-10-25 14:30:59.000200'
 '%Y-%m-%d %H:%M',            # '2006-10-25 14:30'
 '%m/%d/%Y %H:%M:%S',         # '10/25/2006 14:30:59'
 '%m/%d/%Y %H:%M:%S.%f',      # '10/25/2006 14:30:59.000200'
 '%m/%d/%Y %H:%M',            # '10/25/2006 14:30'
 '%m/%d/%y %H:%M:%S',         # '10/25/06 14:30:59'
 '%m/%d/%y %H:%M:%S.%f',      # '10/25/06 14:30:59.000200'
 '%m/%d/%y %H:%M',            # '10/25/06 14:30'
]
```

A list of formats that will be accepted when inputting data on a datetime field. Formats will be tried in order, using the first valid one. Note that these format strings use Python’s datetime module syntax, not the format strings from the date template filter. Date-only formats are not included as datetime fields will automatically try DATE_INPUT_FORMATS in last resort.

When USE_L10N is True, the locale-dictated format has higher precedence and will be applied instead.

See also DATE_INPUT_FORMATS and TIME_INPUT_FORMATS.

DEBUG

Default: False

A boolean that turns on/off debug mode.

Never deploy a site into production with DEBUG turned on.

One of the main features of debug mode is the display of detailed error pages. If your app raises an exception when DEBUG is True, Django will display a detailed traceback, including a lot of metadata about your environment, such as all the currently defined Django settings (from settings.py).
As a security measure, Django will not include settings that might be sensitive, such as `SECRET_KEY`. Specifically, it will exclude any setting whose name includes any of the following:

- 'API'
- 'KEY'
- 'PASS'
- 'SECRET'
- 'SIGNATURE'
- 'TOKEN'

Note that these are partial matches. 'PASS' will also match PASSWORD, just as 'TOKEN' will also match TOKENIZED and so on.

Still, note that there are always going to be sections of your debug output that are inappropriate for public consumption. File paths, configuration options and the like all give attackers extra information about your server.

It is also important to remember that when running with `DEBUG` turned on, Django will remember every SQL query it executes. This is useful when you’re debugging, but it’ll rapidly consume memory on a production server.

Finally, if `DEBUG` is `False`, you also need to properly set the `ALLOWED_HOSTS` setting. Failing to do so will result in all requests being returned as “Bad Request (400)”.

---

**Note:** The default `settings.py` file created by `django-admin startproject` sets `DEBUG = True` for convenience.

---

**DEBUG_PROPAGATE_EXCEPTIONS**

Default: False

If set to True, Django’s exception handling of view functions (`handler500`, or the debug view if `DEBUG` is `True`) and logging of 500 responses (`django.request`) is skipped and exceptions propagate upward.

This can be useful for some test setups. It shouldn’t be used on a live site unless you want your web server (instead of Django) to generate “Internal Server Error” responses. In that case, make sure your server doesn’t show the stack trace or other sensitive information in the response.
DECIMAL_SEPARATOR

Default: '. ' (Dot)

Default decimal separator used when formatting decimal numbers.

Note that if USE_L10N is set to True, then the locale-dictated format has higher precedence and will be applied instead.

See also NUMBER_GROUPING, THOUSAND_SEPARATOR and USE_THOUSAND_SEPARATOR.

DEFAULT_AUTO_FIELD

Default: 'django.db.models.AutoField'

Default primary key field type to use for models that don’t have a field with primary_key=True.

Migrating auto-created through tables

The value of DEFAULT_AUTO_FIELD will be respected when creating new auto-created through tables for many-to-many relationships.

Unfortunately, the primary keys of existing auto-created through tables cannot currently be updated by the migrations framework.

This means that if you switch the value of DEFAULT_AUTO_FIELD and then generate migrations, the primary keys of the related models will be updated, as will the foreign keys from the through table, but the primary key of the auto-created through table will not be migrated.

In order to address this, you should add a RunSQL operation to your migrations to perform the required ALTER TABLE step. You can check the existing table name through sqlmigrate, dbshell, or with the field's remote_field.through._meta.db_table property.

Explicitly defined through models are already handled by the migrations system.

Allowing automatic migrations for the primary key of existing auto-created through tables may be implemented at a later date.

DEFAULT_CHARSET

Default: 'utf-8'

Default charset to use for all HttpResponse objects, if a MIME type isn’t manually specified. Used when constructing the Content-Type header.
DEFAULT_EXCEPTION_REPORTER

Default: `django.views.debug.ExceptionReporter`

Default exception reporter class to be used if none has been assigned to the HttpRequest instance yet. See Custom error reports.

DEFAULT_EXCEPTION_REPORTER_FILTER

Default: `django.views.debug.SafeExceptionReporterFilter`

Default exception reporter filter class to be used if none has been assigned to the HttpRequest instance yet. See Filtering error reports.

DEFAULT_FILE_STORAGE

Default: `django.core.files.storage.FileSystemStorage`

Default file storage class to be used for any file-related operations that don’t specify a particular storage system. See Managing files.

DEFAULT_FROM_EMAIL

Default: `webmaster@localhost`

Default email address to use for various automated correspondence from the site manager(s). This doesn’t include error messages sent to ADMINS and MANAGERS; for that, see SERVER_EMAIL.

DEFAULT_INDEX_TABLESPACE

Default: `''` (Empty string)

Default tablespace to use for indexes on fields that don’t specify one, if the backend supports it (see Tables).

DEFAULT_TABLESPACE

Default: `''` (Empty string)

Default tablespace to use for models that don’t specify one, if the backend supports it (see Tables).
DISALLOWED_USER_AGENTS

Default: [] (Empty list)

List of compiled regular expression objects representing User-Agent strings that are not allowed to visit any page, systemwide. Use this for bots/crawlers. This is only used if `CommonMiddleware` is installed (see Middleware).

EMAIL_BACKEND

Default: `'django.core.mail.backends.smtp.EmailBackend'`

The backend to use for sending emails. For the list of available backends see Sending email.

EMAIL_FILE_PATH

Default: Not defined

The directory used by the file email backend to store output files.

EMAIL_HOST

Default: `'localhost'`

The host to use for sending email.

See also `EMAIL_PORT`.

EMAIL_HOST_PASSWORD

Default: `'` (Empty string)

Password to use for the SMTP server defined in `EMAIL_HOST`. This setting is used in conjunction with `EMAIL_HOST_USER` when authenticating to the SMTP server. If either of these settings is empty, Django won’t attempt authentication.

See also `EMAIL_HOST_USER`. 
**EMAIL_HOST_USER**

Default: '' (Empty string)

Username to use for the SMTP server defined in `EMAIL_HOST`. If empty, Django won’t attempt authentication. See also `EMAIL_HOST_PASSWORD`.

**EMAIL_PORT**

Default: 25

Port to use for the SMTP server defined in `EMAIL_HOST`.

**EMAIL_SUBJECT_PREFIX**

Default: ' [Django] '

Subject-line prefix for email messages sent with `django.core.mail.mail_admins` or `django.core.mail.mail_managers`. You’ll probably want to include the trailing space.

**EMAIL_USE_LOCALTIME**

Default: False

Whether to send the SMTP Date header of email messages in the local time zone (True) or in UTC (False).

**EMAIL_USE_TLS**

Default: False

Whether to use a TLS (secure) connection when talking to the SMTP server. This is used for explicit TLS connections, generally on port 587. If you are experiencing hanging connections, see the implicit TLS setting `EMAIL_USE_SSL`.

**EMAIL_USE_SSL**

Default: False

Whether to use an implicit TLS (secure) connection when talking to the SMTP server. In most email documentation this type of TLS connection is referred to as SSL. It is generally used on port 465. If you are experiencing problems, see the explicit TLS setting `EMAIL_USE_TLS`.

Note that `EMAIL_USE_TLS`/`EMAIL_USE_SSL` are mutually exclusive, so only set one of those settings to True.
**EMAIL_SSL_CERTFILE**

Default: None

If `EMAIL_USE_SSL` or `EMAIL_USE_TLS` is True, you can optionally specify the path to a PEM-formatted certificate chain file to use for the SSL connection.

**EMAIL_SSL_KEYFILE**

Default: None

If `EMAIL_USE_SSL` or `EMAIL_USE_TLS` is True, you can optionally specify the path to a PEM-formatted private key file to use for the SSL connection.

Note that setting `EMAIL_SSL_CERTFILE` and `EMAIL_SSL_KEYFILE` doesn’t result in any certificate checking. They’re passed to the underlying SSL connection. Please refer to the documentation of Python’s `ssl.wrap_socket()` function for details on how the certificate chain file and private key file are handled.

**EMAIL_TIMEOUT**

Default: None

Specifies a timeout in seconds for blocking operations like the connection attempt.

**FILE_UPLOAD_HANDLERS**

Default:

```python
[
    'django.core.files.uploadhandler.MemoryFileUploadHandler',
    'django.core.files.uploadhandler.TemporaryFileUploadHandler',
]
```

A list of handlers to use for uploading. Changing this setting allows complete customization – even replacement – of Django’s upload process.

See Managing files for details.
FILE_UPLOAD_MAX_MEMORY_SIZE

Default: 2621440 (i.e. 2.5 MB).

The maximum size (in bytes) that an upload will be before it gets streamed to the file system. See Managing files for details.

See also DATA_UPLOAD_MAX_MEMORY_SIZE.

FILE_UPLOAD_DIRECTORY_PERMISSIONS

Default: None

The numeric mode to apply to directories created in the process of uploading files.

This setting also determines the default permissions for collected static directories when using the collectstatic management command. See collectstatic for details on overriding it.

This value mirrors the functionality and caveats of the FILE_UPLOAD_PERMISSIONS setting.

FILE_UPLOAD_PERMISSIONS

Default: 0o644

The numeric mode (i.e. 0o644) to set newly uploaded files to. For more information about what these modes mean, see the documentation for os.chmod().

If None, you’ll get operating-system dependent behavior. On most platforms, temporary files will have a mode of 0o600, and files saved from memory will be saved using the system’s standard umask.

For security reasons, these permissions aren’t applied to the temporary files that are stored in FILE_UPLOAD_TEMP_DIR.

This setting also determines the default permissions for collected static files when using the collectstatic management command. See collectstatic for details on overriding it.

Warning: Always prefix the mode with 0o.

If you’re not familiar with file modes, please note that the 0o prefix is very important: it indicates an octal number, which is the way that modes must be specified. If you try to use 644, you’ll get totally incorrect behavior.
**FILE_UPLOAD_TEMP_DIR**

Default: None

The directory to store data to (typically files larger than `FILE_UPLOAD_MAX_MEMORY_SIZE`) temporarily while uploading files. If None, Django will use the standard temporary directory for the operating system. For example, this will default to `/tmp` on *nix-style operating systems.

See [Managing files](https://docs.djangoproject.com/en/4.2/releases/4.2/) for details.

**FIRST_DAY_OF_WEEK**

Default: 0 (Sunday)

A number representing the first day of the week. This is especially useful when displaying a calendar. This value is only used when not using format internationalization, or when a format cannot be found for the current locale.

The value must be an integer from 0 to 6, where 0 means Sunday, 1 means Monday and so on.

**FIXTURE_DIRS**

Default: [] (Empty list)

List of directories searched for fixture files, in addition to the `fixtures` directory of each application, in search order.

Note that these paths should use Unix-style forward slashes, even on Windows.

See [Providing data with fixtures](https://docs.djangoproject.com/en/4.2/releases/4.2/) and [Fixture loading](https://docs.djangoproject.com/en/4.2/releases/4.2/).

**FORCE_SCRIPT_NAME**

Default: None

If not None, this will be used as the value of the `SCRIPT_NAME` environment variable in any HTTP request. This setting can be used to override the server-provided value of `SCRIPT_NAME`, which may be a rewritten version of the preferred value or not supplied at all. It is also used by `django.setup()` to set the URL resolver script prefix outside of the request/response cycle (e.g. in management commands and standalone scripts) to generate correct URLs when `SCRIPT_NAME` is not `/`. 
FORM_RENDERER

Default: 'django.forms.renderers.DjangoTemplates'

The class that renders forms and form widgets. It must implement the low-level render API. Included form renderers are:

- 'django.forms.renderers.DjangoTemplates'
- 'django.forms.renderers.Jinja2'
- 'django.forms.renderers.TemplatesSetting'

FORMAT_MODULE_PATH

Default: None

A full Python path to a Python package that contains custom format definitions for project locales. If not None, Django will check for a formats.py file, under the directory named as the current locale, and will use the formats defined in this file.

For example, if FORMAT_MODULE_PATH is set to mysite.formats, and current language is en (English), Django will expect a directory tree like:

```
mysite/
    formats/
    __init__.py
    en/
    __init__.py
    formats.py
```

You can also set this setting to a list of Python paths, for example:

```
FORMAT_MODULE_PATH = [
    'mysite.formats',
    'some_app.formats',
]
```

When Django searches for a certain format, it will go through all given Python paths until it finds a module that actually defines the given format. This means that formats defined in packages farther up in the list will take precedence over the same formats in packages farther down.

Available formats are:

- DATE_FORMAT
- DATE_INPUT_FORMATS
- DATETIME_FORMAT,
• DATETIME_INPUT_FORMATS
• DECIMAL_SEPARATOR
• FIRST_DAY_OF_WEEK
• MONTH_DAY_FORMAT
• NUMBER_GROUPING
• SHORT_DATE_FORMAT
• SHORT_DATETIME_FORMAT
• THOUSAND_SEPARATOR
• TIME_FORMAT
• TIME_INPUT_FORMATS
• YEAR_MONTH_FORMAT

IGNORABLE_404_URLS

Default: [] (Empty list)

List of compiled regular expression objects describing URLs that should be ignored when reporting HTTP 404 errors via email (see How to manage error reporting). Regular expressions are matched against request's full paths (including query string, if any). Use this if your site does not provide a commonly requested file such as favicon.ico or robots.txt.

This is only used if BrokenLinkEmailsMiddleware is enabled (see Middleware).

INSTALLED_APPS

Default: [] (Empty list)

A list of strings designating all applications that are enabled in this Django installation. Each string should be a dotted Python path to:

• an application configuration class (preferred), or
• a package containing an application.

Learn more about application configurations.

Use the application registry for introspection

Your code should never access INSTALLED_APPS directly. Use django.apps.apps instead.
Application names and labels must be unique in `INSTALLED_APPS`.

Application *names* — the dotted Python path to the application package — must be unique. There is no way to include the same application twice, short of duplicating its code under another name.

Application *labels* — by default the final part of the name — must be unique too. For example, you can’t include both `django.contrib.auth` and `myproject.auth`. However, you can relabel an application with a custom configuration that defines a different *label*.

These rules apply regardless of whether `INSTALLED_APPS` references application configuration classes or application packages.

When several applications provide different versions of the same resource (template, static file, management command, translation), the application listed first in `INSTALLED_APPS` has precedence.

**INTERNAL_IPS**

Default: `[]` (Empty list)

A list of IP addresses, as strings, that:

- Allow the `debug()` context processor to add some variables to the template context.
- Can use the `admindocs bookmarklets` even if not logged in as a staff user.
- Are marked as “internal” (as opposed to “EXTERNAL”) in `AdminEmailHandler` emails.

**LANGUAGE_CODE**

Default: `'en-us'`

A string representing the language code for this installation. This should be in standard language ID format. For example, U.S. English is "en-us". See also the list of language identifiers and Internationalization and localization.

`USE_I18N` must be active for this setting to have any effect.

It serves two purposes:

- If the locale middleware isn’t in use, it decides which translation is served to all users.
- If the locale middleware is active, it provides a fallback language in case the user’s preferred language can’t be determined or is not supported by the website. It also provides the fallback translation when a translation for a given literal doesn’t exist for the user’s preferred language.

See [How Django discovers language preference](#) for more details.
**LANGUAGE_COOKIE_AGE**

Default: *None* (expires at browser close)

The age of the language cookie, in seconds.

**LANGUAGE_COOKIE_DOMAIN**

Default: *None*

The domain to use for the language cookie. Set this to a string such as "example.com" for cross-domain cookies, or use *None* for a standard domain cookie.

Be cautious when updating this setting on a production site. If you update this setting to enable cross-domain cookies on a site that previously used standard domain cookies, existing user cookies that have the old domain will not be updated. This will result in site users being unable to switch the language as long as these cookies persist. The only safe and reliable option to perform the switch is to change the language cookie name permanently (via the `LANGUAGE_COOKIE_NAME` setting) and to add a middleware that copies the value from the old cookie to a new one and then deletes the old one.

**LANGUAGE_COOKIE_HTTPONLY**

Default: *False*

Whether to use HttpOnly flag on the language cookie. If this is set to *True*, client-side JavaScript will not be able to access the language cookie.

See `SESSION_COOKIE_HTTPONLY` for details on HttpOnly.

**LANGUAGE_COOKIE_NAME**

Default: `'django_language'`

The name of the cookie to use for the language cookie. This can be whatever you want (as long as it’s different from the other cookie names in your application). See Internationalization and localization.

**LANGUAGE_COOKIE_PATH**

Default: `'/'`

The path set on the language cookie. This should either match the URL path of your Django installation or be a parent of that path.

This is useful if you have multiple Django instances running under the same hostname. They can use different cookie paths and each instance will only see its own language cookie.
Be cautious when updating this setting on a production site. If you update this setting to use a deeper path than it previously used, existing user cookies that have the old path will not be updated. This will result in site users being unable to switch the language as long as these cookies persist. The only safe and reliable option to perform the switch is to change the language cookie name permanently (via the `LANGUAGE_COOKIE_NAME` setting), and to add a middleware that copies the value from the old cookie to a new one and then deletes the one.

**LANGUAGE_COOKIE_SAMESITE**

Default: None

The value of the SameSite flag on the language cookie. This flag prevents the cookie from being sent in cross-site requests.

See `SESSION_COOKIE_SAMESITE` for details about SameSite.

**LANGUAGE_COOKIE_SECURE**

Default: False

Whether to use a secure cookie for the language cookie. If this is set to True, the cookie will be marked as “secure”, which means browsers may ensure that the cookie is only sent under an HTTPS connection.

**LANGUAGES**

Default: A list of all available languages. This list is continually growing and including a copy here would inevitably become rapidly out of date. You can see the current list of translated languages by looking in `django/conf/global_settings.py`.

The list is a list of two-tuples in the format (language code, language name) – for example, ('ja', 'Japanese'). This specifies which languages are available for language selection. See Internationalization and localization.

Generally, the default value should suffice. Only set this setting if you want to restrict language selection to a subset of the Django-provided languages.

If you define a custom `LANGUAGES` setting, you can mark the language names as translation strings using the `gettext_lazy()` function.

Here’s a sample settings file:

```python
from django.utils.translation import gettext_lazy as _

LANGUAGES = [
    ('de', _('German')),
]  # (continues on next page)
LANGUAGES_BIDI

Default: A list of all language codes that are written right-to-left. You can see the current list of these languages by looking in `django/conf/global_settings.py`.

The list contains language codes for languages that are written right-to-left.

Generally, the default value should suffice. Only set this setting if you want to restrict language selection to a subset of the Django-provided languages. If you define a custom `LANGUAGES` setting, the list of bidirectional languages may contain language codes which are not enabled on a given site.

locale_paths

Default: [] (Empty list)

A list of directories where Django looks for translation files. See How Django discovers translations.

Example:

```python
LOCALE_PATHS = [
    '/home/www/project/common_files/locale',
    '/var/local/translations/locale',
]
```

Django will look within each of these paths for the `<locale_code>/LC_MESSAGES` directories containing the actual translation files.

LOGGING

Default: A logging configuration dictionary.

A data structure containing configuration information. The contents of this data structure will be passed as the argument to the configuration method described in `LOGGING_CONFIG`.

Among other things, the default logging configuration passes HTTP 500 server errors to an email log handler when `DEBUG` is `False`. See also Configuring logging.

You can see the default logging configuration by looking in `django/utils/log.py`.
LOGGING_CONFIG

Default: 'logging.config.dictConfig'

A path to a callable that will be used to configure logging in the Django project. Points at an instance of Python’s dictConfig configuration method by default.

If you set LOGGING_CONFIG to None, the logging configuration process will be skipped.

MANAGERS

Default: [] (Empty list)

A list in the same format as ADMINS that specifies who should get broken link notifications when BrokenLinkEmailsMiddleware is enabled.

MEDIA_ROOT

Default: '' (Empty string)

Absolute filesystem path to the directory that will hold user-uploaded files.

Example: "/var/www/example.com/media/

See also MEDIA_URL.

Warning: MEDIA_ROOT and STATIC_ROOT must have different values. Before STATIC_ROOT was introduced, it was common to rely or fallback on MEDIA_ROOT to also serve static files; however, since this can have serious security implications, there is a validation check to prevent it.

MEDIA_URL

Default: '' (Empty string)

URL that handles the media served from MEDIA_ROOT, used for managing stored files. It must end in a slash if set to a non-empty value. You will need to configure these files to be served in both development and production environments.

If you want to use {{ MEDIA_URL }} in your templates, add 'django.template.context_processors.media' in the 'context_processors' option of TEMPLATES.

Example: "http://media.example.com/"
Warning: There are security risks if you are accepting uploaded content from untrusted users! See the security guide’s topic on User-uploaded content for mitigation details.

Warning: MEDIA_URL and STATIC_URL must have different values. See MEDIA_ROOT for more details.

Note: If MEDIA_URL is a relative path, then it will be prefixed by the server-provided value of SCRIPT_NAME (or / if not set). This makes it easier to serve a Django application in a subpath without adding an extra configuration to the settings.

MIDDLEWARE

Default: None

A list of middleware to use. See Middleware.

MIGRATION_MODULES

Default: {} (Empty dictionary)

A dictionary specifying the package where migration modules can be found on a per-app basis. The default value of this setting is an empty dictionary, but the default package name for migration modules is migrations.

Example:

```python
{
    'blog': 'blog.db_migrations'
}
```

In this case, migrations pertaining to the blog app will be contained in the blog.db_migrations package.

If you provide the app_label argument, makemigrations will automatically create the package if it doesn’t already exist.

When you supply None as a value for an app, Django will consider the app as an app without migrations regardless of an existing migrations submodule. This can be used, for example, in a test settings file to skip migrations while testing (tables will still be created for the apps’ models). To disable migrations for all apps during tests, you can set the MIGRATE to False instead. If MIGRATION_MODULES is used in your general project settings, remember to use the migrate --run-syncdb option if you want to create tables for the app.
MONTH_DAY_FORMAT

Default: 'F j'

The default formatting to use for date fields on Django admin change-list pages—and, possibly, by other parts of the system—in cases when only the month and day are displayed.

For example, when a Django admin change-list page is being filtered by a date drilldown, the header for a given day displays the day and month. Different locales have different formats. For example, U.S. English would say “January 1,” whereas Spanish might say “1 Enero.”

Note that if USE_L10N is set to True, then the corresponding locale-dictated format has higher precedence and will be applied.

See allowed date format strings. See also DATE_FORMAT, DATETIME_FORMAT, TIME_FORMAT and YEAR_MONTH_FORMAT.

NUMBER_GROUPING

Default: 0

Number of digits grouped together on the integer part of a number.

Common use is to display a thousand separator. If this setting is 0, then no grouping will be applied to the number. If this setting is greater than 0, then THOUSAND_SEPARATOR will be used as the separator between those groups.

Some locales use non-uniform digit grouping, e.g. 10,00,00,000 in en_IN. For this case, you can provide a sequence with the number of digit group sizes to be applied. The first number defines the size of the group preceding the decimal delimiter, and each number that follows defines the size of preceding groups. If the sequence is terminated with -1, no further grouping is performed. If the sequence terminates with a 0, the last group size is used for the remainder of the number.

Example tuple for en_IN:

```python
NUMBER_GROUPING = (3, 2, 0)
```

Note that if USE_L10N is set to True, then the locale-dictated format has higher precedence and will be applied instead.

See also DECIMAL_SEPARATOR, THOUSAND_SEPARATOR and USE_THOUSAND_SEPARATOR.
**PREPEND_WWW**

Default: False

Whether to prepend the “www.” subdomain to URLs that don’t have it. This is only used if `CommonMiddleware` is installed (see Middleware). See also `APPEND_SLASH`.

**ROOT_URLCONF**

Default: Not defined

A string representing the full Python import path to your root URLconf, for example "mydjangoapps.urls". Can be overridden on a per-request basis by setting the attribute `urlconf` on the incoming `HttpRequest` object. See How Django processes a request for details.

**SECRET_KEY**

Default: '' (Empty string)

A secret key for a particular Django installation. This is used to provide cryptographic signing, and should be set to a unique, unpredictable value.

django-admin startproject automatically adds a randomly-generated `SECRET_KEY` to each new project.

Uses of the key shouldn’t assume that it’s text or bytes. Every use should go through `force_str()` or `force_bytes()` to convert it to the desired type.

Django will refuse to start if `SECRET_KEY` is not set.

Warning: Keep this value secret.

Running Django with a known `SECRET_KEY` defeats many of Django’s security protections, and can lead to privilege escalation and remote code execution vulnerabilities.

The secret key is used for:

- All sessions if you are using any other session backend than `django.contrib.sessions.backends.cache`, or are using the default `get_session_auth_hash()`.
- All messages if you are using `CookieStorage` or `FallbackStorage`.
- All `PasswordResetView` tokens.
- Any usage of cryptographic signing, unless a different key is provided.

When a secret key is no longer set as `SECRET_KEY` or contained within `SECRET_KEY_FALLBACKS` all of the above will be invalidated. When rotating your secret key, you should move the old key to `SECRET_KEY_FALLBACKS` temporarily. Secret keys are not used for passwords of users and key rotation will not affect them.
Note:  The default `settings.py` file created by `django-admin startproject` creates a unique `SECRET_KEY` for convenience.

**SECRET_KEY_FALLBACKS**

Default:  `[]`

A list of fallback secret keys for a particular Django installation. These are used to allow rotation of the `SECRET_KEY`.

In order to rotate your secret keys, set a new `SECRET_KEY` and move the previous value to the beginning of `SECRET_KEY_FALLBACKS`. Then remove the old values from the end of the `SECRET_KEY_FALLBACKS` when you are ready to expire the sessions, password reset tokens, and so on, that make use of them.

Note:  Signing operations are computationally expensive. Having multiple old key values in `SECRET_KEY_FALLBACKS` adds additional overhead to all checks that don’t match an earlier key.

As such, fallback values should be removed after an appropriate period, allowing for key rotation.

Uses of the secret key values shouldn’t assume that they are text or bytes. Every use should go through `force_str()` or `force_bytes()` to convert it to the desired type.

**SECURE_CONTENT_TYPE_NOSNIFF**

Default:  `True`

If `True`, the `SecurityMiddleware` sets the `X-Content-Type-Options: nosniff` header on all responses that do not already have it.

**SECURE_CROSS_ORIGIN_OPENER_POLICY**

Default:  `'same-origin'`

Unless set to `None`, the `SecurityMiddleware` sets the Cross-Origin Opener Policy header on all responses that do not already have it to the value provided.
SECURE_HSTS_INCLUDE_SUBDOMAINS

Default: False

If True, the SecurityMiddleware adds the includeSubDomains directive to the HTTP Strict Transport Security header. It has no effect unless SECURE_HSTS_SECONDS is set to a non-zero value.

Warning: Setting this incorrectly can irreversibly (for the value of SECURE_HSTS_SECONDS) break your site. Read the HTTP Strict Transport Security documentation first.

SECURE_HSTS_PRELOAD

Default: False

If True, the SecurityMiddleware adds the preload directive to the HTTP Strict Transport Security header. It has no effect unless SECURE_HSTS_SECONDS is set to a non-zero value.

SECURE_HSTS_SECONDS

Default: 0

If set to a non-zero integer value, the SecurityMiddleware sets the HTTP Strict Transport Security header on all responses that do not already have it.

Warning: Setting this incorrectly can irreversibly (for some time) break your site. Read the HTTP Strict Transport Security documentation first.

SECURE_PROXY_SSL_HEADER

Default: None

A tuple representing an HTTP header/value combination that signifies a request is secure. This controls the behavior of the request object’s is_secure() method.

By default, is_secure() determines if a request is secure by confirming that a requested URL uses https://. This method is important for Django’s CSRF protection, and it may be used by your own code or third-party apps.

If your Django app is behind a proxy, though, the proxy may be “swallowing” whether the original request uses HTTPS or not. If there is a non-HTTPS connection between the proxy and Django then is_secure() would always return False - even for requests that were made via HTTPS by the end user. In contrast, if
there is an HTTPS connection between the proxy and Django then *is_secure()* would always return True—even for requests that were made originally via HTTP.

In this situation, configure your proxy to set a custom HTTP header that tells Django whether the request came in via HTTPS, and set `SECURE_PROXY_SSL_HEADER` so that Django knows what header to look for.

Set a tuple with two elements—the name of the header to look for and the required value. For example:

```python
SECURE_PROXY_SSL_HEADER = ('HTTP_X_FORWARDED_PROTO', 'https')
```

This tells Django to trust the `X-Forwarded-Proto` header that comes from our proxy and that the request is guaranteed to be secure (i.e., it originally came in via HTTPS) when:

- the header value is 'https', or
- its initial, leftmost value is 'https' in the case of a comma-separated list of protocols (e.g. 'https, http, http').

Support for a comma-separated list of protocols in the header value was added.

You should only set this setting if you control your proxy or have some other guarantee that it sets/strips this header appropriately.

Note that the header needs to be in the format as used by `request.META`—all caps and likely starting with `HTTP_`. (Remember, Django automatically adds 'HTTP_' to the start of x-header names before making the header available in `request.META`.)

**Warning:** Modifying this setting can compromise your site’s security. Ensure you fully understand your setup before changing it.

Make sure ALL of the following are true before setting this (assuming the values from the example above):

- Your Django app is behind a proxy.
- Your proxy strips the `X-Forwarded-Proto` header from all incoming requests, even when it contains a comma-separated list of protocols. In other words, if end users include that header in their requests, the proxy will discard it.
- Your proxy sets the `X-Forwarded-Proto` header and sends it to Django, but only for requests that originally come in via HTTPS.

If any of those are not true, you should keep this setting set to `None` and find another way of determining HTTPS, perhaps via custom middleware.
SECURE_REDIRECT_EXEMPT

Default: [] (Empty list)

If a URL path matches a regular expression in this list, the request will not be redirected to HTTPS. The SecurityMiddleware strips leading slashes from URL paths, so patterns shouldn’t include them, e.g. SECURE_REDIRECT_EXEMPT = [r'^no-ssl/$', ...]. If SECURE_SSL_REDIRECT is False, this setting has no effect.

SECURE_REFERRER_POLICY

Default: 'same-origin'

If configured, the SecurityMiddleware sets the Referrer Policy header on all responses that do not already have it to the value provided.

SECURE_SSL_HOST

Default: None

If a string (e.g. secure.example.com), all SSL redirects will be directed to this host rather than the originally-requested host (e.g. www.example.com). If SECURE_SSL_REDIRECT is False, this setting has no effect.

SECURE_SSL_REDIRECT

Default: False

If True, the SecurityMiddleware redirects all non-HTTPS requests to HTTPS (except for those URLs matching a regular expression listed in SECURE_REDIRECT_EXEMPT).

Note: If turning this to True causes infinite redirects, it probably means your site is running behind a proxy and can’t tell which requests are secure and which are not. Your proxy likely sets a header to indicate secure requests; you can correct the problem by finding out what that header is and configuring the SECURE_PROXY_SSL_HEADER setting accordingly.
**SERIALIZATION_MODULES**

Default: Not defined

A dictionary of modules containing serializer definitions (provided as strings), keyed by a string identifier for that serialization type. For example, to define a YAML serializer, use:

```
SERIALIZATION_MODULES = {'yaml': 'path.to.yaml_serializer'}
```

**SERVER_EMAIL**

Default: 'root@localhost'

The email address that error messages come from, such as those sent to `ADMINS` and `MANAGERS`.

Why are my emails sent from a different address?

This address is used only for error messages. It is not the address that regular email messages sent with `send_mail()` come from; for that, see `DEFAULT_FROM_EMAIL`.

**SHORT_DATE_FORMAT**

Default: 'm/d/Y' (e.g. 12/31/2003)

An available formatting that can be used for displaying date fields on templates. Note that if `USE_L10N` is set to `True`, then the corresponding locale-dictated format has higher precedence and will be applied. See allowed date format strings.

See also `DATE_FORMAT` and `SHORT_DATETIME_FORMAT`.

**SHORT_DATETIME_FORMAT**

Default: 'm/d/Y P' (e.g. 12/31/2003 4 p.m.)

An available formatting that can be used for displaying datetime fields on templates. Note that if `USE_L10N` is set to `True`, then the corresponding locale-dictated format has higher precedence and will be applied. See allowed date format strings.

See also `DATE_FORMAT` and `SHORT_DATE_FORMAT`.
SIGNING_BACKEND

Default: 'django.core.signing.TimestampSigner'

The backend used for signing cookies and other data.
See also the Cryptographic signing documentation.

SILENCED_SYSTEM_CHECKS

Default: [] (Empty list)

A list of identifiers of messages generated by the system check framework (i.e. ['models.W001']) that you wish to permanently acknowledge and ignore. Silenced checks will not be output to the console.
See also the System check framework documentation.

TEMPLATES

Default: [] (Empty list)

A list containing the settings for all template engines to be used with Django. Each item of the list is a dictionary containing the options for an individual engine.

Here’s a setup that tells the Django template engine to load templates from the templates subdirectory inside each installed application:

```python
TEMPLATES = [
    {
        'BACKEND': 'django.template.backends.django.DjangoTemplates',
        'APP_DIRS': True,
    },
]
```

The following options are available for all backends.

BACKEND

Default: Not defined

The template backend to use. The built-in template backends are:

- 'django.template.backends.django.DjangoTemplates'
- 'django.template.backends.jinja2.Jinja2'

You can use a template backend that doesn’t ship with Django by setting BACKEND to a fully-qualified path (i.e. 'mypackage.whatever.Backend').
NAME

Default: see below

The alias for this particular template engine. It’s an identifier that allows selecting an engine for rendering. Aliases must be unique across all configured template engines.

It defaults to the name of the module defining the engine class, i.e. the next to last piece of `BACKEND`, when it isn’t provided. For example if the backend is `mypackage.whatever.Backend` then its default name is 'whatever'.

DIRS

Default: [] (Empty list)

Directories where the engine should look for template source files, in search order.

APP_DIRS

Default: False

Whether the engine should look for template source files inside installed applications.

Note: The default `settings.py` file created by `django-admin startproject` sets 'APP_DIRS': True.

OPTIONS

Default: {} (Empty dict)

Extra parameters to pass to the template backend. Available parameters vary depending on the template backend. See DjangoTemplates and Jinja2 for the options of the built-in backends.

TEST_RUNNER

Default: 'django.test.runner.DiscoverRunner'

The name of the class to use for starting the test suite. See Using different testing frameworks.
**TEST_NON_SERIALIZED_APPS**

Default: [] (Empty list)

In order to restore the database state between tests for `TransactionTestCases` and database backends without transactions, Django will serialize the contents of all apps when it starts the test run so it can then reload from that copy before running tests that need it.

This slows down the startup time of the test runner; if you have apps that you know don’t need this feature, you can add their full names in here (e.g. 'django.contrib.contenttypes') to exclude them from this serialization process.

**THOUSAND_SEPARATOR**

Default: ',', ' (Comma)

Default thousand separator used when formatting numbers. This setting is used only when `USE_THOUSAND_SEPARATOR` is True and `NUMBER_GROUPING` is greater than 0.

Note that if `USE_L10N` is set to True, then the locale-dictated format has higher precedence and will be applied instead.

See also `NUMBER_GROUPING`, `DECIMAL_SEPARATOR` and `USE_THOUSAND_SEPARATOR`.

**TIME_FORMAT**

Default: 'P' (e.g. 4 p.m.)

The default formatting to use for displaying time fields in any part of the system. Note that if `USE_L10N` is set to True, then the locale-dictated format has higher precedence and will be applied instead. See allowed date format strings.

See also `DATE_FORMAT` and `DATETIME_FORMAT`.

**TIME_INPUT_FORMATS**

Default:

```
[  
    '%H:%M:%S',  # '14:30:59'
    '%H:%M:%S.%f', # '14:30:59.000200'
    '%H:%M',     # '14:30'
]
```

A list of formats that will be accepted when inputting data on a time field. Formats will be tried in order, using the first valid one. Note that these format strings use Python’s datetime module syntax, not the format strings from the date template filter.
When `USE_L10N` is `True`, the locale-dictated format has higher precedence and will be applied instead. See also `DATE_INPUT_FORMATS` and `DATETIME_INPUT_FORMATS`.

**TIME_ZONE**

Default: 'America/Chicago'

A string representing the time zone for this installation. See the list of time zones.

Note: Since Django was first released with the `TIME_ZONE` set to 'America/Chicago', the global setting (used if nothing is defined in your project’s `settings.py`) remains 'America/Chicago' for backwards compatibility. New project templates default to 'UTC'.

Note that this isn’t necessarily the time zone of the server. For example, one server may serve multiple Django-powered sites, each with a separate time zone setting.

When `USE_TZ` is `False`, this is the time zone in which Django will store all datetimes. When `USE_TZ` is `True`, this is the default time zone that Django will use to display datetimes in templates and to interpret datetimes entered in forms.

On Unix environments (where `time.tzset()` is implemented), Django sets the `os.environ['TZ']` variable to the time zone you specify in the `TIME_ZONE` setting. Thus, all your views and models will automatically operate in this time zone. However, Django won’t set the `TZ` environment variable if you’re using the manual configuration option as described in manually configuring settings. If Django doesn’t set the `TZ` environment variable, it’s up to you to ensure your processes are running in the correct environment.

Note: Django cannot reliably use alternate time zones in a Windows environment. If you’re running Django on Windows, `TIME_ZONE` must be set to match the system time zone.

**USE_DEPRECATED_PYTZ**

Default: False

A boolean that specifies whether to use `pytz`, rather than `zoneinfo`, as the default time zone implementation. Deprecated since version 4.0: This transitional setting is deprecated. Support for using `pytz` will be removed in Django 5.0.
USE_I18N
Default: True
A boolean that specifies whether Django’s translation system should be enabled. This provides a way to turn it off, for performance. If this is set to False, Django will make some optimizations so as not to load the translation machinery.

See also LANGUAGE_CODE, USE_L10N and USE_TZ.

Note: The default settings.py file created by django-admin startproject includes USE_I18N = True for convenience.

USE_L10N
Default: True
A boolean that specifies if localized formatting of data will be enabled by default or not. If this is set to True, e.g. Django will display numbers and dates using the format of the current locale.

See also LANGUAGE_CODE, USE_I18N and USE_TZ.

Deprecated since version 4.0: This setting is deprecated. Starting with Django 5.0, localized formatting of data will always be enabled. For example Django will display numbers and dates using the format of the current locale.

USE_THOUSAND_SEPARATOR
Default: False
A boolean that specifies whether to display numbers using a thousand separator. When set to True and USE_L10N is also True, Django will format numbers using the NUMBER_GROUPING and THOUSAND_SEPARATOR settings. These settings may also be dictated by the locale, which takes precedence.

See also DECIMAL_SEPARATOR, NUMBER_GROUPING and THOUSAND_SEPARATOR.

USE_TZ
Default: False

Note: In Django 5.0, the default value will change from False to True.

A boolean that specifies if datetimes will be timezone-aware by default or not. If this is set to True, Django will use timezone-aware datetimes internally.
When `USE_TZ` is False, Django will use naive datetimes in local time, except when parsing ISO 8601 formatted strings, where timezone information will always be retained if present.

See also `TIME_ZONE`, `USE_I18N` and `USE_L10N`.

---

Note: The default `settings.py` file created by `django-admin startproject` includes `USE_TZ = True` for convenience.

---

**USE_X_FORWARDED_HOST**

Default: False

A boolean that specifies whether to use the `X-Forwarded-Host` header in preference to the `Host` header. This should only be enabled if a proxy which sets this header is in use.

This setting takes priority over `USE_X_FORWARDED_PORT`. Per RFC 7239#section-5.3, the `X-Forwarded-Host` header can include the port number, in which case you shouldn’t use `USE_X_FORWARDED_PORT`.

**USE_X_FORWARDED_PORT**

Default: False

A boolean that specifies whether to use the `X-Forwarded-Port` header in preference to the `SERVER_PORT META` variable. This should only be enabled if a proxy which sets this header is in use.

`USE_X_FORWARDED_HOST` takes priority over this setting.

**WSGI_APPLICATION**

Default: None

The full Python path of the WSGI application object that Django’s built-in servers (e.g. `runserver`) will use. The `django-admin startproject` management command will create a standard `wsgi.py` file with an `application` callable in it, and point this setting to that `application`.

If not set, the return value of `django.core.wsgi.get_wsgi_application()` will be used. In this case, the behavior of `runserver` will be identical to previous Django versions.
YEAR_MONTH_FORMAT

Default: 'F Y'

The default formatting to use for date fields on Django admin change-list pages—and, possibly, by other parts of the system—in cases when only the year and month are displayed.

For example, when a Django admin change-list page is being filtered by a date drilldown, the header for a given month displays the month and the year. Different locales have different formats. For example, U.S. English would say “January 2006,” whereas another locale might say “2006/January.”

Note that if USE_L10N is set to True, then the corresponding locale-dictated format has higher precedence and will be applied.

See allowed date format strings. See also DATE_FORMAT, DATETIME_FORMAT, TIME_FORMAT and MONTH_DAY_FORMAT.

X_FRAME_OPTIONS

Default: ‘DENY’

The default value for the X-Frame-Options header used by XFrameOptionsMiddleware. See the clickjacking protection documentation.

6.20.2 Auth

Settings for django.contrib.auth.

AUTHENTICATION_BACKENDS

Default: ['django.contrib.auth.backends.ModelBackend']

A list of authentication backend classes (as strings) to use when attempting to authenticate a user. See the authentication backends documentation for details.

AUTH_USER_MODEL

Default: 'auth.User'

The model to use to represent a User. See Substituting a custom User model.

Warning: You cannot change the AUTH_USER_MODEL setting during the lifetime of a project (i.e. once you have made and migrated models that depend on it) without serious effort. It is intended to be
Set at the project start, and the model it refers to must be available in the first migration of the app that it lives in. See Substituting a custom User model for more details.

**LOGIN_REDIRECT_URL**

Default: '*/accounts/profile/*'

The URL or named URL pattern where requests are redirected after login when the *LoginView* doesn’t get a next GET parameter.

**LOGIN_URL**

Default: '*/accounts/login/*'

The URL or named URL pattern where requests are redirected for login when using the *login_required()* decorator, *LoginRequiredMixin*, or *AccessMixin*.

**LOGOUT_REDIRECT_URL**

Default: None

The URL or named URL pattern where requests are redirected after logout if *LogoutView* doesn’t have a `next_page` attribute.

If None, no redirect will be performed and the logout view will be rendered.

**PASSWORD_RESET_TIMEOUT**

Default: 259200 (3 days, in seconds)

The number of seconds a password reset link is valid for.

Used by the *PasswordResetConfirmView*.

Note: Reducing the value of this timeout doesn’t make any difference to the ability of an attacker to brute-force a password reset token. Tokens are designed to be safe from brute-forcing without any timeout.

This timeout exists to protect against some unlikely attack scenarios, such as someone gaining access to email archives that may contain old, unused password reset tokens.
PASSWORD_HASHERS

See How Django stores passwords.

Default:

```
[
    'django.contrib.auth.hashers.PBKDF2PasswordHasher',
    'django.contrib.auth.hashers.PBKDF2SHA1PasswordHasher',
    'django.contrib.auth.hashers.Argon2PasswordHasher',
    'django.contrib.auth.hashers.BCryptSHA256PasswordHasher',
]
```

AUTH_PASSWORD_VALIDATORS

Default: [] (Empty list)

The list of validators that are used to check the strength of user’s passwords. See Password validation for more details. By default, no validation is performed and all passwords are accepted.

6.20.3 Messages

Settings for django.contrib.messages.

MESSAGE_LEVEL

Default: messages.INFO

Sets the minimum message level that will be recorded by the messages framework. See message levels for more details.

Important

If you override MESSAGE_LEVEL in your settings file and rely on any of the built-in constants, you must import the constants module directly to avoid the potential for circular imports, e.g.:

```
from django.contrib.messages import constants as message_constants
MESSAGE_LEVEL = message_constants.DEBUG
```

If desired, you may specify the numeric values for the constants directly according to the values in the above constants table.
MESSAGE_STORAGE

Default: 'django.contrib.messages.storage.fallback.FallbackStorage'

Controls where Django stores message data. Valid values are:

- 'django.contrib.messages.storage.fallback.FallbackStorage'
- 'django.contrib.messages.storage.session.SessionStorage'
- 'django.contrib.messages.storage.cookie.CookieStorage'

See message storage backends for more details.

The backends that use cookies – CookieStorage and FallbackStorage – use the value of SESSION_COOKIE_DOMAIN, SESSION_COOKIE_SECURE and SESSION_COOKIE_HTTPONLY when setting their cookies.

MESSAGE_TAGS

Default:

```python
{
    messages.DEBUG: 'debug',
    messages.INFO: 'info',
    messages.SUCCESS: 'success',
    messages.WARNING: 'warning',
    messages.ERROR: 'error',
}
```

This sets the mapping of message level to message tag, which is typically rendered as a CSS class in HTML. If you specify a value, it will extend the default. This means you only have to specify those values which you need to override. See Displaying messages above for more details.

---

Important

If you override MESSAGE_TAGS in your settings file and rely on any of the built-in constants, you must import the constants module directly to avoid the potential for circular imports, e.g.:

```python
from django.contrib.messages import constants as message_constants
MESSAGE_TAGS = {message_constants.INFO: ''}
```

If desired, you may specify the numeric values for the constants directly according to the values in the above constants table.
6.20.4 Sessions

Settings for `django.contrib.sessions`.

**SESSION_CACHE_ALIAS**

Default: 'default'

If you’re re using cache-based session storage, this selects the cache to use.

**SESSION_COOKIE_AGE**

Default: 1209600 (2 weeks, in seconds)

The age of session cookies, in seconds.

**SESSION_COOKIE_DOMAIN**

Default: None

The domain to use for session cookies. Set this to a string such as "example.com" for cross-domain cookies, or use None for a standard domain cookie.

To use cross-domain cookies with `CSRF_USE_SESSIONS`, you must include a leading dot (e.g. ".example.com") to accommodate the CSRF middleware’s referer checking.

Be cautious when updating this setting on a production site. If you update this setting to enable cross-domain cookies on a site that previously used standard domain cookies, existing user cookies will be set to the old domain. This may result in them being unable to log in as long as these cookies persist.

This setting also affects cookies set by `django.contrib.messages`.

**SESSION_COOKIE_HTTPONLY**

Default: True

Whether to use HttpOnly flag on the session cookie. If this is set to True, client-side JavaScript will not be able to access the session cookie.

HttpOnly is a flag included in a Set-Cookie HTTP response header. It’s part of the RFC 6265#section-4.1.2.6 standard for cookies and can be a useful way to mitigate the risk of a client-side script accessing the protected cookie data.

This makes it less trivial for an attacker to escalate a cross-site scripting vulnerability into full hijacking of a user’s session. There aren’t many good reasons for turning this off. Your code shouldn’t read session cookies from JavaScript.
**SESSION_COOKIE_NAME**

Default: 'sessionid'

The name of the cookie to use for sessions. This can be whatever you want (as long as it’s different from the other cookie names in your application).

**SESSION_COOKIE_PATH**

Default: '/'

The path set on the session cookie. This should either match the URL path of your Django installation or be parent of that path.

This is useful if you have multiple Django instances running under the same hostname. They can use different cookie paths, and each instance will only see its own session cookie.

**SESSION_COOKIE_SAMESITE**

Default: 'Lax'

The value of the SameSite flag on the session cookie. This flag prevents the cookie from being sent in cross-site requests thus preventing CSRF attacks and making some methods of stealing session cookie impossible.

Possible values for the setting are:

- 'Strict': prevents the cookie from being sent by the browser to the target site in all cross-site browsing context, even when following a regular link.

  For example, for a GitHub-like website this would mean that if a logged-in user follows a link to a private GitHub project posted on a corporate discussion forum or email, GitHub will not receive the session cookie and the user won’t be able to access the project. A bank website, however, most likely doesn’t want to allow any transactional pages to be linked from external sites so the 'Strict' flag would be appropriate.

- 'Lax' (default): provides a balance between security and usability for websites that want to maintain user’s logged-in session after the user arrives from an external link.

  In the GitHub scenario, the session cookie would be allowed when following a regular link from an external website and be blocked in CSRF-prone request methods (e.g. POST).

- 'None' (string): the session cookie will be sent with all same-site and cross-site requests.

- False: disables the flag.

Note: Modern browsers provide a more secure default policy for the SameSite flag and will assume Lax for cookies without an explicit value set.
**SESSION_COOKIE_SECURE**

Default: False

Whether to use a secure cookie for the session cookie. If this is set to True, the cookie will be marked as “secure”, which means browsers may ensure that the cookie is only sent under an HTTPS connection.

Leaving this setting off isn’t a good idea because an attacker could capture an unencrypted session cookie with a packet sniffer and use the cookie to hijack the user’s session.

**SESSION_ENGINE**

Default: 'django.contrib.sessions.backends.db'

Controls where Django stores session data. Included engines are:

- 'django.contrib.sessions.backends.db'
- 'django.contrib.sessions.backends.file'
- 'django.contrib.sessions.backends.cache'
- 'django.contrib.sessions.backends.cached_db'
- 'django.contrib.sessions.backends.signed_cookies'

See Configuring the session engine for more details.

**SESSION_EXPIRE_AT_BROWSER_CLOSE**

Default: False

Whether to expire the session when the user closes their browser. See Browser-length sessions vs. persistent sessions.

**SESSION_FILE_PATH**

Default: None

If you’re using file-based session storage, this sets the directory in which Django will store session data. When the default value (None) is used, Django will use the standard temporary directory for the system.
SESSION_SAVE_EVERY_REQUEST

Default: False

Whether to save the session data on every request. If this is False (default), then the session data will only be saved if it has been modified—that is, if any of its dictionary values have been assigned or deleted. Empty sessions won’t be created, even if this setting is active.

SESSION_SERIALIZER

Default: 'django.contrib.sessions.serializers.JSONSerializer'

Full import path of a serializer class to use for serializing session data. Included serializer is:

- 'django.contrib.sessions.serializers.JSONSerializer'

See Session serialization for details.

6.20.5 Sites

Settings for django.contrib.sites.

SITE_ID

Default: Not defined

The ID, as an integer, of the current site in the django_site database table. This is used so that application data can hook into specific sites and a single database can manage content for multiple sites.

6.20.6 Static Files

Settings for django.contrib.staticfiles.

STATIC_ROOT

Default: None

The absolute path to the directory where collectstatic will collect static files for deployment.

Example: "/var/www/example.com/static/"

If the staticfiles contrib app is enabled (as in the default project template), the collectstatic management command will collect static files into this directory. See the how-to on managing static files for more details about usage.
Warning: This should be an initially empty destination directory for collecting your static files from their permanent locations into one directory for ease of deployment; it is not a place to store your static files permanently. You should do that in directories that will be found by staticfiles’ finders, which by default, are 'static/' app sub-directories and any directories you include in STATICFILES_DIRS.

**STATIC_URL**

Default: None

URL to use when referring to static files located in STATIC_ROOT.

Example: "static/" or "http://static.example.com/

If not None, this will be used as the base path for asset definitions (the Media class) and the staticfiles app. It must end in a slash if set to a non-empty value.

You may need to configure these files to be served in development and will definitely need to do so in production.

Note: If STATIC_URL is a relative path, then it will be prefixed by the server-provided value of SCRIPT_NAME (or / if not set). This makes it easier to serve a Django application in a subpath without adding an extra configuration to the settings.

**STATICFILES_DIRS**

Default: [] (Empty list)

This setting defines the additional locations the staticfiles app will traverse if the FileSystemFinder finder is enabled, e.g. if you use the collectstatic or findstatic management command or use the static file serving view.

This should be set to a list of strings that contain full paths to your additional files directory(ies) e.g.:

```
STATICFILES_DIRS = [
    "/home/special.polls.com/polls/static",
    "/home/polls.com/polls/static",
    "/opt/webfiles/common",
]
```

Note that these paths should use Unix-style forward slashes, even on Windows (e.g. "C:/Users/user/mysite/extra_static_content").
Prefixes (optional)

In case you want to refer to files in one of the locations with an additional namespace, you can optionally provide a prefix as (prefix, path) tuples, e.g.:

```
STATICFILES_DIRS = [
    # ...
    ("downloads", "/opt/webfiles/stats"),
]
```

For example, assuming you have `STATIC_URL` set to 'static/', the `collectstatic` management command would collect the “stats” files in a ‘downloads’ subdirectory of `STATIC_ROOT`.

This would allow you to refer to the local file '/opt/webfiles/stats/polls_20101022.tar.gz' with '/static/downloads/polls_20101022.tar.gz' in your templates, e.g.:

```
<a href="{% static 'downloads/polls_20101022.tar.gz' %}">
```

**STATICFILES_STORAGE**

Default: 'django.contrib.staticfiles.storage.StaticFilesStorage'

The file storage engine to use when collecting static files with the `collectstatic` management command.

A ready-to-use instance of the storage backend defined in this setting can be found at `django.contrib.staticfiles.storage.staticfiles_storage`.

For an example, see Serving static files from a cloud service or CDN.

**STATICFILES_FINDERS**

Default:

```
[
    'django.contrib.staticfiles.finders.FileSystemFinder',
    'django.contrib.staticfiles.finders.AppDirectoriesFinder',
]
```

The list of finder backends that know how to find static files in various locations.

The default will find files stored in the `STATICFILES_DIRS` setting (using `django.contrib.staticfiles.finders.FileSystemFinder`) and in a static subdirectory of each app (using `django.contrib.staticfiles.finders.AppDirectoriesFinder`). If multiple files with the same name are present, the first file that is found will be used.
One finder is disabled by default: `django.contrib.staticfiles.finders.DefaultStorageFinder`. If added to your `STATICFILES_FINDERS` setting, it will look for static files in the default file storage as defined by the `DEFAULT_FILE_STORAGE` setting.

Note: When using the `AppDirectoriesFinder` finder, make sure your apps can be found by staticfiles by adding the app to the `INSTALLED_APPS` setting of your site.

Static file finders are currently considered a private interface, and this interface is thus undocumented.

### 6.20.7 Core Settings Topical Index

**Cache**

6.21 Signals

A list of all the signals that Django sends. All built-in signals are sent using the `send()` method.

See also:

See the documentation on the signal dispatcher for information regarding how to register for and receive signals.

The authentication framework sends signals when a user is logged in / out.
6.21.1 Model signals

The `django.db.models.signals` module defines a set of signals sent by the model system.

Warning: Many of these signals are sent by various model methods like `__init__()` or `save()` that you can override in your own code.

If you override these methods on your model, you must call the parent class’ methods for these signals to be sent.

Note also that Django stores signal handlers as weak references by default, so if your handler is a local function, it may be garbage collected. To prevent this, pass `weak=False` when you call the signal’s `connect()`.

Note: Model signals `sender` model can be lazily referenced when connecting a receiver by specifying its full application label. For example, an `Question` model defined in the `polls` application could be referenced as `polls.Question`. This sort of reference can be quite handy when dealing with circular import dependencies and swappable models.

`pre_init`

django.db.models.signals.pre_init

Whenever you instantiate a Django model, this signal is sent at the beginning of the model’s `__init__()` method.

Arguments sent with this signal:

sender

The model class that just had an instance created.

args

A list of positional arguments passed to `__init__()`.

kwargs

A dictionary of keyword arguments passed to `__init__()`.

For example, the tutorial has this line:

```
q = Question(question_text="What's new?", pub_date=timezone.now())
```

The arguments sent to a `pre_init` handler would be:
### Argument Value

<table>
<thead>
<tr>
<th>Argument</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>sender</td>
<td>Question (the class itself)</td>
</tr>
<tr>
<td>args</td>
<td>[] (an empty list because there were no positional arguments passed to <code>__init__()</code>)</td>
</tr>
<tr>
<td>kwargs</td>
<td>{'question_text': 'What's new?', 'pub_date': <code>datetime.datetime(2012, 2, 26, 13, 0, 0, 775217, tzinfo=&lt;UTC&gt;)</code>}</td>
</tr>
</tbody>
</table>

#### post_init

django.db.models.signals.post_init

Like pre_init, but this one is sent when the `__init__()` method finishes.

Arguments sent with this signal:

- **sender**
  As above: the model class that just had an instance created.

- **instance**
  The actual instance of the model that’s just been created.

---

Note: `instance._state` isn’t set before sending the `post_init` signal, so `_state` attributes always have their default values. For example, `_state.db` is `None`.

---

Warning: For performance reasons, you shouldn’t perform queries in receivers of `pre_init` or `post_init` signals because they would be executed for each instance returned during queryset iteration.

#### pre_save

django.db.models.signals.pre_save

This is sent at the beginning of a model’s `save()` method.

Arguments sent with this signal:

- **sender**
  The model class.

- **instance**
  The actual instance being saved.
**raw**

A boolean; `True` if the model is saved exactly as presented (i.e. when loading a fixture). One should not query/modify other records in the database as the database might not be in a consistent state yet.

**using**

The database alias being used.

**update_fields**

The set of fields to update as passed to `Model.save()`, or `None` if `update_fields` wasn’t passed to `save()`.

**post_save**

django.db.models.signals.post_save

Like `pre_save`, but sent at the end of the `save()` method.

Arguments sent with this signal:

**sender**

The model class.

**instance**

The actual instance being saved.

**created**

A boolean; `True` if a new record was created.

**raw**

A boolean; `True` if the model is saved exactly as presented (i.e. when loading a fixture). One should not query/modify other records in the database as the database might not be in a consistent state yet.

**using**

The database alias being used.

**update_fields**

The set of fields to update as passed to `Model.save()`, or `None` if `update_fields` wasn’t passed to `save()`.

**pre_delete**

django.db.models.signals.pre_delete

Sent at the beginning of a model’s `delete()` method and a queryset’s `delete()` method.

Arguments sent with this signal:

**sender**

The model class.
can write:

```python
instance
    The actual instance being deleted.

using
    The database alias being used.

origin
    The origin of the deletion being the instance of a Model or QuerySet class.

post_delete

django.db.models.signals.post_delete

Like pre_delete, but sent at the end of a model’s delete() method and a queryset’s delete() method.
Arguments sent with this signal:

sender
    The model class.

instance
    The actual instance being deleted.

    Note that the object will no longer be in the database, so be very careful what you do with this instance.

using
    The database alias being used.

origin
    The origin of the deletion being the instance of a Model or QuerySet class.

m2m_changed

django.db.models.signals.m2m_changed

Sent when a ManyToManyField is changed on a model instance. Strictly speaking, this is not a model
signal since it is sent by the ManyToManyField, but since it complements the pre_save/post_save and
pre_delete/post_delete when it comes to tracking changes to models, it is included here.
Arguments sent with this signal:

sender
    The intermediate model class describing the ManyToManyField. This class is automatically created
    when a many-to-many field is defined; you can access it using the through attribute on the many-to-
    many field.

instance
    The instance whose many-to-many relation is updated. This can be an instance of the sender, or of
    the class the ManyToManyField is related to.
action
A string indicating the type of update that is done on the relation. This can be one of the following:

"pre_add"
Sent before one or more objects are added to the relation.

"post_add"
Sent after one or more objects are added to the relation.

"pre_remove"
Sent before one or more objects are removed from the relation.

"post_remove"
Sent after one or more objects are removed from the relation.

"pre_clear"
Sent before the relation is cleared.

"post_clear"
Sent after the relation is cleared.

reverse
Indicates which side of the relation is updated (i.e., if it is the forward or reverse relation that is being modified).

model
The class of the objects that are added to, removed from or cleared from the relation.

pk_set
For the pre_add and post_add actions, this is a set of primary key values that will be, or have been, added to the relation. This may be a subset of the values submitted to be added, since inserts must filter existing values in order to avoid a database IntegrityError.

For the pre_remove and post_remove actions, this is a set of primary key values that was submitted to be removed from the relation. This is not dependent on whether the values actually will be, or have been, removed. In particular, non-existent values may be submitted, and will appear in pk_set, even though they have no effect on the database.

For the pre_clear and post_clear actions, this is None.

using
The database alias being used.

For example, if a Pizza can have multiple Topping objects, modeled like this:

```python
class Topping(models.Model):
    # ...
    pass
```

(continues on next page)
class Pizza(models.Model):
    # ...
    toppings = models.ManyToManyField(Topping)

If we connected a handler like this:

```python
from django.db.models.signals import m2m_changed

def toppings_changed(sender, **kwargs):
    # Do something
    pass

m2m_changed.connect(toppings_changed, sender=Pizza.toppings.through)
```

and then did something like this:

```python
>>> p = Pizza.objects.create(...)
>>> t = Topping.objects.create(...)
>>> p.toppings.add(t)
```

the arguments sent to a `m2m_changed` handler (toppings_changed in the example above) would be:

<table>
<thead>
<tr>
<th>Argument</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>sender</td>
<td>Pizza.toppings.through (the intermediate m2m class)</td>
</tr>
<tr>
<td>instance</td>
<td>p (the Pizza instance being modified)</td>
</tr>
<tr>
<td>action</td>
<td>&quot;pre_add&quot; (followed by a separate signal with &quot;post_add&quot;)</td>
</tr>
<tr>
<td>reverse</td>
<td>False (Pizza contains the ManyToManyField, so this call modifies the forward relation)</td>
</tr>
<tr>
<td>model</td>
<td>Topping (the class of the objects added to the Pizza)</td>
</tr>
<tr>
<td>pk_set</td>
<td>{t.id} (since only Topping t was added to the relation)</td>
</tr>
<tr>
<td>using</td>
<td>&quot;default&quot; (since the default router sends writes here)</td>
</tr>
</tbody>
</table>

And if we would then do something like this:

```python
>>> t.pizza_set.remove(p)
```

the arguments sent to a `m2m_changed` handler would be:
<table>
<thead>
<tr>
<th>Argument</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>sender</td>
<td>Pizza.toppings.through (the intermediate m2m class)</td>
</tr>
<tr>
<td>instance</td>
<td>t (the Topping instance being modified)</td>
</tr>
<tr>
<td>action</td>
<td>&quot;pre_remove&quot; (followed by a separate signal with &quot;post_remove&quot;)</td>
</tr>
<tr>
<td>reverse</td>
<td>True (Pizza contains the ManyToManyField, so this call modifies the reverse relation)</td>
</tr>
<tr>
<td>model</td>
<td>Pizza (the class of the objects removed from the Topping)</td>
</tr>
<tr>
<td>pk_set</td>
<td>{p.id} (since only Pizza p was removed from the relation)</td>
</tr>
<tr>
<td>using</td>
<td>&quot;default&quot; (since the default router sends writes here)</td>
</tr>
</tbody>
</table>

**class_prepared**

django.db.models.signals.class_prepared

Sent whenever a model class has been “prepared” — that is, once model has been defined and registered with Django’s model system. Django uses this signal internally; it’s not generally used in third-party applications.

Since this signal is sent during the app registry population process, and AppConfig.ready() runs after the app registry is fully populated, receivers cannot be connected in that method. One possibility is to connect them AppConfig.__init__() instead, taking care not to import models or trigger calls to the app registry.

Arguments that are sent with this signal:

**sender**

The model class which was just prepared.

### 6.21.2 Management signals

Signals sent by django-admin.

**pre_migrate**

django.db.models.signals.pre_migrate

Sent by the migrate command before it starts to install an application. It’s not emitted for applications that lack a models module.

Arguments sent with this signal:

**sender**

An AppConfig instance for the application about to be migrated/synced.

**app_config**

Same as sender.
verbosity
Indicates how much information manage.py is printing on screen. See the --verbosity flag for details.

Functions which listen for pre_migrate should adjust what they output to the screen based on the value of this argument.

interactive
If interactive is True, it’s safe to prompt the user to input things on the command line. If interactive is False, functions which listen for this signal should not try to prompt for anything.

For example, the django.contrib.auth app only prompts to create a superuser when interactive is True.

stdout
A stream-like object where verbose output should be redirected.

using
The alias of database on which a command will operate.

plan
The migration plan that is going to be used for the migration run. While the plan is not public API, this allows for the rare cases when it is necessary to know the plan. A plan is a list of two-tuples with the first item being the instance of a migration class and the second item showing if the migration was rolled back (True) or applied (False).

apps
An instance of Apps containing the state of the project before the migration run. It should be used instead of the global apps registry to retrieve the models you want to perform operations on.

post_migrate
django.db.models.signals.post_migrate

Sent at the end of the migrate (even if no migrations are run) and flush commands. It’s not emitted for applications that lack a models module.

Handlers of this signal must not perform database schema alterations as doing so may cause the flush command to fail if it runs during the migrate command.

Arguments sent with this signal:

sender
An AppConfig instance for the application that was just installed.

app_config
Same as sender.

verbosity
Indicates how much information manage.py is printing on screen. See the --verbosity flag for details.
Functions which listen for `post_migrate` should adjust what they output to the screen based on the value of this argument.

**interactive**

If `interactive` is True, it’s safe to prompt the user to input things on the command line. If `interactive` is False, functions which listen for this signal should not try to prompt for anything.

For example, the `django.contrib.auth` app only prompts to create a superuser when `interactive` is True.

**stdout**

A stream-like object where verbose output should be redirected.

**using**

The database alias used for synchronization. Defaults to the default database.

**plan**

The migration plan that was used for the migration run. While the plan is not public API, this allows for the rare cases when it is necessary to know the plan. A plan is a list of two-tuples with the first item being the instance of a migration class and the second item showing if the migration was rolled back (True) or applied (False).

**apps**

An instance of `Apps` containing the state of the project after the migration run. It should be used instead of the global `apps` registry to retrieve the models you want to perform operations on.

For example, you could register a callback in an ` AppConfig` like this:

```python
from django.apps import AppConfig
from django.db.models.signals import post_migrate

def my_callback(sender, **kwargs):
    # Your specific logic here
    pass

class MyAppConfig(AppConfig):
    ...

    def ready(self):
        post_migrate.connect(my_callback, sender=self)
```

Note: If you provide an `AppConfig` instance as the sender argument, please ensure that the signal is registered in `ready()`. `AppConfig`s are recreated for tests that run with a modified set of `INSTALLED_APPS` (such as when settings are overridden) and such signals should be connected for each new `AppConfig` instance.
6.21.3 Request/response signals

Signals sent by the core framework when processing a request.

request_started

django.core.signals.request_started

Sent when Django begins processing an HTTP request.
Arguments sent with this signal:

sender
  The handler class — e.g. django.core.handlers.wsgi.WsgiHandler — that handled the request.

environ
  The environ dictionary provided to the request.

request_finished

django.core.signals.request_finished

Sent when Django finishes delivering an HTTP response to the client.
Arguments sent with this signal:

sender
  The handler class, as above.

got_request_exception

django.core.signals.got_request_exception

This signal is sent whenever Django encounters an exception while processing an incoming HTTP request.
Arguments sent with this signal:

sender
  Unused (always None).

request
  The HttpRequest object.
6.21.4 Test signals

Signals only sent when running tests.

setting_changed

django.test.signals.setting_changed

This signal is sent when the value of a setting is changed through the `django.test.TestCase.settings()` context manager or the `django.test.override_settings()` decorator/context manager.

It’s actually sent twice: when the new value is applied (“setup”) and when the original value is restored (“teardown”). Use the `enter` argument to distinguish between the two.

You can also import this signal from `django.core.signals` to avoid importing from `django.test` in non-test situations.

Arguments sent with this signal:

sender
   The settings handler.

setting
   The name of the setting.

value
   The value of the setting after the change. For settings that initially don’t exist, in the “teardown” phase, `value` is `None`.

enter
   A boolean; True if the setting is applied, False if restored.

template_rendered

django.test.signals.template_rendered

Sent when the test system renders a template. This signal is not emitted during normal operation of a Django server—it is only available during testing.

Arguments sent with this signal:

sender
   The `Template` object which was rendered.

template
   Same as sender

context
   The `Context` with which the template was rendered.
6.21.5 Database Wrappers

Signals sent by the database wrapper when a database connection is initiated.

connection_created

django.db.backends.signals.connection_created

Sent when the database wrapper makes the initial connection to the database. This is particularly useful if you’d like to send any post connection commands to the SQL backend.

Arguments sent with this signal:

sender
  The database wrapper class – i.e. django.db.backends.postgresql.DatabaseWrapper or django.db.backends.mysql.DatabaseWrapper, etc.

connection
  The database connection that was opened. This can be used in a multiple-database configuration to differentiate connection signals from different databases.

6.22 Templates

Django’s template engine provides a powerful mini-language for defining the user-facing layer of your application, encouraging a clean separation of application and presentation logic. Templates can be maintained by anyone with an understanding of HTML; no knowledge of Python is required. For introductory material, see Templates topic guide.

6.22.1 The Django template language

This document explains the language syntax of the Django template system. If you’re looking for a more technical perspective on how it works and how to extend it, see The Django template language: for Python programmers.

Django’s template language is designed to strike a balance between power and ease. It’s designed to feel comfortable to those used to working with HTML. If you have any exposure to other text-based template languages, such as Smarty or Jinja2, you should feel right at home with Django’s templates.

Philosophy

If you have a background in programming, or if you’re used to languages which mix programming code directly into HTML, you’ll want to bear in mind that the Django template system is not simply Python
embedded into HTML. This is by design: the template system is meant to express presentation, not program logic.

The Django template system provides tags which function similarly to some programming constructs—an `if` tag for boolean tests, a `for` tag for looping, etc.—but these are not simply executed as the corresponding Python code, and the template system will not execute arbitrary Python expressions. Only the tags, filters and syntax listed below are supported by default (although you can add your own extensions to the template language as needed).

---

**Templates**

A template is a text file. It can generate any text-based format (HTML, XML, CSV, etc.).

A template contains variables, which get replaced with values when the template is evaluated, and tags, which control the logic of the template.

Below is a minimal template that illustrates a few basics. Each element will be explained later in this document.

```python
{% extends "base_generic.html" %}

{% block title %}{{ section.title }}{% endblock %}

{% block content %}
<h1>{{ section.title }}</h1>

{% for story in story_list %}
<h2>
<a href="{{ story.get_absolute_url }}">{{ story.headline|upper }}</a>
</h2>
<p>{{ story.tease|truncatewords:"100" }}</p>
{% endfor %}
{% endblock %}
```

---

**Philosophy**

Why use a text-based template instead of an XML-based one (like Zope’s TAL)? We wanted Django’s template language to be usable for more than just XML/HTML templates. You can use the template language for any text-based format such as emails, JavaScript and CSV.
Variables

Variables look like this: {{ variable }}. When the template engine encounters a variable, it evaluates that variable and replaces it with the result. Variable names consist of any combination of alphanumeric characters and the underscore ("_") but may not start with an underscore, and may not be a number. The dot (".") also appears in variable sections, although that has a special meaning, as indicated below. Importantly, you cannot have spaces or punctuation characters in variable names.

Use a dot (.) to access attributes of a variable.

Behind the scenes

Technically, when the template system encounters a dot, it tries the following lookups, in this order:

- Dictionary lookup
- Attribute or method lookup
- Numeric index lookup

If the resulting value is callable, it is called with no arguments. The result of the call becomes the template value.

This lookup order can cause some unexpected behavior with objects that override dictionary lookup. For example, consider the following code snippet that attempts to loop over a collections.defaultdict:

```{% for k, v in defaultdict.items %}
    Do something with k and v here...
{% endfor %}
```

Because dictionary lookup happens first, that behavior kicks in and provides a default value instead of using the intended .items() method. In this case, consider converting to a dictionary first.

In the above example, {{ section.title }} will be replaced with the title attribute of the section object.

If you use a variable that doesn’t exist, the template system will insert the value of the string_if_invalid option, which is set to '' (the empty string) by default.

Note that “bar” in a template expression like {{ foo.bar }} will be interpreted as a literal string and not using the value of the variable “bar”, if one exists in the template context.

Variable attributes that begin with an underscore may not be accessed as they’re generally considered private.
Filters

You can modify variables for display by using filters.

Filters look like this: `{{ name|lower }}`. This displays the value of the `{{ name }}` variable after being filtered through the `lower` filter, which converts text to lowercase. Use a pipe (`|`) to apply a filter.

Filters can be “chained.” The output of one filter is applied to the next. `{{ text|escape|linebreaks }}` is a common idiom for escaping text contents, then converting line breaks to `<p>` tags.

Some filters take arguments. A filter argument looks like this: `{{ bio|truncatewords:30 }}`. This will display the first 30 words of the `bio` variable.

Filter arguments that contain spaces must be quoted; for example, to join a list with commas and spaces you’d use `{{ list|join:", " }}`.

Django provides about sixty built-in template filters. You can read all about them in the built-in filter reference. To give you a taste of what’s available, here are some of the more commonly used template filters:

- **default**
  If a variable is false or empty, use given default. Otherwise, use the value of the variable. For example:

  ```
  {{ value|default: "nothing" }}
  ```

  If `value` isn’t provided or is empty, the above will display “nothing”.

- **length**
  Returns the length of the value. This works for both strings and lists. For example:

  ```
  {{ value|length }}
  ```

  If `value` is `['a', 'b', 'c', 'd']`, the output will be 4.

- **filesizeformat**
  Formats the value like a “human-readable” file size (i.e. '13 KB', '4.1 MB', '102 bytes', etc.). For example:

  ```
  {{ value|filesizeformat }}
  ```

  If `value` is 123456789, the output would be 117.7 MB.

Again, these are just a few examples; see the built-in filter reference for the complete list.

You can also create your own custom template filters; see How to create custom template tags and filters.

See also:

Django’s admin interface can include a complete reference of all template tags and filters available for a given site. See The Django admin documentation generator.
Tags

Tags look like this: `{% tag %}`). Tags are more complex than variables: Some create text in the output, some control flow by performing loops or logic, and some load external information into the template to be used by later variables.

Some tags require beginning and ending tags (i.e. `{% tag %} ... tag contents ... {% endtag %}`).

Django ships with about two dozen built-in template tags. You can read all about them in the built-in tag reference. To give you a taste of what’s available, here are some of the more commonly used tags:

**for**

Loop over each item in an array. For example, to display a list of athletes provided in `athlete_list`:

```html
<ul>
  {% for athlete in athlete_list %}
    <li>{{ athlete.name }}</li>
  {% endfor %}
</ul>
```

**if**, **elif**, and **else**

Evaluates a variable, and if that variable is “true” the contents of the block are displayed:

```html
{% if athlete_list %}
  Number of athletes: {{ athlete_list|length }}
{% elif athlete_in_locker_room_list %}
  Athletes should be out of the locker room soon!
{% else %}
  No athletes.
{% endif %}
```

In the above, if `athlete_list` is not empty, the number of athletes will be displayed by the `{% athlete_list|length %}` variable. Otherwise, if `athlete_in_locker_room_list` is not empty, the message “Athletes should be out...” will be displayed. If both lists are empty, “No athletes.” will be displayed.

You can also use filters and various operators in the **if** tag:

```html
{% if athlete_list|length > 1 %}
  Team: {% for athlete in athlete_list %} ... {% endfor %}
{% else %}
  Athlete: {{ athlete_list.0.name }}
{% endif %}
```

While the above example works, be aware that most template filters return strings, so mathematical comparisons using filters will generally not work as you expect. `length` is an exception.
**block** and **extends**

Set up **template inheritance** (see below), a powerful way of cutting down on “boilerplate” in templates. Again, the above is only a selection of the whole list; see the built-in tag reference for the complete list. You can also create your own custom template tags; see **How to create custom template tags and filters**.

See also:

Django’s admin interface can include a complete reference of all template tags and filters available for a given site. See **The Django admin documentation generator**.

### Comments

To comment-out part of a line in a template, use the comment syntax: `{# #}`. For example, this template would render as ‘hello’:

```html
{# greeting #}hello
```

A comment can contain any template code, invalid or not. For example:

```html
{# {% if foo %}bar{% else %} #}
```

This syntax can only be used for single-line comments (no newlines are permitted between the `{#` and `#}` delimiters). If you need to comment out a multiline portion of the template, see the **comment** tag.

### Template inheritance

The most powerful—and thus the most complex—part of Django’s template engine is template inheritance. Template inheritance allows you to build a base “skeleton” template that contains all the common elements of your site and defines blocks that child templates can override.

Let’s look at template inheritance by starting with an example:

```html
<!DOCTYPE html>
<html lang="en">
<head>
  <link rel="stylesheet" href="style.css">
  <title>{% block title %}My amazing site{% endblock %}</title>
</head>

<body>
  <div id="sidebar">
    {% block sidebar %}
    <ul>
      (continues on next page)
    </ul>
  </div>
</body>
</html>
```
This template, which we’ll call base.html, defines an HTML skeleton document that you might use for a two-column page. It’s the job of “child” templates to fill the empty blocks with content.

In this example, the block tag defines three blocks that child templates can fill in. All the block tag does is to tell the template engine that a child template may override those portions of the template.

A child template might look like this:

```html
{% extends "base.html" %}

{% block title %}My amazing blog{% endblock %}

{% block content %}
{% for entry in blog_entries %}
  <h2>{{ entry.title }}</h2>
  <p>{{ entry.body }}</p>
{% endfor %}
{% endblock %}
```

The extends tag is the key here. It tells the template engine that this template “extends” another template. When the template system evaluates this template, first it locates the parent—in this case, “base.html”.

At that point, the template engine will notice the three block tags in base.html and replace those blocks with the contents of the child template. Depending on the value of blog_entries, the output might look like:

```html
<!DOCTYPE html>
<html lang="en">
<head>
  <link rel="stylesheet" href="style.css">
  <title>My amazing blog</title>
</head>
```
Note that since the child template didn’t define the `sidebar` block, the value from the parent template is used instead. Content within a `{% block %}` tag in a parent template is always used as a fallback.

You can use as many levels of inheritance as needed. One common way of using inheritance is the following three-level approach:

- Create a `base.html` template that holds the main look-and-feel of your site.

- Create a `base_SECTIONNAME.html` template for each “section” of your site. For example, `base_news.html`, `base_sports.html`. These templates all extend `base.html` and include section-specific styles/design.

- Create individual templates for each type of page, such as a news article or blog entry. These templates extend the appropriate section template.

This approach maximizes code reuse and helps to add items to shared content areas, such as section-wide navigation.

Here are some tips for working with inheritance:

- If you use `{% extends %}` in a template, it must be the first template tag in that template. Template inheritance won’t work, otherwise.

- More `{% block %}` tags in your base templates are better. Remember, child templates don’t have to define all parent blocks, so you can fill in reasonable defaults in a number of blocks, then only define the ones you need later. It’s better to have more hooks than fewer hooks.

- If you find yourself duplicating content in a number of templates, it probably means you should move that content to a `{% block %}` in a parent template.
• If you need to get the content of the block from the parent template, the `{{ block.super }}` variable will do the trick. This is useful if you want to add to the contents of a parent block instead of completely overriding it. Data inserted using `{{ block.super }}` will not be automatically escaped (see the next section), since it was already escaped, if necessary, in the parent template.

• By using the same template name as you are inheriting from, `{% extends %}` can be used to inherit a template at the same time as overriding it. Combined with `{{ block.super }}`, this can be a powerful way to make small customizations. See Extending an overridden template in the Overriding templates How-to for a full example.

• Variables created outside of a `{% block %}` using the template tag as syntax can’t be used inside the block. For example, this template doesn’t render anything:

```html
{% translate "Title" as title %}
{% block content %}{{ title }}{% endblock %}
```

• For extra readability, you can optionally give a name to your `{% endblock %}` tag. For example:

```html
{% block content %}
...
{% endblock content %}
```

In larger templates, this technique helps you see which `{% block %}` tags are being closed.

Finally, note that you can’t define multiple `block` tags with the same name in the same template. This limitation exists because a block tag works in “both” directions. That is, a block tag doesn’t just provide a hole to fill—it also defines the content that fills the hole in the parent. If there were two similarly-named `block` tags in a template, that template’s parent wouldn’t know which one of the blocks’ content to use.

Automatic HTML escaping

When generating HTML from templates, there’s always a risk that a variable will include characters that affect the resulting HTML. For example, consider this template fragment:

```
Hello, {{ name }}
```

At first, this seems like a harmless way to display a user’s name, but consider what would happen if the user entered their name as this:

```
<script>alert('hello')</script>
```

With this name value, the template would be rendered as:

```
Hello, <script>alert('hello')</script>
```

…which means the browser would pop-up a JavaScript alert box!
Django Documentation, Release 4.2.dev20220706084552

Similarly, what if the name contained a '<' symbol, like this?
<b>username

That would result in a rendered template like this:
Hello, <b>username

. . .which, in turn, would result in the remainder of the web page being in bold!
Clearly, user-submitted data shouldn’t be trusted blindly and inserted directly into your web pages, because
a malicious user could use this kind of hole to do potentially bad things. This type of security exploit is called
a Cross Site Scripting (XSS) attack.
To avoid this problem, you have two options:
• One, you can make sure to run each untrusted variable through the escape filter (documented below),
which converts potentially harmful HTML characters to unharmful ones. This was the default solution
in Django for its first few years, but the problem is that it puts the onus on you, the developer / template
author, to ensure you’re escaping everything. It’s easy to forget to escape data.
• Two, you can take advantage of Django’s automatic HTML escaping. The remainder of this section
describes how auto-escaping works.
By default in Django, every template automatically escapes the output of every variable tag. Specifically,
these five characters are escaped:
• < is converted to &lt;
• > is converted to &gt;
• ' (single quote) is converted to &#x27;
• " (double quote) is converted to &quot;
• & is converted to &amp;
Again, we stress that this behavior is on by default. If you’re using Django’s template system, you’re
protected.
How to turn it off
If you don’t want data to be auto-escaped, on a per-site, per-template level or per-variable level, you can
turn it off in several ways.
Why would you want to turn it off? Because sometimes, template variables contain data that you intend to
be rendered as raw HTML, in which case you don’t want their contents to be escaped. For example, you
might store a blob of HTML in your database and want to embed that directly into your template. Or, you
might be using Django’s template system to produce text that is not HTML –like an email message, for
instance.
6.22. Templates

1879


For individual variables

To disable auto-escaping for an individual variable, use the `safe` filter:

<table>
<thead>
<tr>
<th>This will be escaped:  <code>{{ data }}</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>This will not be escaped:  `{{ data</td>
</tr>
</tbody>
</table>

Think of `safe` as shorthand for safe from further escaping or can be safely interpreted as HTML. In this example, if `data` contains `<b>`, the output will be:

<table>
<thead>
<tr>
<th>This will be escaped:  <code>&amp;lt;b&amp;gt;</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>This will not be escaped:  <code>&lt;b&gt;</code></td>
</tr>
</tbody>
</table>

For template blocks

To control auto-escaping for a template, wrap the template (or a particular section of the template) in the `autoescape` tag, like so:

```html
{% autoescape off %}
    Hello {{ name }}
{% endautoescape %}
```

The `autoescape` tag takes either `on` or `off` as its argument. At times, you might want to force auto-escaping when it would otherwise be disabled. Here is an example template:

Auto-escaping is on by default. Hello {{ name }}

```html
{% autoescape off %}
    This will not be auto-escaped:  `{{ data }}`.  

    Nor this:  `{{ other_data }}
    {% autoescape on %}
    Auto-escaping applies again:  `{{ name }}`
    {% endautoescape %}
    {% endautoescape %}
```

The auto-escaping tag passes its effect onto templates that extend the current one as well as templates included via the `include` tag, just like all block tags. For example:

Listing 14: base.html

```html
{% autoescape off %}
<h1>{% block title %}{% endblock %}</h1>
{% block content %}
```

(continues on next page)
Because auto-escaping is turned off in the base template, it will also be turned off in the child template, resulting in the following rendered HTML when the `greeting` variable contains the string `<b>Hello!</b>`:

```
<h1>This &amp; that</h1>
<b>Hello!</b>
```

### Notes

Generally, template authors don’t need to worry about auto-escaping very much. Developers on the Python side (people writing views and custom filters) need to think about the cases in which data shouldn’t be escaped, and mark data appropriately, so things Just Work in the template.

If you’re creating a template that might be used in situations where you’re not sure whether auto-escaping is enabled, then add an `escape` filter to any variable that needs escaping. When auto-escaping is on, there’s no danger of the `escape` filter double-escaping data—the `escape` filter does not affect auto-escaped variables.

### String literals and automatic escaping

As we mentioned earlier, filter arguments can be strings:

```
{{ data|default:"This is a string literal." }}
```

All string literals are inserted without any automatic escaping into the template—they act as if they were all passed through the `safe` filter. The reasoning behind this is that the template author is in control of what goes into the string literal, so they can make sure the text is correctly escaped when the template is written.

This means you would write

```
{{ data|default:"3 &lt; 2" }}
```

...rather than:

```
{{ data|default:"3 < 2" }}  #{ Bad! Don't do this. #}
```
This doesn’t affect what happens to data coming from the variable itself. The variable’s contents are still automatically escaped, if necessary, because they’re beyond the control of the template author.

**Accessing method calls**

Most method calls attached to objects are also available from within templates. This means that templates have access to much more than just class attributes (like field names) and variables passed in from views. For example, the Django ORM provides the “entry_set” syntax for finding a collection of objects related on a foreign key. Therefore, given a model called “comment” with a foreign key relationship to a model called “task” you can loop through all comments attached to a given task like this:

```python
{% for comment in task.comment_set.all %}
    {{ comment }}
{% endfor %}
```

Similarly, QuerySets provide a `count()` method to count the number of objects they contain. Therefore, you can obtain a count of all comments related to the current task with:

```python
{{ task.comment_set.all.count }}
```

You can also access methods you’ve explicitly defined on your own models:

**Listing 16: models.py**

```python

class Task(models.Model):
    def foo(self):
        return "bar"
```
Because Django intentionally limits the amount of logic processing available in the template language, it is not possible to pass arguments to method calls accessed from within templates. Data should be calculated in views, then passed to templates for display.

Custom tag and filter libraries

Certain applications provide custom tag and filter libraries. To access them in a template, ensure the application is in `INSTALLED_APPS` (we’d add `'django.contrib.humanize'` for this example), and then use the `load` tag in a template:

```django
{% load humanize %}

{{ 45000|intcomma }}
```

In the above, the `load` tag loads the `humanize` tag library, which then makes the `intcomma` filter available for use. If you’ve enabled `django.contrib.admindocs`, you can consult the documentation area in your admin to find the list of custom libraries in your installation.

The `load` tag can take multiple library names, separated by spaces. Example:

```django
{% load humanize i18n %}

{{ 45000|intcomma }}
```

See How to create custom template tags and filters for information on writing your own custom template libraries.

Custom libraries and template inheritance

When you load a custom tag or filter library, the tags/filters are only made available to the current template—not any parent or child templates along the template-inheritance path.

For example, if a template `foo.html` has `{% load humanize %}`, a child template (e.g., one that has `{% extends "foo.html" %}`) will not have access to the humanize template tags and filters. The child template is responsible for its own `{% load humanize %}`.

This is a feature for the sake of maintainability and sanity.

The Templates Reference

Covers built-in tags, built-in filters, using an alternative template language, and more.
6.22.2 Built-in template tags and filters

This document describes Django’s built-in template tags and filters. It is recommended that you use the automatic documentation, if available, as this will also include documentation for any custom tags or filters installed.

Built-in tag reference

**autoescape**

Controls the current auto-escaping behavior. This tag takes either `on` or `off` as an argument and that determines whether auto-escaping is in effect inside the block. The block is closed with an `endautoescape` ending tag.

When auto-escaping is in effect, all variable content has HTML escaping applied to it before placing the result into the output (but after any filters have been applied). This is equivalent to manually applying the `escape` filter to each variable.

The only exceptions are variables that are already marked as “safe” from escaping, either by the code that populated the variable, or because it has had the `safe` or `escape` filters applied.

Sample usage:

```html
{% autoescape on %}
    {{ body }}
{% endautoescape %}
```

**block**

Defines a block that can be overridden by child templates. See Template inheritance for more information.

**comment**

Ignores everything between `{% comment %}` and `{% endcomment %}`. An optional note may be inserted in the first tag. For example, this is useful when commenting out code for documenting why the code was disabled.

Sample usage:

```html
<p>Rendered text with {{ pub_date|date:"c" }}</p>
{% comment "Optional note" %}
    <p>Commented out text with {{ create_date|date:"c" }}</p>
{% endcomment %}
```

*comment* tags cannot be nested.
csrf_token

This tag is used for CSRF protection, as described in the documentation for Cross Site Request Forgeries.

cycle

Produces one of its arguments each time this tag is encountered. The first argument is produced on the first encounter, the second argument on the second encounter, and so forth. Once all arguments are exhausted, the tag cycles to the first argument and produces it again.

This tag is particularly useful in a loop:

```plaintext
{% for o in some_list %}
  <tr class="{% cycle 'row1' 'row2' %}">
    ...
  </tr>
{% endfor %}
```

The first iteration produces HTML that refers to class row1, the second to row2, the third to row1 again, and so on for each iteration of the loop.

You can use variables, too. For example, if you have two template variables, rowvalue1 and rowvalue2, you can alternate between their values like this:

```plaintext
{% for o in some_list %}
  <tr class="{% cycle rowvalue1 rowvalue2 %}">
    ...
  </tr>
{% endfor %}
```

Variables included in the cycle will be escaped. You can disable auto-escaping with:

```plaintext
{% for o in some_list %}
  <tr class="{% autoescape off %}{% cycle rowvalue1 rowvalue2 %}{% endautoescape %}">
    ...
  </tr>
{% endfor %}
```

You can mix variables and strings:

```plaintext
{% for o in some_list %}
  <tr class="{% cycle 'row1' rowvalue2 'row3' %}">
    ...
  </tr>
{% endfor %}
```
In some cases you might want to refer to the current value of a cycle without advancing to the next value. To do this, give the {% cycle %} tag a name, using “as”, like this:

```plaintext
{% cycle 'row1' 'row2' as rowcolors %}
```

From then on, you can insert the current value of the cycle wherever you’d like in your template by referencing the cycle name as a context variable. If you want to move the cycle to the next value independently of the original cycle tag, you can use another cycle tag and specify the name of the variable. So, the following template:

```html
<tr>
  <td class="{% cycle 'row1' 'row2' as rowcolors %}">...<td>
  <td class="{{ rowcolors }}">...</td>
</tr>
<tr>
  <td class="{% cycle rowcolors %}">...<td>
  <td class="{{ rowcolors }}">...</td>
</tr>
```

would output:

```html
<tr>
  <td class="row1">...<td>
  <td class="row1">...</td>
</tr>
<tr>
  <td class="row2">...<td>
  <td class="row2">...</td>
</tr>
```

You can use any number of values in a cycle tag, separated by spaces. Values enclosed in single quotes (‘) or double quotes (“) are treated as string literals, while values without quotes are treated as template variables.

By default, when you use the as keyword with the cycle tag, the usage of {% cycle %} that initiates the cycle will itself produce the first value in the cycle. This could be a problem if you want to use the value in a nested loop or an included template. If you only want to declare the cycle but not produce the first value, you can add a silent keyword as the last keyword in the tag. For example:

```plaintext
{% for obj in some_list %}
  {% cycle 'row1' 'row2' as rowcolors silent %}
  <tr class="{{ rowcolors }}">{% include "subtemplate.html" %}</tr>
{% endfor %}
```

This will output a list of <tr> elements with class alternating between row1 and row2. The subtemplate will have access to rowcolors in its context and the value will match the class of the <tr> that encloses it. If
the `silent` keyword were to be omitted, `row1` and `row2` would be emitted as normal text, outside the `<tr>`
element.

When the silent keyword is used on a cycle definition, the silence automatically applies to all subsequent uses
of that specific cycle tag. The following template would output nothing, even though the second call to `{%
cycle %}` doesn’t specify `silent`:

```
{% cycle 'row1' 'row2' as rowcolors silent %}
{% cycle rowcolors %}
```

You can use the `resetcycle` tag to make a `{% cycle %}` tag restart from its first value when it’s next
encountered.

**debug**

Outputs a whole load of debugging information, including the current context and imported modules. `{%
debug %}` outputs nothing when the `DEBUG` setting is `False`.

In older versions, debugging information was displayed when the `DEBUG` setting was `False`.

**extends**

Signals that this template extends a parent template.

This tag can be used in two ways:

- `{% extends "base.html" %}` (with quotes) uses the literal value "base.html" as the name of the par-
  ent template to extend.

- `{% extends variable %}` uses the value of `variable`. If the variable evaluates to a string, Django
  will use that string as the name of the parent template. If the variable evaluates to a `Template` object,
  Django will use that object as the parent template.

See [Template inheritance](#) for more information.

Normally the template name is relative to the template loader’s root directory. A string argument may also
be a relative path starting with `. /` or `../`. For example, assume the following directory structure:

```
dir1/
    template.html
    base2.html
    my/
        base3.html
base1.html
```

In `template.html`, the following paths would be valid:
filter

Filters the contents of the block through one or more filters. Multiple filters can be specified with pipes and filters can have arguments, just as in variable syntax.

Note that the block includes all the text between the `filter` and `endfilter` tags.

Sample usage:

```
{% filter force_escape|lower %}
  This text will be HTML-escaped, and will appear in all lowercase.
{% endfilter %}
```

Note: The `escape` and `safe` filters are not acceptable arguments. Instead, use the `autoescape` tag to manage autoescaping for blocks of template code.

firstof

Outputs the first argument variable that is not “false” (i.e. exists, is not empty, is not a false boolean value, and is not a zero numeric value). Outputs nothing if all the passed variables are “false”.

Sample usage:

```
{% firstof var1 var2 var3 %}
```

This is equivalent to:

```
{% if var1 %}
  {{ var1 }}
{% elif var2 %}
  {{ var2 }}
{% elif var3 %}
  {{ var3 }}
{% endif %}
```

You can also use a literal string as a fallback value in case all passed variables are False:
This tag auto-escapes variable values. You can disable auto-escaping with:

```{% autoescape off %}
   {% firstof var1 var2 var3 "<strong>fallback value</strong>" %}
{% endautoescape %}
```

Or if only some variables should be escaped, you can use:

```{% firstof var1 var2|safe var3 "<strong>fallback value</strong>|safe %}
```

You can use the syntax `{% firstof var1 var2 var3 as value %}` to store the output inside a variable.

### for

Loops over each item in an array, making the item available in a context variable. For example, to display a list of athletes provided in `athlete_list`:

```
<ul>
   {% for athlete in athlete_list %}
      <li>{{ athlete.name }}</li>
   {% endfor %}
</ul>
```

You can loop over a list in reverse by using `{% for obj in list reversed %}`.

If you need to loop over a list of lists, you can unpack the values in each sublist into individual variables. For example, if your context contains a list of (x,y) coordinates called `points`, you could use the following to output the list of points:

```{% for x, y in points %}
   There is a point at {{ x }},{{ y }}
{% endfor %}
```

This can also be useful if you need to access the items in a dictionary. For example, if your context contained a dictionary `data`, the following would display the keys and values of the dictionary:

```{% for key, value in data.items %}
   {{ key }}: {{ value }}
{% endfor %}
```

Keep in mind that for the dot operator, dictionary key lookup takes precedence over method lookup. Therefore if the `data` dictionary contains a key named `items`, `data.items` will return `data['items']` instead.
of `data.items()`. Avoid adding keys that are named like dictionary methods if you want to use those methods in a template (items, values, keys, etc.). Read more about the lookup order of the dot operator in the documentation of template variables.

The for loop sets a number of variables available within the loop:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>forloop.counter</td>
<td>The current iteration of the loop (1-indexed)</td>
</tr>
<tr>
<td>forloop.counter0</td>
<td>The current iteration of the loop (0-indexed)</td>
</tr>
<tr>
<td>forloop.revcounter</td>
<td>The number of iterations from the end of the loop (1-indexed)</td>
</tr>
<tr>
<td>forloop.revcounter0</td>
<td>The number of iterations from the end of the loop (0-indexed)</td>
</tr>
<tr>
<td>forloop.first</td>
<td>True if this is the first time through the loop</td>
</tr>
<tr>
<td>forloop.last</td>
<td>True if this is the last time through the loop</td>
</tr>
<tr>
<td>forloop.parentloop</td>
<td>For nested loops, this is the loop surrounding the current one</td>
</tr>
</tbody>
</table>

for ... empty

The for tag can take an optional `{% empty %}` clause whose text is displayed if the given array is empty or could not be found:

```html
<ul>
{% for athlete in athlete_list %}
  <li>{{ athlete.name }}</li>
{% empty %}
  <li>Sorry, no athletes in this list.</li>
{% endif %}
{% endfor %}
</ul>
```

The above is equivalent to—but shorter, cleaner, and possibly faster than—the following:

```html
<ul>
{% if athlete_list %}
  {% for athlete in athlete_list %}
    <li>{{ athlete.name }}</li>
  {% endfor %}
{% else %}
  <li>Sorry, no athletes in this list.</li>
{% endif %}
</ul>
```
The {% if %} tag evaluates a variable, and if that variable is “true” (i.e. exists, is not empty, and is not a false boolean value) the contents of the block are output:

```html
{% if athlete_list %}
    Number of athletes: {{ athlete_list|length }}
{% elif athlete_in_locker_room_list %}
    Athletes should be out of the locker room soon!
{% else %}
    No athletes.
{% endif %}
```

In the above, if `athlete_list` is not empty, the number of athletes will be displayed by the `{{ athlete_list|length }}` variable.

As you can see, the if tag may take one or several {% elif %} clauses, as well as an {% else %} clause that will be displayed if all previous conditions fail. These clauses are optional.

**Boolean operators**

If tags may use and, or or not to test a number of variables or to negate a given variable:

```html
{% if athlete_list and coach_list %}
    Both athletes and coaches are available.
{% endif %}

{% if not athlete_list %}
    There are no athletes.
{% endif %}

{% if athlete_list or coach_list %}
    There are some athletes or some coaches.
{% endif %}

{% if not athlete_list or coach_list %}
    There are no athletes or there are some coaches.
{% endif %}

{% if athlete_list and not coach_list %}
    There are some athletes and absolutely no coaches.
{% endif %}
```

Use of both and and or clauses within the same tag is allowed, with and having higher precedence than or e.g.:
{% if athlete_list and coach_list or cheerleader_list %}

will be interpreted like:

if (athlete_list and coach_list) or cheerleader_list

Use of actual parentheses in the if tag is invalid syntax. If you need them to indicate precedence, you should use nested if tags.

if tags may also use the operators ==, !=, <, >, <=, >=, in, not in, is, and is not which work as follows:

== operator

Equality. Example:

{% if somevar == "x" %}
   This appears if variable somevar equals the string "x"
{% endif %}

!= operator

Inequality. Example:

{% if somevar != "x" %}
   This appears if variable somevar does not equal the string "x",
   or if somevar is not found in the context
{% endif %}

< operator

Less than. Example:

{% if somevar < 100 %}
   This appears if variable somevar is less than 100.
{% endif %}
> **operator**

Greater than. Example:

```html
{% if somevar > 0 %}
    This appears if variable somevar is greater than 0.
{% endif %}
```

<= **operator**

Less than or equal to. Example:

```html
{% if somevar <= 100 %}
    This appears if variable somevar is less than 100 or equal to 100.
{% endif %}
```

>= **operator**

Greater than or equal to. Example:

```html
{% if somevar >= 1 %}
    This appears if variable somevar is greater than 1 or equal to 1.
{% endif %}
```

**in operator**

Contained within. This operator is supported by many Python containers to test whether the given value is in the container. The following are some examples of how \( x \ in \ y \) will be interpreted:

```html
{% if "bc" in "abcdef" %}
    This appears since "bc" is a substring of "abcdef"
{% endif %}

{% if "hello" in greetings %}
    If greetings is a list or set, one element of which is the string "hello", this will appear.
{% endif %}

{% if user in users %}
    If users is a QuerySet, this will appear if user is an instance that belongs to the QuerySet.
{% endif %}
```
**not in operator**

Not contained within. This is the negation of the `in` operator.

**is operator**

Object identity. Tests if two values are the same object. Example:

```html
{% if somevar is True %}
    This appears if and only if somevar is True.
{% endif %}

{% if somevar is None %}
    This appears if somevar is None, or if somevar is not found in the context.
{% endif %}
```

**is not operator**

Negated object identity. Tests if two values are not the same object. This is the negation of the `is` operator. Example:

```html
{% if somevar is not True %}
    This appears if somevar is not True, or if somevar is not found in the context.
{% endif %}

{% if somevar is not None %}
    This appears if and only if somevar is not None.
{% endif %}
```

**Filters**

You can also use filters in the `if` expression. For example:

```html
{% if messages|length >= 100 %}
    You have lots of messages today!
{% endif %}
```
Complex expressions

All of the above can be combined to form complex expressions. For such expressions, it can be important to know how the operators are grouped when the expression is evaluated - that is, the precedence rules. The precedence of the operators, from lowest to highest, is as follows:

- or
- and
- not
- in
- ==, !=, <, >, <=, >=

(This follows Python exactly). So, for example, the following complex if tag:

```python
{% if a == b or c == d and e %}
```

...will be interpreted as:

```
(a == b) or ((c == d) and e)
```

If you need different precedence, you will need to use nested if tags. Sometimes that is better for clarity anyway, for the sake of those who do not know the precedence rules.

The comparison operators cannot be ‘chained’ like in Python or in mathematical notation. For example, instead of using:

```python
{% if a > b > c %} (WRONG)
```

you should use:

```python
{% if a > b and b > c %}
```

ifchanged

Check if a value has changed from the last iteration of a loop.

The {% ifchanged %} block tag is used within a loop. It has two possible uses.

1. Checks its own rendered contents against its previous state and only displays the content if it has changed. For example, this displays a list of days, only displaying the month if it changes:

```html
<h1>Archive for {{ year }}</h1>

{% for date in days %}
```

(continues on next page)
2. If given one or more variables, check whether any variable has changed. For example, the following shows the date every time it changes, while showing the hour if either the hour or the date has changed:

```
{% for date in days %}
  {% ifchanged date.date %}
    {{ date.date }}
  {% endifchanged %}
  {% ifchanged date.hour %}
    {{ date.hour }}
  {% endifchanged %}
{% endfor %}
```

The `ifchanged` tag can also take an optional `{% else %}` clause that will be displayed if the value has not changed:

```
{% for match in matches %}
  <div style="background-color:"
    {% ifchanged match.ballot_id %}
      cycle "red" "blue"
    {% else %}
      gray
    {% endifchanged %}
  ">
    {{ match }}
  </div>
{% endfor %}
```

`include`

Loads a template and renders it with the current context. This is a way of “including” other templates within a template.

The template name can either be a variable or a hard-coded (quoted) string, in either single or double quotes. This example includes the contents of the template "foo/bar.html":

```
{% include "foo/bar.html" %}
```

Normally the template name is relative to the template loader’s root directory. A string argument may also be a relative path starting with ./ or ../ as described in the `extends` tag.

This example includes the contents of the template whose name is contained in the variable `template_name`: 
The variable may also be any object with a `render()` method that accepts a context. This allows you to reference a compiled Template in your context.

Additionally, the variable may be an iterable of template names, in which case the first that can be loaded will be used, as per `select_template()`.

An included template is rendered within the context of the template that includes it. This example produces the output "Hello, John!":

- Context: variable `person` is set to "John" and variable `greeting` is set to "Hello".

- Template:

```
{% include "name_snippet.html" %}
```

- The `name_snippet.html` template:

```
{{ greeting }}, {{ person|default:"friend" }}!
```

You can pass additional context to the template using keyword arguments:

```
{% include "name_snippet.html" with person="Jane" greeting="Hello" %}
```

If you want to render the context only with the variables provided (or even no variables at all), use the `only` option. No other variables are available to the included template:

```
{% include "name_snippet.html" with greeting="Hi" only %}
```

Note: The `include` tag should be considered as an implementation of "render this subtemplate and include the HTML", not as "parse this subtemplate and include its contents as if it were part of the parent". This means that there is no shared state between included templates – each include is a completely independent rendering process.

Blocks are evaluated before they are included. This means that a template that includes blocks from another will contain blocks that have already been evaluated and rendered - not blocks that can be overridden by, for example, an extending template.
load

 Loads a custom template tag set.

 For example, the following template would load all the tags and filters registered in `somelibrary` and `otherlibrary` located in package `package`:

```latex
{% load somelibrary package.otherlibrary %}
```

You can also selectively load individual filters or tags from a library, using the `from` argument. In this example, the template tags/filters named `foo` and `bar` will be loaded from `somelibrary`:

```latex
{% load foo bar from somelibrary %}
```

See [Custom tag and filter libraries](#) for more information.

lorem

 Displays random “lorem ipsum” Latin text. This is useful for providing sample data in templates.

Usage:

```latex
{% lorem [count] [method] [random] %}
```

The `{% lorem %}` tag can be used with zero, one, two or three arguments. The arguments are:

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>count</td>
<td>A number (or variable) containing the number of paragraphs or words to generate (default is 1).</td>
</tr>
<tr>
<td>method</td>
<td>Either w for words, p for HTML paragraphs or b for plain-text paragraph blocks (default is b).</td>
</tr>
<tr>
<td>random</td>
<td>The word random, which if given, does not use the common paragraph (“Lorem ipsum dolor sit amet...”) when generating text.</td>
</tr>
</tbody>
</table>

Examples:

- `{% lorem %}` will output the common “lorem ipsum” paragraph.
- `{% lorem 3 p %}` will output the common “lorem ipsum” paragraph and two random paragraphs each wrapped in HTML `<p>` tags.
- `{% lorem 2 w random %}` will output two random Latin words.
now

Displays the current date and/or time, using a format according to the given string. Such string can contain format specifiers characters as described in the `date` filter section.

Example:

```
It is {% now "jS F Y H:i" %}
```

Note that you can backslash-escape a format string if you want to use the “raw” value. In this example, both “\o” and “\f” are backslash-escaped, because otherwise each is a format string that displays the year and the time, respectively:

```
It is the {% now "jS \o\f F" %}
```

This would display as “It is the 4th of September”.

Note: The format passed can also be one of the predefined ones `DATE_FORMAT`, `DATETIME_FORMAT`, `SHORT_DATE_FORMAT` or `SHORT_DATETIME_FORMAT`. The predefined formats may vary depending on the current locale and if `Format localization` is enabled, e.g.:

```
It is {% now "SHORT_DATETIME_FORMAT" %}
```

You can also use the syntax `{% now "Y" as current_year %}` to store the output (as a string) inside a variable. This is useful if you want to use `{% now %}` inside a template tag like `blocktranslate` for example:

```
{% now "Y" as current_year %}
{% blocktranslate %}Copyright {{ current_year }}{% endblocktranslate %}
```

regroup

Regroups a list of alike objects by a common attribute.

This complex tag is best illustrated by way of an example: say that `cities` is a list of cities represented by dictionaries containing "name", "population", and "country" keys:

```python
cities = [
    {'name': 'Mumbai', 'population': '19,000,000', 'country': 'India'},
    {'name': 'Calcutta', 'population': '15,000,000', 'country': 'India'},
    {'name': 'New York', 'population': '20,000,000', 'country': 'USA'},
    {'name': 'Chicago', 'population': '7,000,000', 'country': 'USA'},
    {'name': 'Tokyo', 'population': '33,000,000', 'country': 'Japan'},
]
```
...and you’d like to display a hierarchical list that is ordered by country, like this:

- India
  - Mumbai: 19,000,000
  - Calcutta: 15,000,000
- USA
  - New York: 20,000,000
  - Chicago: 7,000,000
- Japan
  - Tokyo: 33,000,000

You can use the `{% regroup %}` tag to group the list of cities by country. The following snippet of template code would accomplish this:

```html
{% regroup cities by country as country_list %}

<ul>
{% for country in country_list %}
  <li>{{ country.grouper }}</li>
  <ul>
    {% for city in country.list %}
    <li>{{ city.name }}: {{ city.population }}</li>
    {% endfor %}
  </ul>
{% endfor %}
</ul>
```

Let’s walk through this example. `{% regroup %}` takes three arguments: the list you want to regroup, the attribute to group by, and the name of the resulting list. Here, we’re regrouping the `cities` list by the `country` attribute and calling the result `country_list`.

 `{% regroup %}` produces a list (in this case, `country_list`) of group objects. Group objects are instances of `namedtuple()` with two fields:

- `grouper` – the item that was grouped by (e.g., the string “India” or “Japan”).
- `list` – a list of all items in this group (e.g., a list of all cities with `country='India'`).

Because `{% regroup %}` produces `namedtuple()` objects, you can also write the previous example as:
Note that `{% regroup %}` does not order its input! Our example relies on the fact that the `cities` list was ordered by `country` in the first place. If the `cities` list did not order its members by `country`, the regrouping would naively display more than one group for a single country. For example, say the `cities` list was set to this (note that the countries are not grouped together):

```python
cities = [
    {'name': 'Mumbai', 'population': '19,000,000', 'country': 'India'},
    {'name': 'New York', 'population': '20,000,000', 'country': 'USA'},
    {'name': 'Calcutta', 'population': '15,000,000', 'country': 'India'},
    {'name': 'Chicago', 'population': '7,000,000', 'country': 'USA'},
    {'name': 'Tokyo', 'population': '33,000,000', 'country': 'Japan'},
]
```

With this input for `cities`, the example `{% regroup %}` template code above would result in the following output:

- India
  - Mumbai: 19,000,000
- USA
  - New York: 20,000,000
- India
  - Calcutta: 15,000,000
- USA
  - Chicago: 7,000,000
- Japan
  - Tokyo: 33,000,000

The easiest solution to this gotcha is to make sure in your view code that the data is ordered according to how you want to display it.
Another solution is to sort the data in the template using the `dictsort` filter, if your data is in a list of dictionaries:

```
{% regroup cities|dictsort:"country" by country as country_list %}
```

### Grouping on other properties

Any valid template lookup is a legal grouping attribute for the `regroup` tag, including methods, attributes, dictionary keys and list items. For example, if the “country” field is a foreign key to a class with an attribute “description,” you could use:

```
{% regroup cities by country.description as country_list %}
```

Or, if `country` is a field with choices, it will have a `get_FOO_display()` method available as an attribute, allowing you to group on the display string rather than the choices key:

```
{% regroup cities by get_country_display as country_list %}
```

```
{{ country.grouper }}
```

will now display the value fields from the choices set rather than the keys.

#### resetcycle

Resets a previous `cycle` so that it restarts from its first item at its next encounter. Without arguments, `{% resetcycle %}` will reset the last `{% cycle %}` defined in the template.

Example usage:

```
{% for coach in coach_list %}
  <h1>{{ coach.name }}</h1>
  {% for athlete in coach.athlete_set.all %}
    <p class="{% cycle 'odd' 'even' %}">{{ athlete.name }}</p>
  {% endfor %}
{% endfor %}
{% resetcycle %}
{% endfor %}
```

This example would return this HTML:

```
<h1>José Mourinho</h1>
<p class="odd">Thibaut Courtois</p>
<p class="even">John Terry</p>
<p class="odd">Eden Hazard</p>
<h1>Carlo Ancelotti</h1>
```

(continues on next page)
Notice how the first block ends with class="odd" and the new one starts with class="odd". Without the {%- resetcycle %} tag, the second block would start with class="even".

You can also reset named cycle tags:

{% for item in list %}
  <p class="{% cycle 'odd' 'even' as stripe %} {% cycle 'major' 'minor' 'minor' 'minor' 'minor' as tick %}">
    {{ item.data }}
  </p>
{% ifchanged item.category %}
  <h1>{{ item.category }}</h1>
{% endifchanged %}
{% endfor %}

In this example, we have both the alternating odd/even rows and a “major” row every fifth row. Only the five-row cycle is reset when a category changes.

**spaceless**

Removes whitespace between HTML tags. This includes tab characters and newlines.

Example usage:

{% spaceless %}
  <p>
    <a href="foo">Foo</a>
  </p>
{% endspaceless %}

This example would return this HTML:

<p><a href="foo">Foo</a></p>

Only space between tags is removed—not space between tags and text. In this example, the space around Hello won’t be stripped:

{% spaceless %}
  <strong>
    Hello
  </strong>
{% endspaceless %}
templatetag

Outputs one of the syntax characters used to compose template tags.

The template system has no concept of “escaping” individual characters. However, you can use the `{% templatetag %}` tag to display one of the template tag character combinations.

The argument tells which template bit to output:

<table>
<thead>
<tr>
<th>Argument</th>
<th>Outputs</th>
</tr>
</thead>
<tbody>
<tr>
<td>openblock</td>
<td><code>{%</code></td>
</tr>
<tr>
<td>closeblock</td>
<td><code>%}</code></td>
</tr>
<tr>
<td>openvariable</td>
<td><code>{{</code></td>
</tr>
<tr>
<td>closevariable</td>
<td><code>}}</code></td>
</tr>
<tr>
<td>openbrace</td>
<td><code>{</code></td>
</tr>
<tr>
<td>closebrace</td>
<td><code>}</code></td>
</tr>
<tr>
<td>opencomment</td>
<td><code>#</code></td>
</tr>
<tr>
<td>closecomment</td>
<td><code>#}</code></td>
</tr>
</tbody>
</table>

Sample usage:

The `{% templatetag openblock %}` characters open a block.

See also the `verbatim` tag for another way of including these characters.

url

Returns an absolute path reference (a URL without the domain name) matching a given view and optional parameters. Any special characters in the resulting path will be encoded using `iri_to_uri()`.

This is a way to output links without violating the DRY principle by having to hard-code URLs in your templates:

```
{% url 'some-url-name' v1 v2 %}
```

The first argument is a URL pattern name. It can be a quoted literal or any other context variable. Additional arguments are optional and should be space-separated values that will be used as arguments in the URL. The example above shows passing positional arguments. Alternatively you may use keyword syntax:
Do not mix both positional and keyword syntax in a single call. All arguments required by the URLconf should be present.

For example, suppose you have a view, `app_views.client`, whose URLconf takes a client ID (here, `client()` is a method inside the views file `app_views.py`). The URLconf line might look like this:

```python
path('client/<int:id>/', app_views.client, name='app-views-client')
```

If this app’s URLconf is included into the project’s URLconf under a path such as this:

```python
path('clients/', include('project_name.app_name.urls'))
```

...then, in a template, you can create a link to this view like this:

```html
{% url 'app-views-client' client.id %}
```

The template tag will output the string `/clients/client/123/`.

Note that if the URL you’re reversing doesn’t exist, you’ll get an `NoReverseMatch` exception raised, which will cause your site to display an error page.

If you’d like to retrieve a URL without displaying it, you can use a slightly different call:

```html
{% url 'some-url-name' arg arg2 as the_url %}

<a href="{{ the_url }}">I'm linking to {{ the_url }}</a>
```

The scope of the variable created by the `as var` syntax is the `{% block %}` in which the `{% url %}` tag appears.

This `{% url ... as var %}` syntax will not cause an error if the view is missing. In practice you’ll use this to link to views that are optional:

```html
{% url 'some-url-name' as the_url %}
{% if the_url %}
  <a href="{{ the_url }}">Link to optional stuff</a>
{% endif %}
```

If you’d like to retrieve a namespaced URL, specify the fully qualified name:

```html
{% url 'myapp:view-name' %}
```

This will follow the normal namespaced URL resolution strategy, including using any hints provided by the context as to the current application.
Warning: Don’t forget to put quotes around the URL pattern name, otherwise the value will be interpreted as a context variable!

verbatim

Stops the template engine from rendering the contents of this block tag.

A common use is to allow a JavaScript template layer that collides with Django’s syntax. For example:

```latex
{% verbatim %}
  {if dying}Still alive.{/if}
{% endverbatim %}
```

You can also designate a specific closing tag, allowing the use of `{% endverbatim %}` as part of the unrendered contents:

```latex
{% verbatim myblock %}
  Avoid template rendering via the {% verbatim %}{% endverbatim %} block.
{% endverbatim myblock %}
```

widthratio

For creating bar charts and such, this tag calculates the ratio of a given value to a maximum value, and then applies that ratio to a constant.

For example:

```html
<img src="bar.png" alt="Bar"
     height="10" width="{% widthratio this_value max_value max_width %}">
```

If `this_value` is 175, `max_value` is 200, and `max_width` is 100, the image in the above example will be 88 pixels wide (because 175/200 = .875; .875 * 100 = 87.5 which is rounded up to 88).

In some cases you might want to capture the result of `widthratio` in a variable. It can be useful, for instance, in a `blocktranslate` like this:

```latex
{% widthratio this_value max_value max_width as width %}
{% blocktranslate %}The width is: {{ width }}{% endblocktranslate %}
```
with

Caches a complex variable under a simpler name. This is useful when accessing an “expensive” method (e.g., one that hits the database) multiple times.

For example:

```{%
with total=business.employees.count 
  {{ total }} employee{{ total|pluralize }}
%

The populated variable (in the example above, total) is only available between the {% with %} and {% endwith %} tags.

You can assign more than one context variable:

```{%
with alpha=1 beta=2 
...
%

Note: The previous more verbose format is still supported: {% with business.employees.count as total %}

Built-in filter reference

add

Adds the argument to the value.

For example:

```{{ value|add:"2" }}```

If value is 4, then the output will be 6.

This filter will first try to coerce both values to integers. If this fails, it’ll attempt to add the values together anyway. This will work on some data types (strings, list, etc.) and fail on others. If it fails, the result will be an empty string.

For example, if we have:

```{{ first|add:second }}```

and first is [1, 2, 3] and second is [4, 5, 6], then the output will be [1, 2, 3, 4, 5, 6].
Warning: Strings that can be coerced to integers will be summed, not concatenated, as in the first example above.

**addslashes**

Adds slashes before quotes. Useful for escaping strings in CSV, for example.

For example:

```python
{{ value|addslashes }}
```

If `value` is "I'm using Django", the output will be "I\'m using Django".

**capfirst**

Capitalizes the first character of the value. If the first character is not a letter, this filter has no effect.

For example:

```python
{{ value|capfirst }}
```

If `value` is "django", the output will be "Django".

**center**

Centers the value in a field of a given width.

For example:

```python
"{{ value|center:15" }}"
```

If `value` is "Django", the output will be " Django ".

**cut**

Removes all values of arg from the given string.

For example:

```python
{{ value|cut:" " }}
```

If `value` is "String with spaces", the output will be "Stringwithspaces".
**date**

Formats a date according to the given format.

Uses a similar format to PHP’s `date()` function with some differences.

---

**Note:** These format characters are not used in Django outside of templates. They were designed to be compatible with PHP to ease transitioning for designers.

Available format strings:

<table>
<thead>
<tr>
<th>Format character</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Day</strong></td>
<td></td>
</tr>
<tr>
<td>d</td>
<td>Day of the month, 2 digits with leading zeros.</td>
</tr>
<tr>
<td>j</td>
<td>Day of the month without leading zeros.</td>
</tr>
<tr>
<td>D</td>
<td>Day of the week, textual, 3 letters.</td>
</tr>
<tr>
<td>l</td>
<td>Day of the week, textual, long.</td>
</tr>
<tr>
<td>S</td>
<td>English ordinal suffix for day of the month, 2 characters.</td>
</tr>
<tr>
<td>w</td>
<td>Day of the week, digits without leading zeros.</td>
</tr>
<tr>
<td>z</td>
<td>Day of the year.</td>
</tr>
<tr>
<td><strong>Week</strong></td>
<td></td>
</tr>
<tr>
<td>W</td>
<td>ISO-8601 week number of year, with weeks starting on Monday.</td>
</tr>
<tr>
<td><strong>Month</strong></td>
<td></td>
</tr>
<tr>
<td>m</td>
<td>Month, 2 digits with leading zeros.</td>
</tr>
<tr>
<td>n</td>
<td>Month without leading zeros.</td>
</tr>
<tr>
<td>M</td>
<td>Month, textual, 3 letters.</td>
</tr>
<tr>
<td>b</td>
<td>Month, textual, 3 letters, lowercase.</td>
</tr>
<tr>
<td>E</td>
<td>Month, locale specific alternative representation usually used for long date representation.</td>
</tr>
<tr>
<td>F</td>
<td>Month, textual, long.</td>
</tr>
<tr>
<td>N</td>
<td>Month abbreviation in Associated Press style. Proprietary extension.</td>
</tr>
<tr>
<td>t</td>
<td>Number of days in the given month.</td>
</tr>
<tr>
<td><strong>Year</strong></td>
<td></td>
</tr>
<tr>
<td>y</td>
<td>Year, 2 digits with leading zeros.</td>
</tr>
<tr>
<td>Y</td>
<td>Year, 4 digits with leading zeros.</td>
</tr>
<tr>
<td>L</td>
<td>Boolean for whether it’s a leap year.</td>
</tr>
<tr>
<td>o</td>
<td>ISO-8601 week-numbering year, corresponding to the ISO-8601 week number (W) which uses leap weeks.</td>
</tr>
<tr>
<td><strong>Time</strong></td>
<td></td>
</tr>
<tr>
<td>g</td>
<td>Hour, 12-hour format without leading zeros.</td>
</tr>
<tr>
<td>G</td>
<td>Hour, 24-hour format without leading zeros.</td>
</tr>
</tbody>
</table>
Table 4 – continued from previous page

<table>
<thead>
<tr>
<th>Format character</th>
<th>Description</th>
<th>Example output</th>
</tr>
</thead>
<tbody>
<tr>
<td>h</td>
<td>Hour, 12-hour format.</td>
<td>'01' to '12'</td>
</tr>
<tr>
<td>H</td>
<td>Hour, 24-hour format.</td>
<td>'00' to '23'</td>
</tr>
<tr>
<td>i</td>
<td>Minutes</td>
<td>'00' to '59'</td>
</tr>
<tr>
<td>s</td>
<td>Seconds, 2 digits with leading zeros.</td>
<td>'00' to '59'</td>
</tr>
<tr>
<td>u</td>
<td>Microseconds</td>
<td>000000 to 999999</td>
</tr>
<tr>
<td>a</td>
<td>'a.m.' or 'p.m.' (Note that this is slightly different than PHP’s output, because this includes periods to match Associated Press style.)</td>
<td>'a.m.'</td>
</tr>
<tr>
<td>A</td>
<td>'AM' or 'PM'.</td>
<td>'AM'</td>
</tr>
<tr>
<td>f</td>
<td>Time, in 12-hour hours and minutes, with minutes left off if they’re zero. Proprietary extension.</td>
<td>'1', '1:30'</td>
</tr>
<tr>
<td>P</td>
<td>Time, in 12-hour hours, minutes and ‘a.m.’ / ‘p.m.’, with minutes left off if they’re zero and the special-casestrings midnight and noon if appropriate. Proprietary extension.</td>
<td>'1 a.m.', '1:30 p.m.', 'midnight', 'noon', '12:30 p.m.'</td>
</tr>
<tr>
<td>e</td>
<td>Timezonename. Could be in any format, or might return an empty string, depending on the datetime.</td>
<td>''</td>
</tr>
<tr>
<td>I</td>
<td>Daylight saving time, whether it’s in effect or not.</td>
<td>' 1' or ' 0'</td>
</tr>
<tr>
<td>D</td>
<td>Difference to Greenwich time in hours.</td>
<td></td>
</tr>
<tr>
<td>T</td>
<td>Time zone of this machine.</td>
<td></td>
</tr>
<tr>
<td>Z</td>
<td>Time zone offset in seconds. The offset for timezones west of UTC is always negative, and for those east of UTC is always positive.</td>
<td>-43200 to 43200</td>
</tr>
</tbody>
</table>

Date/Time

| c                | ISO 8601 format. (Note: unlike other formatters, such as “Z”, “O” or “r”, the “c” formatter will add timezone offset if value is a naive datetime (see datetime.tzinfo).) | 2008-01-02T10:30:00.000123+02:00, or 2008-01-02T10:30:00.000123 if the datetime is naive |
| r                | RFC 5322 formatted date.               | 'Thu, 21 Dec 2000 16:01:07 +0200' |
| U                | Seconds since the Unix Epoch (January 1 1970 00:00:00 UTC). |                |

For example:

```{value|date:"D d M Y"}
```

If `value` is a `datetime` object (e.g., the result of `datetime.datetime.now()`), the output will be the string 'Wed 09 Jan 2008'.

The format passed can be one of the predefined ones `DATE_FORMAT`, `DATETIME_FORMAT`, `SHORT_DATE_FORMAT` or `SHORT_DATETIME_FORMAT`, or a custom format that uses the format specifiers shown in the table above. Note that predefined formats may vary depending on the current locale.

Assuming that `USE_L10N` is `True` and `LANGUAGE_CODE` is, for example, "es", then for:

```{value|date:"SHORT_DATE_FORMAT"}
```

the output would be the string "09/01/2008" (the "SHORT_DATE_FORMAT" format specifier for the es locale as shipped with Django is "d/m/Y").

When used without a format string, the `DATE_FORMAT` format specifier is used. Assuming the same settings as the previous example:
{{ value|date }}

outputs 9 de Enero de 2008 (the DATE_FORMAT format specifier for the es locale is r"j \d\e F \d\e Y"). Both “d” and “e” are backslash-escaped, because otherwise each is a format string that displays the day and the timezone name, respectively.

You can combine date with the time filter to render a full representation of a datetime value. E.g.:

{{ value|date:"D d M Y" }} {{ value|time:"H:i" }}

default

If value evaluates to False, uses the given default. Otherwise, uses the value.

For example:

{{ value|default:"nothing" }}

If value is "" (the empty string), the output will be nothing.

default_if_none

If (and only if) value is None, uses the given default. Otherwise, uses the value.

Note that if an empty string is given, the default value will not be used. Use the default filter if you want to fallback for empty strings.

For example:

{{ value|default_if_none:"nothing" }}

If value is None, the output will be nothing.

dictsort

Takes a list of dictionaries and returns that list sorted by the key given in the argument.

For example:

{{ value|dictsort:"name" }}

If value is:
then the output would be:

```python
[
    {'name': 'amy', 'age': 22},
    {'name': 'joe', 'age': 31},
    {'name': 'zed', 'age': 19},
]
You can also do more complicated things like:

```{% for book in books%}
    * {{ book.title }} ({{ book.author.name }})
{% endfor %}
```

If `books` is:

```python
[
    {'title': '1984', 'author': {'name': 'George', 'age': 45}},
    {'title': 'Timequake', 'author': {'name': 'Kurt', 'age': 75}},
    {'title': 'Alice', 'author': {'name': 'Lewis', 'age': 33}},
]
then the output would be:

* Alice (Lewis)
* 1984 (George)
* Timequake (Kurt)

dictsort can also order a list of lists (or any other object implementing `__getitem__()`) by elements at specified index. For example:

```python
{{ value|dictsort:0 }}
```

If `value` is:

```python
[('a', '42'),
 ('c', 'string'),
(continues on next page)
Django Documentation, Release 4.2.dev20220706084552

(continued from previous page)

('b', 'foo'),
]

then the output would be:
[
('a', '42'),
('b', 'foo'),
('c', 'string'),
]

You must pass the index as an integer rather than a string. The following produce empty output:
{{ values|dictsort:"0" }}

Ordering by elements at specified index is not supported on dictionaries.
In older versions, ordering elements at specified index was supported on dictionaries.
dictsortreversed
Takes a list of dictionaries and returns that list sorted in reverse order by the key given in the argument. This
works exactly the same as the above filter, but the returned value will be in reverse order.
divisibleby
Returns True if the value is divisible by the argument.
For example:
{{ value|divisibleby:"3" }}

If value is 21, the output would be True.
escape
Escapes a string’s HTML. Specifically, it makes these replacements:
• < is converted to &lt;
• > is converted to &gt;
• ' (single quote) is converted to &#x27;
• " (double quote) is converted to &quot;

6.22. Templates

1913


• & is converted to &amp;

Applying escape to a variable that would normally have auto-escaping applied to the result will only result in one round of escaping being done. So it is safe to use this function even in auto-escaping environments. If you want multiple escaping passes to be applied, use the force_escape filter.

For example, you can apply escape to fields when autoescape is off:

```django
{% autoescape off %}
  {{ title|escape }}
{% endautoescape %}
```

**escapejs**

Escapes characters for use in JavaScript strings. This does not make the string safe for use in HTML or JavaScript template literals, but does protect you from syntax errors when using templates to generate JavaScript/JSON.

For example:

```django
{{ value|escapejs }}
```

If value is "testing\n\njavascript 'string" <b>escaping</b>", the output will be "testing\n\njavascript "testing\n\n'javascript 'string" <b>escaping</b>".

**filesizeformat**

Formats the value like a ‘human-readable’ file size (i.e. '13 KB', '4.1 MB', '102 bytes', etc.).

For example:

```django
{{ value|filesizeformat }}
```

If value is 123456789, the output would be 117.7 MB.

File sizes and SI units

Strictly speaking, filesizeformat does not conform to the International System of Units which recommends using KiB, MiB, GiB, etc. when byte sizes are calculated in powers of 1024 (which is the case here). Instead, Django uses traditional unit names (KB, MB, GB, etc.) corresponding to names that are more commonly used.
first

Returns the first item in a list.
For example:

```template
{{ value|first }}
```

If `value` is the list `['a', 'b', 'c']`, the output will be `'a'`.

floatformat

When used without an argument, rounds a floating-point number to one decimal place—but only if there’s a decimal part to be displayed. For example:

<table>
<thead>
<tr>
<th>value</th>
<th>Template</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>34.23234</td>
<td>{{ value</td>
<td>floatformat }}</td>
</tr>
<tr>
<td>34.00000</td>
<td>{{ value</td>
<td>floatformat }}</td>
</tr>
<tr>
<td>34.26000</td>
<td>{{ value</td>
<td>floatformat }}</td>
</tr>
</tbody>
</table>

If used with a numeric integer argument, `floatformat` rounds a number to that many decimal places. For example:

<table>
<thead>
<tr>
<th>value</th>
<th>Template</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>34.23234</td>
<td>{{ value</td>
<td>floatformat:3 }}</td>
</tr>
<tr>
<td>34.00000</td>
<td>{{ value</td>
<td>floatformat:3 }}</td>
</tr>
<tr>
<td>34.26000</td>
<td>{{ value</td>
<td>floatformat:3 }}</td>
</tr>
</tbody>
</table>

Particularly useful is passing 0 (zero) as the argument which will round the float to the nearest integer.

<table>
<thead>
<tr>
<th>value</th>
<th>Template</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>34.23234</td>
<td>{{ value</td>
<td>floatformat:&quot;0&quot; }}</td>
</tr>
<tr>
<td>34.00000</td>
<td>{{ value</td>
<td>floatformat:&quot;0&quot; }}</td>
</tr>
<tr>
<td>39.56000</td>
<td>{{ value</td>
<td>floatformat:&quot;0&quot; }}</td>
</tr>
</tbody>
</table>

If the argument passed to `floatformat` is negative, it will round a number to that many decimal places—but only if there’s a decimal part to be displayed. For example:

<table>
<thead>
<tr>
<th>value</th>
<th>Template</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>34.23234</td>
<td>{{ value</td>
<td>floatformat:&quot;-3&quot; }}</td>
</tr>
<tr>
<td>34.00000</td>
<td>{{ value</td>
<td>floatformat:&quot;-3&quot; }}</td>
</tr>
<tr>
<td>34.26000</td>
<td>{{ value</td>
<td>floatformat:&quot;-3&quot; }}</td>
</tr>
</tbody>
</table>
If the argument passed to `floatformat` has the `g` suffix, it will force grouping by the `THOUSAND_SEPARATOR` for the active locale. For example, when the active locale is `en` (English):

<table>
<thead>
<tr>
<th>value</th>
<th>Template</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>34232.34</td>
<td>{{ value</td>
<td>floatformat:&quot;2g&quot; }}</td>
</tr>
<tr>
<td>34232.06</td>
<td>{{ value</td>
<td>floatformat:&quot;g&quot; }}</td>
</tr>
<tr>
<td>34232.00</td>
<td>{{ value</td>
<td>floatformat:&quot;-3g&quot; }}</td>
</tr>
</tbody>
</table>

Output is always localized (independently of the `{% localize off %}` tag) unless the argument passed to `floatformat` has the `u` suffix, which will force disabling localization. For example, when the active locale is `pl` (Polish):

<table>
<thead>
<tr>
<th>value</th>
<th>Template</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>34.23234</td>
<td>{{ value</td>
<td>floatformat:&quot;3&quot; }}</td>
</tr>
<tr>
<td>34.23234</td>
<td>{{ value</td>
<td>floatformat:&quot;3u&quot; }}</td>
</tr>
</tbody>
</table>

Using `floatformat` with no argument is equivalent to using `floatformat` with an argument of `-1`.

**force_escape**

Applies HTML escaping to a string (see the `escape` filter for details). This filter is applied immediately and returns a new, escaped string. This is useful in the rare cases where you need multiple escaping or want to apply other filters to the escaped results. Normally, you want to use the `escape` filter.

For example, if you want to catch the `<p>` HTML elements created by the `linebreaks` filter:

```
{% autoescape off %}
    {{ body|linebreaks|force_escape }}
{% endautoescape %}
```

**get_digit**

Given a whole number, returns the requested digit, where 1 is the right-most digit, 2 is the second-right-most digit, etc. Returns the original value for invalid input (if input or argument is not an integer, or if argument is less than 1). Otherwise, output is always an integer.

For example:

```
{{ value|get_digit:"2" }}
```

If `value` is 123456789, the output will be 8.
**iriencode**

Converts an IRI (Internationalized Resource Identifier) to a string that is suitable for including in a URL. This is necessary if you’re trying to use strings containing non-ASCII characters in a URL. It’s safe to use this filter on a string that has already gone through the *urlencode* filter.

For example:

```html
{{ value|iriencode }}
```

If `value` is "?test=1&amp;me=2", the output will be "?test=1&amp;me=2".

**join**

Joins a list with a string, like Python’s `str.join(list)`

For example:

```html
{{ value|join: " // " }}
```

If `value` is the list `['a', 'b', 'c']`, the output will be the string "a // b // c".

**json_script**

Safely outputs a Python object as JSON, wrapped in a `<script>` tag, ready for use with JavaScript.

Argument: The optional HTML “id” of the `<script>` tag.

For example:

```html
{{ value|json_script:"hello-data" }}
```

If `value` is the dictionary `{'hello': 'world'}`, the output will be:

```html
<script id="hello-data" type="application/json">"hello": "world"</script>
```

The resulting data can be accessed in JavaScript like this:

```javascript
const value = JSON.parse(document.getElementById('hello-data').textContent);
```

XSS attacks are mitigated by escaping the characters “<”, “>” and “&”. For example if `value` is `{'hello': 'world</script>&amp;'}`, the output is:

```html
<script id="hello-data" type="application/json">"hello": "world\u003C/script\u003E\u0026amp;"
</script>
```
This is compatible with a strict Content Security Policy that prohibits in-page script execution. It also maintains a clean separation between passive data and executable code.

In older versions, the HTML “id” was a required argument.

**last**

Returns the last item in a list.

For example:

```template
{{ value|last }}
```

If `value` is the list ['a', 'b', 'c', 'd'], the output will be the string "d".

**length**

Returns the length of the value. This works for both strings and lists.

For example:

```template
{{ value|length }}
```

If `value` is ['a', 'b', 'c', 'd'] or "abcd", the output will be 4.

The filter returns 0 for an undefined variable.

**length_is**

Returns True if the value’s length is the argument, or False otherwise.

For example:

```template
{{ value|length_is:"4" }}
```

If `value` is ['a', 'b', 'c', 'd'] or "abcd", the output will be True.

**linebreaks**

Replaces line breaks in plain text with appropriate HTML; a single newline becomes an HTML line break (<br>) and a new line followed by a blank line becomes a paragraph break (<p>).

For example:
If `value` is `Joel\nis a slug`, the output will be `<p>Joel<br>is a slug</p>`.

**linebreaksbr**

Converts all newlines in a piece of plain text to HTML line breaks (`<br>`).
For example:

```
{{ value|linebreaksbr }}
```

If `value` is `Joel\nis a slug`, the output will be `Joel<br>is a slug`.

**linenumbers**

Displays text with line numbers.
For example:

```
{{ value|linenumbers }}
```

If `value` is:

```
one
two
three
```

the output will be:

```
1. one  
2. two  
3. three
```

**ljust**

Left-aligns the value in a field of a given width.
Argument: field size
For example:

```
"{{ value|ljust:"10" }}"
```

If `value` is `Django`, the output will be "Django ".

---

**6.22. Templates**

1919
lower

Converts a string into all lowercase.

For example:

```{python}
{{ value|lower }}
```

If `value` is `Totally LOVING this Album!`, the output will be `totally loving this album!`.

make_list

Returns the value turned into a list. For a string, it’s a list of characters. For an integer, the argument is cast to a string before creating a list.

For example:

```{python}
{{ value|make_list }}
```

If `value` is the string "Joel", the output would be the list `[J, o, e, l]`. If `value` is 123, the output will be the list `[1, 2, 3]`.

phone2numeric

Converts a phone number (possibly containing letters) to its numerical equivalent.

The input doesn’t have to be a valid phone number. This will happily convert any string.

For example:

```{python}
{{ value|phone2numeric }}
```

If `value` is 800-COLLECT, the output will be 800-2655328.

pluralize

Returns a plural suffix if the value is not 1, '1', or an object of length 1. By default, this suffix is 's'.

Example:

```{python}
You have {{ num_messages }} message{{ num_messages|pluralize }}.
```

If `num_messages` is 1, the output will be `You have 1 message`. If `num_messages` is 2 the output will be `You have 2 messages`.

For words that require a suffix other than 's', you can provide an alternate suffix as a parameter to the filter.
Example:

```html
You have {{ num_walruses }} walrus{{ num_walruses|pluralize:"es" }}.
```

For words that don’t pluralize by simple suffix, you can specify both a singular and plural suffix, separated by a comma.

Example:

```html
You have {{ num_cherries }} cherr{{ num_cherries|pluralize:"y,ies" }}.
```

Note: Use `blocktranslate` to pluralize translated strings.

### pprint

A wrapper around `pprint.pprint()` — for debugging, really.

### random

Returns a random item from the given list.

For example:

```html
{{ value|random }}
```

If `value` is the list `[ 'a', 'b', 'c', 'd' ]`, the output could be "b".

### rjust

Right-aligns the value in a field of a given width.

Argument: field size

For example:

```html
"{{ value|rjust:"10" }}"
```

If `value` is Django, the output will be "Django".
safe

Marks a string as not requiring further HTML escaping prior to output. When autoescaping is off, this filter has no effect.

Note: If you are chaining filters, a filter applied after safe can make the contents unsafe again. For example, the following code prints the variable as is, unescaped:

```html
{{ var|safe|escape }}
```

safeseq

Applies the safe filter to each element of a sequence. Useful in conjunction with other filters that operate on sequences, such as join. For example:

```html
{{ some_list|safeseq|join:", " }}
```

You couldn’t use the safe filter directly in this case, as it would first convert the variable into a string, rather than working with the individual elements of the sequence.

slice

Returns a slice of the list.

Uses the same syntax as Python’s list slicing. See https://diveinto.org/python3/native-datatypes.html#slicinglists for an introduction.

Example:

```html
{{ some_list|slice:"0:2" }}
```

If some_list is ['a', 'b', 'c'], the output will be ['a', 'b'].

slugify

Converts to ASCII. Converts spaces to hyphens. Removes characters that aren’t alphanumerics, underscores, or hyphens. Converts to lowercase. Also strips leading and trailing whitespace.

For example:

```html
{{ value|slugify }}
```

If value is "Joel is a slug", the output will be "joel-is-a-slug".
**stringformat**

Formats the variable according to the argument, a string formatting specifier. This specifier uses the printf-style String Formatting syntax, with the exception that the leading "%%" is dropped.

For example:

```django
{{ value|stringformat:"E" }}
```

If `value` is 10, the output will be `1.000000E+01`.

**striptags**

Makes all possible efforts to strip all [X]HTML tags.

For example:

```django
{{ value|striptags }}
```

If `value` is "<b>Joel</b> <button>is</button> a <span>slug</span>"", the output will be "Joel is a slug".

---

**No safety guarantee**

Note that `striptags` doesn’t give any guarantee about its output being HTML safe, particularly with non valid HTML input. So NEVER apply the `safe` filter to a `striptags` output. If you are looking for something more robust, you can use the `bleach` Python library, notably its `clean` method.

---

**time**

Formats a time according to the given format.

Given format can be the predefined one `TIME_FORMAT`, or a custom format, same as the `date` filter. Note that the predefined format is locale-dependent.

For example:

```django
{{ value|time:"H:i" }}
```

If `value` is equivalent to `datetime.datetime.now()`, the output will be the string "01:23".

Note that you can backslash-escape a format string if you want to use the “raw” value. In this example, both “h” and “m” are backslash-escaped, because otherwise each is a format string that displays the hour and the month, respectively:
This would display as “01h 23m”.

Another example:

Assuming that `USE_L10N` is `True` and `LANGUAGE_CODE` is, for example, "de", then for:

```python
{{ value|time:"TIME_FORMAT" }}
```

the output will be the string "01:23" (The "TIME_FORMAT" format specifier for the de locale as shipped with Django is "H:i").

The `time` filter will only accept parameters in the format string that relate to the time of day, not the date. If you need to format a `date` value, use the `date` filter instead (or along with `time` if you need to render a full `datetime` value).

There is one exception the above rule: When passed a `datetime` value with attached timezone information (a time-zone-aware `datetime` instance) the `time` filter will accept the timezone-related format specifiers 'e', 'O', 'T' and 'Z'.

When used without a format string, the `TIME_FORMAT` format specifier is used:

```python
{{ value|time }}
```

is the same as:

```python
{{ value|time:"TIME_FORMAT" }}
```

### `timesince`

Formats a date as the time since that date (e.g., “4 days, 6 hours”).

Takes an optional argument that is a variable containing the date to use as the comparison point (without the argument, the comparison point is now). For example, if `blog_date` is a date instance representing midnight on 1 June 2006, and `comment_date` is a date instance for 08:00 on 1 June 2006, then the following would return “8 hours”:

```python
{{ blog_date|timesince:comment_date }}
```

Comparing offset-naive and offset-aware datetimes will return an empty string.

Minutes is the smallest unit used, and “0 minutes” will be returned for any date that is in the future relative to the comparison point.
**timeuntil**

Similar to `timesince`, except that it measures the time from now until the given date or datetime. For example, if today is 1 June 2006 and `conference_date` is a date instance holding 29 June 2006, then `{{ conference_date|timeuntil }}` will return “4 weeks”.

Takes an optional argument that is a variable containing the date to use as the comparison point (instead of now). If `from_date` contains 22 June 2006, then the following will return “1 week”:

```
{{ conference_date|timeuntil:from_date }}
```

Comparing offset-naive and offset-aware datetimes will return an empty string.

Minutes is the smallest unit used, and “0 minutes” will be returned for any date that is in the past relative to the comparison point.

**title**

Converts a string into titlecase by making words start with an uppercase character and the remaining characters lowercase. This tag makes no effort to keep “trivial words” in lowercase.

For example:

```
{{ value|title }}
```

If `value` is "my FIRST post", the output will be "My First Post".

**truncatechars**

Truncates a string if it is longer than the specified number of characters. Truncated strings will end with a translatable ellipsis character (”…”).

Argument: Number of characters to truncate to

For example:

```
{{ value|truncatechars:7 }}
```

If `value` is "Joel is a slug", the output will be "Joel i...".
truncatechars_html

Similar to truncatechars, except that it is aware of HTML tags. Any tags that are opened in the string and not closed before the truncation point are closed immediately after the truncation.

For example:

```html
{{ value|truncatechars_html:7 }}
```

If value is "<p>Joel is a slug</p>" , the output will be "<p>Joel i...".

Newlines in the HTML content will be preserved.

truncatewords

Truncates a string after a certain number of words.

Argument: Number of words to truncate after

For example:

```html
{{ value|truncatewords:2 }}
```

If value is "Joel is a slug", the output will be "Joel is ...".

Newlines within the string will be removed.

truncatewords_html

Similar to truncatewords, except that it is aware of HTML tags. Any tags that are opened in the string and not closed before the truncation point, are closed immediately after the truncation.

This is less efficient than truncatewords, so should only be used when it is being passed HTML text.

For example:

```html
{{ value|truncatewords_html:2 }}
```

If value is "<p>Joel is a slug</p>" , the output will be "<p>Joel is ...</p>".

Newlines in the HTML content will be preserved.
unordered_list

Recursively takes a self-nested list and returns an HTML unordered list—WITHOUT opening and closing <ul> tags.

The list is assumed to be in the proper format. For example, if var contains ['States', ['Kansas', ['Lawrence', 'Topeka'], 'Illinois']], then {{ var|unordered_list }} would return:

```html
<li>States
  <ul>
    <li>Kansas
      <ul>
        <li>Lawrence</li>
        <li>Topeka</li>
      </ul>
    </li>
    <li>Illinois</li>
  </ul>
</li>
```

upper

Converts a string into all uppercase.

For example:

```html
{{ value|upper }}
```

If value is "Joel is a slug", the output will be "JOEL IS A SLUG".

urlencode

Escapes a value for use in a URL.

For example:

```html
{{ value|urlencode }}
```

If value is "https://www.example.org/foo?a=b&c=d", the output will be "https%3A//www.example.org/foo%3Fa%3Db%26c%3Dd".

An optional argument containing the characters which should not be escaped can be provided.

If not provided, the ‘/’ character is assumed safe. An empty string can be provided when all characters should be escaped. For example:
urlize

Converts URLs and email addresses in text into clickable links.

This template tag works on links prefixed with http://, https://, or www. For example, https://goo.gl/aia1t will get converted but goo.gl/aia1t won’t.

It also supports domain-only links ending in one of the original top level domains (.com, .edu, .gov, .int, .mil, .net, and .org). For example, djangoproject.com gets converted.

Links can have trailing punctuation (periods, commas, close-paren) and leading punctuation (opening paren), and urlize will still do the right thing.

Links generated by urlize have a rel="nofollow" attribute added to them.

For example:

```html
{{ value|urlize }}
```

If value is "Check out www.djangoproject.com", the output will be "Check out <a href="http://www.djangoproject.com" rel="nofollow">www.djangoproject.com</a>".

In addition to web links, urlize also converts email addresses into mailto: links. If value is "Send questions to foo@example.com", the output will be "Send questions to <a href="mailto:foo@example.com">foo@example.com</a>".

The urlize filter also takes an optional parameter autoescape. If autoescape is True, the link text and URLs will be escaped using Django’s built-in escape filter. The default value for autoescape is True.

Note: If urlize is applied to text that already contains HTML markup, or to email addresses that contain single quotes ("), things won’t work as expected. Apply this filter only to plain text.

urlizetrunc

Converts URLs and email addresses into clickable links just like urlize, but truncates URLs longer than the given character limit.

Argument: Number of characters that link text should be truncated to, including the ellipsis that’s added if truncation is necessary.

For example:
If `value` is "Check out www.djangoproject.com", the output would be 'Check out <a href="http://www.djangoproject.com" rel="nofollow">www.djangoproject.com</a>'.

As with `urlize`, this filter should only be applied to plain text.

**wordcount**

Returns the number of words. For example:

```html
{{ value|wordcount }}
```

If `value` is "Joel is a slug", the output will be 4.

**wordwrap**

Wraps words at specified line length. Argument: number of characters at which to wrap the text

For example:

```html
{{ value|wordwrap:5 }}
```

If `value` is `Joel is a slug`, the output would be:

```
Joel
is a
slug
```

**yesno**

Maps values for True, False, and (optionally) None, to the strings “yes”, “no”, “maybe”, or a custom mapping passed as a comma-separated list, and returns one of those strings according to the value:

For example:

```html
{{ value|yesno:"yeah,no,maybe" }}
```
### Internationalization tags and filters

Django provides template tags and filters to control each aspect of internationalization in templates. They allow for granular control of translations, formatting, and time zone conversions.

#### i18n

This library allows specifying translatable text in templates. To enable it, set `USE_I18N` to `True`, then load it with `{% load i18n %}`.

See [Internationalization: in template code](#).

#### l10n

This library provides control over the localization of values in templates. You only need to load the library using `{% load l10n %}`, but you’ll often set `USE_L10N` to `True` so that localization is active by default.

See [Controlling localization in templates](#).

#### tz

This library provides control over time zone conversions in templates. Like l10n, you only need to load the library using `{% load tz %}`, but you’ll usually also set `USE_TZ` to `True` so that conversion to local time happens by default.

See [Time zone aware output in templates](#).
Other tags and filters libraries

Django comes with a couple of other template-tag libraries that you have to enable explicitly in your `INSTALLED_APPS` setting and enable in your template with the `{% load %}` tag.

**django.contrib.humanize**

A set of Django template filters useful for adding a “human touch” to data. See `django.contrib.humanize`.

**static**

To link to static files that are saved in `STATIC_ROOT` Django ships with a `static` template tag. If the `django.contrib.staticfiles` app is installed, the tag will serve files using `url()` method of the storage specified by `STATICFILES_STORAGE`. For example:

```html
{% load static %}
<img src="{% static 'images/hi.jpg' %}" alt="Hi!">
```

It is also able to consume standard context variables, e.g. assuming a `user_stylesheet` variable is passed to the template:

```html
{% load static %}
<link rel="stylesheet" href="{% static user_stylesheet %}" media="screen">
```

If you’d like to retrieve a static URL without displaying it, you can use a slightly different call:

```html
{% load static %}
{% static "images/hi.jpg" as myphoto %}
<img src="{{ myphoto }}">
```

Using Jinja2 templates?

See `Jinja2` for information on using the `static` tag with Jinja2.
get_static_prefix

You should prefer the static template tag, but if you need more control over exactly where and how STATIC_URL is injected into the template, you can use the get_static_prefix template tag:

```html
{% load static %}
<img src="{% get_static_prefix %}images/hi.jpg" alt="Hi!">
```

There’s also a second form you can use to avoid extra processing if you need the value multiple times:

```html
{% load static %}
{% get_static_prefix as STATIC_PREFIX %}
<img src="{{ STATIC_PREFIX }}images/hi.jpg" alt="Hi!">
<img src="{{ STATIC_PREFIX }}images/hi2.jpg" alt="Hello!">
```

get_media_prefix

Similar to the get_static_prefix, get_media_prefix populates a template variable with the media prefix MEDIA_URL, e.g.:

```html
{% load static %}
<body data-media-url="{% get_media_prefix %}">
```

By storing the value in a data attribute, we ensure it’s escaped appropriately if we want to use it in a JavaScript context.

6.22.3 The Django template language: for Python programmers

This document explains the Django template system from a technical perspective—how it works and how to extend it. If you’re looking for reference on the language syntax, see The Django template language.

It assumes an understanding of templates, contexts, variables, tags, and rendering. Start with the introduction to the Django template language if you aren’t familiar with these concepts.

Overview

Using the template system in Python is a three-step process:

1. You configure an Engine.
2. You compile template code into a Template.
3. You render the template with a Context.
Django projects generally rely on the high level, backend agnostic APIs for each of these steps instead of the template system’s lower level APIs:

1. For each DjangoTemplates backend in the `TEMPLATES` setting, Django instantiates an Engine. DjangoTemplates wraps Engine and adapts it to the common template backend API.

2. The `django.template.loader` module provides functions such as `get_template()` for loading templates. They return a `django.template.backends.django.Template` which wraps the actual `django.template.Template`.

3. The Template obtained in the previous step has a `render()` method which marshals a context and possibly a request into a `Context` and delegates the rendering to the underlying `Template`.

### Configuring an engine

If you are using the DjangoTemplates backend, this probably isn’t the documentation you’re looking for. An instance of the Engine class described below is accessible using the `engine` attribute of that backend and any attribute defaults mentioned below are overridden by what’s passed by DjangoTemplates.

```python
class Engine(dirs=None, app_dirs=False, context_processors=None, debug=False, loaders=None,
   string_if_invalid='', file_charset='utf-8', libraries=None, builtins=None,
   autoescape=True)
```

When instantiating an Engine all arguments must be passed as keyword arguments:

- **dirs** is a list of directories where the engine should look for template source files. It is used to configure `filesystem.Loader`.
  
  It defaults to an empty list.

- **app_dirs** only affects the default value of `loaders`. See below.
  
  It defaults to False.

- **autoescape** controls whether HTML autoescaping is enabled.
  
  It defaults to True.

```
Warning: Only set it to False if you’re rendering non-HTML templates!
```

- **context_processors** is a list of dotted Python paths to callables that are used to populate the context when a template is rendered with a request. These callables take a request object as their argument and return a dict of items to be merged into the context.
  
  It defaults to an empty list.

See `RequestContext` for more information.
• **debug** is a boolean that turns on/off template debug mode. If it is `True`, the template engine will store additional debug information which can be used to display a detailed report for any exception raised during template rendering.

It defaults to `False`.

• **loaders** is a list of template loader classes, specified as strings. Each *Loader* class knows how to import templates from a particular source. Optionally, a tuple can be used instead of a string. The first item in the tuple should be the *Loader* class name, subsequent items are passed to the *Loader* during initialization.

It defaults to a list containing:

  - `'django.template.loaders.filesystem.Loader'`
  - `'django.template.loaders.app_directories.Loader'` if and only if `app_dirs` is `True`.

These loaders are then wrapped in `django.template.loaders.cached.Loader`.

In older versions, the cached template loader was only enabled by default when `DEBUG` was `False`. See [*Loader types*](#) for details.

• **string_if_invalid** is the output, as a string, that the template system should use for invalid (e.g. misspelled) variables.

It defaults to the empty string.

See [*How invalid variables are handled*](#) for details.

• **file_charset** is the charset used to read template files on disk.

It defaults to `'utf-8'`.

• **'libraries'**: A dictionary of labels and dotted Python paths of template tag modules to register with the template engine. This is used to add new libraries or provide alternate labels for existing ones. For example:

```python
Engine(
    libraries={
        'myapp_tags': 'path.to.myapp.tags',
        'admin.urls': 'django.contrib.admin.templatetags.admin_urls',
    },
)
```

Libraries can be loaded by passing the corresponding dictionary key to the `{% load %}` tag.

• **'builtins'**: A list of dotted Python paths of template tag modules to add to *built-ins*. For example:
Tags and filters from built-in libraries can be used without first calling the {% load %} tag.

```python
static Engine.get_default()
```

Returns the underlying Engine from the first configured DjangoTemplates engine. Raises ImproperlyConfigured if no engines are configured.

It’s required for preserving APIs that rely on a globally available, implicitly configured engine. Any other use is strongly discouraged.

```python
Engine.from_string(template_code)
```

Compiles the given template code and returns a Template object.

```python
Engine.get_template(template_name)
```

Loads a template with the given name, compiles it and returns a Template object.

```python
Engine.select_template(template_name_list)
```

Like get_template(), except it takes a list of names and returns the first template that was found.

### Loading a template

The recommended way to create a Template is by calling the factory methods of the Engine: get_template(), select_template() and from_string().

In a Django project where the TEMPLATES setting defines a DjangoTemplates engine, it’s possible to instantiate a Template directly. If more than one DjangoTemplates engine is defined, the first one will be used.

```python
class Template
```

This class lives at django.template.Template. The constructor takes one argument — the raw template code:

```python
from django.template import Template

template = Template("My name is {{ my_name }}.")
```

Behind the scenes

The system only parses your raw template code once — when you create the Template object. From then on, it’s stored internally as a tree structure for performance.
Even the parsing itself is quite fast. Most of the parsing happens via a single call to a single, short, regular expression.

## Rendering a context

Once you have a compiled `Template` object, you can render a context with it. You can reuse the same template to render it several times with different contexts.

```python
from django.template import Context, Template

template = Template("My name is {{ my_name }}.")

context = Context({'my_name': "Adrian"})
template.render(context)
"My name is Adrian."

context = Context({'my_name': "Dolores"})
template.render(context)
"My name is Dolores."
```

### Variables and lookups

Variable names must consist of any letter (A-Z), any digit (0-9), an underscore (but they must not start with an underscore) or a dot.

Dots have a special meaning in template rendering. A dot in a variable name signifies a lookup. Specifically, when the template system encounters a dot in a variable name, it tries the following lookups, in this order:

- Dictionary lookup. Example: `foo["bar"]`
- Attribute lookup. Example: `foo.bar`
- List-index lookup. Example: `foo[bar]`

Note that "bar" in a template expression like `{{ foo.bar }}` will be interpreted as a literal string and not using the value of the variable "bar", if one exists in the template context.

The template system uses the first lookup type that works. It’s short-circuit logic. Here are a few examples:
from django.template import Context, Template
>>> t = Template("My name is {{ person.first_name }}.")
>>> d = {"person": {"first_name": "Joe", "last_name": "Johnson"}}
>>> t.render(Context(d))
"My name is Joe."

>>> class PersonClass: pass
>>> p = PersonClass()
>>> p.first_name = "Ron"
>>> p.last_name = "Nasty"
>>> t.render(Context({'person': p}))
"My name is Ron."

>>> t = Template("The first stooge in the list is {{ stooges.0 }}.")
>>> c = Context({'stooges': ["Larry", "Curly", "Moe"]})
>>> t.render(c)
"The first stooge in the list is Larry."

If any part of the variable is callable, the template system will try calling it. Example:

>>> class PersonClass2:
...     def name(self):
...         return "Samantha"
... >>> t = Template("My name is {{ person.name }}.")

Callable variables are slightly more complex than variables which only require straight lookups. Here are some things to keep in mind:

- If the variable raises an exception when called, the exception will be propagated, unless the exception has an attribute silent_variable_failure whose value is True. If the exception does have a silent_variable_failure attribute whose value is True, the variable will render as the value of the engine’ s string_if_invalid configuration option (an empty string, by default). Example:

```python
>>> t = Template("My name is {{ person.first_name }}.")
>>> class PersonClass3:
...     def first_name(self):
...         raise AssertionError("foo")
... >>> p = PersonClass3()
... >>> t.render(Context({'person': p}))
Traceback (most recent call last):
  ...
AssertionError: foo
```

(continues on next page)
>>> class SilentAssertionError(Exception):
...     silent_variable_failure = True

>>> class PersonClass4:
...     def first_name(self):
...         raise SilentAssertionError

>>> p = PersonClass4()

>> t.render(Context({'person': p}))
"My name is ."

Note that django.core.exceptions.ObjectDoesNotExist, which is the base class for all Django database API DoesNotExist exceptions, has silent_variable_failure = True. So if you’re using Django templates with Django model objects, any DoesNotExist exception will fail silently.

• A variable can only be called if it has no required arguments. Otherwise, the system will return the value of the engine’s string_if_invalid option.

• There can be side effects when calling some variables, and it’d be either foolish or a security hole to allow the template system to access them.

A good example is the delete() method on each Django model object. The template system shouldn’t be allowed to do something like this:

I will now delete this valuable data. {{ data.delete }}

To prevent this, set an alters_data attribute on the callable variable. The template system won’t call a variable if it has alters_data=True set, and will instead replace the variable with string_if_invalid, unconditionally. The dynamically-generated delete() and save() methods on Django model objects get alters_data=True automatically. Example:

def sensitive_function(self):
    self.database_record.delete()
    sensitive_function.alters_data = True

• Occasionally you may want to turn off this feature for other reasons, and tell the template system to leave a variable uncalled no matter what. To do so, set a do_not_call_in_templates attribute on the callable with the value True. The template system then will act as if your variable is not callable (allowing you to access attributes of the callable, for example).
How invalid variables are handled

Generally, if a variable doesn’t exist, the template system inserts the value of the engine’s `string_if_invalid` configuration option, which is set to '' (the empty string) by default.

Filters that are applied to an invalid variable will only be applied if `string_if_invalid` is set to '' (the empty string). If `string_if_invalid` is set to any other value, variable filters will be ignored.

This behavior is slightly different for the `if`, `for` and `regroup` template tags. If an invalid variable is provided to one of these template tags, the variable will be interpreted as `None`. Filters are always applied to invalid variables within these template tags.

If `string_if_invalid` contains a '%s', the format marker will be replaced with the name of the invalid variable.

For debug purposes only!

While `string_if_invalid` can be a useful debugging tool, it is a bad idea to turn it on as a ‘development default’.

Many templates, including some of Django’s, rely upon the silence of the template system when a nonexistent variable is encountered. If you assign a value other than '' to `string_if_invalid`, you will experience rendering problems with these templates and sites.

Generally, `string_if_invalid` should only be enabled in order to debug a specific template problem, then cleared once debugging is complete.

Built-in variables

Every context contains `True`, `False` and `None`. As you would expect, these variables resolve to the corresponding Python objects.

Limitations with string literals

Django’s template language has no way to escape the characters used for its own syntax. For example, the `templatetag` tag is required if you need to output character sequences like `{%` and `%}`.

A similar issue exists if you want to include these sequences in template filter or tag arguments. For example, when parsing a block tag, Django’s template parser looks for the first occurrence of `%} after a `{`. This prevents the use of "{%}" as a string literal. For example, a `TemplateSyntaxError` will be raised for the following expressions:
The same issue can be triggered by using a reserved sequence in filter arguments:

```template.html
{ tvar="Some string literal with %} in it." %}
{% with tvar="Some string literal with %} in it." %}{% endwith %}
```

If you need to use strings with these sequences, store them in template variables or use a custom template tag or filter to workaround the limitation.

### Playing with Context objects

Most of the time, you’ll instantiate `Context` objects by passing in a fully-populated dictionary to `Context()`. But you can add and delete items from a `Context` object once it’s been instantiated, too, using standard dictionary syntax:

```python
>>> from django.template import Context
>>> c = Context({'foo': 'bar'})
>>> c['foo']
'bar'
>>> del c['foo']
>>> c['foo']
Traceback (most recent call last):
  ... KeyError: 'foo'
>>> c['newvariable'] = 'hello'
>>> c['newvariable']
'hello'
```

- `Context.get(key, otherwise=None)`: Returns the value for `key` if `key` is in the context, else returns `otherwise`.
- `Context.setdefault(key, default=None)`: If `key` is in the context, returns its value. Otherwise inserts `key` with a value of `default` and returns `default`.
- `Context.pop()`
- `Context.push()`

#### exception ContextPopException

A `Context` object is a stack. That is, you can `push()` and `pop()` it. If you `pop()` too much, it’ll raise `django.template.ContextPopException`:
You can also use `push()` as a context manager to ensure a matching `pop()` is called.

```
>>> c = Context()
>>> c['foo'] = 'first level'
>>> with c.push():
...   c['foo'] = 'second level'
...   c['foo']
'second level'
>>> c['foo']
'first level'
```

All arguments passed to `push()` will be passed to the `dict` constructor used to build the new context level.

```
>>> c = Context()
>>> c['foo'] = 'first level'
>>> with c.push(foo='second level'):
...   c['foo']
'second level'
>>> c['foo']
'first level'
```

`Context.update(other_dict)`

In addition to `push()` and `pop()`, the `Context` object also defines an `update()` method. This works like `push()` but takes a dictionary as an argument and pushes that dictionary onto the stack instead of an empty one.
Like `push()`, you can use `update()` as a context manager to ensure a matching `pop()` is called.

```python
>>> c = Context()
>>> c['foo'] = 'first level'
>>> c.update({'foo': 'updated'})
{'foo': 'updated'}
>>> c['foo']
'updated'
>>> c.pop()
{'foo': 'updated'}
>>> c['foo']
'first level'
```

Using a `Context` as a stack comes in handy in some custom template tags.

`Context.flatten()`

Using `flatten()` method you can get whole `Context` stack as one dictionary including built-in variables.

```python
>>> c = Context()
>>> c['foo'] = 'first level'
>>> with c.update({'foo': 'second level'}):
...    c['foo']
'second level'
>>> c['foo']
'first level'
```

A `flatten()` method is also internally used to make `Context` objects comparable.

```python
>>> c1 = Context()
>>> c1['foo'] = 'first level'
>>> c1['bar'] = 'second level'
>>> c2 = Context()
>>> c2.update({'bar': 'second level', 'foo': 'first level'})
{'foo': 'first level', 'bar': 'second level'}
>>> c1 == c2
True
```

Result from `flatten()` can be useful in unit tests to compare `Context` against `dict`:
```python
class ContextTest(unittest.TestCase):
    def test_against_dictionary(self):
        c1 = Context()
        c1['update'] = 'value'
        self.assertEqual(c1.flatten(), {
            'True': True,
            'None': None,
            'False': False,
            'update': 'value',
        })
```

**Using RequestContext**

class RequestContext(request, dict_=None, processors=None)

Django comes with a special `Context` class, `django.template.RequestContext`, that acts slightly differently from the normal `django.template.Context`. The first difference is that it takes an `HttpRequest` as its first argument. For example:

```python
c = RequestContext(request, {
    'foo': 'bar',
})
```

The second difference is that it automatically populates the context with a few variables, according to the engine’s `context_processors` configuration option.

The `context_processors` option is a list of callables – called context processors – that take a request object as their argument and return a dictionary of items to be merged into the context. In the default generated settings file, the default template engine contains the following context processors:

```python
[
    'django.template.context_processors.debug',
    'django.template.context_processors.request',
    'django.contrib.auth.context_processors.auth',
    'django.contrib.messages.context_processors.messages',
]
```

In addition to these, `RequestContext` always enables `django.template.context_processors.csrf`. This is a security related context processor required by the admin and other contrib apps, and, in case of accidental misconfiguration, it is deliberately hardcoded in and cannot be turned off in the `context_processors` option.

Each processor is applied in order. That means, if one processor adds a variable to the context and a second processor adds a variable with the same name, the second will override the first. The default processors are explained below.
When context processors are applied

Context processors are applied on top of context data. This means that a context processor may overwrite variables you’ve supplied to your `Context` or `RequestContext`, so take care to avoid variable names that overlap with those supplied by your context processors.

If you want context data to take priority over context processors, use the following pattern:

```python
from django.template import RequestContext

request_context = RequestContext(request)
request_context.push({'my_name': 'Adrian'})
```

Django does this to allow context data to override context processors in APIs such as `render()` and `TemplateResponse`.

Also, you can give `RequestContext` a list of additional processors, using the optional, third positional argument, `processors`. In this example, the `RequestContext` instance gets an `ip_address` variable:

```python
from django.http import HttpResponse
from django.template import RequestContext, Template

def ip_address_processor(request):
    return {'ip_address': request.META['REMOTE_ADDR']}

def client_ip_view(request):
    template = Template('{{ title }}: {{ ip_address }}')
    context = RequestContext(request, {
        'title': 'Your IP Address',
    }, [ip_address_processor])
    return HttpResponse(template.render(context))
```
Built-in template context processors

Here’s what each of the built-in processors does:

```
django.contrib.auth.context_processors.auth
```

**auth**(request)

If this processor is enabled, every RequestContext will contain these variables:

- **user** – An auth.User instance representing the currently logged-in user (or an AnonymousUser instance, if the client isn’t logged in).
- **perms** – An instance of django.contrib.auth.context_processors.PermWrapper, representing the permissions that the currently logged-in user has.

```
django.template.context_processors.debug
```

**debug**(request)

If this processor is enabled, every RequestContext will contain these two variables – but only if your DEBUG setting is set to True and the request’s IP address (request.META['REMOTE_ADDR']) is in the INTERNAL_IPS setting:

- **debug** – True. You can use this in templates to test whether you’re in DEBUG mode.
- **sql_queries** – A list of {'sql': ..., 'time': ...} dictionaries, representing every SQL query that has happened so far during the request and how long it took. The list is in order by database alias and then by query. It’s lazily generated on access.

```
django.template.context_processors.i18n
```

**i18n**(request)

If this processor is enabled, every RequestContext will contain these variables:

- **LANGUAGES** – The value of the LANGUAGES setting.
- **LANGUAGE_BIDI** – True if the current language is a right-to-left language, e.g. Hebrew, Arabic. False if it’s a left-to-right language, e.g. English, French, German.
- **LANGUAGE_CODE** – request.LANGUAGE_CODE, if it exists. Otherwise, the value of the LANGUAGE_CODE setting.

See i18n template tags for template tags that generate the same values.
django.template.context_processors.media

If this processor is enabled, every RequestContext will contain a variable MEDIA_URL, providing the value of the MEDIA_URL setting.

django.template.context_processors.static

static(request)

If this processor is enabled, every RequestContext will contain a variable STATIC_URL, providing the value of the STATIC_URL setting.

django.template.context_processors.csrf

This processor adds a token that is needed by the csrf_token template tag for protection against Cross Site Request Forgeries.

django.template.context_processors.request

If this processor is enabled, every RequestContext will contain a variable request, which is the current HttpRequest.

django.template.context_processors.tz

tz(request)

If this processor is enabled, every RequestContext will contain a variable TIME_ZONE, providing the name of the currently active time zone.

django.contrib.messages.context_processors.messages

If this processor is enabled, every RequestContext will contain these two variables:

- messages – A list of messages (as strings) that have been set via the messages framework.
- DEFAULT_MESSAGE_LEVELS – A mapping of the message level names to their numeric value.
Writing your own context processors

A context processor has a simple interface: It’s a Python function that takes one argument, an `HttpRequest` object, and returns a dictionary that gets added to the template context.

For example, to add the `DEFAULT_FROM_EMAIL` setting to every context:

```python
from django.conf import settings

def from_email(request):
    return {
        "DEFAULT_FROM_EMAIL": settings.DEFAULT_FROM_EMAIL,
    }
```

Custom context processors can live anywhere in your code base. All Django cares about is that your custom context processors are pointed to by the `context_processors` option in your `TEMPLATES` setting—or the `context_processors` argument of `Engine` if you’re using it directly.

Loading templates

Generally, you’ll store templates in files on your filesystem rather than using the low-level `Template` API yourself. Save templates in a directory specified as a template directory.

Django searches for template directories in a number of places, depending on your template loading settings (see “Loader types” below), but the most basic way of specifying template directories is by using the `DIRS` option.

The `DIRS` option

Tell Django what your template directories are by using the `DIRS` option in the `TEMPLATES` setting in your settings file—or the `dirs` argument of `Engine`. This should be set to a list of strings that contain full paths to your template directories:

```python
TEMPLATES = [
    {
        'BACKEND': 'django.template.backends.django.DjangoTemplates',
        'DIRS': [
            '/home/html/templates/lawrence.com',
            '/home/html/templates/default',
        ],
    },
]
```
Your templates can go anywhere you want, as long as the directories and templates are readable by the web server. They can have any extension you want, such as .html or .txt, or they can have no extension at all. Note that these paths should use Unix-style forward slashes, even on Windows.

Loader types

By default, Django uses a filesystem-based template loader, but Django comes with a few other template loaders, which know how to load templates from other sources.

Some of these other loaders are disabled by default, but you can activate them by adding a 'loaders' option to your DjangoTemplates backend in the TEMPLATES setting or passing a loaders argument to Engine. loaders should be a list of strings or tuples, where each represents a template loader class. Here are the template loaders that come with Django:

django.template.loaders.filesystem.Loader

class filesystem.Loader

Loads templates from the filesystem, according to Dirs.

This loader is enabled by default. However it won’t find any templates until you set Dirs to a non-empty list:

```
TEMPLATES = [{
    'BACKEND': 'django.template.backends.django.DjangoTemplates',
    'DIRS': [BASE_DIR / 'templates'],
}]
```

You can also override 'DIRS' and specify specific directories for a particular filesystem loader:

```
TEMPLATES = [{
    'BACKEND': 'django.template.backends.django.DjangoTemplates',
    'OPTIONS': {
        'loaders': [
            (  
            'django.template.loaders.filesystem.Loader',
            [BASE_DIR / 'templates'],
            ),
        ],
    },
}]
```

django.template.loaders.app_directories.Loader

class app_directories.Loader

Loads templates from Django apps on the filesystem. For each app in INSTALLED_APPS, the loader looks for a templates subdirectory. If the directory exists, Django looks for templates in there.
This means you can store templates with your individual apps. This also helps to distribute Django apps with default templates.

For example, for this setting:

```python
INSTALLED_APPS = ['myproject.polls', 'myproject.music']
```

...then `get_template('foo.html')` will look for `foo.html` in these directories, in this order:

- `/path/to/myproject/polls/templates/`
- `/path/to/myproject/music/templates/`

...and will use the one it finds first.

The order of `INSTALLED_APPS` is significant! For example, if you want to customize the Django admin, you might choose to override the standard `admin/base_site.html` template, from `django.contrib.admin`, with your own `admin/base_site.html` in `myproject.polls`. You must then make sure that `myproject.polls` comes before `django.contrib.admin` in `INSTALLED_APPS`, otherwise `django.contrib.admin`’s will be loaded first and yours will be ignored.

Note that the loader performs an optimization when it first runs: it caches a list of which `INSTALLED_APPS` packages have a `templates` subdirectory.

You can enable this loader by setting `APP_DIRS` to `True`:

```python
TEMPLATES = [{
    'BACKEND': 'django.template.backends.django.DjangoTemplates',
    'APP_DIRS': True,
}]
```

django.template.loaders.cached.Loader

class cached.Loader

While the Django template system is quite fast, if it needs to read and compile your templates every time they’re rendered, the overhead from that can add up.

You configure the cached template loader with a list of other loaders that it should wrap. The wrapped loaders are used to locate unknown templates when they’re first encountered. The cached loader then stores the compiled Template in memory. The cached Template instance is returned for subsequent requests to load the same template.

This loader is automatically enabled if `OPTIONS['loaders']` isn’t specified.

You can manually specify template caching with some custom template loaders using settings like this:

```python
TEMPLATES = [{
    'BACKEND': 'django.template.backends.django.DjangoTemplates',
    'DIRS': [BASE_DIR / 'templates'],
}]
```

(continues on next page)
OPTIONS': {
    'loaders': [
        ('django.template.loaders.cached.Loader', [  
            'django.template.loaders.filesystem.Loader',  
            'django.template.loaders.app_directories.Loader',  
            'path.to.custom.Loader',  
        ]),  
    ],  
},
]

Note: All of the built-in Django template tags are safe to use with the cached loader, but if you’re using custom template tags that come from third party packages, or that you wrote yourself, you should ensure that the Node implementation for each tag is thread-safe. For more information, see template tag thread safety considerations.

The cached template loader was enabled whenever OPTIONS['loaders'] is not specified. Previously it was only enabled when DEBUG was False.

django.template.loaders.locmem.Loader
class locmem.Loader

Loads templates from a Python dictionary. This is useful for testing.

This loader takes a dictionary of templates as its first argument:

```
TEMPLATES = [{
    'BACKEND': 'django.template.backends.django.DjangoTemplates',
    'OPTIONS': {
        'loaders': [
            ('django.template.loaders.locmem.Loader', {  
                'index.html': 'content here',  
            }  
        ]  
    }  
}]
```

This loader is disabled by default.

Django uses the template loaders in order according to the 'loaders' option. It uses each loader until a loader finds a match.
Custom loaders

It’s possible to load templates from additional sources using custom template loaders. Custom Loader classes should inherit from `django.template.loaders.base.Loader` and define the `get_contents()` and `get_template_sources()` methods.

Loader methods

class Loader

Loads templates from a given source, such as the filesystem or a database.

`get_template_sources(template_name)`

A method that takes a `template_name` and yields `Origin` instances for each possible source.

For example, the filesystem loader may receive 'index.html' as a `template_name` argument. This method would yield origins for the full path of `index.html` as it appears in each template directory the loader looks at.

The method doesn’t need to verify that the template exists at a given path, but it should ensure the path is valid. For instance, the filesystem loader makes sure the path lies under a valid template directory.

`get_contents(origin)`

Returns the contents for a template given a `Origin` instance.

This is where a filesystem loader would read contents from the filesystem, or a database loader would read from the database. If a matching template doesn’t exist, this should raise a `TemplateDoesNotExist` error.

`get_template(template_name, skip=None)`

Returns a `Template` object for a given `template_name` by looping through results from `get_template_sources()` and calling `get_contents()`. This returns the first matching template. If no template is found, `TemplateDoesNotExist` is raised.

The optional `skip` argument is a list of origins to ignore when extending templates. This allows templates to extend other templates of the same name. It also used to avoid recursion errors.

In general, it is enough to define `get_template_sources()` and `get_contents()` for custom template loaders. `get_template()` will usually not need to be overridden.

Building your own

For examples, read the source code for Django’s built-in loaders.
Template origin

Templates have an origin containing attributes depending on the source they are loaded from.

class Origin(name, template_name=None, loader=None)

    name
    The path to the template as returned by the template loader. For loaders that read from the file system, this is the full path to the template.
    
    If the template is instantiated directly rather than through a template loader, this is a string value of <unknown_source>.

    template_name
    The relative path to the template as passed into the template loader.
    
    If the template is instantiated directly rather than through a template loader, this is None.

    loader
    The template loader instance that constructed this Origin.
    
    If the template is instantiated directly rather than through a template loader, this is None.

    django.template.loaders.cached.Loader requires all of its wrapped loaders to set this attribute, typically by instantiating the Origin with loader=self.

For information on writing your own custom tags and filters, see How to create custom template tags and filters.

To learn how to override templates in other Django applications, see How to override templates.

6.23 TemplateResponse and SimpleTemplateResponse

Standard HttpResponse objects are static structures. They are provided with a block of pre-rendered content at time of construction, and while that content can be modified, it isn’t in a form that makes it easy to perform modifications.

However, it can sometimes be beneficial to allow decorators or middleware to modify a response after it has been constructed by the view. For example, you may want to change the template that is used, or put additional data into the context.

TemplateResponse provides a way to do just that. Unlike basic HttpResponse objects, TemplateResponse objects retain the details of the template and context that was provided by the view to compute the response. The final output of the response is not computed until it is needed, later in the response process.
6.23.1 SimpleTemplateResponse objects

class SimpleTemplateResponse

Attributes

SimpleTemplateResponse.template_name

The name of the template to be rendered. Accepts a backend-dependent template object (such as those returned by `get_template()`), the name of a template, or a list of template names.

Example: `['foo.html', 'path/to/bar.html']`

SimpleTemplateResponse.context_data

The context data to be used when rendering the template. It must be a `dict`.

Example: `{ 'foo': 123 }`

SimpleTemplateResponse.rendered_content

The current rendered value of the response content, using the current template and context data.

SimpleTemplateResponse.is_rendered

A boolean indicating whether the response content has been rendered.

Methods

SimpleTemplateResponse.__init__(template, context=None, content_type=None, status=None, charset=None, using=None, headers=None)

Instantiates a `SimpleTemplateResponse` object with the given template, context, content type, HTTP status, and charset.

  template

A backend-dependent template object (such as those returned by `get_template()`), the name of a template, or a list of template names.

  context

A `dict` of values to add to the template context. By default, this is an empty dictionary.

  content_type

The value included in the HTTP Content-Type header, including the MIME type specification and the character set encoding. If `content_type` is specified, then its value is used. Otherwise, `'text/html'` is used.

  status

The HTTP status code for the response.
 charset

The charset in which the response will be encoded. If not given it will be extracted from
content_type, and if that is unsuccessful, the DEFAULT_CHARSET setting will be used.

 using

The NAME of a template engine to use for loading the template.

 headers

A dict of HTTP headers to add to the response.

 SimpleTemplateResponse.resolve_context(context)

Preprocesses context data that will be used for rendering a template. Accepts a dict of context data.
By default, returns the same dict.

Override this method in order to customize the context.

 SimpleTemplateResponse.resolve_template(template)

Resolves the template instance to use for rendering. Accepts a backend-dependent template object
(such as those returned by get_template()), the name of a template, or a list of template names.

Returns the backend-dependent template object instance to be rendered.

Override this method in order to customize template loading.

 SimpleTemplateResponse.add_post_render_callback()

Add a callback that will be invoked after rendering has taken place. This hook can be used to defer
certain processing operations (such as caching) until after rendering has occurred.

If the SimpleTemplateResponse has already been rendered, the callback will be invoked immediately.

When called, callbacks will be passed a single argument – the rendered SimpleTemplateResponse in-
stance.

If the callback returns a value that is not None, this will be used as the response instead of the original
response object (and will be passed to the next post rendering callback etc.)

 SimpleTemplateResponse.render()

Sets response.content to the result obtained by SimpleTemplateResponse.rendered_content, runs
all post-rendering callbacks, and returns the resulting response object.

render() will only have an effect the first time it is called. On subsequent calls, it will return the result
obtained from the first call.
6.23.2 TemplateResponse objects

class TemplateResponse

TemplateResponse is a subclass of SimpleTemplateResponse that knows about the current HttpRequest.

Methods

TemplateResponse.__init__(request, template, context=None, content_type=None, status=None, charset=None, using=None, headers=None)

Instantiates a TemplateResponse object with the given request, template, context, content type, HTTP status, and charset.

request
    An HttpRequest instance.

template
    A backend-dependent template object (such as those returned by get_template()), the name of a template, or a list of template names.

context
    A dict of values to add to the template context. By default, this is an empty dictionary.

content_type
    The value included in the HTTP Content-Type header, including the MIME type specification and the character set encoding. If content_type is specified, then its value is used. Otherwise, 'text/html' is used.

status
    The HTTP status code for the response.

charset
    The charset in which the response will be encoded. If not given it will be extracted from content_type, and if that is unsuccessful, the DEFAULT_CHARSET setting will be used.

using
    The NAME of a template engine to use for loading the template.

headers
    A dict of HTTP headers to add to the response.
6.23.3 The rendering process

Before a TemplateResponse instance can be returned to the client, it must be rendered. The rendering process takes the intermediate representation of template and context, and turns it into the final byte stream that can be served to the client.

There are three circumstances under which a TemplateResponse will be rendered:

- When the TemplateResponse instance is explicitly rendered, using the SimpleTemplateResponse.render() method.
- When the content of the response is explicitly set by assigning response.content.
- After passing through template response middleware, but before passing through response middleware.

A TemplateResponse can only be rendered once. The first call to SimpleTemplateResponse.render() sets the content of the response; subsequent rendering calls do not change the response content.

However, when response.content is explicitly assigned, the change is always applied. If you want to force the content to be re-rendered, you can reevaluate the rendered content, and assign the content of the response manually:

```python
# Set up a rendered TemplateResponse
>>> from django.template.response import TemplateResponse
>>> t = TemplateResponse(request, 'original.html', {})
>>> t.render()
>>> print(t.content)
Original content

# Re-rendering doesn't change content
>>> t.template_name = 'new.html'
>>> t.render()
>>> print(t.content)
Original content

# Assigning content does change, no render() call required
>>> t.content = t.rendered_content
>>> print(t.content)
New content
```
Post-render callbacks

Some operations—such as caching—cannot be performed on an unrendered template. They must be performed on a fully complete and rendered response.

If you’re using middleware, you can do that. Middleware provides multiple opportunities to process a response on exit from a view. If you put behavior in the response middleware, it’s guaranteed to execute after template rendering has taken place.

However, if you’re using a decorator, the same opportunities do not exist. Any behavior defined in a decorator is handled immediately.

To compensate for this (and any other analogous use cases), TemplateResponse allows you to register callbacks that will be invoked when rendering has completed. Using this callback, you can defer critical processing until a point where you can guarantee that rendered content will be available.

To define a post-render callback, define a function that takes a single argument—response—and register that function with the template response:

```python
from django.template.response import TemplateResponse

def my_render_callback(response):
    # Do content-sensitive processing
    do_post_processing()

def my_view(request):
    # Create a response
    response = TemplateResponse(request, 'mytemplate.html', {})
    # Register the callback
    response.add_post_render_callback(my_render_callback)
    # Return the response
    return response
```

my_render_callback() will be invoked after the mytemplate.html has been rendered, and will be provided the fully rendered TemplateResponse instance as an argument.

If the template has already been rendered, the callback will be invoked immediately.

### 6.23.4 Using TemplateResponse and SimpleTemplateResponse

A TemplateResponse object can be used anywhere that a normal django.http.HttpResponse can be used. It can also be used as an alternative to calling render().

For example, the following view returns a TemplateResponse with a template and a context containing a queryset:
from django.template.response import TemplateResponse

def blog_index(request):
    return TemplateResponse(request, 'entry_list.html', {'entries': Entry.objects.all()})

6.24 Unicode data

Django supports Unicode data everywhere.

This document tells you what you need to know if you’re writing applications that use data or templates that are encoded in something other than ASCII.

6.24.1 Creating the database

Make sure your database is configured to be able to store arbitrary string data. Normally, this means giving it an encoding of UTF-8 or UTF-16. If you use a more restrictive encoding – for example, latin1 (iso8859-1) – you won’t be able to store certain characters in the database, and information will be lost.

- MySQL users, refer to the MySQL manual for details on how to set or alter the database character set encoding.
- PostgreSQL users, refer to the PostgreSQL manual for details on creating databases with the correct encoding.
- Oracle users, refer to the Oracle manual for details on how to set (section 2) or alter (section 11) the database character set encoding.
- SQLite users, there is nothing you need to do. SQLite always uses UTF-8 for internal encoding.

All of Django’s database backends automatically convert strings into the appropriate encoding for talking to the database. They also automatically convert strings retrieved from the database into strings. You don’t even need to tell Django what encoding your database uses: that is handled transparently.

For more, see the section “The database API” below.

6.24.2 General string handling

Whenever you use strings with Django – e.g., in database lookups, template rendering or anywhere else – you have two choices for encoding those strings. You can use normal strings or bytestrings (starting with a ‘b’).
Warning: A bytestring does not carry any information with it about its encoding. For that reason, we have to make an assumption, and Django assumes that all bytestrings are in UTF-8.

If you pass a string to Django that has been encoded in some other format, things will go wrong in interesting ways. Usually, Django will raise a `UnicodeDecodeError` at some point.

If your code only uses ASCII data, it’s safe to use your normal strings, passing them around at will, because ASCII is a subset of UTF-8.

Don’t be fooled into thinking that if your `DEFAULT_CHARSET` setting is set to something other than `'utf-8'` you can use that other encoding in your bytestrings! `DEFAULT_CHARSET` only applies to the strings generated as the result of template rendering (and email). Django will always assume UTF-8 encoding for internal bytestrings. The reason for this is that the `DEFAULT_CHARSET` setting is not actually under your control (if you are the application developer). It’s under the control of the person installing and using your application—and if that person chooses a different setting, your code must still continue to work. Ergo, it cannot rely on that setting.

In most cases when Django is dealing with strings, it will convert them to strings before doing anything else. So, as a general rule, if you pass in a bytestring, be prepared to receive a string back in the result.

**Translated strings**

Aside from strings and bytestrings, there’s a third type of string-like object you may encounter when using Django. The framework’s internationalization features introduce the concept of a “lazy translation” — a string that has been marked as translated but whose actual translation result isn’t determined until the object is used in a string. This feature is useful in cases where the translation locale is unknown until the string is used, even though the string might have originally been created when the code was first imported.

Normally, you won’t have to worry about lazy translations. Just be aware that if you examine an object and it claims to be a `django.utils.functional.__proxy__` object, it is a lazy translation. Calling `str()` with the lazy translation as the argument will generate a string in the current locale.

For more details about lazy translation objects, refer to the [internationalization documentation](https://docs.djangoproject.com/en/4.2/topics/i18n/).

**Useful utility functions**

Because some string operations come up again and again, Django ships with a few useful functions that should make working with string and bytestring objects a bit easier.
Conversion functions

The `django.utils.encoding` module contains a few functions that are handy for converting back and forth between strings and bytestrings.

- `smart_str(s, encoding='utf-8', strings_only=False, errors='strict')` converts its input to a string. The `encoding` parameter specifies the input encoding. (For example, Django uses this internally when processing form input data, which might not be UTF-8 encoded.) The `strings_only` parameter, if set to True, will result in Python numbers, booleans and `None` not being converted to a string (they keep their original types). The `errors` parameter takes any of the values that are accepted by Python’s `str()` function for its error handling.

- `force_str(s, encoding='utf-8', strings_only=False, errors='strict')` is identical to `smart_str()` in almost all cases. The difference is when the first argument is a lazy translation instance. While `smart_str()` preserves lazy translations, `force_str()` forces those objects to a string (causing the translation to occur). Normally, you’ll want to use `smart_str()`. However, `force_str()` is useful in template tags and filters that absolutely must have a string to work with, not just something that can be converted to a string.

- `smart_bytes(s, encoding='utf-8', strings_only=False, errors='strict')` is essentially the opposite of `smart_str()`. It forces the first argument to a bytestring. The `strings_only` parameter has the same behavior as for `smart_str()` and `force_str()`. This is slightly different semantics from Python’s built-in `str()` function, but the difference is needed in a few places within Django’s internals.

Normally, you’ll only need to use `force_str()`. Call it as early as possible on any input data that might be either a string or a bytestring, and from then on, you can treat the result as always being a string.

URI and IRI handling

Web frameworks have to deal with URLs (which are a type of IRI). One requirement of URLs is that they are encoded using only ASCII characters. However, in an international environment, you might need to construct a URL from an IRI—very loosely speaking, a URI that can contain Unicode characters. Use these functions for quoting and converting an IRI to a URI:

- The `django.utils.encoding.iri_to_uri()` function, which implements the conversion from IRI to URI as required by RFC 3987#section-3.1.

- The `urllib.parse.quote()` and `urllib.parse.quote_plus()` functions from Python’s standard library.

These two groups of functions have slightly different purposes, and it’s important to keep them straight. Normally, you would use `quote()` on the individual portions of the IRI or URI path so that any reserved characters such as ‘&’ or ‘%’ are correctly encoded. Then, you apply `iri_to_uri()` to the full IRI and it converts any non-ASCII characters to the correct encoded values.
Note: Technically, it isn’t correct to say that \texttt{iri\_to\_uri()} implements the full algorithm in the IRI specification. It doesn’t (yet) perform the international domain name encoding portion of the algorithm.

The \texttt{iri\_to\_uri()} function will not change ASCII characters that are otherwise permitted in a URL. So, for example, the character ‘%’ is not further encoded when passed to \texttt{iri\_to\_uri()}. This means you can pass a full URL to this function and it will not mess up the query string or anything like that.

An example might clarify things here:

```python
>>> from urllib.parse import quote
>>> from django.utils.encoding import iri_to_uri

>>> quote('Paris & Orléans')
'Paris%20%26%20Orl%C3%A9ans'

>>> iri_to_uri('/favorites/François/%s' % quote('Paris & Orléans'))
'/favorites/Fran%C3%A7ois/Paris%20%26%20Orl%C3%A9ans'
```

If you look carefully, you can see that the portion that was generated by \texttt{quote()} in the second example was not double-quoted when passed to \texttt{iri\_to\_uri()}. This is a very important and useful feature. It means that you can construct your IRI without worrying about whether it contains non-ASCII characters and then, right at the end, call \texttt{iri\_to\_uri()} on the result.

Similarly, Django provides \texttt{django.utils.encoding.uri\_to\_iri()} which implements the conversion from URI to IRI as per RFC 3987#section-3.2.

An example to demonstrate:

```python
>>> from django.utils.encoding import uri_to_iri

>>> uri_to_iri('/%E2%99%A5%E2%99%A5/?utf8=%E2%9C%93')
'/♡♡/?utf8=✓'

>>> uri_to_iri('%A9hello%3Fworld')
'%A9hello%3Fworld'
```

In the first example, the UTF-8 characters are unquoted. In the second, the percent-encodings remain unchanged because they lie outside the valid UTF-8 range or represent a reserved character.

Both \texttt{iri\_to\_uri()} and \texttt{uri\_to\_iri()} functions are idempotent, which means the following is always true:

\[
\text{iri\_to\_uri(iri\_to\_uri(some\_string))} == \text{iri\_to\_uri(some\_string)}
\]
\[
\text{uri\_to\_iri(uri\_to\_iri(some\_string))} == \text{uri\_to\_iri(some\_string)}
\]

So you can safely call it multiple times on the same URI/IRI without risking double-quoting problems.
6.24.3 Models

Because all strings are returned from the database as `str` objects, model fields that are character based (CharField, TextField, URLField, etc.) will contain Unicode values when Django retrieves data from the database. This is always the case, even if the data could fit into an ASCII bytestring.

You can pass in bytestrings when creating a model or populating a field, and Django will convert it to strings when it needs to.

**Taking care in `get_absolute_url()`**

URLs can only contain ASCII characters. If you’re constructing a URL from pieces of data that might be non-ASCII, be careful to encode the results in a way that is suitable for a URL. The `reverse()` function handles this for you automatically.

If you’re constructing a URL manually (i.e., not using the `reverse()` function), you’ll need to take care of the encoding yourself. In this case, use the `iri_to_uri()` and `quote()` functions that were documented above. For example:

```python
from urllib.parse import quote
from django.utils.encoding import iri_to_uri

def get_absolute_url(self):
    url = '/person/%s/?x=0&y=0' % quote(self.location)
    return iri_to_uri(url)
```

This function returns a correctly encoded URL even if `self.location` is something like “Jack visited Paris & Orléans”. (In fact, the `iri_to_uri()` call isn’t strictly necessary in the above example, because all the non-ASCII characters would have been removed in quoting in the first line.)

6.24.4 Templates

Use strings when creating templates manually:

```python
from django.template import Template
t2 = Template('This is a string template.')
```

But the common case is to read templates from the filesystem. If your template files are not stored with a UTF-8 encoding, adjust the `TEMPLATES` setting. The built-in `django` backend provides the `file_charset` option to change the encoding used to read files from disk.

The `DEFAULT_CHARSET` setting controls the encoding of rendered templates. This is set to UTF-8 by default.
Template tags and filters

A couple of tips to remember when writing your own template tags and filters:

- Always return strings from a template tag’s `render()` method and from template filters.
- Use `force_str()` in preference to `smart_str()` in these places. Tag rendering and filter calls occur as the template is being rendered, so there is no advantage to postponing the conversion of lazy translation objects into strings. It’s easier to work solely with strings at that point.

6.24.5 Files

If you intend to allow users to upload files, you must ensure that the environment used to run Django is configured to work with non-ASCII file names. If your environment isn’t configured correctly, you’ll encounter `UnicodeEncodeError` exceptions when saving files with file names or content that contains non-ASCII characters.

Filesytem support for UTF-8 file names varies and might depend on the environment. Check your current configuration in an interactive Python shell by running:

```python
import sys
sys.getfilesystemencoding()
```

This should output “UTF-8”.

The `LANG` environment variable is responsible for setting the expected encoding on Unix platforms. Consult the documentation for your operating system and application server for the appropriate syntax and location to set this variable. See the How to use Django with Apache and mod_wsgi for examples.

In your development environment, you might need to add a setting to your `.bashrc` analogous to:

```bash
export LANG="en_US.UTF-8"
```

6.24.6 Form submission

HTML form submission is a tricky area. There’s no guarantee that the submission will include encoding information, which means the framework might have to guess at the encoding of submitted data.

Django adopts a “lazy” approach to decoding form data. The data in an `HttpRequest` object is only decoded when you access it. In fact, most of the data is not decoded at all. Only the `HttpRequest.GET` and `HttpRequest.POST` data structures have any decoding applied to them. Those two fields will return their members as Unicode data. All other attributes and methods of `HttpRequest` return data exactly as it was submitted by the client.
By default, the `DEFAULT_CHARSET` setting is used as the assumed encoding for form data. If you need to change this for a particular form, you can set the `encoding` attribute on an `HttpRequest` instance. For example:

```python
def some_view(request):
    # We know that the data must be encoded as KOI8-R (for some reason).
    request.encoding = 'koi8-r'

...```

You can even change the encoding after having accessed `request.GET` or `request.POST`, and all subsequent accesses will use the new encoding.

Most developers won’t need to worry about changing form encoding, but this is a useful feature for applications that talk to legacy systems whose encoding you cannot control.

Django does not decode the data of file uploads, because that data is normally treated as collections of bytes, rather than strings. Any automatic decoding there would alter the meaning of the stream of bytes.

### 6.25 `django.urls` utility functions

#### 6.25.1 `reverse()`

If you need to use something similar to the `url` template tag in your code, Django provides the following function:

```python
reverse(viewname, urlconf=None, args=None, kwargs=None, current_app=None)
```

`viewname` can be a URL pattern name or the callable view object. For example, given the following URL:

```python
from news import views

path('archive/', views.archive, name='news-archive')
```

you can use any of the following to reverse the URL:

```python
# using the named URL
reverse('news-archive')

# passing a callable object
# (This is discouraged because you can't reverse namespaced views this way.)
from news import views
reverse(views.archive)
```

If the URL accepts arguments, you may pass them in `args`. For example:
from django.urls import reverse

def myview(request):
    return HttpResponseRedirect(reverse('arch-summary', args=[1945]))

You can also pass **kwargs instead of **args. For example:

```python
>>> reverse('admin:app_list', kwargs={'app_label': 'auth'})
'/admin/auth/'
```

**args** and **kwargs** cannot be passed to reverse() at the same time.

If no match can be made, reverse() raises a `NoReverseMatch` exception.

The reverse() function can reverse a large variety of regular expression patterns for URLs, but not every possible one. The main restriction at the moment is that the pattern cannot contain alternative choices using the vertical bar ("|") character. You can quite happily use such patterns for matching against incoming URLs and sending them off to views, but you cannot reverse such patterns.

The `current_app` argument allows you to provide a hint to the resolver indicating the application to which the currently executing view belongs. This `current_app` argument is used as a hint to resolve application namespaces into URLs on specific application instances, according to the namespaced URL resolution strategy.

The `urlconf` argument is the URLconf module containing the URL patterns to use for reversing. By default, the root URLconf for the current thread is used.

---

Note: The string returned by reverse() is already urlquoted. For example:

```python
>>> reverse('cities', args=['Orléans'])
'.../Orl%C3%A9ans/
```

Applying further encoding (such as `urllib.parse.quote()`) to the output of reverse() may produce undesirable results.

---

### 6.25.2 reverse_lazy()

A lazily evaluated version of reverse().

**reverse_lazy**(viewname, urlconf=None, args=None, kwargs=None, current_app=None)

It is useful for when you need to use a URL reversal before your project’s URLConf is loaded. Some common cases where this function is necessary are:

- providing a reversed URL as the url attribute of a generic class-based view.
• providing a reversed URL to a decorator (such as the login_url argument for the django.contrib.auth.decorators.permission_required() decorator).

• providing a reversed URL as a default value for a parameter in a function’s signature.

### 6.25.3 resolve()

The resolve() function can be used for resolving URL paths to the corresponding view functions. It has the following signature:

```python
resolve(path, urlconf=None)
```

path is the URL path you want to resolve. As with reverse(), you don’t need to worry about the urlconf parameter. The function returns a ResolverMatch object that allows you to access various metadata about the resolved URL.

If the URL does not resolve, the function raises a Resolver404 exception (a subclass of Http404).

```python
class ResolverMatch

    func
        The view function that would be used to serve the URL.

    args
        The arguments that would be passed to the view function, as parsed from the URL.

    kwargs
        All keyword arguments that would be passed to the view function, i.e. captured_kwargs and extra_kwargs.

    captured_kwargs
        The captured keyword arguments that would be passed to the view function, as parsed from the URL.

    extra_kwargs
        The additional keyword arguments that would be passed to the view function.

    url_name
        The name of the URL pattern that matches the URL.

    route
        The route of the matching URL pattern.

        For example, if path('users/<id>/', ...) is the matching pattern, route will contain 'users/<id>/'.

    tried
        The list of URL patterns tried before the URL either matched one or exhausted available patterns.
```
app_name
    The application namespace for the URL pattern that matches the URL.

app_names
    The list of individual namespace components in the full application namespace for the URL pattern that matches the URL. For example, if the app_name is 'foo:bar', then app_names will be ['foo', 'bar'].
	namespace
    The instance namespace for the URL pattern that matches the URL.

namespaces
    The list of individual namespace components in the full instance namespace for the URL pattern that matches the URL. i.e., if the namespace is foo:bar, then namespaces will be ['foo', 'bar'].

view_name
    The name of the view that matches the URL, including the namespace if there is one.

A ResolverMatch object can then be interrogated to provide information about the URL pattern that matches a URL:

```python
# Resolve a URL
match = resolve('/some/path/')
# Print the URL pattern that matches the URL
print(match.url_name)
```

A ResolverMatch object can also be assigned to a triple:

```python
func, args, kwargs = resolve('/some/path/')
```

One possible use of resolve() would be to test whether a view would raise a Http404 error before redirecting to it:

```python
from urllib.parse import urlparse
from django.urls import resolve
from django.http import Http404, HttpResponseRedirect

def myview(request):
    next = request.META.get('HTTP_REFERER', None) or '/'
    response = HttpResponseRedirect(next)

    # modify the request and response as required, e.g. change locale
    # and set corresponding locale cookie

    view, args, kwargs = resolve(urlparse(next)[2])
    kwargs['request'] = request
```

(continues on next page)
try:
    view(*args, **kwargs)
except Http404:
    return HttpResponseRedirect('/')
return response

6.25.4 get_script_prefix()

get_script_prefix()

Normally, you should always use `reverse()` to define URLs within your application. However, if your application constructs part of the URL hierarchy itself, you may occasionally need to generate URLs. In that case, you need to be able to find the base URL of the Django project within its web server (normally, `reverse()` takes care of this for you). In that case, you can call `get_script_prefix()`, which will return the script prefix portion of the URL for your Django project. If your Django project is at the root of its web server, this is always "/".

6.26 django.urls functions for use in URLconf

6.26.1 path()

path(route, view, kwarg=None, name=None)

Returns an element for inclusion in `urlpatterns`. For example:

```python
from django.urls import include, path

urlpatterns = [
    path('index/', views.index, name='main-view'),
    path('bio/<username>/', views.bio, name='bio'),
    path('articles/<slug:title>/', views.article, name='article-detail'),
    path('articles/<slug:title>/<int:section>/', views.section, name='article-section'),
    path('blog/', include('blog.urls')),
    ...
]
```

The `route` argument should be a string or `gettext_lazy()` (see Translating URLs) that contains a URL pattern. The string may contain angle brackets (like `<username>` above) to capture part of the URL and send it as a keyword argument to the view. The angle brackets may include a converter specification (like the `int` part of `<int:section>`) which limits the characters matched and may also change the type of the
variable passed to the view. For example, `<int:section>` matches a string of decimal digits and converts
the value to an `int`. See How Django processes a request for more details.

The `view` argument is a view function or the result of `as_view()` for class-based views. It can also be an
django.urls.include().

The `kwargs` argument allows you to pass additional arguments to the view function or method. See Passing
extra options to view functions for an example.

See Naming URL patterns for why the `name` argument is useful.

### 6.26.2 re_path()

**re_path**(route, view, kwargs=None, name=None)

Returns an element for inclusion in `urlpatterns`. For example:

```python
from django.urls import include, re_path

urlpatterns = [
    re_path(r'^index/$', views.index, name='index'),
    re_path(r'^bio/(?P<username>\w+)/$', views.bio, name='bio'),
    re_path(r'^blog/$', include('blog.urls')),
    ...
]
```

The `route` argument should be a string or `gettext_lazy()` (see Translating URL patterns) that contains a
regular expression compatible with Python’s `re` module. Strings typically use raw string syntax (r'') so that
they can contain sequences like \d without the need to escape the backslash with another backslash. When
a match is made, captured groups from the regular expression are passed to the view –as named arguments
if the groups are named, and as positional arguments otherwise. The values are passed as strings, without
any type conversion.

When a `route` ends with $ the whole requested URL, matching against `path_info`, must match the regular
expression pattern (`re.fullmatch()` is used).

The `view`, `kwargs` and `name` arguments are the same as for `path()`.

In older versions, a full-match wasn’t required for a `route` which ends with $.
6.26.3 include()

include(module, namespace=None)
include(pattern_list)
include((pattern_list, app_namespace), namespace=None)

A function that takes a full Python import path to another URLconf module that should be “included” in this place. Optionally, the application namespace and instance namespace where the entries will be included into can also be specified.

Usually, the application namespace should be specified by the included module. If an application namespace is set, the namespace argument can be used to set a different instance namespace.

include() also accepts as an argument either an iterable that returns URL patterns or a 2-tuple containing such iterable plus the names of the application namespaces.

Parameters

- **module** – URLconf module (or module name)
- **namespace** *(str)* – Instance namespace for the URL entries being included
- **pattern_list** – Iterable of `path()` and/or `re_path()` instances.
- **app_namespace** *(str)* – Application namespace for the URL entries being included

See Including other URLconfs and URL namespaces and included URLconfs.

6.26.4 register_converter()

register_converter(converter, type_name)

The function for registering a converter for use in `path()` routes.

The converter argument is a converter class, and type_name is the converter name to use in path patterns. See Registering custom path converters for an example.

6.27 django.conf.urls functions for use in URLconfs

6.27.1 static()

static.static(prefix, view=django.views.static.serve, **kwargs)

Helper function to return a URL pattern for serving files in debug mode:
from django.conf import settings
from django.conf.urls.static import static

urlpatterns = [
    # ... the rest of your URLconf goes here ...
] + static(settings.MEDIA_URL, document_root=settings.MEDIA_ROOT)

6.27.2 handler400

handler400

A callable, or a string representing the full Python import path to the view that should be called if the HTTP client has sent a request that caused an error condition and a response with a status code of 400.

By default, this is `django.views.defaults.bad_request()`. If you implement a custom view, be sure it accepts `request` and `exception` arguments and returns an `HttpResponseBadRequest`.

6.27.3 handler403

handler403

A callable, or a string representing the full Python import path to the view that should be called if the user doesn’t have the permissions required to access a resource.

By default, this is `django.views.defaults.permission_denied()`. If you implement a custom view, be sure it accepts `request` and `exception` arguments and returns an `HttpResponseForbidden`.

6.27.4 handler404

handler404

A callable, or a string representing the full Python import path to the view that should be called if none of the URL patterns match.

By default, this is `django.views.defaults.page_not_found()`. If you implement a custom view, be sure it accepts `request` and `exception` arguments and returns an `HttpResponseNotFound`. 
6.27.5 handler500

handler500

A callable, or a string representing the full Python import path to the view that should be called in case of server errors. Server errors happen when you have runtime errors in view code.

By default, this is `django.views.defaults.server_error()`. If you implement a custom view, be sure it accepts a `request` argument and returns an `HttpResponseServerError`.

6.28 Django Utils

This document covers all stable modules in `django.utils`. Most of the modules in `django.utils` are designed for internal use and only the following parts can be considered stable and thus backwards compatible as per the internal release deprecation policy.

6.28.1 `django.utils.cache`

This module contains helper functions for controlling HTTP caching. It does so by managing the `Vary` header of responses. It includes functions to patch the header of response objects directly and decorators that change functions to do that header-patching themselves.

For information on the `Vary` header, see RFC 7231#section-7.1.4.

Essentially, the `Vary` HTTP header defines which headers a cache should take into account when building its cache key. Requests with the same path but different header content for headers named in `Vary` need to get different cache keys to prevent delivery of wrong content.

For example, `internationalization` middleware would need to distinguish caches by the `Accept-language` header.

`patch_cache_control`(response, **kwargs)

This function patches the `Cache-Control` header by adding all keyword arguments to it. The transformation is as follows:

- All keyword parameter names are turned to lowercase, and underscores are converted to hyphens.
- If the value of a parameter is `True` (exactly `True`, not just a true value), only the parameter name is added to the header.
- All other parameters are added with their value, after applying `str()` to it.

`get_max_age`(response)

Returns the max-age from the response Cache-Control header as an integer (or `None` if it wasn’t found or wasn’t an integer).
**patch_response_headers** *(response, cache_timeout=None)*

Adds some useful headers to the given `HttpResponse` object:

- Expires
- Cache-Control

Each header is only added if it isn’t already set.

*cache_timeout* is in seconds. The `CACHE_MIDDLEWARE_SECONDS` setting is used by default.

**add_never_cache_headers** *(response)*

Adds an Expires header to the current date/time.

Addsa Cache-Control: max-age=0, no-cache, no-store, must-revalidate, private header to a response to indicate that a page should never be cached.

Each header is only added if it isn’t already set.

**patch_vary_headers** *(response, newheaders)*

Adds (or updates) the Vary header in the given `HttpResponse` object. `newheaders` is a list of header names that should be in Vary. If headers contains an asterisk, then Vary header will consist of a single asterisk ‘*’, according to RFC7231#section-7.1.4. Otherwise, existing headers in Vary aren’t removed.

**get_cache_key** *(request, key_prefix=None, method='GET', cache=None)*

Returns a cache key based on the request path. It can be used in the request phase because it pulls the list of headers to take into account from the global path registry and uses those to build a cache key to check against.

If there is no headerlist stored, the page needs to be rebuilt, so this function returns `None`.

**learn_cache_key** *(request, response, cache_timeout=None, key_prefix=None, cache=None)*

Learns what headers to take into account for some request path from the response object. It stores those headers in a global path registry so that later access to that path will know what headers to take into account without building the response object itself. The headers are named in the Vary header of the response, but we want to prevent response generation.

The list of headers to use for cache key generation is stored in the same cache as the pages themselves. If the cache ages some data out of the cache, this means that we have to build the response once to get at the Vary header and so at the list of headers to use for the cache key.
6.28.2 django.utils.dateparse

The functions defined in this module share the following properties:

- They accept strings in ISO 8601 date/time formats (or some close alternatives) and return objects from the corresponding classes in Python’s `datetime` module.
- They raise `ValueError` if their input is well formatted but isn’t a valid date or time.
- They return `None` if it isn’t well formatted at all.
- They accept up to picosecond resolution in input, but they truncate it to microseconds, since that’s what Python supports.

`parse_date`(value)

Parses a string and returns a `datetime.date`.

`parse_time`(value)

Parses a string and returns a `datetime.time`.

UTC offsets aren’t supported; if `value` describes one, the result is `None`.

`parse_datetime`(value)

Parses a string and returns a `datetime.datetime`.

UTC offsets are supported; if `value` describes one, the result’s `tzinfo` attribute is a `datetime.timezone` instance.

`parse_duration`(value)

Parses a string and returns a `datetime.timedelta`.

Expects data in the format "DD HH:MM:SS.uuuuuu", "DD HH:MM:SS,uuuuuu", or as specified by ISO 8601 (e.g. P4DT1H15M20S which is equivalent to 4 1:15:20) or PostgreSQL’s day-time interval format (e.g. 3 days 04:05:06).

6.28.3 django.utils.decorators

`method_decorator`(decorator, name="")

Converts a function decorator into a method decorator. It can be used to decorate methods or classes; in the latter case, `name` is the name of the method to be decorated and is required.

`decorator` may also be a list or tuple of functions. They are wrapped in reverse order so that the call order is the order in which the functions appear in the list/tuple.

See `decorating class based views` for example usage.

`decorator_from_middleware`(middleware_class)

Given a middleware class, returns a view decorator. This lets you use middleware functionality on a per-view basis. The middleware is created with no params passed.
It assumes middleware that’s compatible with the old style of Django 1.9 and earlier (having methods like `process_request()`, `process_exception()`, and `process_response()`).

**decorator_from_middleware_with_args(middleware_class)**

Like `decorator_from_middleware`, but returns a function that accepts the arguments to be passed to the `middleware_class`. For example, the `cache_page()` decorator is created from the `CacheMiddleware` like this:

```python
cache_page = decorator_from_middleware_with_args(CacheMiddleware)

@cache_page(3600)
def my_view(request):
    pass
```

**sync_only_middleware(middleware)**

Marks a middleware as **synchronous-only**. (The default in Django, but this allows you to future-proof if the default ever changes in a future release.)

**async_only_middleware(middleware)**

Marks a middleware as **asynchronous-only**. Django will wrap it in an asynchronous event loop when it is called from the WSGI request path.

**sync_and_async_middleware(middleware)**

Marks a middleware as **sync and async compatible**, this allows to avoid converting requests. You must implement detection of the current request type to use this decorator. See asynchronous middleware documentation for details.

### 6.28.4 django.utils.encoding

**smart_str(s, encoding='utf-8', strings_only=False, errors='strict')**

Returns a `str` object representing arbitrary object `s`. Treats byte strings using the `encoding` codec.

If `strings_only` is True, don’t convert (some) non-string-like objects.

**is_protected_type(obj)**

Determine if the object instance is of a protected type.

Objects of protected types are preserved as-is when passed to `force_str(strings_only=True)`.

**force_str(s, encoding='utf-8', strings_only=False, errors='strict')**

Similar to `smart_str()`, except that lazy instances are resolved to strings, rather than kept as lazy objects.

If `strings_only` is True, don’t convert (some) non-string-like objects.
smart_bytes(s, encoding='utf-8', strings_only=False, errors='strict')

Returns a bytestring version of arbitrary object s, encoded as specified in encoding.

If strings_only is True, don’t convert (some) non-string-like objects.

force_bytes(s, encoding='utf-8', strings_only=False, errors='strict')

Similar to smart_bytes, except that lazy instances are resolved to bytestrings, rather than kept as lazy objects.

If strings_only is True, don’t convert (some) non-string-like objects.

iri_to_uri(iri)

Convert an Internationalized Resource Identifier (IRI) portion to a URI portion that is suitable for inclusion in a URL.

This is the algorithm from section 3.1 of RFC 3987#section-3.1, slightly simplified since the input is assumed to be a string rather than an arbitrary byte stream.

Takes an IRI (string or UTF-8 bytes) and returns a string containing the encoded result.

uri_to_iri(uri)

Converts a Uniform Resource Identifier into an Internationalized Resource Identifier.

This is an algorithm from section 3.2 of RFC 3987#section-3.2.

Takes a URI in ASCII bytes and returns a string containing the encoded result.

filepath_to_uri(path)

Convert a file system path to a URI portion that is suitable for inclusion in a URL. The path is assumed to be either UTF-8 bytes, string, or a Path.

This method will encode certain characters that would normally be recognized as special characters for URIs. Note that this method does not encode the ‘ character, as it is a valid character within URIs. See encodeURIComponent() JavaScript function for more details.

Returns an ASCII string containing the encoded result.

escape_uri_path(path)

Escapes the unsafe characters from the path portion of a Uniform Resource Identifier (URI).

6.28.5 django.utils.feedgenerator

Sample usage:

```python
>>> from django.utils import feedgenerator
>>> feed = feedgenerator.Rss201rev2Feed(...)  
...    title='Poynter E-Media Tidbits',
...    link='http://www.poynter.org/column.asp?id=31',
```
...  description="A group blog by the sharpest minds in online media/journalism/publishing.",
...  language="en",
... )
>>> feed.add_item(
...  title="Hello",
...  link="http://www.holovaty.com/test/",
...  description="Testing.",
... )
>>> with open('test.rss', 'w') as fp:
...  feed.write(fp, 'utf-8')

For simplifying the selection of a generator use feedgenerator.DefaultFeed which is currently Rss201rev2Feed

For definitions of the different versions of RSS, see: https://web.archive.org/web/20110718035220/http://diveintomark.org/archives/2004/02/04/incompatible-rss

get_tag_uri(url, date)

  Creates a TagURI.

SyndicationFeed

class SyndicationFeed

  Base class for all syndication feeds. Subclasses should provide write().

  __init__(title, link, description, language=None, author_email=None, author_name=None,  
  author_link=None, subtitle=None, categories=None, feed_url=None,  
  feed_copyright=None, feed_guid=None, ttl=None, **kwargs)

    Initialize the feed with the given dictionary of metadata, which applies to the entire feed.

    Any extra keyword arguments you pass to __init__ will be stored in self.feed.

    All parameters should be strings, except categories, which should be a sequence of strings.

  add_item(title, link, description, author_email=None, author_name=None, author_link=None,  
  pubdate=None, comments=None, unique_id=None, categories=(), item_copyright=None,  
  ttl=None, updateddate=None, enclosures=None, **kwargs)

    Adds an item to the feed. All args are expected to be strings except pubdate and updateddate,  
    which are datetime.datetime objects, and enclosures, which is a list of Enclosure instances.

  num_items()
root_attributes()
    Return extra attributes to place on the root (i.e. feed/channel) element. Called from write().

add_root_elements(handler)
    Add elements in the root (i.e. feed/channel) element. Called from write().

item_attributes(item)
    Return extra attributes to place on each item (i.e. item/entry) element.

add_item_elements(handler, item)
    Add elements on each item (i.e. item/entry) element.

write(outfile, encoding)
    Outputs the feed in the given encoding to outfile, which is a file-like object. Subclasses should
    override this.

writeString(encoding)
    Returns the feed in the given encoding as a string.

latest_post_date()
    Returns the latest pubdate or updateddate for all items in the feed. If no items have either of
    these attributes this returns the current UTC date/time.

Enclosure

class Enclosure
    Represents an RSS enclosure

RssFeed

class RssFeed(SyndicationFeed)

Rss201rev2Feed

class Rss201rev2Feed(RssFeed)
    Spec: https://cyber.harvard.edu/rss/rss.html
RssUserland091Feed

```python
class RssUserland091Feed(RssFeed):
    Spec: http://backend.userland.com/rss091
```

Atom1Feed

```python
class Atom1Feed(SyndicationFeed):
    Spec: RFC 4287
```

### 6.28.6 `django.utils.functional`

```python
class cached_property(func, name=None)
```

The `@cached_property` decorator caches the result of a method with a single `self` argument as a property. The cached result will persist as long as the instance does, so if the instance is passed around and the function subsequently invoked, the cached result will be returned.

Consider a typical case, where a view might need to call a model’s method to perform some computation, before placing the model instance into the context, where the template might invoke the method once more:

```python
# the model
class Person(models.Model):

    def friends(self):
        # expensive computation
        ...
        return friends

# in the view:
if person.friends():
    ...
```

And in the template you would have:

```html
{% for friend in person.friends %}
...
```

Here, `friends()` will be called twice. Since the instance `person` in the view and the template are the same, decorating the `friends()` method with `@cached_property` can avoid that:

```python
from django.utils.functional import cached_property

class Person(models.Model):
```

(continues on next page)
@cached_property
def friends(self):
...

Note that as the method is now a property, in Python code it will need to be accessed appropriately:

```python
# in the view:
if person.friends:
...
```

The cached value can be treated like an ordinary attribute of the instance:

```python
# clear it, requiring re-computation next time it's called
del person.friends # or delattr(person, "friends")

# set a value manually, that will persist on the instance until cleared
person.friends = ["Huckleberry Finn", "Tom Sawyer"]
```

Because of the way the descriptor protocol works, using `del` (or `delattr`) on a `cached_property` that hasn’t been accessed raises `AttributeError`.

As well as offering potential performance advantages, `@cached_property` can ensure that an attribute’s value does not change unexpectedly over the life of an instance. This could occur with a method whose computation is based on `datetime.now()`, or if a change were saved to the database by some other process in the brief interval between subsequent invocations of a method on the same instance.

You can make cached properties of methods. For example, if you had an expensive `get_friends()` method and wanted to allow calling it without retrieving the cached value, you could write:

```python
friends = cached_property(get_friends)
```

While `person.get_friends()` will recompute the friends on each call, the value of the cached property will persist until you delete it as described above:

```python
x = person.friends          # calls first time
y = person.get_friends()   # calls again
z = person.friends         # does not call
x is z                      # is True
```

Deprecated since version 4.1: The `name` parameter is deprecated and will be removed in Django 5.0 as it’s unnecessary as of Python 3.6.

```python
class classproperty(method=None)
```

Similar to `@classmethod`, the `@classproperty` decorator converts the result of a method with a single
cls argument into a property that can be accessed directly from the class.

```
keep_lazy(func, *resultclasses)
```

Django offers many utility functions (particularly in `django.utils`) that take a string as their first argument and do something to that string. These functions are used by template filters as well as directly in other code.

If you write your own similar functions and deal with translations, you’ll face the problem of what to do when the first argument is a lazy translation object. You don’t want to convert it to a string immediately, because you might be using this function outside of a view (and hence the current thread’s locale setting will not be correct).

For cases like this, use the `django.utils.functional.keep_lazy()` decorator. It modifies the function so that if it’s called with a lazy translation as one of its arguments, the function evaluation is delayed until it needs to be converted to a string.

For example:

```python
from django.utils.functional import keep_lazy, keep_lazy_text

def fancy_utility_function(s, ...):
    # Do some conversion on string 's'
    ...

fancy_utility_function = keep_lazy(str)(fancy_utility_function)

# Or more succinctly:
@keep_lazy(str)
def fancy_utility_function(s, ...):
    ...
```

The `keep_lazy()` decorator takes a number of extra arguments (`*args`) specifying the type(s) that the original function can return. A common use case is to have functions that return text. For these, you can pass the `str` type to `keep_lazy` (or use the `keep_lazy_text()` decorator described in the next section).

Using this decorator means you can write your function and assume that the input is a proper string, then add support for lazy translation objects at the end.

```
keep_lazy_text(func)
```

A shortcut for `keep_lazy(str)(func)`.

If you have a function that returns text and you want to be able to take lazy arguments while delaying their evaluation, you can use this decorator:

```python
from django.utils.functional import keep_lazy, keep_lazy_text

# Our previous example was:
```
@keep_lazy(str)
def fancy_utility_function(s, ...):
    ...

# Which can be rewritten as:
@keep_lazy_text
def fancy_utility_function(s, ...):
    ...

6.28.7 django.utils.html

Usually you should build up HTML using Django’s templates to make use of its autoescape mechanism, using the utilities in `django.utils.safestring` where appropriate. This module provides some additional low level utilities for escaping HTML.

escape(text)

Returns the given text with ampersands, quotes and angle brackets encoded for use in HTML. The input is first coerced to a string and the output has `mark_safe()` applied.

conditional_escape(text)

Similar to `escape()`, except that it doesn’t operate on preescaped strings, so it will not double escape.

format_html(format_string,*args,**kwargs)

This is similar to `str.format()`, except that it is appropriate for building up HTML fragments. All args and kwargs are passed through `conditional_escape()` before being passed to `str.format()`.

For the case of building up small HTML fragments, this function is to be preferred over string interpolation using `%` or `str.format()` directly, because it applies escaping to all arguments - just like the template system applies escaping by default.

So, instead of writing:

```python
mark_safe("%s <b>%s</b> %s" % (some_html, escape(some_text), escape(some_other_text), ))
```

You should instead use:

```python
format_html("{} <b>{}</b> {}", mark_safe(some_html), some_text,
```
This has the advantage that you don’t need to apply `escape()` to each argument and risk a bug and an XSS vulnerability if you forget one.

Note that although this function uses `str.format()` to do the interpolation, some of the formatting options provided by `str.format()` (e.g., number formatting) will not work, since all arguments are passed through `conditional_escape()` which (ultimately) calls `force_str()` on the values.

`format_html_join(sep, format_string, args_generator)`

A wrapper of `format_html()`, for the common case of a group of arguments that need to be formatted using the same format string, and then joined using `sep`. `sep` is also passed through `conditional_escape()`.

`args_generator` should be an iterator that returns the sequence of `args` that will be passed to `format_html()`.

For example:

```
format_html_join(
    '\n', "<li>{}</li>",
    (u.first_name, u.last_name) for u in users)
)
```

`json_script(value, element_id=None, encoder=None)`

Escapes all HTML/XML special characters with their Unicode escapes, so value is safe for use with JavaScript. Also wraps the escaped JSON in a `<script>` tag. If the `element_id` parameter is not `None`, the `<script>` tag is given the passed id. For example:

```
>> json_script({"hello": "world"}, element_id="hello-data")
'"<script id="hello-data" type="application/json">{"hello": "world"}</script>"
```

The `encoder`, which defaults to `django.core.serializers.json.DjangoJSONEncoder`, will be used to serialize the data. See JSON serialization for more details about this serializer.

In older versions, the `element_id` argument was required.

The `encoder` argument was added.

`strip_tags(value)`

Tries to remove anything that looks like an HTML tag from the string, that is anything contained within `<`.

Absolutely NO guarantee is provided about the resulting string being HTML safe. So NEVER mark safe the result of a `strip_tag` call without escaping it first, for example with `escape()`.

For example:
strip_tags(value)

If value is "<b>Joel</b> <button>is</button> a <span>slug</span>" the return value will be "Joel is a slug".

If you are looking for a more robust solution, take a look at the bleach Python library.

html_safe()

The __html__() method on a class helps non-Django templates detect classes whose output doesn’t require HTML escaping.

This decorator defines the __html__() method on the decorated class by wrapping __str__() in mark_safe(). Ensure the __str__() method does indeed return text that doesn’t require HTML escaping.

6.28.8 django.utils.http

urlencode(query, doseq=False)

A version of Python’s urllib.parse.urlencode() function that can operate on MultiValueDict and non-string values.

http_date(epoch_seconds=None)

Formats the time to match the RFC 1123#section-5.2.14 date format as specified by HTTP RFC 7231#section-7.1.1.1.

Accepts a floating point number expressed in seconds since the epoch in UTC—such as that outputted by time.time(). If set to None, defaults to the current time.

Outputs a string in the format Wdy, DD Mon YYYY HH:MM:SS GMT.

base36_to_int(s)

Converts a base 36 string to an integer.

int_to_base36(i)

Converts a positive integer to a base 36 string.

urlsafe_base64_encode(s)

Encodes a bytestring to a base64 string for use in URLs, stripping any trailing equal signs.

urlsafe_base64_decode(s)

Decodes a base64 encoded string, adding back any trailing equal signs that might have been stripped.
6.28.9 django.utils.module_loading

Functions for working with Python modules.

import_string(dotted_path)

Imports a dotted module path and returns the attribute/class designated by the last name in the path. Raises ImportError if the import failed. For example:

```
from django.utils.module_loading import import_string
ValidationError = import_string('django.core.exceptions.ValidationError')
```

is equivalent to:

```
from django.core.exceptions import ValidationError
```

6.28.10 django.utils.safestring

Functions and classes for working with “safe strings”: strings that can be displayed safely without further escaping in HTML. Marking something as a “safe string” means that the producer of the string has already turned characters that should not be interpreted by the HTML engine (e.g. ‘<’) into the appropriate entities.

```
class SafeString
    A str subclass that has been specifically marked as “safe” (requires no further escaping) for HTML output purposes.
mark_safe(s)
    Explicitly mark a string as safe for (HTML) output purposes. The returned object can be used everywhere a string is appropriate.
    Can be called multiple times on a single string.
    Can also be used as a decorator.

    For building up fragments of HTML, you should normally be using django.utils.html.format_html() instead.

    String marked safe will become unsafe again if modified. For example:
```
```
>>> type(mystr)
<type 'str'>

6.28.11 django.utils.text

format_lazy(format_string, *args, **kwargs)
A version of str.format() for when format_string, args, and/or kwargs contain lazy objects. The first argument is the string to be formatted. For example:

```python
from django.utils.text import format_lazy
from django.utils.translation import pgettext_lazy

urlpatterns = [
    path(format_lazy('{person}/{int:pk}/', person=pgettext_lazy('URL', 'person')),
         PersonDetailView.as_view(),
]
```

This example allows translators to translate part of the URL. If “person” is translated to “persona”, the regular expression will match persona/(?P<pk>[\d]+)/, e.g. persona/5/.

slugify(value, allow_unicode=False)
Converts a string to a URL slug by:

1. Converting to ASCII if allow_unicode is False (the default).
2. Converting to lowercase.
3. Removing characters that aren’t alphanumeric, underscores, hyphens, or whitespace.
4. Replacing any whitespace or repeated dashes with single dashes.
5. Removing leading and trailing whitespace, dashes, and underscores.

For example:

```python
>>> slugify('Joel is a slug ')
'joel-is-a-slug'
```

If you want to allow Unicode characters, pass allow_unicode=True. For example:

```python
>>> slugify('你好 World', allow_unicode=True)
'你好-world'
```
6.28.12 django.utils.timezone

utc

tzinfo instance that represents UTC.

Deprecatesince version 4.1: This is an alias to datetime.timezone.utc. Use datetime.timezone.utc directly.

get_fixed_timezone(offset)

Returnsa tzinfo instance that represents a time zone with a fixed offset from UTC.

offset is a datetime.tzonedelta or an integer number of minutes. Use positive values for time zones east of UTC and negative values for west of UTC.

get_default_timezone()

Returnsa tzinfo instance that represents the default time zone.

get_default_timezone_name()

Returns the name of the default time zone.

get_current_timezone()

Returns a tzinfo instance that represents the current time zone.

get_current_timezone_name()

Returns the name of the current time zone.

activate(timezone)

Sets the current time zone. The timezone argument must be an instance of a tzinfo subclass or a time zone name.

deactivate()

Unsets the current time zone.

override(timezone)

This is a Python context manager that sets the current time zone on entry with activate(), and restores the previously active time zone on exit. If the timezone argument is None, the current time zone is unset on entry with deactivate() instead.

override is also usable as a function decorator.

localtime(value=None, timezone=None)

Converts an aware datetime to a different time zone, by default the current time zone.

When value is omitted, it defaults to now().

This function doesn’t work on naive datetimes; use make_aware() instead.
localdate(value=None, timezone=None)

Uses localtime() to convert an aware datetime to a date() in a different time zone, by default the current time zone.

When value is omitted, it defaults to now().

This function doesn’t work on naive datetimes.

now()

Returns a datetime that represents the current point in time. Exactly what’s returned depends on the value of USE_TZ:

- If USE_TZ is False, this will be a naive datetime (i.e. a datetime without an associated timezone) that represents the current time in the system’s local timezone.
- If USE_TZ is True, this will be an aware datetime representing the current time in UTC. Note that now() will always return times in UTC regardless of the value of TIME_ZONE; you can use localtime() to get the time in the current time zone.

is_aware(value)

Returns True if value is aware, False if it is naive. This function assumes that value is a datetime.

is_naive(value)

Returns True if value is naive, False if it is aware. This function assumes that value is a datetime.

make_aware(value, timezone=None, is_dst=None)

Returns an aware datetime that represents the same point in time as value in timezone, value being a naive datetime. If timezone is set to None, it defaults to the current time zone.

Deprecated since version 4.0: When using pytz, the pytz.AmbiguousTimeError exception is raised if you try to make value aware during a DST transition where the same time occurs twice (when reverting from DST). Setting is_dst to True or False will avoid the exception by choosing if the time is pre-transition or post-transition respectively.

When using pytz, the pytz.NonExistentTimeError exception is raised if you try to make value aware during a DST transition such that the time never occurred. For example, if the 2:00 hour is skipped during a DST transition, trying to make 2:30 aware in that time zone will raise an exception. To avoid that you can use is_dst to specify how make_aware() should interpret such a nonexistent time. If is_dst=True then the above time would be interpreted as 2:30 DST time (equivalent to 1:30 local time). Conversely, if is_dst=False the time would be interpreted as 2:30 standard time (equivalent to 3:30 local time).

The is_dst parameter has no effect when using non-pytz timezone implementations.

The is_dst parameter is deprecated and will be removed in Django 5.0.

make_naive(value, timezone=None)

Returns a naive datetime that represents in timezone the same point in time as value, value being an aware datetime. If timezone is set to None, it defaults to the current time zone.
6.28.13 django.utils.translation

For a complete discussion on the usage of the following see the translation documentation.

gettext(message)

Translates message and returns it as a string.

pgettext(context, message)

Translates message given the context and returns it as a string.

For more information, see Contextual markers.

gettext_lazy(message)

pgettext_lazy(context, message)

Same as the non-lazy versions above, but using lazy execution.

See lazy translations documentation.

ggettext_noop(message)

Marks strings for translation but doesn’t translate them now. This can be used to store strings in global variables that should stay in the base language (because they might be used externally) and will be translated later.

ngettext(singular, plural, number)

Translates singular and plural and returns the appropriate string based on number.

npgettext(context, singular, plural, number)

Translates singular and plural and returns the appropriate string based on number and the context.

ngettext_lazy(singular, plural, number)

npgettext_lazy(context, singular, plural, number)

Same as the non-lazy versions above, but using lazy execution.

See lazy translations documentation.

activate(language)

Fetches the translation object for a given language and activates it as the current translation object for the current thread.

deactivate()

Deactivates the currently active translation object so that further _ calls will resolve against the default translation object, again.

deactivate_all()

Makes the active translation object a NullTranslations() instance. This is useful when we want delayed translations to appear as the original string for some reason.
override (language, deactivate=False)

A Python context manager that uses `django.utils.translation.activate()` to fetch the translation object for a given language, activates it as the translation object for the current thread and reactivates the previous active language on exit. Optionally, it can deactivate the temporary translation on exit with `django.utils.translation.deactivate()` if the `deactivate` argument is `True`. If you pass `None` as the language argument, a `NullTranslations()` instance is activated within the context.

`override` is also usable as a function decorator.

cHECK_for_language (lang_code)

Checks whether there is a global language file for the given language code (e.g. ‘fr’, ‘pt_BR’). This is used to decide whether a user-provided language is available.

get_language()

Returns the currently selected language code. Returns `None` if translations are temporarily deactivated (by `deactivate_all()` or when `None` is passed to `override()`).

get_language_bidi()

Returns selected language’s BiDi layout:

- False = left-to-right layout
- True = right-to-left layout

get_language_from_request (request, check_path=False)

Analyzes the request to find what language the user wants the system to show. Only languages listed in settings.LANGUAGES are taken into account. If the user requests a sublanguage where we have a main language, we send out the main language.

If `check_path` is `True`, the function first checks the requested URL for whether its path begins with a language code listed in the `LANGUAGES` setting.

get_supported_language_variant (lang_code, strict=False)

Returns `lang_code` if it’s in the `LANGUAGES` setting, possibly selecting a more generic variant. For example, ‘es’ is returned if `lang_code` is ‘es-ar’ and ‘es’ is in `LANGUAGES` but ‘es-ar’ isn’t.

If `strict` is `False` (the default), a country-specific variant may be returned when neither the language code nor its generic variant is found. For example, if only ‘es-co’ is in `LANGUAGES`, that’s returned for `lang_codes` like ‘es’ and ‘es-ar’. Those matches aren’t returned if `strict=True`.

 Raises `LookupError` if nothing is found.

to_locale (language)

Turns a language name (en-us) into a locale name (en_US).

templatize (src)

Turns a Django template into something that is understood by `xgettext`. It does so by translating the Django translation tags into standard `gettext` function invocations.
6.29 Validators

6.29.1 Writing validators

A validator is a callable that takes a value and raises a `ValidationError` if it doesn’t meet some criteria. Validators can be useful for reusing validation logic between different types of fields.

For example, here’s a validator that only allows even numbers:

```python
from django.core.exceptions import ValidationError
from django.utils.translation import gettext_lazy as _

def validate_even(value):
    if value % 2 != 0:
        raise ValidationError(
            _('%(value)s is not an even number'),
            params={'value': value},
        )
```

You can add this to a model field via the field’s `validators` argument:

```python
from django.db import models

class MyModel(models.Model):
    even_field = models.IntegerField(validators=[validate_even])
```

Because values are converted to Python before validators are run, you can even use the same validator with forms:

```python
from django import forms

class MyForm(forms.Form):
    even_field = forms.IntegerField(validators=[validate_even])
```

You can also use a class with a `__call__()` method for more complex or configurable validators. `RegexValidator`, for example, uses this technique. If a class-based validator is used in the `validators` model field option, you should make sure it is serializable by the migration framework by adding `deconstruct()` and `__eq__()` methods.
6.29.2 How validators are run

See the form validation for more information on how validators are run in forms, and Validating objects for how they’re run in models. Note that validators will not be run automatically when you save a model, but if you are using a ModelForm, it will run your validators on any fields that are included in your form. See the ModelForm documentation for information on how model validation interacts with forms.

6.29.3 Built-in validators

The django.core.validators module contains a collection of callable validators for use with model and form fields. They’re used internally but are available for use with your own fields, too. They can be used in addition to, or in lieu of custom field.clean() methods.

**RegexValidator**

```python
class RegexValidator(regex=None, message=None, code=None, inverse_match=None, flags=0)
```

Parameters

- `regex` - If not None, overrides `regex`. Can be a regular expression string or a pre-compiled regular expression.
- `message` - If not None, overrides `message`.
- `code` - If not None, overrides `code`.
- `inverse_match` - If not None, overrides `inverse_match`.
- `flags` - If not None, overrides `flags`. In that case, `regex` must be a regular expression string, or `TypeError` is raised.

A RegexValidator searches the provided `value` for a given regular expression with `re.search()`. By default, raises a ValidationErrors with `message` and `code` if a match is not found. Its behavior can be inverted by setting `inverse_match` to True, in which case the ValidationErrors is raised when a match is found.

**regex**

The regular expression pattern to search for within the provided `value`, using `re.search()`. This may be a string or a pre-compiled regular expression created with `re.compile()`. Defaults to the empty string, which will be found in every possible `value`.

**message**

The error message used by ValidationErrors if validation fails. Defaults to "Enter a valid value".
code

The error code used by `ValidationError` if validation fails. Defaults to "invalid".

inverse_match

The match mode for `regex`. Defaults to `False`.

flags

The `regex flags` used when compiling the regular expression string `regex`. If `regex` is a pre-compiled regular expression, and `flags` is overridden, `TypeError` is raised. Defaults to 0.

**EmailValidator**

```python
class EmailValidator(message=None, code=None, allowlist=None)
```

Parameters

- `message` – If not `None`, overrides `message`.
- `code` – If not `None`, overrides `code`.
- `allowlist` – If not `None`, overrides `allowlist`.

**message**

The error message used by `ValidationError` if validation fails. Defaults to "Enter a valid email address".

**code**

The error code used by `ValidationError` if validation fails. Defaults to "invalid".

**allowlist**

Allowlist of email domains. By default, a regular expression (the `domain_regex` attribute) is used to validate whatever appears after the `@` sign. However, if that string appears in the `allowlist`, this validation is bypassed. If not provided, the default `allowlist` is `['localhost']`. Other domains that don’t contain a dot won’t pass validation, so you’d need to add them to the `allowlist` as necessary.

**URLValidator**

```python
class URLValidator(schemes=None, regex=None, message=None, code=None)
```

A `RegexValidator` subclass that ensures a value looks like a URL, and raises an error code of 'invalid' if it doesn’t.

Loopback addresses and reserved IP spaces are considered valid. Literal IPv6 addresses (RFC 3986#section-3.2.2) and Unicode domains are both supported.

In addition to the optional arguments of its parent `RegexValidator` class, `URLValidator` accepts an extra optional attribute:
schemes

URL/URI scheme list to validate against. If not provided, the default list is ['http', 'https', 'ftp', 'ftps']. As a reference, the IANA website provides a full list of valid URI schemes.

validate_email

validate_email

An EmailValidator instance without any customizations.

validate_slug

validate_slug

A RegexValidator instance that ensures a value consists of only letters, numbers, underscores or hyphens.

validate_unicode_slug

validate_unicode_slug

A RegexValidator instance that ensures a value consists of only Unicode letters, numbers, underscores, or hyphens.

validate_ipv4_address

validate_ipv4_address

A RegexValidator instance that ensures a value looks like an IPv4 address.

validate_ipv6_address

validate_ipv6_address

Uses django.utils.ipv6 to check the validity of an IPv6 address.

validate_ipv46_address

validate_ipv46_address

Uses both validate_ipv4_address and validate_ipv6_address to ensure a value is either a valid IPv4 or IPv6 address.
validate_comma_separated_integer_list

A `RegexValidator` instance that ensures a value is a comma-separated list of integers.

`int_list_validator`

`int_list_validator` (sep=',', message=None, code='invalid', allow_negative=False)

Returns a `RegexValidator` instance that ensures a string consists of integers separated by `sep`. It allows negative integers when `allow_negative` is True.

MaxValueValidator

class MaxValueValidator(limit_value, message=None)

Raises a `ValidationError` with a code of 'max_value' if `value` is greater than `limit_value`, which may be a callable.

MinValueValidator

class MinValueValidator(limit_value, message=None)

Raises a `ValidationError` with a code of 'min_value' if `value` is less than `limit_value`, which may be a callable.

MaxLengthValidator

class MaxLengthValidator(limit_value, message=None)

Raises a `ValidationError` with a code of 'max_length' if the length of `value` is greater than `limit_value`, which may be a callable.

MinLengthValidator

class MinLengthValidator(limit_value, message=None)

Raises a `ValidationError` with a code of 'min_length' if the length of `value` is less than `limit_value`, which may be a callable.
DecimalValidator

class DecimalValidator(max_digits, decimal_places)

Raises ValidationError with the following codes:

• 'max_digits' if the number of digits is larger than max_digits.
• 'max_decimal_places' if the number of decimals is larger than decimal_places.
• 'max_whole_digits' if the number of whole digits is larger than the difference between max_digits and decimal_places.

FileExtensionValidator

class FileExtensionValidator(allowed_extensions, message, code)

Raises a ValidationError with a code of 'invalid_extension' if the extension of value.name (value is a File) isn’t found in allowed_extensions. The extension is compared case-insensitively with allowed_extensions.

| Warning: Don’t rely on validation of the file extension to determine a file’s type. Files can be renamed to have any extension no matter what data they contain. |

validate_image_file_extension

validate_image_file_extension

Uses Pillow to ensure that value.name (value is a File) has a valid image extension.

ProhibitNullCharactersValidator

class ProhibitNullCharactersValidator(message=None, code=None)

Raises a ValidationError if str(value) contains one or more nulls characters ('\x00').

Parameters

• message – If not None, overrides message.
• code – If not None, overrides code.

message

The error message used by ValidationError if validation fails. Defaults to "Null characters are not allowed.".
code

The error code used by ValidationError if validation fails. Defaults to "null_characters_not_allowed".

StepValueValidator

class StepValueValidator(limit_value, message=None)

Raises a ValidationError with a code of 'step_size' if value is not an integral multiple of limit_value, which can be a float, integer or decimal value or a callable.

6.30 Built-in Views

Several of Django’s built-in views are documented in Writing views as well as elsewhere in the documentation.

6.30.1 Serving files in development

static.serve(request, path, document_root, show_indexes=False)

There may be files other than your project’s static assets that, for convenience, you’d like to have Django serve for you in local development. The serve() view can be used to serve any directory you give it. (This view is not hardened for production use and should be used only as a development aid; you should serve these files in production using a real front-end web server).

The most likely example is user-uploaded content in MEDIA_ROOT. django.contrib.staticfiles is intended for static assets and has no built-in handling for user-uploaded files, but you can have Django serve your MEDIA_ROOT by appending something like this to your URLconf:

```python
from django.conf import settings
from django.urls import re_path
from django.views.static import serve

# ... the rest of your URLconf goes here ...

if settings.DEBUG:
    urlpatterns += [
        re_path(r'^media/(?P<path>.*)$', serve, {
            'document_root': settings.MEDIA_ROOT,
        }),
    ]
```
Note, the snippet assumes your MEDIA_URL has a value of 'media/'. This will call the serve() view, passing in the path from the URLconf and the (required) document_root parameter.

Since it can become a bit cumbersome to define this URL pattern, Django ships with a small URL helper function static() that takes as parameters the prefix such as MEDIA_URL and a dotted path to a view, such as 'django.views.static.serve'. Any other function parameter will be transparently passed to the view.

### 6.30.2 Error views

Django comes with a few views by default for handling HTTP errors. To override these with your own custom views, see Customizing error views.

**The 404 (page not found) view**

defaults.page_not_found(request, exception, template_name='404.html')

When you raise Http404 from within a view, Django loads a special view devoted to handling 404 errors. By default, it’s the view django.views.defaults.page_not_found(), which either produces a “Not Found” message or loads and renders the template 404.html if you created it in your root template directory.

The default 404 view will pass two variables to the template: request_path, which is the URL that resulted in the error, and exception, which is a useful representation of the exception that triggered the view (e.g. containing any message passed to a specific Http404 instance).

Three things to note about 404 views:

- The 404 view is also called if Django doesn’t find a match after checking every regular expression in the URLconf.

- The 404 view is passed a RequestContext and will have access to variables supplied by your template context processors (e.g. MEDIA_URL).

- If DEBUG is set to True (in your settings module), then your 404 view will never be used, and your URLconf will be displayed instead, with some debug information.

**The 500 (server error) view**

defaults.server_error(request, template_name='500.html')

Similarly, Django executes special-case behavior in the case of runtime errors in view code. If a view results in an exception, Django will, by default, call the view django.views.defaults.server_error, which either produces a “Server Error” message or loads and renders the template 500.html if you created it in your root template directory.

The default 500 view passes no variables to the 500.html template and is rendered with an empty Context to lessen the chance of additional errors.
If `DEBUG` is set to `True` (in your settings module), then your 500 view will never be used, and the traceback will be displayed instead, with some debug information.

### The 403 (HTTP Forbidden) view

`defaults.permission_denied(request, exception, template_name='403.html')`

In the same vein as the 404 and 500 views, Django has a view to handle 403 Forbidden errors. If a view results in a 403 exception then Django will, by default, call the view `django.views.defaults.permission_denied`. This view loads and renders the template `403.html` in your root template directory, or if this file does not exist, instead serves the text “403 Forbidden”, as per RFC 7231#section-6.5.3 (the HTTP 1.1 Specification). The template context contains `exception`, which is the string representation of the exception that triggered the view.

`django.views.defaults.permission_denied` is triggered by a `PermissionDenied` exception. To deny access in a view you can use code like this:

```python
from django.core.exceptions import PermissionDenied

def edit(request, pk):
    if not request.user.is_staff:
        raise PermissionDenied
    # ...
```

### The 400 (bad request) view

`defaults.bad_request(request, exception, template_name='400.html')`

When a `SuspiciousOperation` is raised in Django, it may be handled by a component of Django (for example resetting the session data). If not specifically handled, Django will consider the current request a ‘bad request’ instead of a server error.

`django.views.defaults.bad_request`, is otherwise very similar to the `server_error` view, but returns with the status code 400 indicating that the error condition was the result of a client operation. By default, nothing related to the exception that triggered the view is passed to the template context, as the exception message might contain sensitive information like filesystem paths.

`bad_request` views are also only used when `DEBUG` is `False`. 
CHAPTER
SEVEN

META-DOCUMENTATION AND MISCELLANY

Documentation that we can’t find a more organized place for. Like that drawer in your kitchen with the scissors, batteries, duct tape, and other junk.

7.1 API stability

Django is committed to API stability and forwards-compatibility. In a nutshell, this means that code you develop against a version of Django will continue to work with future releases. You may need to make minor changes when upgrading the version of Django your project uses: see the “Backwards incompatible changes” section of the release note for the version or versions to which you are upgrading.

At the same time as making API stability a very high priority, Django is also committed to continual improvement, along with aiming for “one way to do it” (eventually) in the APIs we provide. This means that when we discover clearly superior ways to do things, we will deprecate and eventually remove the old ways. Our aim is to provide a modern, dependable web framework of the highest quality that encourages best practices in all projects that use it. By using incremental improvements, we try to avoid both stagnation and large breaking upgrades.

7.1.1 What “stable” means

In this context, stable means:

- All the public APIs (everything in this documentation) will not be moved or renamed without providing backwards-compatible aliases.

- If new features are added to these APIs – which is quite possible – they will not break or change the meaning of existing methods. In other words, “stable” does not (necessarily) mean “complete.”

- If, for some reason, an API declared stable must be removed or replaced, it will be declared deprecated but will remain in the API for at least two feature releases. Warnings will be issued when the deprecated method is called.
See Official releases for more details on how Django’s version numbering scheme works, and how features will be deprecated.

- We’ll only break backwards compatibility of these APIs without a deprecation process if a bug or security hole makes it completely unavoidable.

### 7.1.2 Stable APIs

In general, everything covered in the documentation—with the exception of anything in the internals area—is considered stable.

### 7.1.3 Exceptions

There are a few exceptions to this stability and backwards-compatibility promise.

#### Security fixes

If we become aware of a security problem—hopefully by someone following our security reporting policy—we’ll do everything necessary to fix it. This might mean breaking backwards compatibility; security trumps the compatibility guarantee.

#### APIs marked as internal

Certain APIs are explicitly marked as “internal” in a couple of ways:

- Some documentation refers to internals and mentions them as such. If the documentation says that something is internal, we reserve the right to change it.

- Functions, methods, and other objects prefixed by a leading underscore (_). This is the standard Python way of indicating that something is private; if any method starts with a single _, it’s an internal API.

### 7.2 Design philosophies

This document explains some of the fundamental philosophies Django’s developers have used in creating the framework. Its goal is to explain the past and guide the future.
7.2.1 Overall

Loose coupling

A fundamental goal of Django’s stack is loose coupling and tight cohesion. The various layers of the framework shouldn’t “know” about each other unless absolutely necessary.

For example, the template system knows nothing about web requests, the database layer knows nothing about data display and the view system doesn’t care which template system a programmer uses.

Although Django comes with a full stack for convenience, the pieces of the stack are independent of another wherever possible.

Less code

Django apps should use as little code as possible; they should lack boilerplate. Django should take full advantage of Python’s dynamic capabilities, such as introspection.

Quick development

The point of a web framework in the 21st century is to make the tedious aspects of web development fast. Django should allow for incredibly quick web development.

Don’t repeat yourself (DRY)

Every distinct concept and/or piece of data should live in one, and only one, place. Redundancy is bad. Normalization is good.

The framework, within reason, should deduce as much as possible from as little as possible.

See also:

The discussion of DRY on the Portland Pattern Repository

Explicit is better than implicit

This is a core Python principle listed in PEP 20, and it means Django shouldn’t do too much “magic.” Magic shouldn’t happen unless there’s a really good reason for it. Magic is worth using only if it creates a huge convenience unattainable in other ways, and it isn’t implemented in a way that confuses developers who are trying to learn how to use the feature.
Consistency

The framework should be consistent at all levels. Consistency applies to everything from low-level (the Python coding style used) to high-level (the “experience” of using Django).

7.2.2 Models

Explicit is better than implicit

Fields shouldn’t assume certain behaviors based solely on the name of the field. This requires too much knowledge of the system and is prone to errors. Instead, behaviors should be based on keyword arguments and, in some cases, on the type of the field.

Include all relevant domain logic

Models should encapsulate every aspect of an “object,” following Martin Fowler’s Active Record design pattern.

This is why both the data represented by a model and information about it (its human-readable name, options like default ordering, etc.) are defined in the model class; all the information needed to understand a given model should be stored in the model.

7.2.3 Database API

The core goals of the database API are:

SQL efficiency

It should execute SQL statements as few times as possible, and it should optimize statements internally.

This is why developers need to call save() explicitly, rather than the framework saving things behind the scenes silently.

This is also why the select_related() QuerySet method exists. It’s an optional performance booster for the common case of selecting “every related object.”
Terse, powerful syntax

The database API should allow rich, expressive statements in as little syntax as possible. It should not rely on importing other modules or helper objects.

Joins should be performed automatically, behind the scenes, when necessary.

Every object should be able to access every related object, systemwide. This access should work both ways.

Option to drop into raw SQL easily, when needed

The database API should realize it’s a shortcut but not necessarily an end-all-be-all. The framework should make it easy to write custom SQL—entire statements, or just custom WHERE clauses as custom parameters to API calls.

7.2.4 URL design

Loose coupling

URLs in a Django app should not be coupled to the underlying Python code. Tying URLs to Python function names is a Bad And Ugly Thing.

Along these lines, the Django URL system should allow URLs for the same app to be different in different contexts. For example, one site may put stories at /stories/, while another may use /news/.

Infinite flexibility

URLs should be as flexible as possible. Any conceivable URL design should be allowed.

Encourage best practices

The framework should make it just as easy (or even easier) for a developer to design pretty URLs than ugly ones.

File extensions in web-page URLs should be avoided.

Vignette-style commas in URLs deserve severe punishment.
Definitive URLs

Technically, foo.com/bar and foo.com/bar/ are two different URLs, and search-engine robots (and some web traffic-analyzing tools) would treat them as separate pages. Django should make an effort to “normalize” URLs so that search-engine robots don’t get confused.

This is the reasoning behind the APPEND_SLASH setting.

7.2.5 Template system

Separate logic from presentation

We see a template system as a tool that controls presentation and presentation-related logic—and that’s it. The template system shouldn’t support functionality that goes beyond this basic goal.

Discourage redundancy

The majority of dynamic websites use some sort of common sitewide design—a common header, footer, navigation bar, etc. The Django template system should make it easy to store those elements in a single place, eliminating duplicate code.

This is the philosophy behind template inheritance.

Be decoupled from HTML

The template system shouldn’t be designed so that it only outputs HTML. It should be equally good at generating other text-based formats, or just plain text.

XML should not be used for template languages

Using an XML engine to parse templates introduces a whole new world of human error in editing templates—and incurs an unacceptable level of overhead in template processing.

Assume designer competence

The template system shouldn’t be designed so that templates necessarily are displayed nicely in WYSIWYG editors such as Dreamweaver. That is too severe of a limitation and wouldn’t allow the syntax to be as nice as it is. Django expects template authors are comfortable editing HTML directly.
Treat whitespace obviously

The template system shouldn’t do magic things with whitespace. If a template includes whitespace, the system should treat the whitespace as it treats text—just display it. Any whitespace that’s not in a template tag should be displayed.

Don’t invent a programming language

The goal is not to invent a programming language. The goal is to offer just enough programming-esque functionality, such as branching and looping, that is essential for making presentation-related decisions. The Django Template Language (DTL) aims to avoid advanced logic.

The Django template system recognizes that templates are most often written by designers, not programmers, and therefore should not assume Python knowledge.

Safety and security

The template system, out of the box, should forbid the inclusion of malicious code—such as commands that delete database records.

This is another reason the template system doesn’t allow arbitrary Python code.

Extensibility

The template system should recognize that advanced template authors may want to extend its technology.

This is the philosophy behind custom template tags and filters.

7.2.6 Views

Simplicity

Writing a view should be as simple as writing a Python function. Developers shouldn’t have to instantiate a class when a function will do.

Use request objects

Views should have access to a request object—an object that stores metadata about the current request. The object should be passed directly to a view function, rather than the view function having to access the request data from a global variable. This makes it light, clean and easy to test views by passing in “fake” request objects.
Loose coupling

A view shouldn’t care about which template system the developer uses—or even whether a template system is used at all.

Differentiate between GET and POST

GET and POST are distinct; developers should explicitly use one or the other. The framework should make it easy to distinguish between GET and POST data.

7.2.7 Cache Framework

The core goals of Django’s cache framework are:

Less code

A cache should be as fast as possible. Hence, all framework code surrounding the cache backend should be kept to the absolute minimum, especially for `get()` operations.

Consistency

The cache API should provide a consistent interface across the different cache backends.

Extensibility

The cache API should be extensible at the application level based on the developer’s needs (for example, see Cache key transformation).

7.3 Third-party distributions of Django

Many third-party distributors are now providing versions of Django integrated with their package-management systems. These can make installation and upgrading much easier for users of Django since the integration includes the ability to automatically install dependencies (like database adapters) that Django requires.

Typically, these packages are based on the latest stable release of Django, so if you want to use the development version of Django you’ll need to follow the instructions for installing the development version from our Git repository.

If you’re using Linux or a Unix installation, such as OpenSolaris, check with your distributor to see if they already package Django. If you’re using a Linux distro and don’t know how to find out if a package is
available, then now is a good time to learn. The Django Wiki contains a list of Third Party Distributions to help you out.

7.3.1 For distributors

If you’d like to package Django for distribution, we’d be happy to help out! Please join the django-developers mailing list and introduce yourself.

We also encourage all distributors to subscribe to the django-announce mailing list, which is a (very) low-traffic list for announcing new releases of Django and important bugfixes.
concrete model
A non-abstract \((\text{abstract}=\text{False})\) model.

field
An attribute on a model; a given field usually maps directly to a single database column.

See Models.

generic view
A higher-order view function that provides an abstract/generic implementation of a common idiom or pattern found in view development.

See Class-based views.

model
Models store your application’s data.

See Models.

MTV
“Model-template-view”; a software pattern, similar in style to MVC, but a better description of the way Django does things.

See the FAQ entry.

MVC
Model-view-controller; a software pattern. Django follows MVC to some extent.

project
A Python package –i.e. a directory of code –that contains all the settings for an instance of Django. This would include database configuration, Django-specific options and application-specific settings.

property
Also known as “managed attributes”, and a feature of Python since version 2.2. This is a neat way to implement attributes whose usage resembles attribute access, but whose implementation uses method calls.

See property.
queryset
   An object representing some set of rows to be fetched from the database.

   See Making queries.

slug
   A short label for something, containing only letters, numbers, underscores or hyphens. They’re generally used in URLs. For example, in a typical blog entry URL:

   https://www.djangoproject.com/weblog/2008/apr/12/spring/

   the last bit (spring) is the slug.

template
   A chunk of text that acts as formatting for representing data. A template helps to abstract the presentation of data from the data itself.

   See Templates.

view
   A function responsible for rendering a page.
Release notes for the official Django releases. Each release note will tell you what’s new in each version, and will also describe any backwards-incompatible changes made in that version.

For those upgrading to a new version of Django, you will need to check all the backwards-incompatible changes and deprecated features for each ‘final’ release from the one after your current Django version, up to and including the new version.

## 9.1 Final releases

Below are release notes through Django 4.2 and its patch releases. Newer versions of the documentation contain the release notes for any later releases.

### 9.1.1 4.2 release

**Django 4.2 release notes - UNDER DEVELOPMENT**

Expected April 2023

Welcome to Django 4.2!

These release notes cover the new features, as well as some backwards incompatible changes you’ll want to be aware of when upgrading from Django 4.1 or earlier. We’ve begun the deprecation process for some features.

See the How to upgrade Django to a newer version guide if you’re updating an existing project.
Python compatibility

Django 4.2 supports Python 3.8, 3.9, 3.10, and 3.11. We highly recommend and only officially support the latest release of each series.

What’s new in Django 4.2

Minor features

django.contrib.admin

• ...

django.contrib.admindocs

• ...

django.contrib.auth

• The default iteration count for the PBKDF2 password hasher is increased from 390,000 to 480,000.

django.contrib.contenttypes

• ...

django.contrib.gis

• The GeoJSON serializer now outputs the id key for serialized features, which defaults to the primary key of objects.

django.contrib.messages

• ...
django.contrib.postgres

- The new `trigram_strict_word_similar` lookup, and the `TrigramStrictWordSimilarity()` and `TrigramStrictWordDistance()` expressions allow using trigram strict word similarity.

django.contrib.redirects

- ...

django.contrib.sessions

- ...

django.contrib.sitemaps

- ...

django.contrib.sites

- ...

django.contrib.staticfiles

- ...

django.contrib.syndication

- ...

Cache

- ...
CSRF

• ...

Decorators

• ...

Email

• ...

Error Reporting

• ...

File Storage

• ...

File Uploads

• ...

Forms

• ...

Generic Views

• ...
Internationalization

• ...

Logging

• ...

Management Commands

• `makemessages` command now supports locales with private sub-tags such as `nl_NL-x-informal`.
• The new `makemigrations --update` option merges model changes into the latest migration and optimizes the resulting operations.

Migrations

• ...

Models

• ...

Requests and Responses

• ...

Security

• ...

Serialization

• ...

9.1. Final releases 2017
Signals

• ...

Templates

• ...

Tests

• ...

URLs

• ...

Utilities

• The new encoder parameter for `django.utils.html.json_script()` function allows customizing a JSON encoder class.

• The private internal vendored copy of `urllib.parse.urlsplit()` now strips '\r', '\n', and '\t' (see CVE-2022-0391 and bpo-43882). This is to protect projects that may be incorrectly using the internal `url_has_allowed_host_and_scheme()` function, instead of using one of the documented functions for handling URL redirects. The Django functions were not affected.

Validators

• ...

Backwards incompatible changes in 4.2

Database backend API

This section describes changes that may be needed in third-party database backends.

• ...

2018 Chapter 9. Release notes
Dropped support for MariaDB 10.3

Upstream support for MariaDB 10.3 ends in May 2023. Django 4.2 supports MariaDB 10.4 and higher.

Dropped support for PostgreSQL 11

Upstream support for PostgreSQL 11 ends in November 2023. Django 4.2 supports PostgreSQL 12 and higher.

Miscellaneous

- The undocumented `SimpleTemplateResponse.rendering_attrs` and `TemplateResponse.rendering_attrs` are renamed to `non_picklable_attrs`.

Features deprecated in 4.2

Miscellaneous

- The `BaseUserManager.make_random_password()` method is deprecated. See recipes and best practices for using Python’s `secrets` module to generate passwords.

9.1.2 4.1 release

Django 4.1 release notes - UNDER DEVELOPMENT

Expected August 2022

Welcome to Django 4.1!

These release notes cover the new features, as well as some backwards incompatible changes you’ll want to be aware of when upgrading from Django 4.0 or earlier. We’ve begun the deprecation process for some features.

See the How to upgrade Django to a newer version guide if you’re updating an existing project.
Python compatibility

Django 4.1 supports Python 3.8, 3.9, and 3.10. We highly recommend and only officially support the latest release of each series.

What’s new in Django 4.1

Asynchronous handlers for class-based views

View subclasses may now define async HTTP method handlers:

```python
import asyncio
from django.http import HttpResponse
from django.views import View

class AsyncView(View):
    async def get(self, request, *args, **kwargs):
        # Perform view logic using await.
        await asyncio.sleep(1)
        return HttpResponse("Hello async world!")
```

See Asynchronous class-based views for more details.

Asynchronous ORM interface

QuerySet now provides an asynchronous interface for all data access operations. These are named as-per the existing synchronous operations but with an a prefix, for example `acreate()`, `aget()`, and so on.

The new interface allows you to write asynchronous code without needing to wrap ORM operations in `sync_to_async()`:

```python
async for author in Author.objects.filter(name__startswith="A"):
    book = await author.books.afirst()
```

Note that, at this stage, the underlying database operations remain synchronous, with contributions ongoing to push asynchronous support down into the SQL compiler, and integrate asynchronous database drivers. The new asynchronous queryset interface currently encapsulates the necessary `sync_to_async()` operations for you, and will allow your code to take advantage of developments in the ORM’s asynchronous support as it evolves.

See Asynchronous queries for details and limitations.
Validation of Constraints

*Check, unique, and exclusion* constraints defined in the *Meta.constraints* option are now checked during model validation.

Form rendering accessibility

In order to aid users with screen readers, and other assistive technology, new `<div>` based form templates are available from this release. These provide more accessible navigation than the older templates, and are able to correctly group related controls, such as radio-lists, into fieldsets.

The new templates are recommended, and will become the default form rendering style when outputting a form, like `{{ form }}` in a template, from Django 5.0.

In order to ease adopting the new output style, the default form and formset templates are now configurable at the project level via the `FORM_RENDERER` setting.

See the Forms section (below) for full details.

CSRF_COOKIE_MASKED setting

The new `CSRF_COOKIE_MASKED` transitional setting allows specifying whether to mask the CSRF cookie.

`CsrfViewMiddleware` no longer masks the CSRF cookie like it does the CSRF token in the DOM. If you are upgrading multiple instances of the same project to Django 4.1, you should set `CSRF_COOKIE_MASKED` to `True` during the transition, in order to allow compatibility with the older versions of Django. Once the transition to 4.1 is complete you can stop overriding `CSRF_COOKIE_MASKED`.

This setting is deprecated as of this release and will be removed in Django 5.0.

Minor features

django.contrib.admin

- The admin dark mode CSS variables are now applied in a separate stylesheet and template block.
- *ModelAdmin List Filters* providing custom *FieldListFilter* subclasses can now control the query string value separator when filtering for multiple values using the `__in` lookup.
- The admin *history view* is now paginated.
- Related widget wrappers now have a link to object’s change form.
- The *AdminSite.get_app_list()* method now allows changing the order of apps and models on the admin index page.
django.contrib.auth

- The default iteration count for the PBKDF2 password hasher is increased from 320,000 to 390,000.
- The `RemoteUserBackend.configure_user()` method now allows synchronizing user attributes with attributes in a remote system such as an LDAP directory.

django.contrib.gis

- The new `GEOSGeometry.make_valid()` method allows converting invalid geometries to valid ones.
- The new `clone` argument for `GEOSGeometry.normalize()` allows creating a normalized clone of the geometry.

django.contrib.postgres

- The new `BitXor()` aggregate function returns an `int` of the bitwise XOR of all non-null input values.
- `SpGistIndex` now supports covering indexes on PostgreSQL 14+.
- `ExclusionConstraint` now supports covering exclusion constraints using SP-GiST indexes on PostgreSQL 14+.
- The new `default_bounds` attribute of `DateTimeRangeField` and `DecimalRangeField` allows specifying bounds for list and tuple inputs.
- `ExclusionConstraint` now allows specifying operator classes with the `OpClass()` expression.

django.contrib.sitemaps

- The default sitemap index template `<sitemapindex>` now includes the `<lastmod>` timestamp where available, through the new `get_latest_lastmod()` method. Custom sitemap index templates should be updated for the adjusted context variables.

django.contrib.staticfiles

- `ManifestStaticFilesStorage` now replaces paths to CSS source map references with their hashed counterparts.
Database backends

- Third-party database backends can now specify the minimum required version of the database using the `DatabaseFeatures.minimum_database_version` attribute which is a tuple (e.g. (10, 0) means “10.0”). If a minimum version is specified, backends must also implement `DatabaseWrapper.get_database_version()`, which returns a tuple of the current database version. The backend’s `DatabaseWrapper.init_connection_state()` method must call `super()` in order for the check to run.

Forms

- The default template used to render forms when cast to a string, e.g. in templates as {{ form }}, is now configurable at the project-level by setting `form_template_name` on the class provided for `FORM_RENDERER`. `Form.template_name` is now a property deferring to the renderer, but may be overridden with a string value to specify the template name per-form class.

  Similarly, the default template used to render formsets can be specified via the matching `formset_template_name` renderer attribute.

- The new `div.html` form template, referencing `Form.template_name_div` attribute, and matching `Form.as_div()` method, render forms using HTML `<div>` elements.

  This new output style is recommended over the existing `as_table()`, `as_p()` and `as_ul()` styles, as the template implements `<fieldset>` and `<legend>` to group related inputs and is easier for screen reader users to navigate.

  The div-based output will become the default rendering style from Django 5.0.

- In order to smooth adoption of the new `<div>` output style, two transitional form renderer classes are available: `django.forms.renderers.DjangoDivFormRenderer` and `django.forms.renderers.Jinja2DivFormRenderer`, for the Django and Jinja2 template backends respectively.

  You can apply one of these via the `FORM_RENDERER` setting. For example:

  ```
  FORM_RENDERER = "django.forms.renderers.DjangoDivFormRenderer"
  ```

  Once the `<div>` output style is the default, from Django 5.0, these transitional renderers will be deprecated, for removal in Django 6.0. The `FORM_RENDERER` declaration can be removed at that time.

- If the new `<div>` output style is not appropriate for your project, you should define a renderer subclass specifying `form_template_name` and `formset_template_name` for your required style, and set `FORM_RENDERER` accordingly.

  For example, for the `<p>` output style used by `as_p()`, you would define a form renderer setting `form_template_name` to "django/forms/p.html" and `formset_template_name` to "django/forms/formsets/p.html".
• The new `legend_tag()` allows rendering field labels in `<legend>` tags via the new `tag` argument of `label_tag()`.

• The new `edit_only` argument for `modelformset_factory()` and `inlineformset_factory()` allows preventing new objects creation.

• The `js` and `css` class attributes of `Media` now allow using hashable objects, not only path strings, as long as those objects implement the `__html__()` method (typically when decorated with the `html_safe()` decorator).

• The new `BoundField.use_fieldset` and `Widget.use_fieldset` attributes help to identify widgets where its inputs should be grouped in a `<fieldset>` with a `<legend>`.

• The error_messages argument for `BaseFormSet` now allows customizing error messages for invalid number of forms by passing 'too_few_forms' and 'too_many_forms' keys.

• `IntegerField`, `FloatField`, and `DecimalField` now optionally accept a `step_size` argument. This is used to set the `step` HTML attribute, and is validated on form submission.

Internationalization

• The `i18n_patterns()` function now supports languages with both scripts and regions.

Management Commands

• `makemigrations --no-input` now logs default answers and reasons why migrations cannot be created.

• The new `makemigrations --scriptable` option diverts log output and input prompts to `stderr`, writing only paths of generated migration files to `stdout`.

• The new `migrate --prune` option allows deleting nonexistent migrations from the `django_migrations` table.

• Python files created by `startproject`, `startapp`, `optimizemigration`, `makemigrations`, and `squashmigrations` are now formatted using the `black` command if it is present on your `PATH`.

• The new `optimizemigration` command allows optimizing operations for a migration.

Migrations

• The new `RenameIndex` operation allows renaming indexes defined in the `Meta.indexes` or `index_together` options.

• The migrations autodetector now generates `RenameIndex` operations instead of `RemoveIndex` and `AddIndex`, when renaming indexes defined in the `Meta.indexes`.
• The migrations autodetector now generates `RenameIndex` operations instead of `AlterIndexTogether` and `AddIndex`, when moving indexes defined in the `Meta.index_together` to the `Meta.indexes`.

Models

• The `order_by` argument of the `Window` expression now accepts string references to fields and transforms.

• The new `CONN_HEALTH_CHECKS` setting allows enabling health checks for persistent database connections in order to reduce the number of failed requests, e.g. after database server restart.

• `QuerySet.bulk_create()` now supports updating fields when a row insertion fails uniqueness constraints. This is supported on MariaDB, MySQL, PostgreSQL, and SQLite 3.24+.

• `QuerySet.iterator()` now supports prefetching related objects as long as the `chunk_size` argument is provided. In older versions, no prefetching was done.

• `Q` objects and querysets can now be combined using `^` as the exclusive or (XOR) operator. XOR is natively supported on MariaDB and MySQL. For databases that do not support XOR, the query will be converted to an equivalent using `AND`, `OR`, and `NOT`.

• The new `Field.non_db_attrs` attribute allows customizing attributes of fields that don’t affect a column definition.

• On PostgreSQL, `AutoField`, `BigAutoField`, and `SmallAutoField` are now created as identity columns rather than serial columns with sequences.

Requests and Responses

• `HttpResponse.set_cookie()` now supports `timedelta` objects for the `max_age` argument.

Security

• The new `SECRET_KEY_FALLBACKS` setting allows providing a list of values for secret key rotation.

• The `SECURE_PROXY_SSL_HEADER` setting now supports a comma-separated list of protocols in the header value.
Signals

- The `pre_delete` and `post_delete` signals now dispatch the origin of the deletion.

Templates

- `json_script` template filter now allows wrapping in a `<script>` tag without the HTML `id` attribute.
- The cached template loader is now enabled in development, when `DEBUG` is `True`, and `OPTIONS['loaders']` isn’t specified. You may specify `OPTIONS['loaders']` to override this, if necessary.

Tests

- The `DiscoverRunner` now supports running tests in parallel on macOS, Windows, and any other systems where the default `multiprocessing` start method is `spawn`.
- A nested atomic block marked as durable in `django.test.TestCase` now raises a `RuntimeError`, the same as outside of tests.
- `SimpleTestCase.assertFormError()` and `assertFormsetError()` now support passing a form/formset object directly.

URLs

- The new `ResolverMatch.captured_kwargs` attribute stores the captured keyword arguments, as parsed from the URL.
- The new `ResolverMatch.extra_kwargs` attribute stores the additional keyword arguments passed to the view function.

Utilities

- `SimpleLazyObject` now supports addition operations.
- `mark_safe()` now preserves lazy objects.
Validators

- The new `StepValueValidator` checks if a value is an integral multiple of a given step size. This new validator is used for the new `step_size` argument added to form fields representing numeric values.

Backwards incompatible changes in 4.1

Database backend API

This section describes changes that may be needed in third-party database backends.

- `BaseDatabaseFeatures.has_case_insensitive_like` is changed from `True` to `False` to reflect the behavior of most databases.

- `DatabaseIntrospection.get_key_columns()` is removed. Use `DatabaseIntrospection.get_relations()` instead.

- `DatabaseOperations.ignore_conflicts_suffix_sql()` method is replaced by `DatabaseOperations.on_conflict_suffix_sql()` that accepts the `fields`, `on_conflict`, `update_fields`, and `unique_fields` arguments.

- The `ignore_conflicts` argument of the `DatabaseOperations.insert_statement()` method is replaced by `on_conflict` that accepts `django.db.models.constants.OnConflict`.

- Several date and time methods on `DatabaseOperations` now take `sql` and `params` arguments instead of `field_name` and return 2-tuple containing some SQL and the parameters to be interpolated into that SQL. The changed methods have these new signatures:

  - `DatabaseOperations.date_extract_sql(lookup_type, sql, params)`
  - `DatabaseOperations.datetime_extract_sql(lookup_type, sql, params, tzname)`
  - `DatabaseOperations.time_extract_sql(lookup_type, sql, params)`
  - `DatabaseOperations.date_trunc_sql(lookup_type, sql, params, tzname=None)`
  - `DatabaseOperations.datetime_trunc_sql(self, lookup_type, sql, params, tzname)`
  - `DatabaseOperations.time_trunc_sql(lookup_type, sql, params, tzname=None)`
  - `DatabaseOperations.datetime_cast_date_sql(sql, params, tzname)`
  - `DatabaseOperations.datetime_cast_time_sql(sql, params, tzname)`
django.contrib.gis

- Support for GDAL 2.1 is removed.
- Support for PostGIS 2.4 is removed.

Dropped support for PostgreSQL 10

Upstream support for PostgreSQL 10 ends in November 2022. Django 4.1 supports PostgreSQL 11 and higher.

Dropped support for MariaDB 10.2

Upstream support for MariaDB 10.2 ends in May 2022. Django 4.1 supports MariaDB 10.3 and higher.

Admin changelist searches spanning multi-valued relationships changes

Admin changelist searches using multiple search terms are now applied in a single call to `filter()`, rather than in sequential `filter()` calls.

For multi-valued relationships, this means that rows from the related model must match all terms rather than any term. For example, if `search_fields` is set to `['child__name', 'child__age']`, and a user searches for 'Jamal 17', parent rows will be returned only if there is a relationship to some 17-year-old child named Jamal, rather than also returning parents who merely have a younger or older child named Jamal in addition to some other 17-year-old.

See the Spanning multi-valued relationships topic for more discussion of this difference. In Django 4.0 and earlier, `get_search_results()` followed the second example query, but this undocumented behavior led to queries with excessive joins.

Reverse foreign key changes for unsaved model instances

In order to unify the behavior with many-to-many relations for unsaved model instances, a reverse foreign key now raises `ValueError` when calling `related managers` for unsaved objects.

Miscellaneous

- Related managers for `ForeignKey`, `ManyToManyField`, and `GenericRelation` are now cached on the `Model` instance to which they belong.
- The Django test runner now returns a non-zero error code for unexpected successes from tests marked with `unittest.expectedFailure()`.
- `CsrfViewMiddleware` no longer masks the CSRF cookie like it does the CSRF token in the DOM.
• `CsrfViewMiddleware` now uses `request.META['CSRF_COOKIE']` for storing the unmasked CSRF secret rather than a masked version. This is an undocumented, private API.

• The `ModelAdmin.actions` and `inlines` attributes now default to an empty tuple rather than an empty list to discourage unintended mutation.

• The `type="text/css"` attribute is no longer included in `<link>` tags for CSS form media.

• formset: added and formset: removed JavaScript events are now pure JavaScript events and don’t depend on jQuery. See Inline form events for more details on the change.

• The `exc_info` argument of the undocumented `django.utils.log.log_response()` function is replaced by exception.

• The `size` argument of the undocumented `django.views.static.was_modified_since()` function is removed.

• The admin logout UI now uses POST requests.

• The undocumented `InlineAdminFormSet.non_form_errors` property is replaced by the `non_form_errors()` method. This is consistent with `BaseFormSet`.

• As per above, the cached template loader is now enabled in development. You may specify `OPTIONS['loaders']` to override this, if necessary.

• The undocumented `django.contrib.auth.views.SuccessURLAllowedHostsMixin` mixin is replaced by RedirectURLMixin.

• `BaseConstraint` subclasses must implement `validate()` method to allow those constraints to be used for validation.

• The undocumented `URLResolver._is_callback()`, `URLResolver._callback_strs`, and `URLPattern.lookup_str()` are moved to `django.contrib.admindocs.utils`.

• The `Model.full_clean()` method now converts an `exclude` value to the `set`. It’s also preferable to pass an `exclude` value as a `set` to the `Model.clean_fields()`, `Model.full_clean()`, `Model.validate_unique()`, and `Model.validate_constraints()` methods.

• The minimum supported version of `asgiref` is increased from 3.4.1 to 3.5.2.

Features deprecated in 4.1

Log out via GET

Logging out via GET requests to the built-in logout view is deprecated. Use POST requests instead.

If you want to retain the user experience of an HTML link, you can use a form that is styled to appear as a link:
<form id="logout-form" method="post" action="{% url 'admin:logout' %}">
  {% csrf_token %}
  <button type="submit">{% translate "Log out" %}</button>
</form>

#logout-form {
  display: inline;
}
#logout-form button {
  background: none;
  border: none;
  cursor: pointer;
  padding: 0;
  text-decoration: underline;
}

Miscellaneous

- The context for sitemap index templates of a flat list of URLs is deprecated. Custom sitemap index templates should be updated for the adjusted context variables, expecting a list of objects with location and optional lastmod attributes.

- CSRF_COOKIE_MASKED transitional setting is deprecated.

- The name argument of django.utils.functional.cached_property() is deprecated as it’s unnecessary as of Python 3.6.

- The opclasses argument of django.contrib.postgres.constraints.ExclusionConstraint is deprecated in favor of using OpClass() in ExclusionConstraint.expressions. To use it, you need to add 'django.contrib.postgres' in your INSTALLED_APPS.

After making this change, makemigrations will generate a new migration with two operations: RemoveConstraint and AddConstraint. Since this change has no effect on the database schema, the SeparateDatabaseAndState operation can be used to only update the migration state without running any SQL. Move the generated operations into the state_operations argument of SeparateDatabaseAndState. For example:

```
class Migration(migrations.Migration):
    ...

    operations = [
        migrations.SeparateDatabaseAndState(
            database_operations=[],
            state_operations=[
```

(continues on next page)
migrations.RemoveConstraint(
    ...
),
migrations.AddConstraint(
    ...
),
],
)
]

- The undocumented ability to pass errors=None to SimpleTestCase.assertFormError() and assertFormsetError() is deprecated. Use errors=[] instead.

- django.contrib.sessions.serializers.PickleSerializer is deprecated due to the risk of remote code execution.

- The usage of QuerySet.iterator() on a queryset that prefetches related objects without providing the chunk_size argument is deprecated. In older versions, no prefetching was done. Providing a value for chunk_size signifies that the additional query per chunk needed to prefetch is desired.

- Passing unsaved model instances to related filters is deprecated. In Django 5.0, the exception will be raised.

- created=True is added to the signature of RemoteUserBackend.configure_user(). Support for RemoteUserBackend subclasses that do not accept this argument is deprecated.

- The django.utils.timezone.utc alias to datetime.timezone.utc is deprecated. Use datetime.timezone.utc directly.

- Passing a response object and a form/formset name to SimpleTestCase.assertFormError() and assertFormsetError() is deprecated. Use:

  ```python
  assertFormError(response.context[\'form_name\'], ...)  
  assertFormsetError(response.context[\'formset_name\'], ...)  
  ```

  or pass the form/formset object directly instead.

- The undocumented django.contrib.gis.admin.OpenLayersWidget is deprecated.

- django.contrib.auth.hashers.CryptPasswordHasher is deprecated.

- The ability to pass nulls_first=False or nulls_last=False to Expression.asc() and Expression.desc() methods, and the OrderBy expression is deprecated. Use None instead.

- The "django/forms/default.html" and "django/forms/formsets/default.html" templates which are a proxy to the table-based templates are deprecated. Use the specific template instead.

9.1. Final releases 2031
Features removed in 4.1

These features have reached the end of their deprecation cycle and are removed in Django 4.1.

See Features deprecated in 3.2 for details on these changes, including how to remove usage of these features.

- Support for assigning objects which don’t support creating deep copies with `copy.deepcopy()` to class attributes in `TestCase.setUpTestData()` is removed.

- Support for using a boolean value in `BaseCommand.requires_system_checks` is removed.

- The `whitelist` argument and `domain_whitelist` attribute of `django.core.validators.EmailValidator` are removed.

- The `default_app_config` application configuration variable is removed.

- `TransactionTestCase.assertQuerysetEqual()` no longer calls `repr()` on a queryset when compared to string values.

- The `django.core.cache.backends.memcached.MemcachedCache` backend is removed.

- Support for the pre-Django 3.2 format of messages used by `django.contrib.messages.storage.cookie.CookieStorage` is removed.

9.1.3 4.0 release

Django 4.0.7 release notes

Expected August 2, 2022

Django 4.0.7 fixes several bugs in 4.0.6.

Bugfixes

- ...

Django 4.0.6 release notes

July 4, 2022

Django 4.0.6 fixes a security issue with severity “high” in 4.0.5.
**CVE-2022-34265: Potential SQL injection via Trunc(kind) and Extract(lookup_name) arguments**

*Trunc()* and *Extract()* database functions were subject to SQL injection if untrusted data was used as a kind/lookup_name value.

Applications that constrain the lookup name and kind choice to a known safe list are unaffected.

**Django 4.0.5 release notes**

June 1, 2022

Django 4.0.5 fixes several bugs in 4.0.4.

**Bugfixes**

- Fixed a bug in Django 4.0 where not all *OPTIONS* were passed to a Redis client (#33681).
- Fixed a bug in Django 4.0 that caused a crash of *QuerySet.filter()* on *IsNull()* expressions (#33705).
- Fixed a bug in Django 4.0 where a hidden quick filter toolbar in the admin’s navigation sidebar was focusable (#33725).

**Django 4.0.4 release notes**

April 11, 2022

Django 4.0.4 fixes two security issues with severity “high” and two bugs in 4.0.3.

**CVE-2022-28346: Potential SQL injection in QuerySet.annotate(), aggregate(), and extra()**

*QuerySet.annotate()* , *aggregate()* , and *extra()* methods were subject to SQL injection in column aliases, using a suitably crafted dictionary, with dictionary expansion, as the **kwargs passed to these methods.

**CVE-2022-28347: Potential SQL injection via QuerySet.explain(**options) on PostgreSQL**

*QuerySet.explain()* method was subject to SQL injection in option names, using a suitably crafted dictionary, with dictionary expansion, as the **options argument.
Bugfixes

- Fixed a regression in Django 4.0 that caused ignoring multiple `FilteredRelation()` relationships to the same field (#33598).
- Fixed a regression in Django 3.2.4 that caused the auto-reloader to no longer detect changes when the `DIRS` option of the `TEMPLATES` setting contained an empty string (#33628).

Django 4.0.3 release notes

March 1, 2022

Django 4.0.3 fixes several bugs in 4.0.2. Also, all Python code in Django is reformatted with black.

Bugfixes

- Prevented, following a regression in Django 4.0.1, `makemigrations` from generating infinite migrations for a model with `ManyToManyField` to a lowercased swappable model such as `'auth.user'` (#33515).
- Fixed a regression in Django 4.0 that caused a crash when rendering invalid inlines with `readonly_fields` in the admin (#33547).

Django 4.0.2 release notes

February 1, 2022

Django 4.0.2 fixes two security issues with severity “medium” and several bugs in 4.0.1. Also, the latest string translations from Transifex are incorporated, with a special mention for Bulgarian (fully translated).

CVE-2022-22818: Possible XSS via `{% debug %}` template tag

The `{% debug %}` template tag didn’t properly encode the current context, posing an XSS attack vector.

In order to avoid this vulnerability, `{% debug %}` no longer outputs information when the `DEBUG` setting is `False`, and it ensures all context variables are correctly escaped when the `DEBUG` setting is `True`. 
CVE-2022-23833: Denial-of-service possibility in file uploads

Passing certain inputs to multipart forms could result in an infinite loop when parsing files.

Bugfixes

- Fixed a bug in Django 4.0 where `TestCase.captureOnCommitCallbacks()` could execute callbacks multiple times (#33410).
- Fixed a regression in Django 4.0 where `help_text` was HTML-escaped in automatically-generated forms (#33419).
- Fixed a regression in Django 4.0 that caused displaying an incorrect name for class-based views on the technical 404 debug page (#33425).
- Fixed a regression in Django 4.0 that caused an incorrect `repr` of `ResolverMatch` for class-based views (#33426).
- Fixed a regression in Django 4.0 that caused a crash of `makemigrations` on models without `Meta.order_with_respect_to` but with a field named `_order` (#33449).
- Fixed a regression in Django 4.0 that caused incorrect `ModelAdmin.radio_fields` layout in the admin (#33407).
- Fixed a duplicate operation regression in Django 4.0 that caused a migration crash when altering a primary key type for a concrete parent model referenced by a foreign key (#33462).
- Fixed a bug in Django 4.0 that caused a crash of `QuerySet.aggregate()` after `annotate()` on an aggregate function with a `default` (#33468).
- Fixed a regression in Django 4.0 that caused a crash of `makemigrations` when renaming a field of a renamed model (#33480).

Django 4.0.1 release notes

January 4, 2022

Django 4.0.1 fixes one security issue with severity “medium”, two security issues with severity “low”, and several bugs in 4.0.
CVE-2021-45115: Denial-of-service possibility in UserAttributeSimilarityValidator

UserAttributeSimilarityValidator incurred significant overhead evaluating submitted password that were artificially large in relative to the comparison values. On the assumption that access to user registration was unrestricted this provided a potential vector for a denial-of-service attack.

In order to mitigate this issue, relatively long values are now ignored by UserAttributeSimilarityValidator.

This issue has severity “medium” according to the Django security policy.

CVE-2021-45116: Potential information disclosure in dictsort template filter

Due to leveraging the Django Template Language’s variable resolution logic, the dictsort template filter was potentially vulnerable to information disclosure or unintended method calls, if passed a suitably crafted key.

In order to avoid this possibility, dictsort now works with a restricted resolution logic, that will not call methods, nor allow indexing on dictionaries.

As a reminder, all untrusted user input should be validated before use.

This issue has severity “low” according to the Django security policy.

CVE-2021-45452: Potential directory-traversal via Storage.save()

Storage.save() allowed directory-traversal if directly passed suitably crafted file names.

This issue has severity “low” according to the Django security policy.

Bugfixes

- Fixed a regression in Django 4.0 that caused a crash of assertFormsetError() on a formset named form (#33346).
- Fixed a bug in Django 4.0 that caused a crash on booleans with the RedisCache backend (#33361).
- Relaxed the check added in Django 4.0 to reallow use of a duck-typed HttpRequest in django.views.decorators.cache.cache_control() and never_cache() decorators (#33350).
- Fixed a regression in Django 4.0 that caused creating bogus migrations for models that reference swap-pable models such as auth.User (#33366).
- Fixed a long standing bug in Geometry Collections and Polygon that caused a crash on some platforms (reported on macOS based on the ARM64 architecture) (#32600).
Django 4.0 release notes

Welcome to Django 4.0!

These release notes cover the new features, as well as some backwards incompatible changes you’ll want to be aware of when upgrading from Django 3.2 or earlier. We’ve begun the deprecation process for some features.

See the How to upgrade Django to a newer version guide if you’re updating an existing project.

Python compatibility

Django 4.0 supports Python 3.8, 3.9, and 3.10. We highly recommend and only officially support the latest release of each series.

The Django 3.2.x series is the last to support Python 3.6 and 3.7.

What’s new in Django 4.0

zoneinfo default timezone implementation

The Python standard library’s zoneinfo is now the default timezone implementation in Django.

This is the next step in the migration from using pytz to using zoneinfo. Django 3.2 allowed the use of non-pytz time zones. Django 4.0 makes zoneinfo the default implementation. Support for pytz is now deprecated and will be removed in Django 5.0.

zoneinfo is part of the Python standard library from Python 3.9. The backports.zoneinfo package is automatically installed alongside Django if you are using Python 3.8.

The move to zoneinfo should be largely transparent. Selection of the current timezone, conversion of date-time instances to the current timezone in forms and templates, as well as operations on aware datetimes in UTC are unaffected.

However, if you are working with non-UTC time zones, and using the pytz normalize() and localize() APIs, possibly with the TIME_ZONE setting, you will need to audit your code, since pytz and zoneinfo are not entirely equivalent.

To give time for such an audit, the transitional USE_DEPRECATED_PYTZ setting allows continued use of pytz during the 4.x release cycle. This setting will be removed in Django 5.0.

In addition, a pytz_deprecation_shim package, created by the zoneinfo author, can be used to assist with the migration from pytz. This package provides shims to help you safely remove pytz, and has a detailed migration guide showing how to move to the new zoneinfo APIs.
Using `pytz_deprecation_shim` and the `USE_DEPRECATED_PYTZ` transitional setting is recommended if you need a gradual update path.

**Functional unique constraints**

The new `*expressions` positional argument of `UniqueConstraint()` enables creating functional unique constraints on expressions and database functions. For example:

```python
from django.db import models
from django.db.models import UniqueConstraint
from django.db.models.functions import Lower

class MyModel(models.Model):
    first_name = models.CharField(max_length=255)
    last_name = models.CharField(max_length=255)

    class Meta:
        constraints = [
            UniqueConstraint(
                Lower('first_name'),
                Lower('last_name').desc(),
                name='first_last_name_unique',
            ),
        ]
```

Functional unique constraints are added to models using the `Meta.constraints` option.

**scrypt password hasher**

The new `scrypt password hasher` is more secure and recommended over PBKDF2. However, it’s not the default as it requires OpenSSL 1.1+ and more memory.

**Redis cache backend**

The new `django.core.cache.backends.redis.RedisCache` cache backend provides built-in support for caching with Redis. `redis-py` 3.0.0 or higher is required. For more details, see the documentation on caching with Redis in Django.
Template based form rendering

Forms, Formsets, and ErrorList are now rendered using the template engine to enhance customization. See the new render(), get_context(), and template_name for Form and formset rendering for Formset.

Minor features

django.contrib.admin

- The admin/base.html template now has a new block header which contains the admin site header.
- The new ModelAdmin.get_formset_kwargs() method allows customizing the keyword arguments passed to the constructor of a formset.
- The navigation sidebar now has a quick filter toolbar.
- The new context variable model which contains the model class for each model is added to the AdminSite.each_context() method.
- The new ModelAdmin.search_help_text attribute allows specifying a descriptive text for the search box.
- The InlineModelAdmin.verbose_name_plural attribute now fallbacks to the InlineModelAdmin.verbose_name + 's'.
- jQuery is upgraded from version 3.5.1 to 3.6.0.

django.contrib.admindocs

- The admindocs now allows esoteric setups where ROOT_URLCONF is not a string.
- The model section of the admindocs now shows cached properties.

django.contrib.auth

- The default iteration count for the PBKDF2 password hasher is increased from 260,000 to 320,000.
- The new LoginView.next_page attribute and get_default_redirect_url() method allow customizing the redirect after login.
**django.contrib.gis**

- Added support for SpatiaLite 5.
- *GDALRaster* now allows creating rasters in any GDAL virtual filesystem.
- The new *GISModelAdmin* class allows customizing the widget used for *GeometryField*. This is encouraged instead of deprecated *GeoModelAdmin* and *OSMGeoAdmin*.

**django.contrib.postgres**

- The PostgreSQL backend now supports connecting by a service name. See *PostgreSQL connection settings* for more details.
- The new *AddConstraintNotValid* operation allows creating check constraints on PostgreSQL without verifying that all existing rows satisfy the new constraint.
- The new *ValidateConstraint* operation allows validating check constraints which were created using *AddConstraintNotValid* on PostgreSQL.
- The new *ArraySubquery()* expression allows using subqueries to construct lists of values on PostgreSQL.
- The new *trigram_word_similar* lookup, and the *TrigramWordDistance()* and *TrigramWordSimilarity()* expressions allow using trigram word similarity.

**django.contrib.staticfiles**

- *ManifestStaticFilesStorage* now replaces paths to JavaScript source map references with their hashed counterparts.
- The new *manifest_storage* argument of *ManifestFilesMixin* and *ManifestStaticFilesStorage* allows customizing the manifest file storage.

**Cache**

- The new async API for *django.core.cache.backends.base.BaseCache* begins the process of making cache backends async-compatible. The new async methods all have a prefixed names, e.g. *aadd()* , *aget()* , *aset()* , *aget_or_set()* , or *adelete_many()*.

  Going forward, the *a* prefix will be used for async variants of methods generally.
CSRF

- CSRF protection now consults the Origin header, if present. To facilitate this, some changes to the CSRF_TRUSTED_ORIGINS setting are required.

Forms

- ModelChoiceField now includes the provided value in the params argument of a raised ValidationError for the invalid_choice error message. This allows custom error messages to use the %(value)s placeholder.
- BaseFormSet now renders non-form errors with an additional class of nonform to help distinguish them from form-specific errors.
- BaseFormSet now allows customizing the widget used when deleting forms via can_delete by setting the deletion_widget attribute or overriding get_deletion_widget() method.

Internationalization

- Added support and translations for the Malay language.

Generic Views

- DeleteView now uses FormMixin, allowing you to provide a Form subclass, with a checkbox for example, to confirm deletion. In addition, this allows DeleteView to function with django.contrib.messages.views.SuccessMessageMixin.

In accordance with FormMixin, object deletion for POST requests is handled in form_valid(). Custom delete logic in delete() handlers should be moved to form_valid(), or a shared helper method, as needed.

Logging

- The alias of the database used in an SQL call is now passed as extra context along with each message to the django.db.backends logger.
Management Commands

- The `runserver` management command now supports the `--skip-checks` option.
- On PostgreSQL, `dbshell` now supports specifying a password file.
- The `shell` command now respects `sys.__interactivehook__` at startup. This allows loading shell history between interactive sessions. As a consequence, `readline` is no longer loaded if running in isolated mode.
- The new `BaseCommand.suppressed_base_arguments` attribute allows suppressing unsupported default command options in the help output.
- The new `startapp --exclude` and `startproject --exclude` options allow excluding directories from the template.

Models

- New `QuerySet.contains(obj)` method returns whether the queryset contains the given object. This tries to perform the query in the simplest and fastest way possible.
- The new `precision` argument of the `Round()` database function allows specifying the number of decimal places after rounding.
- `QuerySet.bulk_create()` now sets the primary key on objects when using SQLite 3.35+.
- `DurationField` now supports multiplying and dividing by scalar values on SQLite.
- `QuerySet.bulk_update()` now returns the number of objects updated.
- The new `Expression.empty_result_set_value` attribute allows specifying a value to return when the function is used over an empty result set.
- The `skip_locked` argument of `QuerySet.select_for_update()` is now allowed on MariaDB 10.6+.
- `Lookup` expressions may now be used in `QuerySet` annotations, aggregations, and directly in filters.
- The new `default` argument for built-in aggregates allows specifying a value to be returned when the queryset (or grouping) contains no entries, rather than `None`.

Requests and Responses

- The `SecurityMiddleware` now adds the Cross-Origin Opener Policy header with a value of `'same-origin'` to prevent cross-origin popups from sharing the same browsing context. You can prevent this header from being added by setting the `SECURE_CROSS_ORIGIN_OPENER_POLICY` setting to `None`.
Signals

- The new stdout argument for `pre_migrate()` and `post_migrate()` signals allows redirecting output to a stream-like object. It should be preferred over `sys.stdout` and `print()` when emitting verbose output in order to allow proper capture when testing.

Templates

- `floatformat` template filter now allows using the `u` suffix to force disabling localization.

Tests

- The new `serialized_aliases` argument of `django.test.utils.setup_databases()` determines which `DATABASES` aliases test databases should have their state serialized to allow usage of the serialized rollback feature.
- Django test runner now supports a `--buffer` option with parallel tests.
- The new `logger` argument to `DiscoverRunner` allows a Python logger to be used for logging.
- The new `DiscoverRunner.log()` method provides a way to log messages that uses the `DiscoverRunner.logger`, or prints to the console if not set.
- Django test runner now supports a `--shuffle` option to execute tests in a random order.
- The `test --parallel` option now supports the value `auto` to run one test process for each processor core.
- `TestCase.captureOnCommitCallbacks()` now captures new callbacks added while executing `transaction.on_commit()` callbacks.

Backwards incompatible changes in 4.0

Database backend API

This section describes changes that may be needed in third-party database backends.

- `DatabaseOperations.year_lookup_bounds_for_date_field()` and `year_lookup_bounds_for_datetime_field()` methods now take the optional `iso_year` argument in order to support bounds for ISO-8601 week-numbering years.
- The second argument of `DatabaseSchemaEditor._unique_sql()` and `_create_unique_sql()` methods is now `fields` instead of `columns`.
django.contrib.gis

- Support for PostGIS 2.3 is removed.
- Support for GDAL 2.0 and GEOS 3.5 is removed.

Dropped support for PostgreSQL 9.6

Upstream support for PostgreSQL 9.6 ends in November 2021. Django 4.0 supports PostgreSQL 10 and higher. Also, the minimum supported version of psycopg2 is increased from 2.5.4 to 2.8.4, as psycopg2 2.8.4 is the first release to support Python 3.8.

Dropped support for Oracle 12.2 and 18c

Upstream support for Oracle 12.2 ends in March 2022 and for Oracle 18c it ends in June 2021. Django 3.2 will be supported until April 2024. Django 4.0 officially supports Oracle 19c.

CSRF_TRUSTED_ORIGINS changes

Format change

Values in the CSRF_TRUSTED_ORIGINS setting must include the scheme (e.g. 'http://' or 'https://') instead of only the hostname.

Also, values that started with a dot, must now also include an asterisk before the dot. For example, change '.example.com' to 'https://*.example.com'.

A system check detects any required changes.

Configuring it may now be required

As CSRF protection now consults the Origin header, you may need to set CSRF_TRUSTED_ORIGINS, particularly if you allow requests from subdomains by setting CSRF_COOKIE_DOMAIN (or SESSION_COOKIE_DOMAIN if CSRF_USE_SESSIONS is enabled) to a value starting with a dot.
SecurityMiddleware no longer sets the X-XSS-Protection header

The SecurityMiddleware no longer sets the X-XSS-Protection header if the SECURE_BROWSER_XSS_FILTER setting is True. The setting is removed.

Most modern browsers don’t honor the X-XSS-Protection HTTP header. You can use Content-Security-Policy without allowing 'unsafe-inline' scripts instead.

If you want to support legacy browsers and set the header, use this line in a custom middleware:

```python
response.headers.setdefault('X-XSS-Protection', '1; mode=block')
```

Migrations autodetector changes

The migrations autodetector now uses model states instead of model classes. Also, migration operations for ForeignKey and ManyToManyField fields no longer specify attributes which were not passed to the fields during initialization.

As a side-effect, running `makemigrations` might generate no-op AlterField operations for ManyToManyField and ForeignKey fields in some cases.

DeleteView changes

`DeleteView` now uses `FormMixin` to handle POST requests. As a consequence, any custom deletion logic in `delete()` handlers should be moved to `form_valid()`, or a shared helper method, if required.

Table and column naming scheme changes on Oracle

Django 4.0 inadvertently changed the table and column naming scheme on Oracle. This causes errors for models and fields with names longer than 30 characters. Unfortunately, renaming some Oracle tables and columns is required. Use the upgrade script in 33789 to generate `RENAME` statements to change naming scheme.

Miscellaneous

- Support for `cx_Oracle < 7.0` is removed.
- To allow serving a Django site on a subpath without changing the value of `STATIC_URL`, the leading slash is removed from that setting (now 'static/') in the default `startproject` template.
- The `AdminSite` method for the admin index view is no longer decorated with `never_cache` when accessed directly, rather than via the recommended `AdminSite.urls` property, or `AdminSite.get_urls()` method.
- Unsupported operations on a sliced queryset now raise `TypeError` instead of `AssertionError`.

9.1. Final releases
• The undocumented `django.test.runner.reorder_suite()` function is renamed to `reorder_tests()`. It now accepts an iterable of tests rather than a test suite, and returns an iterator of tests.

• Calling `FileSystemStorage.delete()` with an empty name now raises `ValueError` instead of `AssertionError`.

• Calling `EmailMultiAlternatives.attach_alternative()` or `EmailMessage.attach()` with an invalid content or mimetype arguments now raise `ValueError` instead of `AssertionError`.

• `assertHTMLEqual()` no longer considers a non-boolean attribute without a value equal to an attribute with the same name and value.

• Tests that fail to load, for example due to syntax errors, now always match when using `test --tag`.

• The undocumented `django.contrib.admin.utils.lookup_needs_distinct()` function is renamed to `lookup_spawns_duplicates()`.

• The undocumented `HttpRequest.get_raw_uri()` method is removed. The `HttpRequest.build_absolute_uri()` method may be a suitable alternative.

• The object argument of undocumented `ModelAdmin.log_addition()`, `log_change()`, and `log_deletion()` methods is renamed to `obj`.

• `RssFeed`, `Atom1Feed`, and their subclasses now emit elements with no content as self-closing tags.

• `NodeList.render()` no longer casts the output of `render()` method for individual nodes to a string. `Node.render()` should always return a string as documented.

• The `where_class` property of `django.db.models.sql.query.Query` and the `where_class` argument to the private `get_extra_restriction()` method of `ForeignObject` and `ForeignObjectRel` are removed. If needed, initialize `django.db.models.sql.where.WhereNode` instead.

• The `filter_clause` argument of the undocumented `Query.add_filter()` method is replaced by two positional arguments `filter_lhs` and `filter_rhs`.

• `CsrfViewMiddleware` now uses `request.META['CSRF_COOKIE_NEEDS_UPDATE']` in place of `request.META['CSRF_COOKIE_USED']`, `request.csrf_cookie_needs_reset`, and `response.csrf_cookie_set` to track whether the CSRF cookie should be sent. This is an undocumented, private API.

• The undocumented `TRANSLATOR_COMMENT_MARK` constant is moved from `django.template.base` to `django.utils.translation.template`.

• The `real_apps` argument of the undocumented `django.db.migrations.state.ProjectState.__init__()` method must now be a set if provided.

• `RadioSelect` and `CheckboxSelectMultiple` widgets are now rendered in `<div>` tags so they are announced more concisely by screen readers. If you need the previous behavior, override the widget `template` with the appropriate template from Django 3.2.
• The \texttt{floatformat} template filter no longer depends on the \texttt{USE\_L10N} setting and always returns localized output. Use the \texttt{u} suffix to disable localization.

• The default value of the \texttt{USE\_L10N} setting is changed to \texttt{True}. See the Localization section above for more details.

• As part of the move to zoneinfo, \texttt{django.utils.timezone.utc} is changed to alias \texttt{datetime.timezone.utc}.

• The minimum supported version of \texttt{asgiref} is increased from 3.3.2 to 3.4.1.

Features deprecated in 4.0

Use of pytz time zones

As part of the move to zoneinfo, use of \texttt{pytz} time zones is deprecated.

Accordingly, the \texttt{is\_dst} arguments to the following are also deprecated:

- \texttt{django.db.models.query.QuerySet.datetimes()}
- \texttt{django.db.models.functions.Trunc()}
- \texttt{django.db.models.functions.TruncSecond()}
- \texttt{django.db.models.functions.TruncMinute()}
- \texttt{django.db.models.functions.TruncHour()}
- \texttt{django.db.models.functions.TruncDay()}
- \texttt{django.db.models.functions.TruncWeek()}
- \texttt{django.db.models.functions.TruncMonth()}
- \texttt{django.db.models.functions.TruncQuarter()}
- \texttt{django.db.models.functions.TruncYear()}
- \texttt{django.utils.timezone.make_aware()}

Support for use of \texttt{pytz} will be removed in Django 5.0.

Time zone support

In order to follow good practice, the default value of the \texttt{USE\_TZ} setting will change from \texttt{False} to \texttt{True}, and time zone support will be enabled by default, in Django 5.0.

Note that the default \texttt{settings.py} file created by \texttt{django-admin startproject} includes \texttt{USE\_TZ = True} since Django 1.4.

You can set \texttt{USE\_TZ} to \texttt{False} in your project settings before then to opt-out.
Localization

In order to follow good practice, the default value of the `USE_L10N` setting is changed from `False` to `True`. Moreover `USE_L10N` is deprecated as of this release. Starting with Django 5.0, by default, any date or number displayed by Django will be localized.

The `{% localize %}` tag and the `localize/unlocalize` filters will still be honored by Django.

Miscellaneous

- `SERIALIZE` test setting is deprecated as it can be inferred from the `databases` with the `serialized_rollback` option enabled.
- The undocumented `django.utils.baseconv` module is deprecated.
- The undocumented `django.utils.datetime_safe` module is deprecated.
- The default sitemap protocol for sitemaps built outside the context of a request will change from `http` to `https` in Django 5.0.
- The `extra_tests` argument for `DiscoverRunner.build_suite()` and `DiscoverRunner.run_tests()` is deprecated.
- The `ArrayAgg`, `JSONBAgg`, and `StringAgg` aggregates will return `None` when there are no rows instead of `[]`, `[]`, and `'` respectively in Django 5.0. If you need the previous behavior, explicitly set `default` to `Value([])`, `Value('[]')`, or `Value('')`.
- The `django.contrib.gis.admin.GeoModelAdmin` and `OSMGeoAdmin` classes are deprecated. Use `ModelAdmin` and `GISModelAdmin` instead.
- Since form rendering now uses the template engine, the undocumented `BaseForm._html_output()` helper method is deprecated.
- The ability to return a `str` from `ErrorList` and `ErrorDict` is deprecated. It is expected these methods return a `SafeString`.

Features removed in 4.0

These features have reached the end of their deprecation cycle and are removed in Django 4.0.

See Features deprecated in 3.0 for details on these changes, including how to remove usage of these features.

- `django.utils.http.urlquote()`, `urlquote_plus()`, `urlunquote()`, and `urlunquote_plus()` are removed.
- `django.utils.encoding.force_text()` and `smart_text()` are removed.
• `django.utils.translation.ugettext()`, `ugettext_lazy()`, `ugettext_noop()`, `ungettext()`, and `ungettext_lazy()` are removed.

• `django.views.i18n.set_language()` doesn’t set the user language in `request.session` (key `_language`).

• `alias=None` is required in the signature of `django.db.models.Expression.get_group_by_cols()` subclasses.

• `django.utils.text.unescape_entities()` is removed.

• `django.utils.http.is_safe_url()` is removed.

See `Features deprecated in 3.1` for details on these changes, including how to remove usage of these features.

• The `PASSWORD_RESET_TIMEOUT_DAYS` setting is removed.

• The `isnull` lookup no longer allows using non-boolean values as the right-hand side.

• The `django.db.models.query_utils.InvalidQuery` exception class is removed.

• The `django-admin.py` entry point is removed.

• The `HttpRequest.is_ajax()` method is removed.

• Support for the pre-Django 3.1 encoding format of cookies values used by `django.contrib.messages.storage.cookie.CookieStorage` is removed.

• Support for the pre-Django 3.1 password reset tokens in the admin site (that use the SHA-1 hashing algorithm) is removed.

• Support for the pre-Django 3.1 encoding format of sessions is removed.

• Support for the pre-Django 3.1 `django.core.signing.Signer` signatures (encoded with the SHA-1 algorithm) is removed.

• Support for the pre-Django 3.1 `django.core.signing.dumps()` signatures (encoded with the SHA-1 algorithm) in `django.core.signing.loads()` is removed.

• Support for the pre-Django 3.1 user sessions (that use the SHA-1 algorithm) is removed.

• The `get_response` argument for `django.utils.deprecation.MiddlewareMixin.__init__()` is required and doesn’t accept `None`.

• The `providing_args` argument for `django.dispatch.Signal` is removed.

• The `length` argument for `django.utils.crypto.get_random_string()` is required.

• The `list` message for `ModelMultipleChoiceField` is removed.

• Support for passing raw column aliases to `QuerySet.order_by()` is removed.

• The `NullBooleanField` model field is removed, except for support in historical migrations.

• `django.conf.urls.url()` is removed.
• The `django.contrib.postgres.fields.JSONField` model field is removed, except for support in historical migrations.

• `django.contrib.postgres.fields.jsonb.KeyTransform` and `django.contrib.postgres.fields.jsonb.KeyTextTransform` are removed.

• `django.contrib.postgres.forms.JSONField` is removed.

• The `{% ifequal %}` and `{% ifnotequal %}` template tags are removed.

• The `DEFAULT_HASHING_ALGORITHM` transitional setting is removed.

9.1.4 3.2 release

Django 3.2.14 release notes

July 4, 2022

Django 3.2.14 fixes a security issue with severity “high” in 3.2.13.

CVE-2022-34265: Potential SQL injection via `Trunc(kind)` and `Extract(lookup_name)` arguments

`Trunc()` and `Extract()` database functions were subject to SQL injection if untrusted data was used as a `kind/lookup_name` value.

Applications that constrain the lookup name and kind choice to a known safe list are unaffected.

Django 3.2.13 release notes

April 11, 2022

Django 3.2.13 fixes two security issues with severity “high” in 3.2.12 and a regression in 3.2.4.

CVE-2022-28346: Potential SQL injection in `QuerySet.annotate()`, `aggregate()`, and `extra()` methods

`QuerySet.annotate()`, `aggregate()`, and `extra()` methods were subject to SQL injection in column aliases, using a suitably crafted dictionary, with dictionary expansion, as the `**kwargs` passed to these methods.
CVE-2022-28347: Potential SQL injection via `QuerySet.explain(**options)` on PostgreSQL

`QuerySet.explain()` method was subject to SQL injection in option names, using a suitably crafted dictionary, with dictionary expansion, as the `**options` argument.

Bugfixes

- Fixed a regression in Django 3.2.4 that caused the auto-reloader to no longer detect changes when the `DIRS` option of the `TEMPLATES` setting contained an empty string (#33628).

Django 3.2.12 release notes

February 1, 2022

Django 3.2.12 fixes two security issues with severity “medium” in 3.2.11.

CVE-2022-22818: Possible XSS via `{% debug %}` template tag

The `{% debug %}` template tag didn’t properly encode the current context, posing an XSS attack vector. In order to avoid this vulnerability, `{% debug %}` no longer outputs information when the `DEBUG` setting is `False`, and it ensures all context variables are correctly escaped when the `DEBUG` setting is `True`.

CVE-2022-23833: Denial-of-service possibility in file uploads

Passing certain inputs to multipart forms could result in an infinite loop when parsing files.

Django 3.2.11 release notes

January 4, 2022

Django 3.2.11 fixes one security issue with severity “medium” and two security issues with severity “low” in 3.2.10.

CVE-2021-45115: Denial-of-service possibility in `UserAttributeSimilarityValidator`

`UserAttributeSimilarityValidator` incurred significant overhead evaluating submitted password that were artificially large in relative to the comparison values. On the assumption that access to user registration was unrestricted this provided a potential vector for a denial-of-service attack. In order to mitigate this issue, relatively long values are now ignored by `UserAttributeSimilarityValidator`.

9.1. Final releases
This issue has severity “medium” according to the Django security policy.

CVE-2021-45116: Potential information disclosure in dictsort template filter

Due to leveraging the Django Template Language’s variable resolution logic, the dictsort template filter was potentially vulnerable to information disclosure or unintended method calls, if passed a suitably crafted key.

In order to avoid this possibility, dictsort now works with a restricted resolution logic, that will not call methods, nor allow indexing on dictionaries.

As a reminder, all untrusted user input should be validated before use.

This issue has severity “low” according to the Django security policy.

CVE-2021-45452: Potential directory-traversal via Storage.save()

Storage.save() allowed directory-traversal if directly passed suitably crafted file names.

This issue has severity “low” according to the Django security policy.

Django 3.2.10 release notes

December 7, 2021

Django 3.2.10 fixes a security issue with severity “low” and a bug in 3.2.9.

CVE-2021-44420: Potential bypass of an upstream access control based on URL paths

HTTP requests for URLs with trailing newlines could bypass an upstream access control based on URL paths.

Bugfixes

- Fixed a regression in Django 3.2 that caused a crash of setUpTestData() with BinaryField on PostgreSQL, which is memoryview-backed (#33333).
Django 3.2.9 release notes

November 1, 2021

Django 3.2.9 fixes a bug in 3.2.8 and adds compatibility with Python 3.10.

Bugfixes

- Fixed a bug in Django 3.2 that caused a migration crash on SQLite when altering a field with a functional index (#33194).

Django 3.2.8 release notes

October 5, 2021

Django 3.2.8 fixes two bugs in 3.2.7.

Bugfixes

- Fixed a bug in Django 3.2 that caused incorrect links on read-only fields in the admin (#33077).
- Fixed a regression in Django 3.2 that caused incorrect selection of items across all pages when actions were placed both on the top and bottom of the admin change-list view (#33083).

Django 3.2.7 release notes

September 1, 2021

Django 3.2.7 fixes a bug in 3.2.6.

Bugfixes

- Fixed a regression in Django 3.2 that caused the incorrect offset extraction from fixed offset timezones (#32992).

Django 3.2.6 release notes

August 2, 2021

Django 3.2.6 fixes several bugs in 3.2.5.
Bugfixes

- Fixed a regression in Django 3.2 that caused a crash validating "NaN" input with a `forms.DecimalField` when additional constraints, e.g. `max_value`, were specified (#32949).

- Fixed a bug in Django 3.2 where a system check would crash on a model with a reverse many-to-many relation inherited from a parent class (#32947).

Django 3.2.5 release notes

July 1, 2021

Django 3.2.5 fixes a security issue with severity “high” and several bugs in 3.2.4. Also, the latest string translations from Transifex are incorporated.

CVE-2021-35042: Potential SQL injection via unsanitized `QuerySet.order_by()` input

Unsanitized user input passed to `QuerySet.order_by()` could bypass intended column reference validation in path marked for deprecation resulting in a potential SQL injection even if a deprecation warning is emitted. As a mitigation the strict column reference validation was restored for the duration of the deprecation period. This regression appeared in 3.1 as a side effect of fixing #31426.

The issue is not present in the main branch as the deprecated path has been removed.

Bugfixes

- Fixed a regression in Django 3.2 that caused a crash of `QuerySet.values_list(..., named=True)` after `prefetch_related()` (#32812).

- Fixed a bug in Django 3.2 that caused a migration crash on MySQL 8.0.13+ when altering `BinaryField`, `JSONField`, or `TextField` to non-nullable (#32503).

- Fixed a regression in Django 3.2 that caused a migration crash on MySQL 8.0.13+ when adding nullable `BinaryField`, `JSONField`, or `TextField` with a default value (#32832).

- Fixed a bug in Django 3.2 where a system check would crash on a model with an invalid `app_label` (#32863).
Django 3.2.4 release notes

June 2, 2021

Django 3.2.4 fixes two security issues and several bugs in 3.2.3.

**CVE-2021-33203: Potential directory traversal via admindocs**

Staff members could use the `admindocs TemplateDetailView` view to check the existence of arbitrary files. Additionally, if (and only if) the default admindocs templates have been customized by the developers to also expose the file contents, then not only the existence but also the file contents would have been exposed.

As a mitigation, path sanitation is now applied and only files within the template root directories can be loaded.

**CVE-2021-33571: Possible indeterminate SSRF, RFI, and LFI attacks since validators accepted leading zeros in IPv4 addresses**

`URLValidator`, `validate_ipv4_address()`, and `validate_ipv46_address()` didn’t prohibit leading zeros in octal literals. If you used such values you could suffer from indeterminate SSRF, RFI, and LFI attacks.

`validate_ipv4_address()` and `validate_ipv46_address()` validators were not affected on Python 3.9.5+.

**Bugfixes**

- Fixed a bug in Django 3.2 where a final catch-all view in the admin didn’t respect the server-provided value of `SCRIPT_NAME` when redirecting unauthenticated users to the login page (#32754).
- Fixed a bug in Django 3.2 where a system check would crash on an abstract model (#32733).
- Prevented unnecessary initialization of unused caches following a regression in Django 3.2 (#32747).
- Fixed a crash in Django 3.2 that could occur when running `mod_wsgi` with the recommended settings while the Windows `colorama` library was installed (#32740).
- Fixed a bug in Django 3.2 that would trigger the auto-reloader for template changes when directory paths were specified with strings (#32744).
- Fixed a regression in Django 3.2 that caused a crash of auto-reloader with `AttributeError`, e.g. inside a Conda environment (#32783).
- Fixed a regression in Django 3.2 that caused a loss of precision for operations with `DecimalField` on MySQL (#32793).
Django 3.2.3 release notes

May 13, 2021

Django 3.2.3 fixes several bugs in 3.2.2.

**Bugfixes**

- Prepared for `mysqlclient > 2.0.3` support (#32732).
- Fixed a regression in Django 3.2 that caused the incorrect filtering of querysets combined with the `|` operator (#32717).
- Fixed a regression in Django 3.2.1 where saving `FileField` would raise a `SuspiciousFileOperation` even when a custom `upload_to` returns a valid file path (#32718).

Django 3.2.2 release notes

May 6, 2021

Django 3.2.2 fixes a security issue and a bug in 3.2.1.

**CVE-2021-32052: Header injection possibility since `URLValidator` accepted newlines in input on Python 3.9.5+**

On Python 3.9.5+, `URLValidator` didn’t prohibit newlines and tabs. If you used values with newlines in HTTP response, you could suffer from header injection attacks. Django itself wasn’t vulnerable because `HttpResponse` prohibits newlines in HTTP headers.

Moreover, the `URLField` form field which uses `URLValidator` silently removes newlines and tabs on Python 3.9.5+, so the possibility of newlines entering your data only existed if you are using this validator outside of the form fields.

This issue was introduced by the bpo-43882 fix.

**Bugfixes**

- Prevented, following a regression in Django 3.2.1, `makemigrations` from generating infinite migrations for a model with `Meta.ordering` contained `OrderBy` expressions (#32714).
Django 3.2.1 release notes

May 4, 2021

Django 3.2.1 fixes a security issue and several bugs in 3.2.

CVE-2021-31542: Potential directory-traversal via uploaded files

MultiPartParser, UploadedFile, and FieldFile allowed directory-traversal via uploaded files with suitably crafted file names.

In order to mitigate this risk, stricter basename and path sanitation is now applied.

Bugfixes

- Corrected detection of GDAL 3.2 on Windows (#32544).
- Fixed a bug in Django 3.2 where subclasses of BigAutoField and SmallAutoField were not allowed for the DEFAULT_AUTO_FIELD setting (#32620).
- Fixed a regression in Django 3.2 that caused a crash of QuerySet.values() / values_list() after QuerySet.union(), intersection(), and difference() when it was ordered by an unannotated field (#32627).
- Restored, following a regression in Django 3.2, displaying an exception message on the technical 404 debug page (#32637).
- Fixed a bug in Django 3.2 where a system check would crash on a reverse one-to-one relationships in CheckConstraint.check or UniqueConstraint.condition (#32635).
- Fixed a regression in Django 3.2 that caused a crash of ModelAdmin.search_fields when searching against phrases with unbalanced quotes (#32649).
- Fixed a bug in Django 3.2 where variable lookup errors were logged rendering the sitemap template if alternates were not defined (#32648).
- Fixed a regression in Django 3.2 that caused a crash when combining Q() objects which contains boolean expressions (#32548).
- Fixed a regression in Django 3.2 that caused a crash of QuerySet.update() on a queryset ordered by inherited or joined fields on MySQL and MariaDB (#32645).
- Fixed a regression in Django 3.2 that caused a crash when decoding a cookie value, used by django.contrib.messages.storage.cookie.CookieStorage, in the pre-Django 3.2 format (#32643).
- Fixed a regression in Django 3.2 that stopped the shift-key modifier selecting multiple rows in the admin changelist (#32647).
• Fixed a bug in Django 3.2 where a system check would crash on the `STATICFILES_DIRS` setting with a list of 2-tuples of `(prefix, path)` (#32665).

• Fixed a long standing bug involving queryset bitwise combination when used with subqueries that began manifesting in Django 3.2, due to a separate fix using `Exists` to exclude() multi-valued relationships (#32650).

• Fixed a bug in Django 3.2 where variable lookup errors were logged when rendering some admin templates (#32681).

• Fixed a bug in Django 3.2 where an admin changelist would crash when deleting objects filtered against multi-valued relationships (#32682). The admin changelist now uses `Exists()` instead of `QuerySet.distinct()` because calling `delete()` after `distinct()` is not allowed in Django 3.2 to address a data loss possibility.

• Fixed a regression in Django 3.2 where the calling process environment would not be passed to the `dbshell` command on PostgreSQL (#32687).

• Fixed a performance regression in Django 3.2 when building complex filters with subqueries (#32632). As a side-effect the private API to check `django.db.sql.query.Query` equality is removed.

**Django 3.2 release notes**

April 6, 2021

Welcome to Django 3.2!

These release notes cover the new features, as well as some backwards incompatible changes you’ll want to be aware of when upgrading from Django 3.1 or earlier. We’ve begun the deprecation process for some features.

See the How to upgrade Django to a newer version guide if you’re updating an existing project.

Django 3.2 is designated as a long-term support release. It will receive security updates for at least three years after its release. Support for the previous LTS, Django 2.2, will end in April 2022.

**Python compatibility**

Django 3.2 supports Python 3.6, 3.7, 3.8, 3.9, and 3.10 (as of 3.2.9). We highly recommend and only officially support the latest release of each series.
What’s new in Django 3.2

Automatic AppConfig discovery

Most pluggable applications define an AppConfig subclass in an apps.py submodule. Many define a default_app_config variable pointing to this class in their __init__.py.

When the apps.py submodule exists and defines a single AppConfig subclass, Django now uses that configuration automatically, so you can remove default_app_config.

default_app_config made it possible to declare only the application’s path in INSTALLED_APPS (e.g. 'django.contrib.admin') rather than the app config’s path (e.g. 'django.contrib.admin.apps/AdminConfig'). It was introduced for backwards-compatibility with the former style, with the intent to switch the ecosystem to the latter, but the switch didn’t happen.

With automatic AppConfig discovery, default_app_config is no longer needed. As a consequence, it’s deprecated.

See Configuring applications for full details.

Customizing type of auto-created primary keys

When defining a model, if no field in a model is defined with primary_key=True an implicit primary key is added. The type of this implicit primary key can now be controlled via the DEFAULT_AUTO_FIELD setting and AppConfig.default_auto_field attribute. No more needing to override primary keys in all models.

Maintaining the historical behavior, the default value for DEFAULT_AUTO_FIELD is AutoField. Starting with 3.2 new projects are generated with DEFAULT_AUTO_FIELD set to BigAutoField. Also, new apps are generated with AppConfig.default_auto_field set to BigAutoField. In a future Django release the default value of DEFAULT_AUTO_FIELD will be changed to BigAutoField.

To avoid unwanted migrations in the future, either explicitly set DEFAULT_AUTO_FIELD to AutoField:

```
DEFAULT_AUTO_FIELD = 'django.db.models.AutoField'
```

or configure it on a per-app basis:

```
from django.apps import AppConfig

class MyAppConfig(AppConfig):
    default_auto_field = 'django.db.models.AutoField'
    name = 'my_app'
```

or on a per-model basis:
from django.db import models

class MyModel(models.Model):
    id = models.AutoField(primary_key=True)

In anticipation of the changing default, a system check will provide a warning if you do not have an explicit setting for `DEFAULT_AUTO_FIELD`.

When changing the value of `DEFAULT_AUTO_FIELD`, migrations for the primary key of existing auto-created through tables cannot be generated currently. See the `DEFAULT_AUTO_FIELD` docs for details on migrating such tables.

**Functional indexes**

The new *expressions* positional argument of `Index()` enables creating functional indexes on expressions and database functions. For example:

```python
from django.db import models
from django.db.models import F, Index, Value
from django.db.models.functions import Lower, Upper

class MyModel(models.Model):
    first_name = models.CharField(max_length=255)
    last_name = models.CharField(max_length=255)
    height = models.IntegerField()
    weight = models.IntegerField()

    class Meta:
        indexes = [
            Index(
                Lower('first_name'),
                Upper('last_name').desc(),
                name='first_last_name_idx',
            ),
            Index(
                F('height') / (F('weight') + Value(5)),
                name='calc_idx',
            ),
        ]
```

Functional indexes are added to models using the `Meta.indexes` option.
pymemcache support

The new `django.core.cache.backends.memcached.PyMemcacheCache` cache backend allows using the `pymemcache` library for memcached. `pymemcache` 3.4.0 or higher is required. For more details, see the documentation on caching in Django.

New decorators for the admin site

The new `display()` decorator allows for easily adding options to custom display functions that can be used with `list_display` or `readonly_fields`.

Likewise, the new `action()` decorator allows for easily adding options to action functions that can be used with `actions`.

Using the `@display` decorator has the advantage that it is now possible to use the `@property` decorator when needing to specify attributes on the custom method. Prior to this it was necessary to use the `property()` function instead after assigning the required attributes to the method.

Using decorators has the advantage that these options are more discoverable as they can be suggested by completion utilities in code editors. They are merely a convenience and still set the same attributes on the functions under the hood.

Minor features

django.contrib.admin

- `ModelAdmin.search_fields` now allows searching against quoted phrases with spaces.
- Read-only related fields are now rendered as navigable links if target models are registered in the admin.
- The admin now supports theming, and includes a dark theme that is enabled according to browser settings. See Theming support for more details.
- `ModelAdmin.autocomplete_fields` now respects `ForeignKey.to_field` and `ForeignKey.limit_choices_to` when searching a related model.
- The admin now installs a final catch-all view that redirects unauthenticated users to the login page, regardless of whether the URL is otherwise valid. This protects against a potential model enumeration privacy issue.

Although not recommended, you may set the new `AdminSite.finalCatchAllView` to `False` to disable the catch-all view.
django.contrib.auth

- The default iteration count for the PBKDF2 password hasher is increased from 216,000 to 260,000.
- The default variant for the Argon2 password hasher is changed to Argon2id. `memory_cost` and `parallelism` are increased to 102,400 and 8 respectively to match the argon2-cffi defaults.

  Increasing the `memory_cost` pushes the required memory from 512 KB to 100 MB. This is still rather conservative but can lead to problems in memory constrained environments. If this is the case, the existing hasher can be subclassed to override the defaults.

- The default salt entropy for the Argon2, MD5, PBKDF2, SHA-1 password hashers is increased from 71 to 128 bits.

django.contrib.contenttypes

- The new `absolute_max` argument for `generic_inlineformset_factory()` allows customizing the maximum number of forms that can be instantiated when supplying POST data. See Limiting the maximum number of instantiated forms for more details.

- The new `can_delete_extra` argument for `generic_inlineformset_factory()` allows removal of the option to delete extra forms. See `can_delete_extra` for more information.

django.contrib.gis

- The `GDALRaster.transform()` method now supports `SpatialReference`.
- The `DataSource` class now supports `pathlib.Path`.
- The `LayerMapping` class now supports `pathlib.Path`.

django.contrib.postgres

- The new `ExclusionConstraint.include` attribute allows creating covering exclusion constraints on PostgreSQL 12+.
- The new `ExclusionConstraint.opclasses` attribute allows setting PostgreSQL operator classes.
- The new `JSONBAgg.ordering` attribute determines the ordering of the aggregated elements.
- The new `JSONBAgg.distinct` attribute determines if aggregated values will be distinct.
- The `CreateExtension` operation now checks that the extension already exists in the database and skips the migration if so.
- The new `CreateCollation` and `RemoveCollation` operations allow creating and dropping collations on PostgreSQL. See Managing collations using migrations for more details.
• Lookups for `ArrayField` now allow (non-nested) arrays containing expressions as right-hand sides.

• The new `OpClass()` expression allows creating functional indexes on expressions with a custom operator class. See `Functional indexes` for more details.

**django.contrib.sitemaps**

• The new `Sitemap` attributes `alternates`, `languages` and `x_default` allow generating sitemap alternates to localized versions of your pages.

**django.contrib.syndication**

• The new `item_comments` hook allows specifying a comments URL per feed item.

**Database backends**

• Third-party database backends can now skip or mark as expected failures tests in Django’s test suite using the new `DatabaseFeatures.django_test_skips` and `django_test_expected_failures` attributes.

**Decorators**

• The new `no_append_slash()` decorator allows individual views to be excluded from `APPEND_SLASH` URL normalization.

**Error Reporting**

• Custom `ExceptionReporter` subclasses can now define the `html_template_path` and `text_template_path` properties to override the templates used to render exception reports.

**File Uploads**

• The new `FileUploadHandler.upload_interrupted()` callback allows handling interrupted uploads.
Forms

- The new `absolute_max` argument for `formset_factory()`, `inlineformset_factory()`, and `modelformset_factory()` allows customizing the maximum number of forms that can be instantiated when supplying `POST` data. See Limiting the maximum number of instantiated forms for more details.

- The new `can_delete_extra` argument for `formset_factory()`, `inlineformset_factory()`, and `modelformset_factory()` allows removal of the option to delete extra forms. See `can_delete_extra` for more information.

- `BaseFormSet` now reports a user facing error, rather than raising an exception, when the management form is missing or has been tampered with. To customize this error message, pass the `error_messages` argument with the key `missing_management_form` when instantiating the formset.

Generic Views

- The `week_format` attributes of `WeekMixin` and `WeekArchiveView` now support the '%W' ISO 8601 week format.

Management Commands

- `loaddata` now supports fixtures stored in XZ archives (.xz) and LZMA archives (.lzma).

- `dumpdata` now can compress data in the bz2, gz, lzma, or xz formats.

- `makemigrations` can now be called without an active database connection. In that case, check for a consistent migration history is skipped.

- `BaseCommand.requires_system_checks` now supports specifying a list of tags. System checks registered in the chosen tags will be checked for errors prior to executing the command. In previous versions, either all or none of the system checks were performed.

- Support for colored terminal output on Windows is updated. Various modern terminal environments are automatically detected, and the options for enabling support in other cases are improved. See Syntax coloring for more details.
Migrations

- The new `Operation.migration_name_fragment` property allows providing a filename fragment that will be used to name a migration containing only that operation.
- Migrations now support serialization of pure and concrete path objects from `pathlib`, and `os.PathLike` instances.

Models

- The new `no_key` parameter for `QuerySet.select_for_update()`, supported on PostgreSQL, allows acquiring weaker locks that don’t block the creation of rows that reference locked rows through a foreign key.
- `When()` expression now allows using the `condition` argument with `lookups`.
- The new `Index.include` and `UniqueConstraint.include` attributes allow creating covering indexes and covering unique constraints on PostgreSQL 11+.
- The new `UniqueConstraint.opclasses` attribute allows setting PostgreSQL operator classes.
- The `QuerySet.update()` method now respects the `order_by()` clause on MySQL and MariaDB.
- `FilteredRelation()` now supports nested relations.
- The `of` argument of `QuerySet.select_for_update()` is now allowed on MySQL 8.0.1+.
- `Value()` expression now automatically resolves its `output_field` to the appropriate `Field` subclass based on the type of its provided `value` for `bool`, `bytes`, `float`, `int`, `str`, `datetime.date`, `datetime.datetime`, `datetime.time`, `datetime.timedelta`, `decimal.Decimal`, and `uuid.UUID` instances. As a consequence, resolving an `output_field` for database functions and combined expressions may now crash with mixed types when using `Value()`. You will need to explicitly set the `output_field` in such cases.
- The new `QuerySet.alias()` method allows creating reusable aliases for expressions that don’t need to be selected but are used for filtering, ordering, or as a part of complex expressions.
- The new `Collate` function allows filtering and ordering by specified database collations.
- The `field_name` argument of `QuerySet.in_bulk()` now accepts distinct fields if there’s only one field specified in `QuerySet.distinct()`.
- The new `tzinfo` parameter of the `TruncDate` and `TruncTime` database functions allows truncating datetimes in a specific timezone.
- The new `db_collation` argument for `CharField` and `TextField` allows setting a database collation for the field.
- Added the `Random` database function.
• Aggregation functions, \( F() \), \( \text{OuterRef}() \), and other expressions now allow using transforms. See Expressions can reference transforms for details.

• The new \texttt{durable} argument for \texttt{atomic()} guarantees that changes made in the atomic block will be committed if the block exits without errors. A nested atomic block marked as \texttt{durable} will raise a \texttt{RuntimeError}.

• Added the \texttt{JSONObject} database function.

Pagination

• The new \texttt{django.core.paginator.Paginator.get_elided_page_range()} method allows generating a page range with some of the values elided. If there are a large number of pages, this can be helpful for generating a reasonable number of page links in a template.

Requests and Responses

• Response headers are now stored in \texttt{HttpResponse.headers}. This can be used instead of the original dict-like interface of \texttt{HttpResponse} objects. Both interfaces will continue to be supported. See Setting header fields for details.

• The new \texttt{headers} parameter of \texttt{HttpResponse}, \texttt{SimpleTemplateResponse}, and \texttt{TemplateResponse} allows setting response headers on instantiation.

Security

• The \texttt{SECRET_KEY} setting is now checked for a valid value upon first access, rather than when settings are first loaded. This enables running management commands that do not rely on the \texttt{SECRET_KEY} without needing to provide a value. As a consequence of this, calling \texttt{configure()} without providing a valid \texttt{SECRET_KEY}, and then going on to access \texttt{settings.SECRET_KEY} will now raise an \texttt{ImproperlyConfigured} exception.

• The new \texttt{Signer.sign_object()} and \texttt{Signer.unsign_object()} methods allow signing complex data structures. See Protecting complex data structures for more details.

Also, \texttt{signing.dumps()} and \texttt{loads()} become shortcuts for \texttt{TimestampSigner.sign_object()} and \texttt{unsign_object()}. 
Serialization

- The new JSONL serializer allows using the JSON Lines format with `dumpdata` and `loaddata`. This can be useful for populating large databases because data is loaded line by line into memory, rather than being loaded all at once.

Signals

- `Signal.send_robust()` now logs exceptions.

Templates

- `floatformat` template filter now allows using the g suffix to force grouping by the `THOUSAND_SEPARATOR` for the active locale.
- Templates cached with `Cached template loaders` are now correctly reloaded in development.

Tests

- Objects assigned to class attributes in `TestCase.setUpTestData()` are now isolated for each test method. Such objects are now required to support creating deep copies with `copy.deepcopy()`. Assigning objects which don’t support `deepcopy()` is deprecated and will be removed in Django 4.1.
- `DiscoverRunner` now enables `faulthandler` by default. This can be disabled by using the `test --no-faulthandler` option.
- `DiscoverRunner` and the `test` management command can now track timings, including database setup and total run time. This can be enabled by using the `test --timing` option.
- `Client` now preserves the request query string when following 307 and 308 redirects.
- The new `TestCase.captureOnCommitCallbacks()` method captures callback functions passed to `transaction.on_commit()` in a list. This allows you to test such callbacks without using the slower `TransactionTestCase`.
- `TransactionTestCase.assertQuerysetEqual()` now supports direct comparison against another queryset rather than being restricted to comparison against a list of string representations of objects when using the default value for the `transform` argument.
Utilities

- The new depth parameter of `django.utils.timesince.timesince()` and `django.utils.timesince.timeuntil()` functions allows specifying the number of adjacent time units to return.

Validators

- Built-in validators now include the provided value in the `params` argument of a raised `ValidationError`. This allows custom error messages to use the `%{value}` placeholder.
- The `ValidationError` equality operator now ignores `messages` and `params` ordering.

Backwards incompatible changes in 3.2

Database backend API

This section describes changes that may be needed in third-party database backends.

- The new `DatabaseFeatures.introspected_field_types` property replaces these features:
  - `can_introspect_autofield`
  - `can_introspect_big_integer_field`
  - `can_introspect_binary_field`
  - `can_introspect_decimal_field`
  - `can_introspect_duration_field`
  - `can_introspect_ip_address_field`
  - `can_introspect_positive_integer_field`
  - `can_introspect_small_integer_field`
  - `can_introspect_time_field`
  - `introspected_big_auto_field_type`
  - `introspected_small_auto_field_type`
  - `introspected_boolean_field_type`

- To enable support for covering indexes (`Index.include`) and covering unique constraints (`UniqueConstraint.include`), set `DatabaseFeatures.supports_covering_indexes` to `True`.

- Third-party database backends must implement support for column database collations on `CharField` and `TextField` or set `DatabaseFeatures.supports_collation_on_charfield` and `DatabaseFeatures.supports_collation_on_textfield` to `False`. If non-deterministic collations are not supported, set `supports_non_deterministic_collations` to `False`. 
• `DatabaseOperations.random_function_sql()` is removed in favor of the new `Random` database function.

• `DatabaseOperations.date_trunc_sql()` and `DatabaseOperations.time_trunc_sql()` now take the optional `tzone` argument in order to truncate in a specific timezone.

• `DatabaseClient.runshell()` now gets arguments and an optional dictionary with environment variables to the underlying command-line client from `DatabaseClient.settings_to_cmd_args_env()` method. Third-party database backends must implement `DatabaseClient.settings_to_cmd_args_env()` or override `DatabaseClient.runshell()`.

• Third-party database backends must implement support for functional indexes (`Index.expressions`) or set `DatabaseFeatures.supports_expression_indexes` to `False`. If `COLLATE` is not a part of the `CREATE INDEX` statement, set `DatabaseFeatures.collate_as_index_expression` to `True`.

django.contrib.admin

• Pagination links in the admin are now 1-indexed instead of 0-indexed, i.e. the query string for the first page is `?p=1` instead of `?p=0`.

• The new admin catch-all view will break URL patterns routed after the admin URLs and matching the admin URL prefix. You can either adjust your URL ordering or, if necessary, set `AdminSite.final_catch_all_view` to `False`, disabling the catch-all view. See What’s new in Django 3.2 for more details.

• Minified JavaScript files are no longer included with the admin. If you require these files to be minified, consider using a third party app or external build tool. The minified vendored JavaScript files packaged with the admin (e.g. `jquery.min.js`) are still included.

• `ModelAdmin.prepopulated_fields` no longer strips English stop words, such as 'a' or 'an'.

django.contrib.gis

• Support for PostGIS 2.2 is removed.

• The Oracle backend now clones polygons (and geometry collections containing polygons) before reorienting them and saving them to the database. They are no longer mutated in place. You might notice this if you use the polygons after a model is saved.
Dropped support for PostgreSQL 9.5

Upstream support for PostgreSQL 9.5 ends in February 2021. Django 3.2 supports PostgreSQL 9.6 and higher.

Dropped support for MySQL 5.6

The end of upstream support for MySQL 5.6 is April 2021. Django 3.2 supports MySQL 5.7 and higher.

Miscellaneous

- Django now supports non-pytz time zones, such as Python 3.9+’s zoneinfo module and its backport.
- The undocumented `SpatialiteOperations.proj4_version()` method is renamed to `proj_version()`.
- `slugify()` now removes leading and trailing dashes and underscores.
- The `intcomma` and `intword` template filters no longer depend on the `USE_L10N` setting.
- Support for `argon2-cffi < 19.1.0` is removed.
- The cache keys no longer include the language when internationalization is disabled (`USE_I18N = False`) and localization is enabled (`USE_L10N = True`). After upgrading to Django 3.2 in such configurations, the first request to any previously cached value will be a cache miss.
- `ForeignKey.validate()` now uses `_base_manager` rather than `_default_manager` to check that related instances exist.
- When an application defines an ` AppConfig` subclass in an `apps.py` submodule, Django now uses this configuration automatically, even if it isn’t enabled with `default_app_config`. Set `default = False` in the ` AppConfig` subclass if you need to prevent this behavior. See What’s new in Django 3.2 for more details.
- Instantiating an abstract model now raises `TypeError`.
- Keyword arguments to `setup_databases()` are now keyword-only.
- The undocumented `django.utils.http.limited_parse_qsl()` function is removed. Please use `urllib.parse.parse_qsl()` instead.
- `django.test.utils.TestContextDecorator` now uses `addCleanup()` so that cleanups registered in the `setUp()` method are called before `TestContextDecorator.disable()`.
- `SessionMiddleware` now raises a `SessionInterrupted` exception instead of `SuspiciousOperation` when a session is destroyed in a concurrent request.
- The `django.db.models.Field` equality operator now correctly distinguishes inherited field instances across models. Additionally, the ordering of such fields is now defined.
• The undocumented `django.core.files.locks.lock()` function now returns `False` if the file cannot be locked, instead of raising `BlockingIOError`.

• The password reset mechanism now invalidatestokens when the user email is changed.

• `makemessages` command no longer processes invalid locales specified using `makemessages --locale` option, when they contain hyphens (`'-'`).

• The `django.contrib.auth.forms.ReadOnlyPasswordHashField` form field is now disabled by default. Therefore `UserChangeForm.clean_password()` is no longer required to return the initial value.

• The `cache.get_many()`, `get_or_set()`, `has_key()`, `incr()`, `decr()`, `incr_version()`, and `decr_version()` cache operations now correctly handle `None` stored in the cache, in the same way as any other value, instead of behaving as though the key didn’t exist.

Due to a `python-memcached` limitation, the previous behavior is kept for the deprecated `MemcachedCache` backend.

• The minimum supported version of SQLite is increased from 3.8.3 to 3.9.0.

• `CookieStorage` now stores messages in the RFC 6265 compliant format. Support for cookies that use the old format remains until Django 4.1.

• The minimum supported version of `asgiref` is increased from 3.2.10 to 3.3.2.

Features deprecated in 3.2

Miscellaneous

• Assigning objects which don’t support creating deep copies with `copy.deepcopy()` to class attributes in `TestCase.setUpTestData()` is deprecated.

• Using a boolean value in `BaseCommand.requires_system_checks` is deprecated. Use `__all__` instead of `True`, and `[]` (an empty list) instead of `False`.

• The `whitelist` argument and `domain_whitelist` attribute of `EmailValidator` are deprecated. Use `allowlist` instead of `whitelist`, and `domain_allowlist` instead of `domain_whitelist`. You may need to rename `whitelist` in existing migrations.

• The `default_app_config` application configuration variable is deprecated, due to the now automatic `AppConfig` discovery. See What’s new in Django 3.2 for more details.

• Automatically calling `repr()` on a queryset in `TransactionTestCase.assertQuerysetEqual()`, when compared to string values, is deprecated. If you need the previous behavior, explicitly set `transform` to `repr`.

• The `django.core.cache.backends.memcached.MemcachedCache` backend is deprecated as `python-memcached` has some problems and seems to be unmaintained. Use `django.core.cache.backends.%s`
cache.backends.memcached.PyMemcacheCache or django.core.cache.backends.memcached.PyLibMCCache instead.

- The format of messages used by django.contrib.messages.storage.cookie.CookieStorage is different from the format generated by older versions of Django. Support for the old format remains until Django 4.1.

### 9.1.5 3.1 release

**Django 3.1.14 release notes**

December 7, 2021

**CVE-2021-44420: Potential bypass of an upstream access control based on URL paths**

HTTP requests for URLs with trailing newlines could bypass an upstream access control based on URL paths.

**Django 3.1.13 release notes**

July 1, 2021

Django 3.1.13 fixes a security issue with severity “high” in 3.1.12.

**CVE-2021-35042: Potential SQL injection via unsanitized QuerySet.order_by() input**

Unsanitized user input passed to QuerySet.order_by() could bypass intended column reference validation in path marked for deprecation resulting in a potential SQL injection even if a deprecation warning is emitted.

As a mitigation the strict column reference validation was restored for the duration of the deprecation period. This regression appeared in 3.1 as a side effect of fixing #31426.

The issue is not present in the main branch as the deprecated path has been removed.

**Django 3.1.12 release notes**

June 2, 2021

Django 3.1.12 fixes two security issues in 3.1.11.
CVE-2021-33203: Potential directory traversal via admindocs

Staff members could use the `admindocs TemplateDetailView` view to check the existence of arbitrary files. Additionally, if (and only if) the default admindocs templates have been customized by the developers to also expose the file contents, then not only the existence but also the file contents would have been exposed. As a mitigation, path sanitation is now applied and only files within the template root directories can be loaded.

CVE-2021-33571: Possible indeterminate SSRF, RFI, and LFI attacks since validators accepted leading zeros in IPv4 addresses

`URLValidator`, `validate_ipv4_address()`, and `validate_ipv46_address()` didn’t prohibit leading zeros in octal literals. If you used such values you could suffer from indeterminate SSRF, RFI, and LFI attacks. `validate_ipv4_address()` and `validate_ipv46_address()` validators were not affected on Python 3.9.5+.

Django 3.1.11 release notes

May 13, 2021

Django 3.1.11 fixes a regression in 3.1.9.

Bugfixes

- Fixed a regression in Django 3.1.9 where saving `FileField` would raise a `SuspiciousFileOperation` even when a custom `upload_to` returns a valid file path (#32718).

Django 3.1.10 release notes

May 6, 2021

Django 3.1.10 fixes a security issue in 3.1.9.

CVE-2021-32052: Header injection possibility since URLValidator accepted newlines in input on Python 3.9.5+

On Python 3.9.5+, `URLValidator` didn’t prohibit newlines and tabs. If you used values with newlines in HTTP response, you could suffer from header injection attacks. Django itself wasn’t vulnerable because `HttpResponse` prohibits newlines in HTTP headers.
Moreover, the URLField form field which uses URLValidator silently removes newlines and tabs on Python 3.9.5+, so the possibility of newlines entering your data only existed if you are using this validator outside of the form fields.

This issue was introduced by the bpo-43882 fix.

Django 3.1.9 release notes

May 4, 2021

Django 3.1.9 fixes a security issue in 3.1.8.

CVE-2021-31542: Potential directory-traversal via uploaded files

MultiPartParser, UploadedFile, and FieldFile allowed directory-traversal via uploaded files with suitably crafted file names.

In order to mitigate this risk, stricter basename and path sanitation is now applied.

Django 3.1.8 release notes

April 6, 2021

Django 3.1.8 fixes a security issue with severity “low” and a bug in 3.1.7.

CVE-2021-28658: Potential directory-traversal via uploaded files

MultiPartParser allowed directory-traversal via uploaded files with suitably crafted file names.

Built-in upload handlers were not affected by this vulnerability.

Bugfixes

- Fixed a bug in Django 3.1 where the output was hidden on a test error or failure when using test --pdb with the --buffer option (#32560).
Django 3.1.7 release notes

February 19, 2021

Django 3.1.7 fixes a security issue and a bug in 3.1.6.

CVE-2021-23336: Web cache poisoning via django.utils.http.limited_parse_qsl()

Django contains a copy of urllib.parse.parse_qs() which was added to backport some security fixes. A further security fix has been issued recently such that parse_qs() no longer allows using ; as a query parameter separator by default. Django now includes this fix. See bpo-42967 for further details.

Bugfixes

• Fixed a regression in Django 3.1 that caused RuntimeError instead of connection errors when using only the 'postgres' database (#32403).

Django 3.1.6 release notes

February 1, 2021

Django 3.1.6 fixes a security issue with severity “low” and a bug in 3.1.5.

CVE-2021-3281: Potential directory-traversal via archive.extract()

The django.utils.archive.extract() function, used by startapp --template and startproject --template, allowed directory-traversal via an archive with absolute paths or relative paths with dot segments.

Bugfixes

• Fixed an admin layout issue in Django 3.1 where changelist filter controls would become squashed (#32391).
Django 3.1.5 release notes

January 4, 2021

Django 3.1.5 fixes several bugs in 3.1.4.

Bugfixes

- Fixed __isnull=True lookup on key transforms for JSONField with Oracle and SQLite (#32252).
- Fixed a bug in Django 3.1 that caused a crash when processing middlewares in an async context with a middleware that raises a MiddlewareNotUsed exception (#32299).
- Fixed a regression in Django 3.1 that caused the incorrect prefixing of STATIC_URL and MEDIA_URL settings, by the server-provided value of SCRIPT_NAME (or / if not set), when set to a URL specifying the protocol but without a top-level domain, e.g. http://myhost/ (#32304).

Django 3.1.4 release notes

December 1, 2020

Django 3.1.4 fixes several bugs in 3.1.3.

Bugfixes

- Fixed setting the Content-Length HTTP header in AsyncRequestFactory (#32162).
- Fixed passing extra HTTP headers to AsyncRequestFactory request methods (#32159).
- Fixed crash of key transforms for JSONField on PostgreSQL when using on a Subquery() annotation (#32182).
- Fixed a regression in Django 3.1 that caused a crash of auto-reloader for certain invocations of runserver on Windows with Python 3.7 and below (#32202).
- Fixed a regression in Django 3.1 that caused the incorrect grouping by a Q object annotation (#32200).
- Fixed a regression in Django 3.1 that caused suppressing connection errors when JSONField is used on SQLite (#32224).
- Fixed a crash on SQLite, when QuerySet.values() / values_list() contained key transforms for JSONField returning non-string primitive values (#32203).
Django 3.1.3 release notes

November 2, 2020

Django 3.1.3 fixes several bugs in 3.1.2 and adds compatibility with Python 3.9.

Bugfixes

- Fixed a regression in Django 3.1.2 that caused the incorrect height of the admin changelist search bar (#32072).
- Fixed a regression in Django 3.1.2 that caused the incorrect width of the admin changelist search bar on a filtered page (#32091).
- Fixed displaying Unicode characters in `forms.JSONField` and read-only `models.JSONField` values in the admin (#32080).
- Fixed a regression in Django 3.1 that caused a crash of `ArrayAgg` and `StringAgg` with `ordering` on key transforms for `JSONField` (#32096).
- Fixed a regression in Django 3.1 that caused a crash of `__in` lookup when using key transforms for `JSONField` in the lookup value (#32096).
- Fixed a regression in Django 3.1 that caused a crash of `ExpressionWrapper` with key transforms for `JSONField` (#32096).
- Fixed a regression in Django 3.1 that caused a migrations crash on PostgreSQL when adding an `ExclusionConstraint` with key transforms for `JSONField` in expressions (#32096).
- Fixed a regression in Django 3.1 where `ProtectedError.protected_objects` and `RestrictedError.restricted_objects` attributes returned iterators instead of set of objects (#32107).
- Fixed a regression in Django 3.1.2 that caused incorrect form input layout on small screens in the admin change form view (#32069).
- Fixed a regression in Django 3.1 that invalidated pre-Django 3.1 password reset tokens (#32130).
- Added support for `asgi`ref 3.3 (#32128).
- Fixed a regression in Django 3.1 that caused incorrect textarea layout on medium-sized screens in the admin change form view with the sidebar open (#32127).
- Fixed a regression in Django 3.0.7 that didn’t use `Subquery()` aliases in the `GROUP BY` clause (#32152).
Django 3.1.2 release notes

October 1, 2020

Django 3.1.2 fixes several bugs in 3.1.1.

Bugfixes

- Fixed a bug in Django 3.1 where FileField instances with a callable storage were not correctly deconstructed (#31941).
- Fixed a regression in Django 3.1 where the QuerySet.ordered attribute returned incorrectly True for GROUP BY queries (e.g. .annotate().values()) on models with Meta.ordering. A model’s Meta.ordering doesn’t affect such queries (#31990).
- Fixed a regression in Django 3.1 where a queryset would crash if it contained an aggregation and a Q object annotation (#32007).
- Fixed a bug in Django 3.1 where a test database was not synced during creation when using the MIGRATE test database setting (#32012).
- Fixed a django.contrib.admin.EmptyFieldListFilter crash when using on a GenericRelation (#32038).
- Fixed a regression in Django 3.1.1 where the admin changelist filter sidebar would not scroll for a long list of available filters (#31986).

Django 3.1.1 release notes

September 1, 2020

Django 3.1.1 fixes two security issues and several bugs in 3.1.

CVE-2020-24583: Incorrect permissions on intermediate-level directories on Python 3.7+

On Python 3.7+, FILE_UPLOAD_DIRECTORY_PERMISSIONS mode was not applied to intermediate-level directories created in the process of uploading files and to intermediate-level collected static directories when using the collectstatic management command.

You should review and manually fix permissions on existing intermediate-level directories.
CVE-2020-24584: Permission escalation in intermediate-level directories of the file system cache on Python 3.7+

On Python 3.7+, the intermediate-level directories of the file system cache had the system’s standard umask rather than 0o077 (no group or others permissions).

**Bugfixes**

- Fixed wrapping of translated action labels in the admin’s navigation sidebar for East Asian languages (#31853).
- Fixed wrapping of long model names in the admin’s navigation sidebar (#31854).
- Fixed encoding session data while upgrading multiple instances of the same project to Django 3.1 (#31864).
- Adjusted admin’s navigation sidebar template to reduce debug logging when rendering (#31865).
- Fixed a data loss possibility in the `select_for_update()`. When using related fields pointing to a proxy model in the of argument, the corresponding model was not locked (#31866).
- Fixed a data loss possibility, following a regression in Django 2.0, when copying model instances with a cached fields value (#31863).
- Fixed a regression in Django 3.1 that caused a crash when decoding an invalid session data (#31895).
- Reverted a deprecation in Django 3.1 that caused a crash when passing deprecated keyword arguments to a queryset in TemplateView.get_context_data() (#31877).
- Enforced thread sensitivity of the MiddlewareMixin.process_request() and process_response() hooks when in an async context (#31905).
- Fixed __in lookup on key transforms for JSONField with MariaDB, MySQL, Oracle, and SQLite (#31936).
- Fixed a regression in Django 3.1 that caused permission errors in CommonPasswordValidator and settings.py generated by the startproject command, when user didn’t have permissions to all intermediate directories in a Django installation path (#31912).
- Fixed detecting an async get_response callable in various builtin middlewares (#31928).
- Fixed a QuerySet.order_by() crash on PostgreSQL when ordering and grouping by JSONField with a custom decoder (#31956). As a consequence, fetching a JSONField with raw SQL now returns a string instead of preloaded data. You will need to explicitly call json.loads() in such cases.
- Fixed a QuerySet.delete() crash on MySQL, following a performance regression in Django 3.1 on MariaDB 10.3.2+, when filtering against an aggregate function (#31965).
- Fixed a django.contrib.admin.EmptyFieldListFilter crash when using on reverse relations (#31952).
• Prevented content overflowing in the admin changelist view when the navigation sidebar is enabled (#31901).

Django 3.1 release notes

August 4, 2020

Welcome to Django 3.1!

These release notes cover the new features, as well as some backwards incompatible changes you’ll want to be aware of when upgrading from Django 3.0 or earlier. We’ve dropped some features that have reached the end of their deprecation cycle, and we’ve begun the deprecation process for some features.

See the How to upgrade Django to a newer version guide if you’re updating an existing project.

Python compatibility

Django 3.1 supports Python 3.6, 3.7, 3.8, and 3.9 (as of 3.1.3). We highly recommend and only officially support the latest release of each series.

What’s new in Django 3.1

Asynchronous views and middleware support

Django now supports a fully asynchronous request path, including:

• Asynchronous views
• Asynchronous middleware
• Asynchronous tests and test client

To get started with async views, you need to declare a view using async def:

```python
async def my_view(request):
    await asyncio.sleep(0.5)
    return HttpResponse('Hello, async world!')
```

All asynchronous features are supported whether you are running under WSGI or ASGI mode. However, there will be performance penalties using async code in WSGI mode. You can read more about the specifics in Asynchronous support documentation.

You are free to mix async and sync views, middleware, and tests as much as you want. Django will ensure that you always end up with the right execution context. We expect most projects will keep the majority of their views synchronous, and only have a select few running in async mode - but it is entirely your choice.
Django’s ORM, cache layer, and other pieces of code that do long-running network calls do not yet support async access. We expect to add support for them in upcoming releases. Async views are ideal, however, if you are doing a lot of API or HTTP calls inside your view, you can now natively do all those HTTP calls in parallel to considerably speed up your view’s execution.

Asynchronous support should be entirely backwards-compatible and we have tried to ensure that it has no speed regressions for your existing, synchronous code. It should have no noticeable effect on any existing Django projects.

**JSONField for all supported database backends**

Django now includes `models.JSONField` and `forms.JSONField` that can be used on all supported database backends. Both fields support the use of custom JSON encoders and decoders. The model field supports the introspection, lookups, and transforms that were previously PostgreSQL-only:

```python
from django.db import models

class ContactInfo(models.Model):
    data = models.JSONField()

ContactInfo.objects.create(data={
    'name': 'John',
    'cities': ['London', 'Cambridge'],
    'pets': {'dogs': ['Rufus', 'Meg']},
})
ContactInfo.objects.filter(
    data__name='John',
    data__pets__has_key='dogs',
    data__cities__contains='London',
).delete()
```

If your project uses `django.contrib.postgres.fields.JSONField`, plus the related form field and transforms, you should adjust to use the new fields, and generate and apply a database migration. For now, the old fields and transforms are left as a reference to the new ones and are deprecated as of this release.

**DEFAULT_HASHING_ALGORITHM settings**

The new `DEFAULT_HASHING_ALGORITHM` transitional setting allows specifying the default hashing algorithm to use for encoding cookies, password reset tokens in the admin site, user sessions, and signatures created by `django.core.signing.Signer` and `django.core.signing.dumps()`.

Support for SHA-256 was added in Django 3.1. If you are upgrading multiple instances of the same project to Django 3.1, you should set `DEFAULT_HASHING_ALGORITHM` to ‘sha1’ during the transition, in order to allow
compatibility with the older versions of Django. Note that this requires Django 3.1.1+. Once the transition to 3.1 is complete you can stop overriding `DEFAULT_HASHING_ALGORITHM`.

This setting is deprecated as of this release, because support for tokens, cookies, sessions, and signatures that use SHA-1 algorithm will be removed in Django 4.0.

**Minor features**

**django.contrib.admin**

- The new `django.contrib.admin.EmptyFieldListFilter` for `ModelAdmin.list_filter` allows filtering on empty values (empty strings and nulls) in the admin changelist view.
- Filters in the right sidebar of the admin changelist view now contain a link to clear all filters.
- The admin now has a sidebar on larger screens for easier navigation. It is enabled by default but can be disabled by using a custom `AdminSite` and setting `AdminSite.enable_nav_sidebar` to `False`.

Rendering the sidebar requires access to the current request in order to set CSS and ARIA role affordances. This requires using `'django.template.context_processors.request'` in the `'context_processors'` option of `OPTIONS`.
- Initially empty extra inlines can now be removed, in the same way as dynamically created ones.
- XRegExp is upgraded from version 2.0.0 to 3.2.0.
- jQuery is upgraded from version 3.4.1 to 3.5.1.
- Select2 library is upgraded from version 4.0.7 to 4.0.13.

**django.contrib.auth**

- The default iteration count for the PBKDF2 password hasher is increased from 180,000 to 216,000.
- The new `PASSWORD_RESET_TIMEOUT` setting allows defining the number of seconds a password reset link is valid for. This is encouraged instead of the deprecated `PASSWORD_RESET_TIMEOUT_DAYS` setting, which will be removed in Django 4.0.
- The password reset mechanism now uses the SHA-256 hashing algorithm. Support for tokens that use the old hashing algorithm remains until Django 4.0.
- `AbstractBaseUser.get_session_auth_hash()` now uses the SHA-256 hashing algorithm. Support for user sessions that use the old hashing algorithm remains until Django 4.0.
django.contrib.contenttypes

- The new `remove_stale_contenttypes --include-stale-apps` option allows removing stale content types from previously installed apps that have been removed from `INSTALLED_APPS`.

django.contrib.gis

- `relate` lookup is now supported on MariaDB.
- Added the `LinearRing.is_counterclockwise` property.
- `AsGeoJSON` is now supported on Oracle.
- Added the `AsWKB` and `AsWKT` functions.
- Added support for PostGIS 3 and GDAL 3.

django.contrib.humanize

- `intword` template filter now supports negative integers.

django.contrib.postgres

- The new `BloomIndex` class allows creating `bloom` indexes in the database. The new `BloomExtension` migration operation installs the `bloom` extension to add support for this index.
- `get_FOO_display()` now supports `ArrayField` and `RangeField`.
- The new `rangefield.lower_inc`, `rangefield.lower_inf`, `rangefield.upper_inc`, and `rangefield.upper_inf` lookups allow querying `RangeField` by a bound type.
- `rangefield.contained_by` now supports `SmallAutoField`, `AutoField`, `BigAutoField`, `SmallIntegerField`, and `DecimalField`.
- `SearchQuery` now supports 'websearch' search type on PostgreSQL 11+.
- `SearchQuery.value` now supports query expressions.
- The new `SearchHeadline` class allows highlighting search results.
- `search` lookup now supports query expressions.
- The new `cover_density` parameter of `SearchRank` allows ranking by cover density.
- The new `normalization` parameter of `SearchRank` allows rank normalization.
- The new `ExclusionConstraint.deferrable` attribute allows creating deferrable exclusion constraints.
django.contrib.sessions

- The `SESSION_COOKIE_SAMESITE` setting now allows 'None' (string) value to explicitly state that the cookie is sent with all same-site and cross-site requests.

django.contrib.staticfiles

- The `STATICFILES_DIRS` setting now supports `pathlib.Path`.

Cache

- The `cache_control()` decorator and `patch_cache_control()` method now support multiple field names in the `no-cache` directive for the `Cache-Control` header, according to RFC 7234#section-5.2.2.2.
- `delete()` now returns `True` if the key was successfully deleted, `False` otherwise.

CSRF

- The `CSRF_COOKIE_SAMESITE` setting now allows 'None' (string) value to explicitly state that the cookie is sent with all same-site and cross-site requests.

Email

- The `EMAIL_FILE_PATH` setting, used by the file email backend, now supports `pathlib.Path`.

Error Reporting

- `django.views.debug.SafeExceptionReporterFilter` now filters sensitive values from `request.META` in exception reports.
- The new `SafeExceptionReporterFilter.cleansed_substitute` and `SafeExceptionReporterFilter.hidden_settings` attributes allow customization of sensitive settings and `request.META` filtering in exception reports.
- The technical 404 debug view now respects `DEFAULT_EXCEPTION_REPORTER_FILTER` when applying settings filtering.
- The new `DEFAULT_EXCEPTION_REPORTER` allows providing a `django.views.debug.ExceptionReporter` subclass to customize exception report generation. See Custom error reports for details.
File Storage

- **FileSystemStorage.save()** method now supports `pathlib.Path`.
- **FileField** and **ImageField** now accept a callable for **storage**. This allows you to modify the used storage at runtime, selecting different stores for different environments, for example.

Forms

- **ModelChoiceIterator**, used by **ModelChoiceField** and **ModelMultipleChoiceField**, now uses **ModelChoiceIteratorValue** that can be used by widgets to access model instances. See `Iterating relationship choices` for details.
- **django.forms.DateTimeField** now accepts dates in a subset of ISO 8601 datetime formats, including optional timezone, e.g. 2019-10-10T06:47, 2019-10-10T06:47:23+04:00, or 2019-10-10T06:47:23Z. The timezone will always be retained if provided, with timezone-aware datetimes being returned even when **USE_TZ** is False.
  Additionally, **DateTimeField** now uses **DATE_INPUT_FORMATS** in addition to **DATETIME_INPUT_FORMATS** when converting a field input to a **datetime** value.
- **MultiWidget.widgets** now accepts a dictionary which allows customizing subwidget **name** attributes.
- The new **BoundField.widget_type** property can be used to dynamically adjust form rendering based upon the widget type.

Internationalization

- The **LANGUAGE_COOKIE_SAMESITE** setting now allows 'None' (string) value to explicitly state that the cookie is sent with all same-site and cross-site requests.
- Added support and translations for the Algerian Arabic, Igbo, Kyrgyz, Tajik, and Turkmen languages.

Management Commands

- The new **check --database** option allows specifying database aliases for running the **database** system checks. Previously these checks were enabled for all configured **DATABASES** by passing the **database** tag to the command.
- The new **migrate --check** option makes the command exit with a non-zero status when unapplied migrations are detected.
- The new **returncode** argument for **CommandError** allows customizing the exit status for management commands.
• The new `dbshell -- ARGUMENTS` option allows passing extra arguments to the command-line client for the database.

• The `flush` and `sqlflush` commands now include SQL to reset sequences on SQLite.

Models

• The new `ExtractIsoWeekDay` function extracts ISO-8601 week days from `DateField` and `DateTimeField`, and the new `iso_week_day` lookup allows querying by an ISO-8601 day of week.

• `QuerySet.explain()` now supports:
  – `TREE` format on MySQL 8.0.16+,
  – `analyze` option on MySQL 8.0.18+ and MariaDB.

• Added `PositiveBigIntegerField` which acts much like a `PositiveIntegerField` except that it only allows values under a certain (database-dependent) limit. Values from 0 to 9223372036854775807 are safe in all databases supported by Django.

• The new `RESTRICT` option for `on_delete` argument of `ForeignKey` and `OneToOneField` emulates the behavior of the SQL constraint `ON DELETE RESTRICT`.

• `CheckConstraint.check` now supports boolean expressions.

• The `RelatedManager.add()`, `create()`, and `set()` methods now accept callables as values in the `through_defaults` argument.

• The new `is_dst` parameter of the `QuerySet.datetimes()` determines the treatment of nonexistent and ambiguous datetimes.

• The new `F` expression `bitxor()` method allows bitwise XOR operation.

• `QuerySet.bulk_create()` now sets the primary key on objects when using MariaDB 10.5+.

• The `DatabaseOperations.sql_flush()` method now generates more efficient SQL on MySQL by using `DELETE` instead of `TRUNCATE` statements for tables which don’t require resetting sequences.

• SQLite functions are now marked as `deterministic` on Python 3.8+. This allows using them in check constraints and partial indexes.

• The new `UniqueConstraint.deferrable` attribute allows creating deferrable unique constraints.
Pagination

- *Paginator* can now be iterated over to yield its pages.

Requests and Responses

- If `ALLOWED_HOSTS` is empty and `DEBUG=True`, subdomains of localhost are now allowed in the `Host` header, e.g. `static.localhost`.

- `HttpResponse.set_cookie()` and `HttpResponse.set_signed_cookie()` now allow using `samesite='None'` (string) to explicitly state that the cookie is sent with all same-site and cross-site requests.

- The new `HttpRequest.accepts()` method returns whether the request accepts the given MIME type according to the `Accept` HTTP header.

Security

- The `SECURE_REFERRER_POLICY` setting now defaults to `'same-origin'`. With this configured, `SecurityMiddleware` sets the `Referrer Policy` header to `same-origin` on all responses that do not already have it. This prevents the `Referer` header being sent to other origins. If you need the previous behavior, explicitly set `SECURE_REFERRER_POLICY` to `None`.

- The default algorithm of `django.core.signing.Signer`, `django.core.signing.loads()`, and `django.core.signing.dumps()` is changed to the SHA-256. Support for signatures made with the old SHA-1 algorithm remains until Django 4.0.

  Also, the new `algorithm` parameter of the `Signer` allows customizing the hashing algorithm.

Templates

- The renamed `translate` and `blocktranslate` template tags are introduced for internationalization in template code. The older `trans` and `blocktrans` template tags aliases continue to work, and will be retained for the foreseeable future.

- The `include` template tag now accepts iterables of template names.
Tests

- *SimpleTestCase* now implements the `debug()` method to allow running a test without collecting the result and catching exceptions. This can be used to support running tests under a debugger.
- The new `MIGRATE` test database setting allows disabling of migrations during a test database creation.
- Django test runner now supports a `test --buffer` option to discard output for passing tests.
- `DiscoverRunner` now skips running the system checks on databases not referenced by tests.
- `TransactionTestCase` teardown is now faster on MySQL due to `flush` command improvements. As a side effect the latter doesn’t automatically reset sequences on teardown anymore. Enable `TransactionTestCase.reset_sequences` if your tests require this feature.

URLs

- Path converters can now raise `ValueError` in `to_url()` to indicate no match when reversing URLs.

Utilities

- `filepath_to_uri()` now supports `pathlib.Path`.
- `parse_duration()` now supports comma separators for decimal fractions in the ISO 8601 format.
- `parse_datetime()`, `parse_duration()`, and `parse_time()` now support comma separators for milliseconds.

Miscellaneous

- The SQLite backend now supports `pathlib.Path` for the `NAME` setting.
- The `settings.py` generated by the `startproject` command now uses `pathlib.Path` instead of `os.path` for building filesystem paths.
- The `TIME_ZONE` setting is now allowed on databases that support time zones.

Backwards incompatible changes in 3.1

Database backend API

This section describes changes that may be needed in third-party database backends.

- `DatabaseOperations.fetch_returned_insert_columns()` now requires an additional `returning_params` argument.
connection.timezone property is now 'UTC' by default, or the TIME_ZONE when USE_TZ is True on databases that support time zones. Previously, it was None on databases that support time zones.

connection._nodb_connection property is changed to the connection._nodb_cursor() method and now returns a context manager that yields a cursor and automatically closes the cursor and connection upon exiting the with statement.

DatabaseClient.runshell() now requires an additional parameters argument as a list of extra arguments to pass on to the command-line client.

The sequences positional argument of DatabaseOperations.sql_flush() is replaced by the boolean keyword-only argument reset_sequences. If True, the sequences of the truncated tables will be reset.

The allow_cascade argument of DatabaseOperations.sql_flush() is now a keyword-only argument.

The using positional argument of DatabaseOperations.execute_sql_flush() is removed. The method now uses the database of the called instance.

Third-party database backends must implement support for JSONField or set DatabaseFeatures.supports_json_field to False. If storing primitives is not supported, set DatabaseFeatures.supports_primitives_in_json_field to False. If there is a true datatype for JSON, set DatabaseFeatures.has_native_json_field to True. If jsonfield.contains and jsonfield.contained_by are not supported, set DatabaseFeatures.supports_json_field_contains to False.

Third party database backends must implement introspection for JSONField or set can_introspect_json_field to False.

Dropped support for MariaDB 10.1

Upstream support for MariaDB 10.1 ends in October 2020. Django 3.1 supports MariaDB 10.2 and higher.

contrib.admin browser support

The admin no longer supports the legacy Internet Explorer browser. See the admin FAQ for details on supported browsers.

AbstractUser.first_name max_length increased to 150

A migration for django.contrib.auth.models.User.first_name is included. If you have a custom user model inheriting from AbstractUser, you’ll need to generate and apply a database migration for your user model.

If you want to preserve the 30 character limit for first names, use a custom form:
from django import forms
from django.contrib.auth.forms import UserChangeForm

class MyUserChangeForm(UserChangeForm):
    first_name = forms.CharField(max_length=30, required=False)

If you wish to keep this restriction in the admin when editing users, set UserAdmin.form to use this form:

from django.contrib.auth.admin import UserAdmin
from django.contrib.auth.models import User

class MyUserAdmin(UserAdmin):
    form = MyUserChangeForm

admin.site.unregister(User)
admin.site.register(User, MyUserAdmin)

Miscellaneous

- The cache keys used by cache and generated by make_template_fragment_key() are different from the keys generated by older versions of Django. After upgrading to Django 3.1, the first request to any previously cached template fragment will be a cache miss.

- The logic behind the decision to return a redirection fallback or a 204 HTTP response from the set_language() view is now based on the Accept HTTP header instead of the X-Requested-With HTTP header presence.

- The compatibility imports of django.core.exceptions.EmptyResultSet in django.db.models.query, django.db.models.sql, and django.db.models.sql.datastructures are removed.

- The compatibility import of django.core.exceptions.FieldDoesNotExist in django.db.models.fields is removed.

- The compatibility imports of django.forms.utils.pretty_name() and django.forms.boundfield.BoundField in django.forms.forms are removed.

- The compatibility imports of Context, ContextPopException, and RequestContext in django.template.base are removed.

- The compatibility import of django.contrib.admin.helpers.ACTION_CHECKBOX_NAME in django.contrib.admin is removed.

- The STATIC_URL and MEDIA_URL settings set to relative paths are now prefixed by the server-provided value of SCRIPT_NAME (or / if not set). This change should not affect settings set to valid URLs or absolute paths.

- ConditionalGetMiddleware no longer adds the ETag header to responses with an empty content.
• `django.utils.decorators.classproperty()` decorator is made public and moved to `django.utils.functional.classproperty()`.

• `floatformat` template filter now outputs (positive) 0 for negative numbers which round to zero.

• `Meta.ordering` and `Meta.unique_together` options on models in `django.contrib` modules that were formerly tuples are now lists.

• The admin calendar widget now handles two-digit years according to the Open Group Specification, i.e. values between 69 and 99 are mapped to the previous century, and values between 0 and 68 are mapped to the current century.

• Date-only formats are removed from the default list for `DATETIME_INPUT_FORMATS`.

• The `FileInput` widget no longer renders with the `required` HTML attribute when initial data exists.

• The undocumented `django.views.debug.ExceptionReporterFilter` class is removed. As per the Custom error reports documentation, classes to be used with `DEFAULT_EXCEPTION_REPORTER_FILTER` need to inherit from `django.views.debug.SafeExceptionReporterFilter`.

• The cache timeout set by `cache_page()` decorator now takes precedence over the `max-age` directive from the Cache-Control header.

• Providing a non-local remote field in the `ForeignKey.to_field` argument now raises `FieldError`.

• `SECURE_REFERRER_POLICY` now defaults to `same-origin`. See the What's New Security section above for more details.

• `check` management command now runs the database system checks only for database aliases specified using `check --database` option.

• `migrate` management command now runs the database system checks only for a database to migrate.

• The admin CSS classes `row1` and `row2` are removed in favor of `:nth-child(odd)` and `:nth-child(even)` pseudo-classes.

• The `make_password()` function now requires its argument to be a string or bytes. Other types should be explicitly cast to one of these.

• The undocumented `version` parameter to the `AsKML` function is removed.

• `JSON` and `YAML` serializers, used by `dumpdata`, now dump all data with Unicode by default. If you need the previous behavior, pass `ensure_ascii=True` to JSON serializer, or `allow_unicode=False` to YAML serializer.

• The auto-reloader no longer monitors changes in built-in Django translation files.

• The minimum supported version of `mysqlclient` is increased from 1.3.13 to 1.4.0.

• The undocumented `django.contrib.postgres.forms.InvalidJSONInput` and `django.contrib.postgres.forms.JSONString` are moved to `django.forms.fields`.

• The undocumented `django.contrib.postgres.fields.jsonb.JsonAdapter` class is removed.
• The `{% localize off %}` tag and `unlocalize` filter no longer respect `DECIMAL_SEPARATOR` setting.

• The minimum supported version of `asgiref` is increased from 3.2 to 3.2.10.

• The `Media` class now renders `<script>` tags without the `type` attribute to follow WHATWG recommendations.

• `ModelChoiceIterator`, used by `ModelChoiceField` and `ModelMultipleChoiceField`, now yields 2-tuple choices containing `ModelChoiceIteratorValue` instances as the first value element in each choice. In most cases this proxies transparently, but if you need the field value itself, use the `ModelChoiceIteratorValue.value` attribute instead.

**Features deprecated in 3.1**

**PostgreSQL JSONField**

django.contrib.postgres.fields.JSONField and django.contrib.postgres.forms.JSONField are deprecated in favor of `models.JSONField` and `forms.JSONField`.

The undocumented django.contrib.postgres.fields.jsonb.KeyTransform and django.contrib.postgres.fields.jsonb.KeyTextTransform are also deprecated in favor of the transforms in django.db.models.fields.json.

The new JSONFields, KeyTransform, and KeyTextTransform can be used on all supported database back-ends.

**Miscellaneous**

• `PASSWORD_RESET_TIMEOUT_DAYS` setting is deprecated in favor of `PASSWORD_RESET_TIMEOUT`.

• The undocumented usage of the `isnull` lookup with non-boolean values as the right-hand side is deprecated, use `True` or `False` instead.

• The barely documented django.db.models.query_utils.InvalidQuery exception class is deprecated in favor of `FieldDoesNotExist` and `FieldError`.

• The django-admin.py entry point is deprecated in favor of django-admin.

• The `HttpRequest.is_ajax()` method is deprecated as it relied on a jQuery-specific way of signifying AJAX calls, while current usage tends to use the JavaScript Fetch API. Depending on your use case, you can either write your own AJAX detection method, or use the new `HttpRequest.accepts()` method if your code depends on the client Accept HTTP header.

If you are writing your own AJAX detection method, `request.isajax()` can be reproduced exactly as `request.headers.get('x-requested-with') == 'XMLHttpRequest'`.

• Passing `None` as the first argument to `django.utils.deprecation.MiddlewareMixin.__init__()` is deprecated.
• The encoding format of cookies values used by `CookieStorage` is different from the format generated by older versions of Django. Support for the old format remains until Django 4.0.

• The encoding format of sessions is different from the format generated by older versions of Django. Support for the old format remains until Django 4.0.

• The purely documentational `providing_args` argument for `Signal` is deprecated. If you rely on this argument as documentation, you can move the text to a code comment or docstring.

• Calling `django.utils.crypto.get_random_string()` without a `length` argument is deprecated.

• The `list` message for `ModelMultipleChoiceField` is deprecated in favor of `invalid_list`.

• Passing raw column aliases to `QuerySet.order_by()` is deprecated. The same result can be achieved by passing aliases in a `RawSQL` instead beforehand.

• The `NullBooleanField` model field is deprecated in favor of `BooleanField(null=True)`.

• `django.conf.urls.url()` alias of `django.urls.re_path()` is deprecated.

• The `{% ifequal %}` and `{% ifnotequal %}` template tags are deprecated in favor of `{% if %}`. `{% if %}` covers all use cases, but if you need to continue using these tags, they can be extracted from Django to a module and included as a built-in tag in the `'builtins'` option in `OPTIONS`.

• `DEFAULT_HASHING_ALGORITHM` transitional setting is deprecated.

**Features removed in 3.1**

These features have reached the end of their deprecation cycle and are removed in Django 3.1.

See **Features deprecated in 2.2** for details on these changes, including how to remove usage of these features.

• `django.utils.timezone.FixedOffset` is removed.

• `django.core.paginator.QuerySetPaginator` is removed.

• A model’s `Meta.ordering` doesn’t affect `GROUP BY` queries.

• `django.contrib.postgres.fields.FloatRangeField` and `django.contrib.postgres.forms.FloatRangeField` are removed.

• The `FILE_CHARSET` setting is removed.

• `django.contrib.staticfiles.storage.CachedStaticFilesStorage` is removed.

• The `RemoteUserBackend.configure_user()` method requires `request` as the first positional argument.

• Support for `SimpleTestCase.allow_database_queries` and `TransactionTestCase.multi_db` is removed.
9.1.6 3.0 release

Django 3.0.14 release notes

April 6, 2021

Django 3.0.14 fixes a security issue with severity “low” in 3.0.13.

CVE-2021-28658: Potential directory-traversal via uploaded files

MultiPartParser allowed directory-traversal via uploaded files with suitably crafted file names.
Built-in upload handlers were not affected by this vulnerability.

Django 3.0.13 release notes

February 19, 2021

Django 3.0.13 fixes a security issue in 3.0.12.

CVE-2021-23336: Web cache poisoning via django.utils.http.limited_parse_qsl()

Django contains a copy of urllib.parse.parse_qsl() which was added to backport some security fixes.
A further security fix has been issued recently such that parse_qsl() no longer allows using ; as a query parameter separator by default. Django now includes this fix. See bpo-42967 for further details.

Django 3.0.12 release notes

February 1, 2021

Django 3.0.12 fixes a security issue with severity “low” in 3.0.11.

CVE-2021-3281: Potential directory-traversal via archive.extract()

The django.utils.archive.extract() function, used by startapp --template and startproject --template, allowed directory-traversal via an archive with absolute paths or relative paths with dot segments.
Django 3.0.11 release notes

November 2, 2020

Django 3.0.11 fixes a regression in 3.0.7 and adds compatibility with Python 3.9.

Bugfixes

- Fixed a regression in Django 3.0.7 that didn’t use Subquery() aliases in the GROUP BY clause (#32152).

Django 3.0.10 release notes

September 1, 2020

Django 3.0.10 fixes two security issues and two data loss bugs in 3.0.9.

CVE-2020-24583: Incorrect permissions on intermediate-level directories on Python 3.7+

On Python 3.7+, FILE_UPLOAD_DIRECTORY_PERMISSIONS mode was not applied to intermediate-level directories created in the process of uploading files and to intermediate-level collected static directories when using the collectstatic management command.

You should review and manually fix permissions on existing intermediate-level directories.

CVE-2020-24584: Permission escalation in intermediate-level directories of the file system cache on Python 3.7+

On Python 3.7+, the intermediate-level directories of the file system cache had the system’s standard umask rather than 0o077 (no group or others permissions).

Bugfixes

- Fixed a data loss possibility in the select_for_update(). When using related fields pointing to a proxy model in the of argument, the corresponding model was not locked (#31866).
- Fixed a data loss possibility, following a regression in Django 2.0, when copying model instances with a cached fields value (#31863).
Django 3.0.9 release notes

August 3, 2020

Django 3.0.9 fixes several bugs in 3.0.8.

**Bugfixes**

- Allowed setting the `SameSite` cookie flag in `HttpResponse.delete_cookie()` (#31790).
- Fixed crash when sending emails to addresses with display names longer than 75 chars on Python 3.6.11+, 3.7.8+, and 3.8.4+ (#31784).

Django 3.0.8 release notes

July 1, 2020

Django 3.0.8 fixes several bugs in 3.0.7.

**Bugfixes**

- Fixed messages of `InvalidCacheKey` exceptions and `CacheKeyWarning` warnings raised by cache key validation (#31654).
- Fixed a regression in Django 3.0.7 that caused a queryset crash when grouping by a many-to-one relationship (#31660).
- Reallowed, following a regression in Django 3.0, non-expressions having a `filterable` attribute to be used as the right-hand side in queryset filters (#31664).
- Fixed a regression in Django 3.0.2 that caused a migration crash on PostgreSQL when adding a foreign key to a model with a namespaced `db_table` (#31735).
- Added compatibility for `cx_Oracle` 8 (#31751).

Django 3.0.7 release notes

June 3, 2020

Django 3.0.7 fixes two security issues and several bugs in 3.0.6.
CVE-2020-13254: Potential data leakage via malformed memcached keys

In cases where a memcached backend does not perform key validation, passing malformed cache keys could result in a key collision, and potential data leakage. In order to avoid this vulnerability, key validation is added to the memcached cache backends.

CVE-2020-13596: Possible XSS via admin ForeignKeyRawIdWidget

Query parameters for the admin ForeignKeyRawIdWidget were not properly URL encoded, posing an XSS attack vector. ForeignKeyRawIdWidget now ensures query parameters are correctly URL encoded.

Bugfixes

- Fixed a regression in Django 3.0 by restoring the ability to use field lookups in Meta.ordering (#31538).
- Fixed a regression in Django 3.0 where QuerySet.values() and values_list() crashed if a queryset contained an aggregation and a subquery annotation (#31566).
- Fixed a regression in Django 3.0 where aggregates used wrong annotations when a queryset has multiple subqueries annotations (#31568).
- Fixed a regression in Django 3.0 where QuerySet.values() and values_list() crashed if a queryset contained an aggregation and an Exists() annotation on Oracle (#31584).
- Fixed a regression in Django 3.0 where all resolved Subquery() expressions were considered equal (#31607).
- Fixed a regression in Django 3.0.5 that affected translation loading for apps providing translations for territorial language variants as well as a generic language, where the project has different plural equations for the language (#31570).
- Tracking a jQuery security release, upgraded the version of jQuery used by the admin from 3.4.1 to 3.5.1.

Django 3.0.6 release notes

May 4, 2020

Django 3.0.6 fixes a bug in 3.0.5.
Bugfixes

- Fixed a regression in Django 3.0 that caused a crash when filtering a `Subquery()` annotation of a query-set containing a single related field against a `SimpleLazyObject (#31420)`.

Django 3.0.5 release notes

April 1, 2020

Django 3.0.5 fixes several bugs in 3.0.4.

Bugfixes

- Added the ability to handle `.po` files containing different plural equations for the same language (#30439).
- Fixed a regression in Django 3.0 where `QuerySet.values()` and `values_list()` crashed if a queryset contained an aggregation and `Subquery()` annotation that collides with a field name (#31377).

Django 3.0.4 release notes

March 4, 2020

Django 3.0.4 fixes a security issue and several bugs in 3.0.3.

CVE-2020-9402: Potential SQL injection via `tolerance` parameter in GIS functions and aggregates on Oracle

GIS functions and aggregates on Oracle were subject to SQL injection, using a suitably crafted `tolerance`.

Bugfixes

- Fixed a data loss possibility when using caching from async code (#31253).
- Fixed a regression in Django 3.0 that caused a file response using a temporary file to be closed incorrectly (#31240).
- Fixed a data loss possibility in the `select_for_update()`. When using related fields or parent link fields with `Multi-table inheritance` in the `of` argument, the corresponding models were not locked (#31246).
- Fixed a regression in Django 3.0 that caused misplacing parameters in logged SQL queries on Oracle (#31271).
- Fixed a regression in Django 3.0.3 that caused misplacing parameters of SQL queries when subtracting `DateField` or `DateTimeField` expressions on MySQL (#31312).
- Fixed a regression in Django 3.0 that didn’t include subqueries spanning multivalued relations in the GROUP BY clause (#31150).

**Django 3.0.3 release notes**

February 3, 2020

Django 3.0.3 fixes a security issue and several bugs in 3.0.2.

**CVE-2020-7471: Potential SQL injection via StringAgg(delimiter)**

[StringAgg](#) aggregation function was subject to SQL injection, using a suitably crafted delimiter.

**Bugfixes**

- Fixed a regression in Django 3.0 that caused a crash when subtracting `DateField`, `DateTimeField`, or `TimeField` from a `Subquery()` annotation (#31133).
- Fixed a regression in Django 3.0 where `QuerySet.values()` and `values_list()` crashed if a queryset contained an aggregation and `Exists()` annotation (#31136).
- Relaxed the system check added in Django 3.0 to reallow use of a sublanguage in the `LANGUAGE_CODE` setting, when a base language is available in Django but the sublanguage is not (#31141).
- Added support for using enumeration types `TextChoices`, `IntegerChoices`, and `Choices` in templates (#31154).
- Fixed a system check to ensure the `max_length` attribute fits the longest choice, when a named group contains only non-string values (#31155).
- Fixed a regression in Django 2.2 that caused a crash of `ArrayAgg` and `StringAgg` with `filter` argument when used in a `Subquery` (#31097).
- Fixed a regression in Django 2.2.7 that caused `get_FOO_display()` to work incorrectly when overriding inherited choices (#31124).
- Fixed a regression in Django 3.0 that caused a crash of `QuerySet.prefetch_related()` for `GenericForeignKey` with a custom `ContentType` foreign key (#31190).
Django 3.0.2 release notes

January 2, 2020

Django 3.0.2 fixes several bugs in 3.0.1.

Bugfixes

- Fixed a regression in Django 3.0 that didn’t include columns referenced by a `Subquery()` in the `GROUP BY` clause (#31094).
- Fixed a regression in Django 3.0 where `QuerySet.exists()` crashed if a queryset contained an aggregation over a `Subquery()` (#31109).
- Fixed a regression in Django 3.0 that caused a migration crash on PostgreSQL 10+ when adding a foreign key and changing data in the same migration (#31106).
- Fixed a regression in Django 3.0 where loading fixtures crashed for models defining a `default` for the primary key (#31071).

Django 3.0.1 release notes

December 18, 2019

Django 3.0.1 fixes a security issue and several bugs in 3.0.

CVE-2019-19844: Potential account hijack via password reset form

By submitting a suitably crafted email address making use of Unicode characters, that compared equal to an existing user email when lower-cased for comparison, an attacker could be sent a password reset token for the matched account.

In order to avoid this vulnerability, password reset requests now compare the submitted email using the stricter, recommended algorithm for case-insensitive comparison of two identifiers from Unicode Technical Report 36, section 2.11.2(B)(2). Upon a match, the email containing the reset token will be sent to the email address on record rather than the submitted address.
Bugfixes

- Fixed a regression in Django 3.0 by restoring the ability to use Django inside Jupyter and other environments that force an async context, by adding an option to disable Async safety mechanism with DJANGO_ALLOW_ASYNC_UNSAFE environment variable (#31056).

- Fixed a regression in Django 3.0 where RegexPattern, used by re_path(), returned positional arguments to be passed to the view when all optional named groups were missing (#31061).

- Reallowed, following a regression in Django 3.0, Window expressions to be used in conditions outside of queryset filters, e.g. in when conditions (#31060).

- Fixed a data loss possibility in SplitArrayField. When using with ArrayField(BooleanField()), all values after the first True value were marked as checked instead of preserving passed values (#31073).

Django 3.0 release notes

December 2, 2019

Welcome to Django 3.0!

These release notes cover the new features, as well as some backwards incompatible changes you’ll want to be aware of when upgrading from Django 2.2 or earlier. We’ve dropped some features that have reached the end of their deprecation cycle, and we’ve begun the deprecation process for some features.

See the How to upgrade Django to a newer version guide if you’re updating an existing project.

Python compatibility

Django 3.0 supports Python 3.6, 3.7, 3.8, and 3.9 (as of 3.0.11). We highly recommend and only officially support the latest release of each series.

The Django 2.2.x series is the last to support Python 3.5.

Third-party library support for older version of Django

Following the release of Django 3.0, we suggest that third-party app authors drop support for all versions of Django prior to 2.2. At that time, you should be able to run your package’s tests using python -Wd so that deprecation warnings appear. After making the deprecation warning fixes, your app should be compatible with Django 3.0.
What’s new in Django 3.0

MariaDB support

Django now officially supports MariaDB 10.1 and higher. See MariaDB notes for more details.

ASGI support

Django 3.0 begins our journey to making Django fully async-capable by providing support for running as an ASGI application.

This is in addition to our existing WSGI support. Django intends to support both for the foreseeable future. Async features will only be available to applications that run under ASGI, however.

At this stage async support only applies to the outer ASGI application. Internally everything remains synchronous. Asynchronous middleware, views, etc. are not yet supported. You can, however, use ASGI middleware around Django’s application, allowing you to combine Django with other ASGI frameworks.

There is no need to switch your applications over unless you want to start experimenting with asynchronous code, but we have documentation on deploying with ASGI if you want to learn more.

Note that as a side-effect of this change, Django is now aware of asynchronous event loops and will block you calling code marked as “async unsafe” - such as ORM operations - from an asynchronous context. If you were using Django from async code before, this may trigger if you were doing it incorrectly. If you see a SynchronousOnlyOperation error, then closely examine your code and move any database operations to be in a synchronous child thread.

Exclusion constraints on PostgreSQL

The new ExclusionConstraint class enable adding exclusion constraints on PostgreSQL. Constraints are added to models using the Meta.constraints option.

Filter expressions

Expressions that output BooleanField may now be used directly in QuerySet filters, without having to first annotate and then filter against the annotation.
Enumerations for model field choices

Custom enumeration types `TextChoices`, `IntegerChoices`, and `Choices` are now available as a way to define `Field.choices`. `TextChoices` and `IntegerChoices` types are provided for text and integer fields. The `Choices` class allows defining a compatible enumeration for other concrete data types. These custom enumeration types support human-readable labels that can be translated and accessed via a property on the enumeration or its members. See `Enumeration types` for more details and examples.

Minor features

django.contrib.admin

- Added support for the `admin_order_field` attribute on properties in `ModelAdmin.list_display`.
- The new `ModelAdmin.get_inlines()` method allows specifying the inlines based on the request or model instance.
- Select2 library is upgraded from version 4.0.3 to 4.0.7.
- jQuery is upgraded from version 3.3.1 to 3.4.1.

django.contrib.auth

- The new `reset_url_token` attribute in `PasswordResetConfirmView` allows specifying a token parameter displayed as a component of password reset URLs.
- Added `BaseBackend` class to ease customization of authentication backends.
- Added `get_user_permissions()` method to mirror the existing `get_group_permissions()` method.
- Added `HTML autocomplete` attribute to widgets of username, email, and password fields in `django.contrib.auth.forms` for better interaction with browser password managers.
- `createsuperuser` now falls back to environment variables for password and required fields, when a corresponding command line argument isn’t provided in non-interactive mode.
- `REQUIRED_FIELDS` now supports `ManyToManyFields`.
- The new `UserManager.with_perm()` method returns users that have the specified permission.
- The default iteration count for the PBKDF2 password hasher is increased from 150,000 to 180,000.
django.contrib.gis

- Allowed MySQL spatial lookup functions to operate on real geometries. Previous support was limited to bounding boxes.
- Added the `GeometryDistance` function, supported on PostGIS.
- Added support for the `furlong` unit in `Distance`.
- The `GEOIP_PATH` setting now supports `pathlib.Path`.
- The `GeoIP2` class now accepts `pathlib.Path` path.

django.contrib.postgres

- The new `RangeOperators` helps to avoid typos in SQL operators that can be used together with `RangeField`.
- The new `RangeBoundary` expression represents the range boundaries.
- The new `AddIndexConcurrently` and `RemoveIndexConcurrently` classes allow creating and dropping indexes CONCURRENTLY on PostgreSQL.

django.contrib.sessions

- The new `get_session_cookie_age()` method allows dynamically specifying the session cookie age.

django.contrib.syndication

- Added the `language` class attribute to the `django.contrib.syndication.views.Feed` to customize a feed language. The default value is `get_language()` instead of `LANGUAGE_CODE`.

Cache

- `add_never_cache_headers()` and `never_cache()` now add the `private` directive to Cache-Control headers.
File Storage

- The new `Storage.get_alternative_name()` method allows customizing the algorithm for generating filenames if a file with the uploaded name already exists.

Forms

- Formsets may control the widget used when ordering forms via `can_order` by setting the `ordering_widget` attribute or overriding `get_ordering_widget()`.

Internationalization

- Added the `LANGUAGE_COOKIE_HTTPONLY`, `LANGUAGE_COOKIE_SAMESITE`, and `LANGUAGE_COOKIE_SECURE` settings to set the HttpOnly, SameSite, and Secure flags on language cookies. The default values of these settings preserve the previous behavior.
- Added support and translations for the Uzbek language.

Logging

- The new `reporter_class` parameter of `AdminEmailHandler` allows providing an `django.views.debug.ExceptionReporter` subclass to customize the traceback text sent to site `ADMINS` when `DEBUG` is False.

Management Commands

- The new `compilemessages --ignore` option allows ignoring specific directories when searching for `.po` files to compile.
- `showmigrations --list` now shows the applied datetimes when `--verbosity` is 2 and above.
- On PostgreSQL, `dbshell` now supports client-side TLS certificates.
- `inspectdb` now introspects `OneToOneField` when a foreign key has a unique or primary key constraint.
- The new `--skip-checks` option skips running system checks prior to running the command.
- The `startapp --template` and `startproject --template` options now support templates stored in XZ archives (`.tar.xz`, `.txz`) and LZMA archives (`.tar.lzma`, `.tlz`).

9.1. Final releases
Models

- Added hash database functions `MD5`, `SHA1`, `SHA224`, `SHA256`, `SHA384`, and `SHA512`.
- Added the `Sign` database function.
- The new `is_dst` parameter of the `Trunc` database functions determines the treatment of nonexistent and ambiguous datetimes.
- `connection.queries` now shows `COPY ... TO` statements on PostgreSQL.
- `FilePathField` now accepts a callable for `path`.
- Allowed symmetrical intermediate table for self-referential `ManyToManyField`.
- The `name` attributes of `CheckConstraint`, `UniqueConstraint`, and `Index` now support app label and class interpolation using the `%(app_label)s` and `%(class)s` placeholders.
- The new `Field.descriptor_class` attribute allows model fields to customize the get and set behavior by overriding their descriptors.
- `Avg` and `Sum` now support the `distinct` argument.
- Added `SmallAutoField` which acts much like an `AutoField` except that it only allows values under a certain (database-dependent) limit. Values from 1 to 32767 are safe in all databases supported by Django.
- `AutoField`, `BigAutoField`, and `SmallAutoField` now inherit from `IntegerField`, `BigIntegerField` and `SmallIntegerField` respectively. System checks and validators are now also properly inherited.
- `FilePathField.upload_to` now supports `pathlib.Path`.
- `CheckConstraint` is now supported on MySQL 8.0.16+.

- The new `allows_group_by_selected_pks_on_model()` method of `django.db.backends.base.BaseDatabaseFeatures` allows optimization of `GROUP BY` clauses to require only the selected models’ primary keys. By default, it’s supported only for managed models on PostgreSQL.

To enable the `GROUP BY` primary key-only optimization for unmanaged models, you have to subclass the PostgreSQL database engine, overriding the features class `allows_group_by_selected_pks_on_model()` method as you require. See `Subclassing the built-in database backends` for an example.
Requests and Responses

- Allowed `HttpResponse` to be initialized with `memoryview` content.
- For use in, for example, Django templates, `HttpRequest.headers` now allows lookups using underscores (e.g. `user_agent`) in place of hyphens.

Security

- `X_FRAME_OPTIONS` now defaults to `'DENY'`. In older versions, the `X_FRAME_OPTIONS` setting defaults to `'SAMEORIGIN'`. If your site uses frames of itself, you will need to explicitly set `X_FRAME_OPTIONS = 'SAMEORIGIN'` for them to continue working.
- `SECURE_CONTENT_TYPE_NOSNIFF` now defaults to `True`. With this enabled, `SecurityMiddleware` sets the X-Content-Type-Options: nosniff header on all responses that do not already have it.
- `SecurityMiddleware` can now send the `Referrer-Policy` header.

Tests

- The new test `Client` argument `raise_request_exception` allows controlling whether or not exceptions raised during the request should also be raised in the test. The value defaults to `True` for backwards compatibility. If it is `False` and an exception occurs, the test client will return a 500 response with the attribute `exc_info`, a tuple providing information of the exception that occurred.
- Tests and test cases to run can be selected by test name pattern using the new `test -k` option.
- HTML comparison, as used by `assertHTMLEqual()`, now treats text, character references, and entity references that refer to the same character as equivalent.
- Django test runner now supports headless mode for selenium tests on supported browsers. Add the `--headless` option to enable this mode.
- Django test runner now supports `--start-at` and `--start-after` options to run tests starting from a specific top-level module.
- Django test runner now supports a `--pdb` option to spawn a debugger at each error or failure.
Backwards incompatible changes in 3.0

Model.save() when providing a default for the primary key

Model.save() no longer attempts to find a row when saving a new Model instance and a default value for the primary key is provided, and always performs a single INSERT query. In older Django versions, Model.save() performed either an INSERT or an UPDATE based on whether or not the row exists.

This makes calling Model.save() while providing a default primary key value equivalent to passing force_insert=True to model’s save(). Attempts to use a new Model instance to update an existing row will result in an IntegrityError.

In order to update an existing model for a specific primary key value, use the update_or_create() method or QuerySet.filter(pk=...).update(....) instead. For example:

```python
>>> MyModel.objects.update_or_create(pk=existing_pk, defaults={'name': 'new name'})
```

```python
>>> MyModel.objects.filter(pk=existing_pk).update(name='new name')
```

Database backend API

This section describes changes that may be needed in third-party database backends.

- The second argument of DatabaseIntrospection.get_geometry_type() is now the row description instead of the column name.

- DatabaseIntrospection.get_field_type() may no longer return tuples.

- If the database can create foreign keys in the same SQL statement that adds a field, add SchemaEditor.sql_create_column_inline_fk with the appropriate SQL; otherwise, set DatabaseFeatures.can_create_inline_fk = False.

- DatabaseFeatures.can_return_id_from_insert and can_return_ids_from_bulk_insert are renamed to can_return_columns_from_insert and can_return_rows_from_bulk_insert.

- Database functions now handle `datetime.timezone` formats when created using `datetime.timedelta` instances (e.g. `timezone(timedelta(hours=5))`, which would output ‘UTC+05:00’). Third-party backends should handle this format when preparing `DateTimeField` in `datetime_cast_date_sql()`, `datetime_extract_sql()`, etc.

- Entries for AutoField, BigAutoField, and SmallAutoField are added to DatabaseOperations.integer_field_ranges to support the integer range validators on these field types. Third-party backends may need to customize the default entries.

- DatabaseOperations.fetch_returned_insert_id() is replaced by `fetch_returned_insert_columns()` which returns a list of values returned by the INSERT ... RETURNING statement, instead of a single value.
• DatabaseOperations.return_insert_id() is replaced by return_insert_columns() that accepts a fields argument, which is an iterable of fields to be returned after insert. Usually this is only the auto-generated primary key.

django.contrib.admin

• Admin’s model history change messages now prefers more readable field labels instead of field names.

django.contrib.gis

• Support for PostGIS 2.1 is removed.
• Support for SpatiaLite 4.1 and 4.2 is removed.
• Support for GDAL 1.11 and GEOS 3.4 is removed.

Dropped support for PostgreSQL 9.4

Upstream support for PostgreSQL 9.4 ends in December 2019. Django 3.0 supports PostgreSQL 9.5 and higher.

Dropped support for Oracle 12.1

Upstream support for Oracle 12.1 ends in July 2021. Django 2.2 will be supported until April 2022. Django 3.0 officially supports Oracle 12.2 and 18c.

Removed private Python 2 compatibility APIs

While Python 2 support was removed in Django 2.0, some private APIs weren’t removed from Django so that third party apps could continue using them until the Python 2 end-of-life.

Since we expect apps to drop Python 2 compatibility when adding support for Django 3.0, we’re removing these APIs at this time.

• django.test.utils.str_prefix() - Strings don’t have ‘u’ prefixes in Python 3.
• django.test.utils.patch_logger() - Use unittest.TestCase.assertLogs() instead.
• django.utils.lru_cache.lru_cache() - Alias of functools.lru_cache().
• django.utils.decorators.available_attrs() - This function returns functools.WRAPPER_ASSIGNMENTS.
• django.utils._os.abspathu() - Alias of os.path.abspath().
• django.utils._os.upath() and npath() - These functions do nothing on Python 3.
• django.utils.six - Remove usage of this vendored library or switch to six.
• django.utils.encoding.python_2_unicode_compatible() - Alias of six.python_2_unicode_compatible().
• django.utils.functional.curry() - Use functools.partial() or functools.partialmethod. See 5b1c389603a353625ae1603ba345147356336afb.
• django.utils.safestring.SafeBytes - Unused since Django 2.0.

**New default value for the FILE_UPLOAD_PERMISSIONS setting**

In older versions, the `FILE_UPLOAD_PERMISSIONS` setting defaults to `None`. With the default `FILE_UPLOAD_HANDLERS`, this results in uploaded files having different permissions depending on their size and which upload handler is used.

`FILE_UPLOAD_PERMISSIONS` now defaults to `0o644` to avoid this inconsistency.

**New default values for security settings**

To make Django projects more secure by default, some security settings now have more secure default values:

• `X_FRAME_OPTIONS` now defaults to 'DENY'.
• `SECURE_CONTENT_TYPE_NOSNIFF` now defaults to `True`.

See the What’s New Security section above for more details on these changes.

**Miscellaneous**

• `ContentType.__str__()` now includes the model’s `app_label` to disambiguate models with the same name in different apps.
• Because accessing the language in the session rather than in the cookie is deprecated, `LocaleMiddleware` no longer looks for the user’s language in the session and `django.contrib.auth.logout()` no longer preserves the session’s language after logout.
• `django.utils.html.escape()` now uses `html.escape()` to escape HTML. This converts `¹` to `&#x27;` instead of the previous equivalent decimal code `&#39;`.
• The `django-admin test -k` option now works as the `unittest -k` option rather than as a shortcut for `--keepdb`.
• Support for `pywatchman < 1.2.0` is removed.
• `urlencode()` now encodes iterable values as they are when `doseq=False`, rather than iterating them, bringing it into line with the standard library `urllib.parse.urlencode()` function.
Django Documentation, Release 4.2.dev20220706084552

• intword template filter now translates 1.0 as a singular phrase and all other numeric values as plural. This may be incorrect for some languages.

• Assigning a value to a model’s ForeignKey or OneToOneField '_id' attribute now unset the corresponding field. Accessing the field afterward will result in a query.

• patch_vary_headers() now handles an asterisk '*' according to RFC 7231#section-7.1.4, i.e. if a list of header field names contains an asterisk, then the Vary header will consist of a single asterisk '*'.

• On MySQL 8.0.16+, PositiveIntegerField and PositiveSmallIntegerField now include a check constraint to prevent negative values in the database.

• alias=None is added to the signature of Expression.get_group_by_cols().

• RegexPattern, used by re_path(), no longer returns keyword arguments with None values to be passed to the view for the optional named groups that are missing.

Features deprecated in 3.0
django.utils.encoding.force_text() and smart_text()

The smart_text() and force_text() aliases (since Django 2.0) of smart_str() and force_str() are deprecated. Ignore this deprecation if your code supports Python 2 as the behavior of smart_str() and force_str() is different there.

Miscellaneous
django.utils.http.urlquote(), urlquote_plus(), urlunquote(), and urlunquote_plus() are deprecated in favor of the functions that they’re aliases for: urllib.parse.quote(), quote_plus(), unquote(), and unquote_plus().

django.utils.translation.ugettext(), ugettext_lazy(), ugettext_noop(), ungettext(), and ungettext_lazy() are deprecated in favor of the functions that they’re aliases for: django.utils.translation.gettext(), gettext_lazy(), gettext_noop(), ngettext(), and ngettext_lazy().

• To limit creation of sessions and hence favor some caching strategies, django.views.i18n.set_language() will stop setting the user’s language in the session in Django 4.0. Since Django 2.1, the language is always stored in the LANGUAGE_COOKIE_NAME cookie.

django.utils.text.unescape_entities() is deprecated in favor of html.unescape(). Note that unlike unescape_entities(), html.unescape() evaluates lazy strings immediately.

• To avoid possible confusion as to effective scope, the private internal utility is_safe_url() is renamed to url_has_allowed_host_and_scheme(). That a URL has an allowed host and scheme doesn’t in general imply that it’s “safe”. It may still be quoted incorrectly, for example. Ensure to also use iri_to_uri() on the path component of untrusted URLs.

9.1. Final releases
Features removed in 3.0

These features have reached the end of their deprecation cycle and are removed in Django 3.0.

See Features deprecated in 2.0 for details on these changes, including how to remove usage of these features.

- The `django.db.backends.postgresql_psycopg2` module is removed.
- `django.shortcuts.render_to_response()` is removed.
- The `DEFAULT_CONTENT_TYPE` setting is removed.
- `HttpRequest.xreadlines()` is removed.
- Support for the `context` argument of `Field.from_db_value()` and `Expression.convert_value()` is removed.
- The `field_name` keyword argument of `QuerySet.earliest()` and `latest()` is removed.

See Features deprecated in 2.1 for details on these changes, including how to remove usage of these features.

- The `ForceRHR` GIS function is removed.
- `django.utils.http.cookie_date()` is removed.
- The `staticfiles` and `admin_static` template tag libraries are removed.
- `django.contrib.staticfiles.templatetags.staticfiles.static()` is removed.

9.1.7 2.2 release

Django 2.2.28 release notes

April 11, 2022

Django 2.2.28 fixes two security issues with severity “high” in 2.2.27.

CVE-2022-28346: Potential SQL injection in `QuerySet.annotate()`, `aggregate()`, and `extra()`

`QuerySet.annotate()`, `aggregate()`, and `extra()` methods were subject to SQL injection in column aliases, using a suitably crafted dictionary, with dictionary expansion, as the `**kwargs` passed to these methods.
CVE-2022-28347: Potential SQL injection via `QuerySet.explain(**options)` on PostgreSQL

`QuerySet.explain()` method was subject to SQL injection in option names, using a suitably crafted dictionary, with dictionary expansion, as the `**options` argument.

Django 2.2.27 release notes

February 1, 2022

Django 2.2.27 fixes two security issues with severity “medium” in 2.2.26.

CVE-2022-22818: Possible XSS via `{% debug %}` template tag

The `{% debug %}` template tag didn’t properly encode the current context, posing an XSS attack vector. In order to avoid this vulnerability, `{% debug %}` no longer outputs information when the `DEBUG` setting is `False`, and it ensures all context variables are correctly escaped when the `DEBUG` setting is `True`.

CVE-2022-23833: Denial-of-service possibility in file uploads

Passing certain inputs to multipart forms could result in an infinite loop when parsing files.

Django 2.2.26 release notes

January 4, 2022

Django 2.2.26 fixes one security issue with severity “medium” and two security issues with severity “low” in 2.2.25.

CVE-2021-45115: Denial-of-service possibility in `UserAttributeSimilarityValidator`

`UserAttributeSimilarityValidator` incurred significant overhead evaluating submitted password that were artificially large in relative to the comparison values. On the assumption that access to user registration was unrestricted this provided a potential vector for a denial-of-service attack.

In order to mitigate this issue, relatively long values are now ignored by `UserAttributeSimilarityValidator`.

This issue has severity “medium” according to the Django security policy.
CVE-2021-45116: Potential information disclosure in `dictsort` template filter

Due to leveraging the Django Template Language’s variable resolution logic, the `dictsort` template filter was potentially vulnerable to information disclosure or unintended method calls, if passed a suitably crafted key.

In order to avoid this possibility, `dictsort` now works with a restricted resolution logic, that will not call methods, nor allow indexing on dictionaries.

As a reminder, all untrusted user input should be validated before use.

This issue has severity “low” according to the Django security policy.

CVE-2021-45452: Potential directory-traversal via `Storage.save()`

`Storage.save()` allowed directory-traversal if directly passed suitably crafted file names.

This issue has severity “low” according to the Django security policy.

Django 2.2.25 release notes

December 7, 2021

Django 2.2.25 fixes a security issue with severity “low” in 2.2.24.

CVE-2021-44420: Potential bypass of an upstream access control based on URL paths

HTTP requests for URLs with trailing newlines could bypass an upstream access control based on URL paths.

Django 2.2.24 release notes

June 2, 2021

Django 2.2.24 fixes two security issues in 2.2.23.

CVE-2021-33203: Potential directory traversal via `admindocs`

Staff members could use the `admindocs TemplateDetailView` view to check the existence of arbitrary files. Additionally, if (and only if) the default admindocs templates have been customized by the developers to also expose the file contents, then not only the existence but also the file contents would have been exposed.

As a mitigation, path sanitation is now applied and only files within the template root directories can be loaded.
CVE-2021-33571: Possible indeterminate SSRF, RFI, and LFI attacks since validators accepted leading zeros in IPv4 addresses

URLValidator, validate_ipv4_address(), and validate_ipv46_address() didn’t prohibit leading zeros in octal literals. If you used such values you could suffer from indeterminate SSRF, RFI, and LFI attacks. validate_ipv4_address() and validate_ipv46_address() validators were not affected on Python 3.9.5+.

Django 2.2.23 release notes

May 13, 2021

Django 2.2.23 fixes a regression in 2.2.21.

Bugfixes

- Fixed a regression in Django 2.2.21 where saving FileField would raise a SuspiciousFileOperation even when a custom upload_to returns a valid file path (#32718).

Django 2.2.22 release notes

May 6, 2021

Django 2.2.22 fixes a security issue in 2.2.21.

CVE-2021-32052: Header injection possibility since URLValidator accepted newlines in input on Python 3.9.5+

On Python 3.9.5+, URLValidator didn’t prohibit newlines and tabs. If you used values with newlines in HTTP response, you could suffer from header injection attacks. Django itself wasn’t vulnerable because HttpResponse prohibits newlines in HTTP headers.

Moreover, the URLField form field which uses URLValidator silently removes newlines and tabs on Python 3.9.5+, so the possibility of newlines entering your data only existed if you are using this validator outside of the form fields.

This issue was introduced by the bpo-43882 fix.
Django 2.2.21 release notes

May 4, 2021
Django 2.2.21 fixes a security issue in 2.2.20.

**CVE-2021-31542: Potential directory-traversal via uploaded files**

*MultiPartParser*, *UploadedFile*, and *FieldFile* allowed directory-traversal via uploaded files with suitably crafted file names.

In order to mitigate this risk, stricter basename and path sanitation is now applied.

Django 2.2.20 release notes

April 6, 2021
Django 2.2.20 fixes a security issue with severity “low” in 2.2.19.

**CVE-2021-28658: Potential directory-traversal via uploaded files**

*MultiPartParser* allowed directory-traversal via uploaded files with suitably crafted file names.

Built-in upload handlers were not affected by this vulnerability.

Django 2.2.19 release notes

February 19, 2021
Django 2.2.19 fixes a security issue in 2.2.18.

**CVE-2021-23336: Web cache poisoning via django.utils.http.limited_parse_qsl()**

Django contains a copy of *urllib.parse.parse_qsl()* which was added to backport some security fixes. A further security fix has been issued recently such that *parse_qsl()* no longer allows using ; as a query parameter separator by default. Django now includes this fix. See [bpo-42967](https://docs.djangoproject.com/en/4.2/releases/2.2/) for further details.
Django 2.2.18 release notes

February 1, 2021

Django 2.2.18 fixes a security issue with severity “low” in 2.2.17.

CVE-2021-3281: Potential directory-traversal via archive.extract()

The django.utils.archive.extract() function, used by startapp --template and startproject --template, allowed directory-traversal via an archive with absolute paths or relative paths with dot segments.

Django 2.2.17 release notes

November 2, 2020

Django 2.2.17 adds compatibility with Python 3.9.

Django 2.2.16 release notes

September 1, 2020

Django 2.2.16 fixes two security issues and two data loss bugs in 2.2.15.

CVE-2020-24583: Incorrect permissions on intermediate-level directories on Python 3.7+

On Python 3.7+, FILE_UPLOAD_DIRECTORY_PERMISSIONS mode was not applied to intermediate-level directories created in the process of uploading files and to intermediate-level collected static directories when using the collectstatic management command.

You should review and manually fix permissions on existing intermediate-level directories.

CVE-2020-24584: Permission escalation in intermediate-level directories of the file system cache on Python 3.7+

On Python 3.7+, the intermediate-level directories of the file system cache had the system’s standard umask rather than 0o077 (no group or others permissions).
Bugfixes

- Fixed a data loss possibility in the `select_for_update()`. When using related fields pointing to a proxy model in the `of` argument, the corresponding model was not locked (#31866).
- Fixed a data loss possibility, following a regression in Django 2.0, when copying model instances with a cached fields value (#31863).

Django 2.2.15 release notes

August 3, 2020
Django 2.2.15 fixes two bugs in 2.2.14.

Bugfixes

- Allowed setting the `SameSite` cookie flag in `HttpResponse.delete_cookie()` (#31790).
- Fixed crash when sending emails to addresses with display names longer than 75 chars on Python 3.6.11+, 3.7.8+, and 3.8.4+ (#31784).

Django 2.2.14 release notes

July 1, 2020
Django 2.2.14 fixes a bug in 2.2.13.

Bugfixes

- Fixed messages of `InvalidCacheKey` exceptions and `CacheKeyWarning` warnings raised by cache key validation (#31654).

Django 2.2.13 release notes

June 3, 2020
Django 2.2.13 fixes two security issues and a regression in 2.2.12.
CVE-2020-13254: Potential data leakage via malformed memcached keys

In cases where a memcached backend does not perform key validation, passing malformed cache keys could result in a key collision, and potential data leakage. In order to avoid this vulnerability, key validation is added to the memcached cache backends.

CVE-2020-13596: Possible XSS via admin ForeignKeyRawIdWidget

Query parameters for the admin ForeignKeyRawIdWidget were not properly URL encoded, posing an XSS attack vector. ForeignKeyRawIdWidget now ensures query parameters are correctly URL encoded.

Bugfixes

- Fixed a regression in Django 2.2.12 that affected translation loading for apps providing translations for territorial language variants as well as a generic language, where the project has different plural equations for the language (#31570).
- Tracking a jQuery security release, upgraded the version of jQuery used by the admin from 3.3.1 to 3.5.1.

Django 2.2.12 release notes

April 1, 2020

Django 2.2.12 fixes a bug in 2.2.11.

Bugfixes

- Added the ability to handle .po files containing different plural equations for the same language (#30439).

Django 2.2.11 release notes

March 4, 2020

Django 2.2.11 fixes a security issue and a data loss bug in 2.2.10.
CVE-2020-9402: Potential SQL injection via tolerance parameter in GIS functions and aggregates on Oracle

GIS functions and aggregates on Oracle were subject to SQL injection, using a suitably crafted tolerance.

Bugfixes

- Fixed a data loss possibility in the `select_for_update()`. When using related fields or parent link fields with Multi-table inheritance in the `of` argument, the corresponding models were not locked (#31246).

Django 2.2.10 release notes

February 3, 2020

Django 2.2.10 fixes a security issue in 2.2.9.

CVE-2020-7471: Potential SQL injection via StringAgg(delimiter)

StringAgg aggregation function was subject to SQL injection, using a suitably crafted delimiter.

Django 2.2.9 release notes

December 18, 2019

Django 2.2.9 fixes a security issue and a data loss bug in 2.2.8.

CVE-2019-19844: Potential account hijack via password reset form

By submitting a suitably crafted email address making use of Unicode characters, that compared equal to an existing user email when lower-cased for comparison, an attacker could be sent a password reset token for the matched account.

In order to avoid this vulnerability, password reset requests now compare the submitted email using the stricter, recommended algorithm for case-insensitive comparison of two identifiers from Unicode Technical Report 36, section 2.11.2(B)(2). Upon a match, the email containing the reset token will be sent to the email address on record rather than the submitted address.
Bugfixes

- Fixed a data loss possibility in `SplitArrayField`. When using with `ArrayField(BooleanField())`, all values after the first `True` value were marked as checked instead of preserving passed values (#31073).

Django 2.2.8 release notes

December 2, 2019

Django 2.2.8 fixes a security issue, several bugs in 2.2.7, and adds compatibility with Python 3.8.

Since Django 2.1, a Django model admin displaying a parent model with related model inlines, where the user has view-only permissions to a parent model but edit permissions to the inline model, would display a read-only view of the parent model but editable forms for the inline.

Submitting these forms would not allow direct edits to the parent model, but would trigger the parent model’s `save()` method, and cause pre and post-save signal handlers to be invoked. This is a privilege escalation as a user who lacks permission to edit a model should not be able to trigger its save-related signals.

To resolve this issue, the permission handling code of the Django admin interface has been changed. Now, if a user has only the “view” permission for a parent model, the entire displayed form will not be editable, even if the user has permission to edit models included in inlines.

This is a backwards-incompatible change, and the Django security team is aware that some users of Django were depending on the ability to allow editing of inlines in the admin form of an otherwise view-only parent model.

Given the complexity of the Django admin, and in-particular the permissions related checks, it is the view of the Django security team that this change was necessary: that it is not currently feasible to maintain the existing behavior while escaping the potential privilege escalation in a way that would avoid a recurrence of similar issues in the future, and that would be compatible with Django’s safe by default philosophy.

For the time being, developers whose applications are affected by this change should replace the use of inlines in read-only parents with custom forms and views that explicitly implement the desired functionality. In the longer term, adding a documented, supported, and properly-tested mechanism for partially-editable multi-model forms to the admin interface may occur in Django itself.
Bugfixes

- Fixed a data loss possibility in the admin changelist view when a custom formset’s prefix contains regular expression special characters, e.g. '$' (#31031).

- Fixed a regression in Django 2.2.1 that caused a crash when migrating permissions for proxy models with a multiple database setup if the default entry was empty (#31021).

- Fixed a data loss possibility in the `select_for_update()`. When using 'self' in the of argument with multi-table inheritance, a parent model was locked instead of the queryset’s model (#30953).

Django 2.2.7 release notes

November 4, 2019

Django 2.2.7 fixes several bugs in 2.2.6.

Bugfixes

- Fixed a crash when using a contains, contained_by, has_key, has_keys, or has_any_keys lookup on `django.contrib.postgres.fields.JSONField`, if the right or left hand side of an expression is a key transform (#30826).

- Prevented `migrate --plan` from showing that RunPython operations are irreversible when reverse_code callables don’t have docstrings or when showing a forward migration plan (#30870).

- Fixed migrations crash on PostgreSQL when adding an `Index` with fields ordering and opclasses (#30903).

- Restored the ability to override `get_FOO_display()` (#30931).

Django 2.2.6 release notes

October 1, 2019

Django 2.2.6 fixes several bugs in 2.2.5.

Bugfixes

- Fixed migrations crash on SQLite when altering a model containing partial indexes (#30754).

- Fixed a regression in Django 2.2.4 that caused a crash when filtering with a Subquery() annotation of a queryset containing `django.contrib.postgres.fields.JSONField` or `HStoreField` (#30769).
Django 2.2.5 release notes

September 2, 2019

Django 2.2.5 fixes several bugs in 2.2.4.

Bugfixes

• Relaxed the system check added in Django 2.2 for models to realow use of the same `db_table` by multiple models when database routers are installed (#30673).

• Fixed crash of `KeyTransform()` for `django.contrib.postgres.fields.JSONField` and `HStoreField` when using on expressions with params (#30672).

• Fixed a regression in Django 2.2 where `ModelAdmin.list_filter` choices to foreign objects don’t respect a model’s `Meta.ordering` (#30449).

Django 2.2.4 release notes

August 1, 2019

Django 2.2.4 fixes security issues and several bugs in 2.2.3.

CVE-2019-14232: Denial-of-service possibility in `django.utils.text.Truncator`

If `django.utils.text.Truncator`’s `chars()` and `words()` methods were passed the `html=True` argument, they were extremely slow to evaluate certain inputs due to a catastrophic backtracking vulnerability in a regular expression. The `chars()` and `words()` methods are used to implement the `truncatechars_html` and `truncatewords_html` template filters, which were thus vulnerable.

The regular expressions used by `Truncator` have been simplified in order to avoid potential backtracking issues. As a consequence, trailing punctuation may now at times be included in the truncated output.

CVE-2019-14233: Denial-of-service possibility in `strip_tags()`

Due to the behavior of the underlying `HTMLParser`, `django.utils.html.strip_tags()` would be extremely slow to evaluate certain inputs containing large sequences of nested incomplete HTML entities. The `strip_tags()` method is used to implement the corresponding `striptags` template filter, which was thus also vulnerable.

`strip_tags()` now avoids recursive calls to `HTMLParser` when progress removing tags, but necessarily incomplete HTML entities, stops being made.
Remember that absolutely NO guarantee is provided about the results of `strip_tags()` being HTML safe. So NEVER mark safe the result of a `strip_tags()` call without escaping it first, for example with `django.utils.html.escape()`.

**CVE-2019-14234:** SQL injection possibility in key and index lookups for JSONField/HStoreField

*Key and index lookups* for `django.contrib.postgres.fields.JSONField` and *key lookups* for `HStoreField` were subject to SQL injection, using a suitably crafted dictionary, with dictionary expansion, as the **kwargs passed to `QuerySet.filter()`.

**CVE-2019-14235:** Potential memory exhaustion in `django.utils.encoding.uri_to_iri()`

If passed certain inputs, `django.utils.encoding.uri_to_iri()` could lead to significant memory usage due to excessive recursion when re-percent-encoding invalid UTF-8 octet sequences.

`uri_to_iri()` now avoids recursion when re-percent-encoding invalid UTF-8 octet sequences.

**Bugfixes**

- Fixed a regression in Django 2.2 when ordering a `QuerySet.union()`, `intersection()`, or `difference()` by a field type present more than once results in the wrong ordering being used (#30628).
- Fixed a migration crash on PostgreSQL when adding a check constraint with a `contains` lookup on `DateRangeField` or `DateTimeRangeField`, if the right hand side of an expression is the same type (#30621).
- Fixed a regression in Django 2.2 where auto-reloader crashes if a file path contains nulls characters (‘\x00’) (#30506).
- Fixed a regression in Django 2.2 where auto-reloader crashes if a translation directory cannot be resolved (#30647).

**Django 2.2.3 release notes**

July 1, 2019

Django 2.2.3 fixes a security issue and several bugs in 2.2.2. Also, the latest string translations from Transifex are incorporated.
CVE-2019-12781: Incorrect HTTP detection with reverse-proxy connecting via HTTPS

When deployed behind a reverse-proxy connecting to Django via HTTPS, `django.http.HttpRequest.scheme` would incorrectly detect client requests made via HTTP as using HTTPS. This entails incorrect results for `is_secure()`, and `build_absolute_uri()`, and that HTTP requests would not be redirected to HTTPS in accordance with `SECURE_SSL_REDIRECT`.

`HttpRequest.scheme` now respects `SECURE_PROXY_SSL_HEADER`, if it is configured, and the appropriate header is set on the request, for both HTTP and HTTPS requests.

If you deploy Django behind a reverse-proxy that forwards HTTP requests, and that connects to Django via HTTPS, be sure to verify that your application correctly handles code paths relying on `scheme`, `is_secure()`, `build_absolute_uri()`, and `SECURE_SSL_REDIRECT`.

**Bugfixes**

- Fixed a regression in Django 2.2 where `Avg`, `StdDev`, and `Variance` crash with `filter` argument (#30542).
- Fixed a regression in Django 2.2.2 where auto-reloader crashes with `AttributeError`, e.g. when using `ipdb` (#30588).

**Django 2.2.2 release notes**

June 3, 2019

Django 2.2.2 fixes security issues and several bugs in 2.2.1.

CVE-2019-12308: AdminURLFieldWidget XSS

The clickable “Current URL” link generated by `AdminURLFieldWidget` displayed the provided value without validating it as a safe URL. Thus, an unvalidated value stored in the database, or a value provided as a URL query parameter payload, could result in an clickable JavaScript link.

`AdminURLFieldWidget` now validates the provided value using `URLValidator` before displaying the clickable link. You may customize the validator by passing a `validator_class` kwarg to `AdminURLFieldWidget.__init__`, e.g. when using `formfield_overrides`. 
Patched bundled jQuery for CVE-2019-11358: Prototype pollution

jQuery before 3.4.0, mishandles `jQuery.extend(true, {}, ...)` because of `Object.prototype` pollution. If an unsanitized source object contained an enumerable `__proto__` property, it could extend the native `Object.prototype`.

The bundled version of jQuery used by the Django admin has been patched to allow for the `select2` library’s use of `jQuery.extend()`.

**Bugfixes**

- Fixed a regression in Django 2.2 that stopped Show/Hide toggles working on dynamically added admin inlines (#30459).
- Fixed a regression in Django 2.2 where deprecation message crashes if `Meta.ordering` contains an expression (#30463).
- Fixed a regression in Django 2.2.1 where `SearchVector` generates SQL with a redundant `Coalesce` call (#30488).
- Fixed a regression in Django 2.2 where auto-reloader doesn’t detect changes in `manage.py` file when using `StatReloader` (#30479).
- Fixed crash of `ArrayAgg` and `StringAgg` with `ordering` argument when used in a `Subquery` (#30315).
- Fixed a regression in Django 2.2 that caused a crash of auto-reloader when an exception with custom signature is raised (#30516).
- Fixed a regression in Django 2.2.1 where auto-reloader unnecessarily reloads translation files multiple times when using `StatReloader` (#30523).

**Django 2.2.1 release notes**

May 1, 2019

Django 2.2.1 fixes several bugs in 2.2.

**Bugfixes**

- Fixed a regression in Django 2.1 that caused the incorrect quoting of database user password when using `dbshell` on Oracle (#30307).
- Added compatibility for `psycopg2 2.8` (#30331).
- Fixed a regression in Django 2.2 that caused a crash when loading the template for the technical 500 debug page (#30324).
• Fixed crash of `ordering` argument in `ArrayAgg` and `StringAgg` when it contains an expression with `params` (#30332).

• Fixed a regression in Django 2.2 that caused a single instance fast-delete to not set the primary key to `None` (#30330).

• Prevented `makemigrations` from generating infinite migrations for check constraints and partial indexes when `condition` contains a `range` object (#30350).

• Reverted an optimization in Django 2.2 (#29725) that caused the inconsistent behavior of `count()` and `exists()` on a reverse many-to-many relationship with a custom manager (#30325).

• Fixed a regression in Django 2.2 where `Paginator` crashes if `object_list` is a queryset ordered or aggregated over a nested `JSONField` key transform (#30335).

• Fixed a regression in Django 2.2 where `IntegerField` validation of database limits crashes if `limit_value` attribute in a custom validator is callable (#30328).

• Fixed a regression in Django 2.2 where `SearchVector` generates SQL that is not indexable (#30385).

• Fixed a regression in Django 2.2 that caused an exception to be raised when a custom error handler could not be imported (#30318).

• Relaxed the system check added in Django 2.2 for the admin app’s dependencies to realow use of `SessionMiddleware` subclasses, rather than requiring `django.contrib.sessions` to be in `INSTALLED_APPS` (#30312).

• Increased the default timeout when using `Watchman` to 5 seconds to prevent falling back to `StatReloader` on larger projects and made it customizable via the `DJANGO_WATCHMAN_TIMEOUT` environment variable (#30361).

• Fixed a regression in Django 2.2 that caused a crash when migrating permissions for proxy models if the target permissions already existed. For example, when a permission had been created manually or a model had been migrated from concrete to proxy (#30351).

• Fixed a regression in Django 2.2 that caused a crash of `runserver` when URLConf modules raised exceptions (#30323).

• Fixed a regression in Django 2.2 where changes were not reliably detected by auto-reloader when using `StatReloader` (#30323).

• Fixed a migration crash on Oracle and PostgreSQL when adding a check constraint with a `contains`, `startswith`, or `endswith` lookup (or their case-insensitive variant) (#30408).

• Fixed a migration crash on Oracle and SQLite when adding a check constraint with `condition` contains `|` (OR) operator (#30412).
**Django 2.2 release notes**

April 1, 2019

Welcome to Django 2.2!

These release notes cover the new features, as well as some backwards incompatible changes you’ll want to be aware of when upgrading from Django 2.1 or earlier. We’ve begun the deprecation process for some features.

See the How to upgrade Django to a newer version guide if you’re updating an existing project.

Django 2.2 is designated as a long-term support release. It will receive security updates for at least three years after its release. Support for the previous LTS, Django 1.11, will end in April 2020.

**Python compatibility**

Django 2.2 supports Python 3.5, 3.6, 3.7, 3.8 (as of 2.2.8), and 3.9 (as of 2.2.17). We highly recommend and only officially support the latest release of each series.

**What’s new in Django 2.2**

**Constraints**

The new `CheckConstraint` and `UniqueConstraint` classes enable adding custom database constraints. Constraints are added to models using the `Meta.constraints` option.

**Minor features**

**django.contrib.admin**

- Added a CSS class to the column headers of `TabularInline`.

**django.contrib.auth**

- The `HttpRequest` is now passed as the first positional argument to `RemoteUserBackend.configure_user()`, if it accepts it.
django.contrib.gis

- Added Oracle support for the *Envelope* function.
- Added SpatiaLite support for the *coveredby* and *covers* lookups.

django.contrib.postgres

- The new *ordering* argument for *ArrayAgg* and *StringAgg* determines the ordering of the aggregated elements.
- The new *BTreeIndex*, *HashIndex* and *SpGistIndex* classes allow creating B-Tree, hash, and SP-GiST indexes in the database.
- *BrinIndex* now has the *autosummarize* parameter.
- The new *search_type* parameter of *SearchQuery* allows searching for a phrase or raw expression.

django.contrib.staticfiles

- Added path matching to the *collectstatic --ignore* option so that patterns like /vendor/* . js can be used.

Database backends

- Added result streaming for *QuerySet.iterator()* on SQLite.

Generic Views

- The new *View.setup* hook initializes view attributes before calling *dispatch()* . It allows mixins to set up instance attributes for reuse in child classes.

Internationalization

- Added support and translations for the Armenian language.
Management Commands

- The new `--force-color` option forces colorization of the command output.
- `inspectdb` now creates models for foreign tables on PostgreSQL.
- `inspectdb --include-views` now creates models for materialized views on Oracle and PostgreSQL.
- The new `inspectdb --include-partitions` option allows creating models for partition tables on PostgreSQL. In older versions, models are created child tables instead the parent.
- `inspectdb` now introspects `DurationField` for Oracle and PostgreSQL, and `AutoField` for SQLite.
- On Oracle, `dbshell` is wrapped with `rlwrap`, if available. `rlwrap` provides a command history and editing of keyboard input.
- The new `makemigrations --no-header` option avoids writing header comments in generated migration file(s). This option is also available for `squashmigrations`.
- `runserver` can now use `Watchman` to improve the performance of watching a large number of files for changes.

Migrations

- The new `migrate --plan` option prints the list of migration operations that will be performed.
- `NoneType` can now be serialized in migrations.
- You can now register custom serializers for migrations.

Models

- Added support for PostgreSQL operator classes (`Index.opclasses`).
- Added support for partial indexes (`Index.condition`).
- Added the `NullIf` and `Reverse` database functions, as well as many `math` database functions.
- Setting the new `ignore_conflicts` parameter of `QuerySet.bulk_create()` to `True` tells the database to ignore failure to insert rows that fail uniqueness constraints or other checks.
- The new `ExtractIsoYear` function extracts ISO-8601 week-numbering years from `DateField` and `DateTimeField`, and the new `iso_year` lookup allows querying by an ISO-8601 week-numbering year.
- The new `QuerySet.bulk_update()` method allows efficiently updating specific fields on multiple model instances.
- Django no longer always starts a transaction when a single query is being performed, such as `Model.save()`, `QuerySet.update()`, and `Model.delete()`. This improves the performance of autocommit by reducing the number of database round trips.
• Added SQLite support for the \textit{StdDev} and \textit{Variance} functions.

• The handling of \texttt{DISTINCT} aggregation is added to the \texttt{Aggregate} class. Adding \texttt{allow\_distinct = True} as a class attribute on \texttt{Aggregate} subclasses allows a \texttt{distinct} keyword argument to be specified on initialization to ensure that the aggregate function is only called for each distinct value of expressions.

• The \texttt{RelatedManager.add()}, \texttt{create()}, \texttt{remove()}, \texttt{set()}, \texttt{get\_or\_create()}, and \texttt{update\_or\_create()} methods are now allowed on many-to-many relationships with intermediate models. The new \texttt{through\_defaults} argument is used to specify values for new intermediate model instance(s).

Requests and Responses

• Added \texttt{HttpRequest.headers} to allow simple access to a request’s headers.

Serialization

• You can now deserialize data using natural keys containing forward references by passing \texttt{handle\_forward\_references=True} to \texttt{serializers.deserialize()}. Additionally, \texttt{loaddata} handles forward references automatically.

Tests

• The new \texttt{SimpleTestCase.assertURLEqual()} assertion checks for a given URL, ignoring the ordering of the query string. \texttt{assertRedirects()} uses the new assertion.

• The test \texttt{Client} now supports automatic JSON serialization of list and tuple data when \texttt{content\_type='application/json'}.

• The new \texttt{ORACLE\_MANAGED\_FILES} test database setting allows using Oracle Managed Files (OMF) tables.

• Deferrable database constraints are now checked at the end of each \texttt{TestCase} test on SQLite 3.20+, just like on other backends that support deferrable constraints. These checks aren’t implemented for older versions of SQLite because they would require expensive table introspection there.

• \texttt{DiscoverRunner} now skips the setup of databases not referenced by tests.
 URLs

- The new `ResolverMatch.route` attribute stores the route of the matching URL pattern.

 Validators

- `MaxValueValidator`, `MinValueValidator`, `MinLengthValidator`, and `MaxLengthValidator` now accept a callable `limit_value`.

 Backwards incompatible changes in 2.2

 Database backend API

This section describes changes that may be needed in third-party database backends.

- Third-party database backends must implement support for table check constraints or set `DatabaseFeatures.supports_table_check_constraints` to `False`.
- Third party database backends must implement support for ignoring constraints or uniqueness errors while inserting or set `DatabaseFeatures.supports_ignore_conflicts` to `False`.
- Third party database backends must implement introspection for `DurationField` or set `DatabaseFeatures.can_introspect_duration_field` to `False`.
- `DatabaseFeatures.uses_savepoints` now defaults to `True`.
- Third party database backends must implement support for partial indexes or set `DatabaseFeatures.supports_partial_indexes` to `False`.
- `DatabaseIntrospection.table_name_converter()` and `column_name_converter()` are removed. Third party database backends may need to instead implement `DatabaseIntrospection.identifier_converter()`. In that case, the constraint names that `DatabaseIntrospection.get_constraints()` returns must be normalized by `identifier_converter()`.
- SQL generation for indexes is moved from `Index` to `SchemaEditor` and these `SchemaEditor` methods are added:
  - `_create_primary_key_sql()` and `_delete_primary_key_sql()`  
  - `_create_check_sql()` and `_delete_check_sql()`  

- The third argument of `DatabaseWrapper.__init__()`, `allow_thread_sharing`, is removed.
Admin actions are no longer collected from base ModelAdmin classes

For example, in older versions of Django:

```python
from django.contrib import admin

class BaseAdmin(admin.ModelAdmin):
    actions = ['a']

class SubAdmin(BaseAdmin):
    actions = ['b']
```

SubAdmin would have actions 'a' and 'b'.

Now actions follows standard Python inheritance. To get the same result as before:

```python
class SubAdmin(BaseAdmin):
    actions = BaseAdmin.actions + ['b']
```

django.contrib.gis

- Support for GDAL 1.9 and 1.10 is dropped.

TransactionTestCase serialized data loading

Initial data migrations are now loaded in TransactionTestCase at the end of the test, after the database flush. In older versions, this data was loaded at the beginning of the test, but this prevents the test --keepdb option from working properly (the database was empty at the end of the whole test suite). This change shouldn’t have an impact on your tests unless you’ve customized TransactionTestCase’s internals.

sqlparse is required dependency

To simplify a few parts of Django’s database handling, sqlparse 0.2.2+ is now a required dependency. It’s automatically installed along with Django.
cached_property aliases

In usage like:

```python
from django.utils.functional import cached_property
class A:
    @cached_property
def base(self):
        return ...
    alias = base
```

alias is not cached. Where the problem can be detected (Python 3.6 and later), such usage now
raises TypeError: Cannot assign the same cached_property to two different names ('base' and 'alias').

Use this instead:

```python
import operator
class A:
    ...
    alias = property(operator.attrgetter('base'))
```

Permissions for proxy models

Permissions for proxy models are now created using the content type of the proxy model rather than the
content type of the concrete model. A migration will update existing permissions when you run `migrate`.

In the admin, the change is transparent for proxy models having the same app_label as their concrete model. However, in older versions, users with permissions for a proxy model with a different app_label than its concrete model couldn’t access the model in the admin. That’s now fixed, but you might want to audit the permissions assignments for such proxy models ([add|view|change|delete]_myproxy) prior to upgrading to ensure the new access is appropriate.

Finally, proxy model permission strings must be updated to use their own app_label. For example, for app.MyProxyModel inheriting from other_app.ConcreteModel, update user.has_perm('other_app.add_myproxymodel') to user.has_perm('app.add_myproxymodel').
Merging of form Media assets

Form Media assets are now merged using a topological sort algorithm, as the old pairwise merging algorithm is insufficient for some cases. CSS and JavaScript files which don’t include their dependencies may now be sorted incorrectly (where the old algorithm produced results correctly by coincidence).

Audit all Media classes for any missing dependencies. For example, widgets depending on django.jQuery must specify js=['admin/js/jquery.init.js', ...] when declaring form media assets.

Miscellaneous

- To improve readability, the UUIDField form field now displays values with dashes, e.g. 550e8400-e29b-41d4-a716-446655440000 instead of 550e8400e29b41d4a716446655440000.

- On SQLite, PositiveIntegerField and PositiveSmallIntegerField now include a check constraint to prevent negative values in the database. If you have existing invalid data and run a migration that recreates a table, you’ll see CHECK constraint failed.

- For consistency with WSGI servers, the test client now sets the Content-Length header to a string rather than an integer.

- The return value of django.utils.text.slugify() is no longer marked as HTML safe.

- The default truncation character used by the urlizetrunc, truncatechars, truncatechars_html, truncatewords, and truncatewords_html template filters is now the real ellipsis character (…) instead of 3 dots. You may have to adapt some test output comparisons.

- Support for bytestring paths in the template filesystem loader is removed.

- django.utils.http.urlsafe_base64_encode() now returns a string instead of a bytestring, and django.utils.http.urlsafe_base64_decode() may no longer be passed a bytestring.

- Support for cx_Oracle < 6.0 is removed.

- The minimum supported version of mysqlclient is increased from 1.3.7 to 1.3.13.

- The minimum supported version of SQLite is increased from 3.7.15 to 3.8.3.

- In an attempt to provide more semantic query data, NullBooleanSelect now renders <option> values of unknown, true, and false instead of 1, 2, and 3. For backwards compatibility, the old values are still accepted as data.

- Group.name max_length is increased from 80 to 150 characters.

- Tests that violate deferrable database constraints now error when run on SQLite 3.20+, just like on other backends that support such constraints.

- To catch usage mistakes, the test Client and django.utils.httpurlencode() now raise TypeError if None is passed as a value to encode because None can’t be encoded in GET and POST data. Either pass an empty string or omit the value.
• The `ping_google` management command now defaults to `https` instead of `http` for the sitemap’s URL. If your site uses `http`, use the new `ping_google --sitemap-uses-http` option. If you use the `ping_google()` function, set the new `sitemap_uses_https` argument to `False`.

• `runserver` no longer supports `pyinotify` (replaced by Watchman).

• The `Avg`, `StdDev`, and `Variance` aggregate functions now return a `Decimal` instead of a `float` when the input is `Decimal`.

• Tests will fail on SQLite if apps without migrations have relations to apps with migrations. This has been a documented restriction since migrations were added in Django 1.7, but it fails more reliably now. You’ll see tests failing with errors like `no such table: <app_label>_<model>`. This was observed with several third-party apps that had models in tests without migrations. You must add migrations for such models.

• Providing an integer in the `key` argument of the `cache.delete()` or `cache.get()` now raises `ValueError`.

• Plural equations for some languages are changed, because the latest versions from Transifex are incorporated.

Note: The ability to handle `.po` files containing different plural equations for the same language was added in Django 2.2.12.

---

**Features deprecated in 2.2**

**Model `Meta.ordering` will no longer affect GROUP BY queries**

A model’s `Meta.ordering` affecting GROUP BY queries (such as `.annotate().values()`) is a common source of confusion. Such queries now issue a deprecation warning with the advice to add an `order_by()` to retain the current query. `Meta.ordering` will be ignored in such queries starting in Django 3.1.

**Miscellaneous**

• `django.utils.timezone.FixedOffset` is deprecated in favor of `datetime.timezone`.

• The undocumented `QuerySetPaginator` alias of `django.core.paginator.Paginator` is deprecated.

• The `FloatRangeField` model and form fields in `django.contrib.postgres` are deprecated in favor of a new name, `DecimalRangeField`, to match the underlying `numrange` data type used in the database.

• The `FILE_CHARSET` setting is deprecated. Starting with Django 3.1, files read from disk must be UTF-8 encoded.
• `django.contrib.staticfiles.storage.CachedStaticFilesStorage` is deprecated due to the intractable problems that it has. Use `ManifestStaticFilesStorage` or a third-party cloud storage instead.

• `RemoteUserBackend.configure_user()` is now passed `request` as the first positional argument, if it accepts it. Support for overrides that don’t accept it will be removed in Django 3.1.

• The `SimpleTestCase.allow_database_queries`, `TransactionTestCase.multi_db`, and `TestCase.multi_db` attributes are deprecated in favor of `SimpleTestCase.databases`, `TransactionTestCase.databases`, and `TestCase.databases`. These new attributes allow databases dependencies to be declared in order to prevent unexpected queries against non-default databases to leak state between tests. The previous behavior of `allow_database_queries=True` and `multi_db=True` can be achieved by setting `databases= '__all__'`.

### 9.1.8 2.1 release

**Django 2.1.15 release notes**

December 2, 2019

Django 2.1.15 fixes a security issue and a data loss bug in 2.1.14.

**CVE-2019-19118: Privilege escalation in the Django admin.**

Since Django 2.1, a Django model admin displaying a parent model with related model inlines, where the user has view-only permissions to a parent model but edit permissions to the inline model, would display a read-only view of the parent model but editable forms for the inline.

Submitting these forms would not allow direct edits to the parent model, but would trigger the parent model’s `save()` method, and cause pre and post-save signal handlers to be invoked. This is a privilege escalation as a user who lacks permission to edit a model should not be able to trigger its save-related signals.

To resolve this issue, the permission handling code of the Django admin interface has been changed. Now, if a user has only the “view” permission for a parent model, the entire displayed form will not be editable, even if the user has permission to edit models included in inlines.

This is a backwards-incompatible change, and the Django security team is aware that some users of Django were depending on the ability to allow editing of inlines in the admin form of an otherwise view-only parent model.

Given the complexity of the Django admin, and in-particular the permissions related checks, it is the view of the Django security team that this change was necessary: that it is not currently feasible to maintain the existing behavior while escaping the potential privilege escalation in a way that would avoid a recurrence of similar issues in the future, and that would be compatible with Django’s safe by default philosophy.
For the time being, developers whose applications are affected by this change should replace the use of inlines in read-only parents with custom forms and views that explicitly implement the desired functionality. In the longer term, adding a documented, supported, and properly-tested mechanism for partially-editable multi-model forms to the admin interface may occur in Django itself.

**Bugfixes**

- Fixed a data loss possibility in the `select_for_update()`. When using 'self' in the of argument with multi-table inheritance, a parent model was locked instead of the queryset’s model (#30953).

**Django 2.1.14 release notes**

November 4, 2019

Django 2.1.14 fixes a regression in 2.1.13.

**Bugfixes**

- Fixed a crash when using a `contains`, `contained_by`, `has_key`, `has_keys`, or `has_any_keys` lookup on `django.contrib.postgres.fields.JSONField`, if the right or left hand side of an expression is a key transform (#30826).

**Django 2.1.13 release notes**

October 1, 2019

Django 2.1.13 fixes a regression in 2.1.11.

**Bugfixes**

- Fixed a crash when filtering with a `Subquery()` annotation of a queryset containing `django.contrib.postgres.fields.JSONField` or `HStoreField` (#30769).

**Django 2.1.12 release notes**

September 2, 2019

Django 2.1.12 fixes a regression in 2.1.11.
Bugfixes

• Fixed crash of `KeyTransform()` for `django.contrib.postgres.fields.JSONField` and `HStoreField` when using on expressions with params (#30672).

Django 2.1.11 release notes

August 1, 2019

Django 2.1.11 fixes security issues in 2.1.10.

**CVE-2019-14232: Denial-of-service possibility in `django.utils.text.Truncator`**

If `django.utils.text.Truncator`’s `chars()` and `words()` methods were passed the `html=True` argument, they were extremely slow to evaluate certain inputs due to a catastrophic backtracking vulnerability in a regular expression. The `chars()` and `words()` methods are used to implement the `truncatemarks_html` and `truncatemarks_html` template filters, which were thus vulnerable.

The regular expressions used by `Truncator` have been simplified in order to avoid potential backtracking issues. As a consequence, trailing punctuation may now at times be included in the truncated output.

**CVE-2019-14233: Denial-of-service possibility in `strip_tags()`**

Due to the behavior of the underlying `HTMLParser`, `django.utils.html.strip_tags()` would be extremely slow to evaluate certain inputs containing large sequences of nested incomplete HTML entities. The `strip_tags()` method is used to implement the corresponding `striptags` template filter, which was thus also vulnerable.

`strip_tags()` now avoids recursive calls to `HTMLParser` when progress removing tags, but necessarily incomplete HTML entities, stops being made.

Remember that absolutely NO guarantee is provided about the results of `strip_tags()` being HTML safe. So NEVER mark safe the result of a `strip_tags()` call without escaping it first, for example with `django.utils.html.escape()`.

**CVE-2019-14234: SQL injection possibility in key and index lookups for `JSONField/HStoreField`**

`Key and index lookups` for `django.contrib.postgres.fields.JSONField` and `key lookups` for `HStoreField` were subject to SQL injection, using a suitably crafted dictionary, with dictionary expansion, as the `**kwargs` passed to `QuerySet.filter()`.
CVE-2019-14235: Potential memory exhaustion in `django.utils.encoding.uri_to_iri()`

If passed certain inputs, `django.utils.encoding.uri_to_iri()` could lead to significant memory usage due to excessive recursion when re-percent-encoding invalid UTF-8 octet sequences.

`uri_to_iri()` now avoids recursion when re-percent-encoding invalid UTF-8 octet sequences.

Django 2.1.10 release notes

July 1, 2019
Django 2.1.10 fixes a security issue in 2.1.9.

CVE-2019-12781: Incorrect HTTP detection with reverse-proxy connecting via HTTPS

When deployed behind a reverse-proxy connecting to Django via HTTPS, `django.http.HttpRequest.scheme` would incorrectly detect client requests made via HTTP as using HTTPS. This entails incorrect results for `is_secure()`, and `build_absolute_uri()`, and that HTTP requests would not be redirected to HTTPS in accordance with `SECURE_SSL_REDIRECT`.

`HttpRequest.scheme` now respects `SECURE_PROXY_SSL_HEADER`, if it is configured, and the appropriate header is set on the request, for both HTTP and HTTPS requests.

If you deploy Django behind a reverse-proxy that forwards HTTP requests, and that connects to Django via HTTPS, be sure to verify that your application correctly handles code paths relying on `scheme`, `is_secure()`, `build_absolute_uri()`, and `SECURE_SSL_REDIRECT`.

Django 2.1.9 release notes

June 3, 2019
Django 2.1.9 fixes security issues in 2.1.8.

CVE-2019-12308: AdminURLFieldWidget XSS

The clickable “Current URL” link generated by `AdminURLFieldWidget` displayed the provided value without validating it as a safe URL. Thus, an unvalidated value stored in the database, or a value provided as a URL query parameter payload, could result in an clickable JavaScript link.

`AdminURLFieldWidget` now validates the provided value using `URLValidator` before displaying the clickable link. You may customize the validator by passing a `validator_class` kwarg to `AdminURLFieldWidget.__init__`, e.g. when using `formfield_overrides`. 
Patched bundled jQuery for CVE-2019-11358: Prototype pollution

jQuery before 3.4.0, mishandles `jQuery.extend(true, {}, ...)` because of `Object.prototype` pollution. If an unsanitized source object contained an enumerable `__proto__` property, it could extend the native `Object.prototype`.

The bundled version of jQuery used by the Django admin has been patched to allow for the `select2` library’s use of `jQuery.extend()`.

**Django 2.1.8 release notes**

April 1, 2019

Django 2.1.8 fixes a bug in 2.1.7.

**Bugfixes**

- Prevented admin inlines for a `ManyToManyField`’s implicit through model from being editable if the user only has the view permission (#30289).

**Django 2.1.7 release notes**

February 11, 2019

Django 2.1.7 fixes a packaging error in 2.1.6.

**Bugfixes**

- Corrected packaging error from 2.1.6 (#30175).

**Django 2.1.6 release notes**

February 11, 2019

Django 2.1.6 fixes a security issue and a bug in 2.1.5.
CVE-2019-6975: Memory exhaustion in `django.utils.numberformat.format()`

If `django.utils.numberformat.format()` — used by `contrib.admin` as well as the `floatformat`, `filesizeformat`, and `intcomma` templates filters — received a `Decimal` with a large number of digits or a large exponent, it could lead to significant memory usage due to a call to `'{:f}'.format()`. To avoid this, decimals with more than 200 digits are now formatted using scientific notation.

**Bugfixes**

- Made the `obj` argument of `InlineModelAdmin.has_add_permission()` optional to restore backwards compatibility with third-party code that doesn’t provide it (#30097).

Django 2.1.5 release notes

January 4, 2019

Django 2.1.5 fixes a security issue and several bugs in 2.1.4.

CVE-2019-3498: Content spoofing possibility in the default 404 page

An attacker could craft a malicious URL that could make spoofed content appear on the default page generated by the `django.views.defaults.page_not_found()` view.

The URL path is no longer displayed in the default 404 template and the `request_path` context variable is now quoted to fix the issue for custom templates that use the path.

**Bugfixes**

- Fixed compatibility with `mysqlclient` 1.3.14 (#30013).
- Fixed a schema corruption issue on SQLite 3.26+. You might have to drop and rebuild your SQLite database if you applied a migration while using an older version of Django with SQLite 3.26 or later (#29182).
- Prevented SQLite schema alterations while foreign key checks are enabled to avoid the possibility of schema corruption (#30023).
- Fixed a regression in Django 2.1.4 (which enabled keep-alive connections) where request body data isn’t properly consumed for such connections (#30015).
- Fixed a regression in Django 2.1.4 where `InlineModelAdmin.has_change_permission()` is incorrectly called with a non-`None` `obj` argument during an object add (#30050).
Django 2.1.4 release notes

December 3, 2018

Django 2.1.4 fixes several bugs in 2.1.3.

Bugfixes

- Corrected the default password list that CommonPasswordValidator uses by lowercasing all passwords to match the format expected by the validator (#29952).
- Prevented repetitive calls to geos_version_tuple() in the WKBWriter class in an attempt to fix a random crash involving LooseVersion (#29959).
- Fixed keep-alive support in runserver after it was disabled to fix another issue in Django 2.0 (#29849).
- Fixed admin view-only change form crash when using ModelAdmin.prepopulated_fields (#29929).
- Fixed “Please correct the errors below” error message when editing an object in the admin if the user only has the “view” permission on inlines (#29930).

Django 2.1.3 release notes

November 1, 2018

Django 2.1.3 fixes several bugs in 2.1.2.

Bugfixes

- Fixed a regression in Django 2.0 where combining Q objects with __in lookups and lists crashed (#29838).
- Fixed a regression in Django 1.11 where django-admin shell may hang on startup (#29774).
- Fixed a regression in Django 2.0 where test databases aren’t reused with manage.py test --keepdb on MySQL (#29827).
- Fixed a regression where cached foreign keys that use to_field were incorrectly cleared in Model.save() (#29896).
- Fixed a regression in Django 2.0 where FileSystemStorage crashes with FileExistsError if concurrent saves try to create the same directory (#29890).
Django 2.1.2 release notes

October 1, 2018

Django 2.1.2 fixes a security issue and several bugs in 2.1.1. Also, the latest string translations from Transifex are incorporated.

**CVE-2018-16984: Password hash disclosure to “view only” admin users**

If an admin user has the change permission to the user model, only part of the password hash is displayed in the change form. Admin users with the view (but not change) permission to the user model were displayed the entire hash. While it’s typically infeasible to reverse a strong password hash, if your site uses weaker password hashing algorithms such as MD5 or SHA1, it could be a problem.

**Bugfixes**

- Fixed a regression where nonexistent joins in \( F() \) no longer raised `FieldError` (#29727).
- Fixed a regression where files starting with a tilde or underscore weren’t ignored by the migrations loader (#29749).
- Made migrations detect changes to `Meta.default_related_name` (#29755).
- Added compatibility for `cx_Oracle` 7 (#29759).
- Fixed a regression in Django 2.0 where unique index names weren’t quoted (#29778).
- Fixed a regression where sliced queries with multiple columns with the same name crashed on Oracle 12.1 (#29630).
- Fixed a crash when a user with the view (but not change) permission made a POST request to an admin user change form (#29809).

Django 2.1.1 release notes

August 31, 2018

Django 2.1.1 fixes several bugs in 2.1.
Bugfixes

- Fixed a race condition in `QuerySet.update_or_create()` that could result in data loss (#29499).
- Fixed a regression where `QueryDict.urlencode()` crashed if the dictionary contains a non-string value (#29627).
- Fixed a regression in Django 2.0 where using `manage.py test --keepdb` fails on PostgreSQL if the database exists and the user doesn’t have permission to create databases (#29613).
- Fixed a regression in Django 2.0 where combining Q objects with __in lookups and lists crashed (#29643).
- Fixed translation failure of DurationField’s “overflow” error message (#29623).
- Fixed a regression where the admin change form crashed if the user doesn’t have the ‘add’ permission to a model that uses `TabularInline` (#29637).
- Fixed a regression where a related_query_name reverse accessor wasn’t set up when a `GenericRelation` is declared on an abstract base model (#29653).
- Fixed the test client’s JSON serialization of a request data dictionary for structured content type suffixes (#29662).
- Made the admin change view redirect to the changelist view after a POST if the user has the ‘view’ permission (#29663).
- Fixed admin change view crash for view-only users if the form has an extra form field (#29682).
- Fixed a regression in Django 2.0.5 where `QuerySet.values()` or `values_list()` after combining query-sets with `extra()` with `union()`, `difference()`, or `intersection()` crashed due to mismatching columns (#29694).
- Fixed crash if `InlineModelAdmin.has_add_permission()` doesn’t accept the obj argument (#29723).

Django 2.1 release notes

August 1, 2018

Welcome to Django 2.1!

These release notes cover the new features, as well as some backwards incompatible changes you’ll want to be aware of when upgrading from Django 2.0 or earlier. We’ve dropped some features that have reached the end of their deprecation cycle, and we’ve begun the deprecation process for some features.

See the How to upgrade Django to a newer version guide if you’re updating an existing project.
Python compatibility

Django 2.1 supports Python 3.5, 3.6, and 3.7. Django 2.0 is the last version to support Python 3.4. We highly recommend and only officially support the latest release of each series.

What’s new in Django 2.1

Model “view” permission

A “view” permission is added to the model `Meta.default_permissions`. The new permissions will be created automatically when running `migrate`.

This allows giving users read-only access to models in the admin. `ModelAdmin.has_view_permission()` is new. The implementation is backwards compatible in that there isn’t a need to assign the “view” permission to allow users who have the “change” permission to edit objects.

There are a couple of backwards incompatible considerations.

Minor features

django.contrib.admin

- `ModelAdmin.search_fields` now accepts any lookup such as `field__exact`.
- jQuery is upgraded from version 2.2.3 to 3.3.1.
- The new `ModelAdmin.delete_queryset()` method allows customizing the deletion process of the “delete selected objects” action.
- You can now override the default admin site.
- The new `ModelAdmin.sortable_by` attribute and `ModelAdmin.get_sortable_by()` method allow limiting the columns that can be sorted in the change list page.
- The `admin_order_field` attribute for elements in `ModelAdmin.list_display` may now be a query expression.
- The new `ModelAdmin.get_deleted_objects()` method allows customizing the deletion process of the delete view and the “delete selected” action.
- The `actions.html`, `change_list_results.html`, `date_hierarchy.html`, `pagination.html`, `prepopulated_fields_js.html`, `search_form.html`, and `submit_line.html` templates can now be overridden per app or per model (besides overridden globally).
- The admin change list and change form object tools can now be overridden per app, per model, or globally with `change_list_object_tools.html` and `change_form_object_tools.html` templates.
• `InlineModelAdmin.has_add_permission()` is now passed the parent object as the second positional argument, `obj`.

• Admin actions may now specify permissions to limit their availability to certain users.

django.contrib.auth

• `createsuperuser` now gives a prompt to allow bypassing the `AUTH_PASSWORD_VALIDATORS` checks.

django.contrib.gis

• The new `GEOSGeometry.buffer_with_style()` method is a version of `buffer()` that allows customizing the style of the buffer.

• `OpenLayersWidget` is now based on OpenLayers 4.6.5 (previously 3.20.1).

django.contrib.sessions

• Added the `SESSION_COOKIE_SAMESITE` setting to set the `SameSite` cookie flag on session cookies.

Cache

• The local-memory cache backend now uses a least-recently-used (LRU) culling strategy rather than a pseudo-random one.

• The new `touch()` method of the low-level cache API updates the timeout of cache keys.

CSRF

• Added the `CSRF_COOKIE_SAMESITE` setting to set the `SameSite` cookie flag on CSRF cookies.

Forms

• The widget for `ImageField` now renders with the HTML attribute `accept="image/*"`. 
Internationalization

- Added the `get_supported_language_variant()` function.
- Untranslated strings for territorial language variants now use the translations of the generic language. For example, untranslated `pt_BR` strings use `pt` translations.

Management Commands

- The new `inspectdb --include-views` option allows creating models for database views.
- The `BaseCommand` class now uses a custom help formatter so that the standard options like `--verbosity` or `--settings` appear last in the help output, giving a more prominent position to subclassed command’s options.

Migrations

- Added support for serialization of `functools.partialmethod` objects.
- To support frozen environments, migrations may be loaded from `.pyc` files.

Models

- Models can now use `__init_subclass__() from PEP 487`.
- A `BinaryField` may now be set to `editable=True` if you wish to include it in model forms.
- A number of new text database functions are added: `Chr, Left, LPad, LTrim, Ord, Repeat, Replace, Right, RPad, RTrim, and Trim`.
- The new `TruncWeek` function truncates `DateField` and `DateTimeField` to the Monday of a week.
- Query expressions can now be negated using a minus sign.
- `QuerySet.order_by()` and `distinct(*fields)` now support using field transforms.
- `BooleanField` can now be `null=True`. This is encouraged instead of `NullBooleanField`, which will likely be deprecated in the future.
- The new `QuerySet.explain()` method displays the database’s execution plan of a queryset’s query.
- `QuerySet.raw()` now supports `prefetch_related()`.
Requests and Responses

- Added `HttpRequest.get_full_path_info()`.
- Added the `samesite` argument to `HttpResponse.set_cookie()` to allow setting the `SameSite` cookie flag.
- The new `as_attachment` argument for `FileResponse` sets the `Content-Disposition` header to make the browser ask if the user wants to download the file. `FileResponse` also tries to set the `Content-Type` and `Content-Length` headers where appropriate.

Templates

- The new `json_script` filter safely outputs a Python object as JSON, wrapped in a `<script>` tag, ready for use with JavaScript.

Tests

- Added test `Client` support for 307 and 308 redirects.
- The test `Client` now serializes a request data dictionary as JSON if `content_type='application/json'`. You can customize the JSON encoder with test client’s `json_encoder` parameter.
- The new `SimpleTestCase.assertWarnsMessage()` method is a simpler version of `assertWarnsRegex()`.

Backwards incompatible changes in 2.1

Database backend API

This section describes changes that may be needed in third-party database backends.

- To adhere to PEP 249, exceptions where a database doesn’t support a feature are changed from `NotImplementedError` to `django.db.NotSupportedError`.
- Renamed the `allow_sliced_subqueries` database feature flag to `allow_sliced_subqueries_with_in`.
- `DatabaseOperations.distinct_sql()` now requires an additional `params` argument and returns a tuple of SQL and parameters instead of an SQL string.
- `DatabaseFeatures.introspected_boolean_field_type` is changed from a method to a property.
django.contrib.gis

- Support for SpatiaLite 4.0 is removed.

Dropped support for MySQL 5.5

The end of upstream support for MySQL 5.5 is December 2018. Django 2.1 supports MySQL 5.6 and higher.

Dropped support for PostgreSQL 9.3

The end of upstream support for PostgreSQL 9.3 is September 2018. Django 2.1 supports PostgreSQL 9.4 and higher.

Removed BCryptPasswordHasher from the default PASSWORD_HASHERS setting

If you used bcrypt with Django 1.4 or 1.5 (before BCryptSHA256PasswordHasher was added in Django 1.6), you might have some passwords that use the BCryptPasswordHasher hasher.

You can check if that’s the case like this:

```python
from django.contrib.auth import get_user_model
User = get_user_model()
User.objects.filter(password__startswith='bcrypt$$')
```

If you want to continue to allow those passwords to be used, you’ll have to define the PASSWORD_HASHERS setting (if you don’t already) and include 'django.contrib.auth.hashers.BCryptPasswordHasher'.

Moved wrap_label widget template context variable

To fix the lack of <label> when using RadioSelect and CheckboxSelectMultiple with MultiWidget, the wrap_label context variable now appears as an attribute of each option. For example, in a custom input_option.html template, change `{% if wrap_label %}` to `{% if widget.wrap_label %}`.

SameSite cookies

The cookies used for django.contrib.sessions, django.contrib.messages, and Django’s CSRF protection now set the SameSite flag to Lax by default. Browsers that respect this flag won’t send these cookies on cross-origin requests. If you rely on the old behavior, set the SESSION_COOKIE_SAMESITE and/or CSRF_COOKIE_SAMESITE setting to None.
Considerations for the new model “view” permission

Custom admin forms need to take the view-only case into account

With the new “view” permission, existing custom admin forms may raise errors when a user doesn’t have the change permission because the form might access nonexistent fields. Fix this by overriding `ModelAdmin.get_form()` and checking if the user has the “change” permissions and returning the default form if not:

```python
class MyAdmin(admin.ModelAdmin):
    def get_form(self, request, obj=None, **kwargs):
        if not self.has_change_permission(request, obj):
            return super().get_form(request, obj, **kwargs)
        return CustomForm
```

New default view permission could allow unwanted access to admin views

If you have a custom permission with a codename of the form `view_<modelname>`, the new view permission handling in the admin will allow view access to the changelist and detail pages for those models. If this is unwanted, you must change your custom permission codename.

Miscellaneous

- The minimum supported version of `mysqlclient` is increased from 1.3.3 to 1.3.7.
- Support for SQLite < 3.7.15 is removed.
- The date format of `Set-Cookie`’s `Expires` directive is changed to follow RFC 7231#section-7.1.1 instead of Netscape’s cookie standard. Hyphens present in dates like Thu, 25-Dec-2018 22:26:13 GMT are removed. This change should be merely cosmetic except perhaps for antiquated browsers that don’t parse the new format.
- `allowed_hosts` is now a required argument of private API `django.utils.http.is_safe_url()`.
- The `multiple` attribute rendered by the `SelectMultiple` widget now uses HTML5 boolean syntax rather than XHTML’s `multiple="multiple"`.
- HTML rendered by form widgets no longer includes a closing slash on void elements, e.g. `<br>`. This is incompatible within XHTML, although some widgets already used aspects of HTML5 such as boolean attributes.
- The value of `SelectDateWidget`’s empty options is changed from 0 to an empty string, which mainly may require some adjustments in tests that compare HTML.
- `User.has_usable_password()` and the `is_password_usable()` function no longer return `False` if the password is `None` or an empty string, or if the password uses a hasher that’s not in the
**PASSWORD_HASHERS** setting. This undocumented behavior was a regression in Django 1.6 and prevented users with such passwords from requesting a password reset. Audit your code to confirm that your usage of these APIs don’t rely on the old behavior.

- Since migrations are now loaded from .pyc files, you might need to delete them if you’re working in a mixed Python 2 and Python 3 environment.

- Using `None` as a `django.contrib.postgres.fields.JSONField` lookup value now matches objects that have the specified key and a null value rather than objects that don’t have the key.

- The admin CSS class `field-box` is renamed to `fieldBox` to prevent conflicts with the class given to model fields named “box”.

- Since the admin’s actions.html, change_list_results.html, date_hierarchy.html, pagination.html, prepopulated_fields_js.html, search_form.html, and submit_line.html templates can now be overridden per app or per model, you may need to rename existing templates with those names that were written for a different purpose.

- `QuerySet.raw()` now caches its results like regular querysets. Use `iterator()` if you don’t want caching.

- The database router `allow_relation()` method is called in more cases. Improperly written routers may need to be updated accordingly.

- Translations are no longer deactivated before running management commands. If your custom command requires translations to be deactivated (for example, to insert untranslated content into the database), use the new `@no_translations` decorator.

- Management commands no longer allow the abbreviated forms of the `--settings` and `--pythonpath` arguments.

- The private `django.db.models.sql.constants.QUERY_TERMS` constant is removed. The `get_lookup()` and `get_lookups()` methods of the Lookup Registration API may be suitable alternatives. Compared to the `QUERY_TERMS` constant, they allow your code to also account for any custom lookups that have been registered.

- Compatibility with `py-bcrypt` is removed as it’s unmaintained. Use `bcrypt` instead.

**Features deprecated in 2.1**

**Miscellaneous**

- The ForceRHR GIS function is deprecated in favor of the new `ForcePolygonCW` function.

- `django.utils.http.cookie_date()` is deprecated in favor of `http_date()`, which follows the format of the latest RFC.

- `{% load staticfiles %}` and `{% load admin_static %}` are deprecated in favor of `{% load static %}`, which works the same.
• `django.contrib.staticfiles.templatetags.static()` is deprecated in favor of `django.templatetags.static.static()`.

• Support for `InlineModelAdmin.has_add_permission()` methods that don’t accept `obj` as the second positional argument will be removed in Django 3.0.

**Features removed in 2.1**

These features have reached the end of their deprecation cycle and are removed in Django 2.1. See [Features deprecated in 1.11](https://docs.djangoproject.com/en/4.2/releases/2.1/) for details, including how to remove usage of these features.

• `contrib.auth.views.login()`, `logout()`, `password_change()`, `password_change_done()`, `password_reset()`, `password_reset_done()`, `password_reset_confirm()`, and `password_reset_complete()` are removed.

• The `extra_context` parameter of `contrib.auth.views.logout_then_login()` is removed.

• `django.test.runner.setup_databases()` is removed.

• `django.utils.translation.string_concat()` is removed.

• `django.core.cache.backends.memcached.PyLibMCCache` no longer supports passing `pylibmc` behavior settings as top-level attributes of `OPTIONS`.

• The `host` parameter of `django.utils.http.is_safe_url()` is removed.

• Silencing of exceptions raised while rendering the `{% include %}` template tag is removed.

• `DatabaseIntrospection.get_indexes()` is removed.

• The `authenticate()` method of authentication backends requires `request` as the first positional argument.

• The `django.db.models.permalink()` decorator is removed.

• The `USE_ETAGS` setting is removed. `CommonMiddleware` and `django.utils.cache.patch_response_headers()` no longer set ETags.

• The `Model._meta.has_auto_field` attribute is removed.

• `url()`’s support for inline flags in regular expression groups (`(?i)`, `(?L)`, `(?m)`, `(?s)`, and `(?u)`) is removed.

• Support for `Widget.render()` methods without the `renderer` argument is removed.
9.1.9 2.0 release

Django 2.0.13 release notes

February 12, 2019

Django 2.0.13 fixes a regression in 2.0.12/2.0.11.

**Bugfixes**

- Fixed crash in `django.utils.numberformat.format_number()` when the number has over 200 digits (#30177).

Django 2.0.12 release notes

February 11, 2019

Django 2.0.12 fixes a packaging error in 2.0.11.

**Bugfixes**

- Corrected packaging error from 2.0.11 (#30175).

Django 2.0.11 release notes

February 11, 2019

Django 2.0.11 fixes a security issue in 2.0.10.

**CVE-2019-6975: Memory exhaustion in `django.utils.numberformat.format()`**

If `django.utils.numberformat.format()` -used by contrib.admin as well as the floatformat, filesizeformat, and intcomma templates filters -received a Decimal with a large number of digits or a large exponent, it could lead to significant memory usage due to a call to `'{:f}'.format()`.

To avoid this, decimals with more than 200 digits are now formatted using scientific notation.
Django 2.0.10 release notes

January 4, 2019

Django 2.0.10 fixes a security issue and several bugs in 2.0.9.

CVE-2019-3498: Content spoofing possibility in the default 404 page

An attacker could craft a malicious URL that could make spoofed content appear on the default page generated by the `django.views.defaults.page_not_found()` view.

The URL path is no longer displayed in the default 404 template and the `request_path` context variable is now quoted to fix the issue for custom templates that use the path.

Bugfixes

- Prevented repetitive calls to `geos_version_tuple()` in the `WKBWriter` class in an attempt to fix a random crash involving ` LooseVersion` since Django 2.0.6 (#29959).
- Fixed a schema corruption issue on SQLite 3.26+. You might have to drop and rebuild your SQLite database if you applied a migration while using an older version of Django with SQLite 3.26 or later (#29182).
- Prevented SQLite schema alterations while foreign key checks are enabled to avoid the possibility of schema corruption (#30023).

Django 2.0.9 release notes

October 1, 2018

Django 2.0.9 fixes a data loss bug in 2.0.8.

Bugfixes

- Fixed a race condition in `QuerySet.update_or_create()` that could result in data loss (#29499).
Django 2.0.8 release notes

August 1, 2018

Django 2.0.8 fixes a security issue and several bugs in 2.0.7.

**CVE-2018-14574: Open redirect possibility in CommonMiddleware**

If the `CommonMiddleware` and the `APPEND_SLASH` setting are both enabled, and if the project has a URL pattern that accepts any path ending in a slash (many content management systems have such a pattern), then a request to a maliciously crafted URL of that site could lead to a redirect to another site, enabling phishing and other attacks.

`CommonMiddleware` now escapes leading slashes to prevent redirects to other domains.

**Bugfixes**

- Fixed a regression in Django 2.0.7 that broke the `regex` lookup on MariaDB (even though MariaDB isn’t officially supported) (#29544).
- Fixed a regression where `django.template.Template` crashed if the `template_string` argument is lazy (#29617).

Django 2.0.7 release notes

July 2, 2018

Django 2.0.7 fixes several bugs in 2.0.6.

**Bugfixes**

- Fixed admin changelist crash when using a query expression without `asc()` or `desc()` in the page’s ordering (#29428).
- Fixed admin check crash when using a query expression in `ModelAdmin.ordering` (#29428).
- Fixed `_regex` and `_iregex` lookups with MySQL 8 (#29451).
- Fixed migrations crash with namespace packages on Python 3.7 (#28814).
Django 2.0.6 release notes

June 1, 2018

Django 2.0.6 fixes several bugs in 2.0.5.

Bugfixes

- Fixed a regression that broke custom template filters that use decorators (#29400).
- Fixed detection of custom URL converters in included patterns (#29415).
- Fixed a regression that added an unnecessary subquery to the GROUP BY clause on MySQL when using a RawSQL annotation (#29416).
- Fixed WKBWriter.write() and write_hex() for empty polygons on GEOS 3.6.1+ (#29460).
- Fixed a regression in Django 1.10 that could result in large memory usage when making edits using ModelAdmin.list_editable (#28462).

Django 2.0.5 release notes

May 1, 2018

Django 2.0.5 fixes several bugs in 2.0.4.

Bugfixes

- Corrected the import paths that inspectdb generates for django.contrib.postgres fields (#29307).
- Fixed a regression in Django 1.11.8 where altering a field with a unique constraint may drop and rebuild more foreign keys than necessary (#29193).
- Fixed crashes in django.contrib.admindocs when a view is a callable object, such as django.contrib.syndication.views.Feed (#29296).
- Fixed a regression in Django 2.0.4 where QuerySet.values() or values_list() after combining an annotated and unannotated queryset with union(), difference(), or intersection() crashed due to mismatching columns (#29286).
Django 2.0.4 release notes

April 2, 2018

Django 2.0.4 fixes several bugs in 2.0.3.

Bugfixes

- Fixed a crash when filtering with an `Exists()` annotation of a queryset containing a single field (#29195).
- Fixed admin autocomplete widget’s translations for zh-hans and zh-hant languages (#29213).
- Corrected admin’s autocomplete widget to add a space after custom classes (#29221).
- Fixed `PasswordResetConfirmView` crash when using a user model with a UUIDField primary key and the reset URL contains an encoded primary key value that decodes to an invalid UUID (#29206).
- Fixed a regression in Django 1.11.8 where combining two annotated `values_list()` querysets with `union()`, `difference()`, or `intersection()` crashed due to mismatching columns (#29229).
- Fixed a regression in Django 1.11 where an empty choice could be initially selected for the `SelectMultiple` and `CheckboxSelectMultiple` widgets (#29273).
- Fixed a regression in Django 2.0 where `OpenLayersWidget` deserialization ignored the widget map’s SRID and assumed 4326 (WGS84) (#29116).

Django 2.0.3 release notes

March 6, 2018

Django 2.0.3 fixes two security issues and several bugs in 2.0.2. Also, the latest string translations from Transifex are incorporated.

CVE-2018-7536: Denial-of-service possibility in `urlize` and `urlizetrunc` template filters

The `django.utils.html.urlize()` function was extremely slow to evaluate certain inputs due to catastrophic backtracking vulnerabilities in two regular expressions. The `urlize()` function is used to implement the `urlize` and `urlizetrunc` template filters, which were thus vulnerable.

The problematic regular expressions are replaced with parsing logic that behaves similarly.
CVE-2018-7537: Denial-of-service possibility in truncatechars_html and truncatewords_html template filters

If django.utils.text.Truncator’s chars() and words() methods were passed the html=True argument, they were extremely slow to evaluate certain inputs due to a catastrophic backtracking vulnerability in a regular expression. The chars() and words() methods are used to implement the truncatechars_html and truncatewords_html template filters, which were thus vulnerable.

The backtracking problem in the regular expression is fixed.

Bugfixes

- Fixed a regression that caused sliced QuerySet.distinct().order_by() followed by count() to crash (#29108).
- Prioritized the datetime and time input formats without %f for the Thai locale to fix the admin time picker widget displaying “undefined” (#29109).
- Fixed crash with QuerySet.order_by(Exists(...)) (#29118).
- Made Q.deconstruct() deterministic with multiple keyword arguments (#29125). You may need to modify Q’s in existing migrations, or accept an autogenerated migration.
- Fixed a regression where a when() expression with a list argument crashes (#29166).
- Fixed crash when using a Window() expression in a subquery (#29172).
- Fixed AbstractBaseUser.normalize_username() crash if the username argument isn’t a string (#29176).

Django 2.0.2 release notes

February 1, 2018

Django 2.0.2 fixes a security issue and several bugs in 2.0.1.

CVE-2018-6188: Information leakage in AuthenticationForm

A regression in Django 1.11.8 made AuthenticationForm run its confirm_login_allowed() method even if an incorrect password is entered. This can leak information about a user, depending on what messages confirm_login_allowed() raises. If confirm_login_allowed() isn’t overridden, an attacker enter an arbitrary username and see if that user has been set to is_active=False. If confirm_login_allowed() is overridden, more sensitive details could be leaked.

This issue is fixed with the caveat that AuthenticationForm can no longer raise the “This account is inactive.” error if the authentication backend rejects inactive users (the default authentication backend, ModelBackend,
has done that since Django 1.10). This issue will be revisited for Django 2.1 as a fix to address the caveat will likely be too invasive for inclusion in older versions.

**Bugfixes**

- Fixed hidden content at the bottom of the “The install worked successfully!” page for some languages (#28885).
- Fixed incorrect foreign key nullification if a model has two foreign keys to the same model and a target model is deleted (#29016).
- Fixed regression in the use of `QuerySet.values_list(...)`, `flat=True` followed by `annotate()` (#29067).
- Fixed a regression where a queryset that annotates with geometry objects crashes (#29054).
- Fixed a regression where `contrib.auth.authenticate()` crashes if an authentication backend doesn’t accept `request` and a later one does (#29071).
- Fixed a regression where `makemigrations` crashes if a migrations directory doesn’t have an `__init__.py` file (#29091).
- Fixed crash when entering an invalid uuid in `ModelAdmin.raw_id_fields` (#29094).

**Django 2.0.1 release notes**

January 1, 2018

Django 2.0.1 fixes several bugs in 2.0.

**Bugfixes**

- Fixed a regression in Django 1.11 that added newlines between `MultiWidget`’s subwidgets (#28890).
- Fixed incorrect class-based model index name generation for models with quoted `db_table` (#28876).
- Fixed incorrect foreign key constraint name for models with quoted `db_table` (#28876).
- Fixed a regression in caching of a `GenericForeignKey` when the referenced model instance uses more than one level of multi-table inheritance (#28856).
- Reallowed filtering a queryset with `GeometryField=None` (#28896).
- Corrected admin check to allow a `OneToOneField` in `ModelAdmin.autocomplete_fields` (#28898).
- Fixed a regression on SQLite where `DecimalField` returned a result with trailing zeros in the fractional part truncated (#28915).
- Fixed crash in the `testserver` command startup (#28941).
• Fixed crash when coercing a translatable URL pattern to `str` (#28947).
• Fixed crash on SQLite when renaming a field in a model referenced by a `ManyToManyField` (#28884).
• Fixed a crash when chaining `values()` or `values_list()` after `QuerySet.select_for_update(of=..)` (#28944).
• Fixed admin changelist crash when using a query expression in the page’s ordering (#28958).

**Django 2.0 release notes**

December 2, 2017

Welcome to Django 2.0!

These release notes cover the new features, as well as some backwards incompatible changes you’ll want to be aware of when upgrading from Django 1.11 or earlier. We’ve dropped some features that have reached the end of their deprecation cycle, and we’ve begun the deprecation process for some features.

This release starts Django’s use of a loose form of semantic versioning, but there aren’t any major backwards incompatible changes that might be expected of a 2.0 release. Upgrading should be a similar amount of effort as past feature releases.

See the How to upgrade Django to a newer version guide if you’re updating an existing project.

**Python compatibility**

Django 2.0 supports Python 3.4, 3.5, 3.6, and 3.7. We highly recommend and only officially support the latest release of each series.

The Django 1.11.x series is the last to support Python 2.7.

Django 2.0 will be the last release series to support Python 3.4. If you plan a deployment of Python 3.4 beyond the end-of-life for Django 2.0 (April 2019), stick with Django 1.11 LTS (supported until April 2020) instead. Note, however, that the end-of-life for Python 3.4 is March 2019.

**Third-party library support for older version of Django**

Following the release of Django 2.0, we suggest that third-party app authors drop support for all versions of Django prior to 1.11. At that time, you should be able to run your package’s tests using `python -Wd` so that deprecation warnings do appear. After making the deprecation warning fixes, your app should be compatible with Django 2.0.
What’s new in Django 2.0

Simplified URL routing syntax

The new `django.urls.path()` function allows a simpler, more readable URL routing syntax. For example, this example from previous Django releases:

```python
url(r'^articles/(?P<year>[0-9]{4})/$', views.year_archive),
```

could be written as:

```python
path('articles/<int:year>/', views.year_archive),
```

The new syntax supports type coercion of URL parameters. In the example, the view will receive the `year` keyword argument as an integer rather than as a string. Also, the URLs that will match are slightly less constrained in the rewritten example. For example, the year 10000 will now match since the year integers aren’t constrained to be exactly four digits long as they are in the regular expression.

The `django.conf.urls.url()` function from previous versions is now available as `django.urls.re_path()`. The old location remains for backwards compatibility, without an imminent deprecation. The old `django.conf.urls.include()` function is now importable from `django.urls` so you can use `from django.urls import include, path, re_path` in your URLconf.

The URL dispatcher document is rewritten to feature the new syntax and provide more details.

Mobile-friendly contrib.admin

The admin is now responsive and supports all major mobile devices. Older browsers may experience varying levels of graceful degradation.

Window expressions

The new `Window` expression allows adding an `OVER` clause to querysets. You can use window functions and aggregate functions in the expression.

Minor features

django.contrib.admin

- The new `ModelAdmin.autocomplete_fields` attribute and `ModelAdmin.get_autocomplete_fields()` method allow using a Select2 search widget for ForeignKey and ManyToManyField.
django.contrib.auth

- The default iteration count for the PBKDF2 password hasher is increased from 36,000 to 100,000.

django.contrib.gis

- Added MySQL support for the `AsGeoJSON` function, `GeoHash` function, `IsValid` function, `isvalid` lookup, and distance lookups.
- Added the `Azimuth` and `LineLocatePoint` functions, supported on PostGIS and SpatiaLite.
- Any `GEOSGeometry` imported from GeoJSON now has its SRID set.
- Added the `OSMWidget.default_zoom` attribute to customize the map’s default zoom level.
- Made metadata readable and editable on rasters through the `metadata`, `info`, and `metadata` attributes.
- Allowed passing driver-specific creation options to `GDALRaster` objects using `papsz_options`.
- Allowed creating `GDALRaster` objects in GDAL’s internal virtual filesystem. Rasters can now be created from and converted to binary data in-memory.
- The new `GDALBand.color_interp()` method returns the color interpretation for the band.

django.contrib.postgres

- The new `distinct` argument for `ArrayAgg` determines if concatenated values will be distinct.
- The new `RandomUUID` database function returns a version 4 UUID. It requires use of PostgreSQL’s `pgcrypto` extension which can be activated using the new `CryptoExtension` migration operation.
- `django.contrib.postgres.indexes.GinIndex` now supports the `fastupdate` and `gin_pending_list_limit` parameters.
- The new `GistIndex` class allows creating GiST indexes in the database. The new `BtreeGistExtension` migration operation installs the `btree_gist` extension to add support for operator classes that aren’t built-in.
- `inspectdb` can now introspect `JSONField` and various `RangeFields` (django.contrib.postgres must be in `INSTALLED_APPS`).
django.contrib.sitemaps

- Added the protocol keyword argument to the `GenericSitemap` constructor.

Cache

- `cache.set_many()` now returns a list of keys that failed to be inserted. For the built-in backends, failed inserts can only happen on memcached.

File Storage

- `File.open()` can be used as a context manager, e.g. with `with file.open() as f:`.

Forms

- The new `date_attrs` and `time_attrs` arguments for `SplitDateTimeWidget` and `SplitHiddenDateTimeWidget` allow specifying different HTML attributes for the `DateInput` and `TimeInput` (or hidden) subwidgets.
- The new `Form.errors.get_json_data()` method returns form errors as a dictionary suitable for including in a JSON response.

Generic Views

- The new `ContextMixin.extra_context` attribute allows adding context in `View.as_view()`.

Management Commands

- `inspectdb` now translates MySQL’s unsigned integer columns to `PositiveIntegerField` or `PositiveSmallIntegerField`.
- The new `makemessages --add-location` option controls the comment format in `.po` files.
- `loaddata` can now read from stdin.
- The new `diffsettings --output` option allows formatting the output in a unified diff format.
- On Oracle, `inspectdb` can now introspect `AutoField` if the column is created as an identity column.
- On MySQL, `dbshell` now supports client-side TLS certificates.
Migrations

- The new `squashmigrations` `--squashed-name` option allows naming the squashed migration.

Models

- The new `StrIndex` database function finds the starting index of a string inside another string.
- On Oracle, `AutoField` and `BigAutoField` are now created as *identity columns*.
- The new `chunk_size` parameter of `QuerySet.iterator()` controls the number of rows fetched by the Python database client when streaming results from the database. For databases that don’t support server-side cursors, it controls the number of results Django fetches from the database adapter.
- `QuerySet.earliest()`, `QuerySet.latest()`, and `Meta.get_latest_by` now allow ordering by several fields.
- Added the `ExtractQuarter` function to extract the quarter from `DateField` and `DateTimeField`, and exposed it through the `quarter` lookup.
- Added the `TruncQuarter` function to truncate `DateField` and `DateTimeField` to the first day of a quarter.
- Added the `db_tablespace` parameter to class-based indexes.
- If the database supports a native duration field (Oracle and PostgreSQL), `Extract` now works with `DurationField`.
- Added the `of` argument to `QuerySet.select_for_update()`, supported on PostgreSQL and Oracle, to lock only rows from specific tables rather than all selected tables. It may be helpful particularly when `select_for_update()` is used in conjunction with `select_related()`.
- The new `field_name` parameter of `QuerySet.in_bulk()` allows fetching results based on any unique model field.
- `CursorWrapper.callproc()` now takes an optional dictionary of keyword parameters, if the backend supports this feature. Of Django’s built-in backends, only Oracle supports it.
- The new `connection.execute_wrapper()` method allows installing wrappers around execution of database queries.
- The new `filter` argument for built-in aggregates allows adding different conditionals to multiple aggregations over the same fields or relations.
- Added support for expressions in `Meta.ordering`.
- The new `named` parameter of `QuerySet.values_list()` allows fetching results as named tuples.
- The new `FilteredRelation` class allows adding an ON clause to querysets.
Pagination

- Added `Paginator.get_page()` to provide the documented pattern of handling invalid page numbers.

Requests and Responses

- The `runserver` web server supports HTTP 1.1.

Templates

- To increase the usefulness of `Engine.get_default()` in third-party apps, it now returns the first engine if multiple DjangoTemplates engines are configured in `TEMPLATES` rather than raising `ImproperlyConfigured`.
- Custom template tags may now accept keyword-only arguments.

Tests

- Added threading support to `LiveServerTestCase`.
- Added settings that allow customizing the test tablespace parameters for Oracle: `DATAFILE_SIZE`, `DATAFILE_TMP_SIZE`, `DATAFILE_EXTSIZE`, and `DATAFILE_TMP_EXTSIZE`.

Validators

- The new `ProhibitNullCharactersValidator` disallows the null character in the input of the `CharField` form field and its subclasses. Null character input was observed from vulnerability scanning tools. Most databases silently discard null characters, but psycopg2 2.7+ raises an exception when trying to save a null character to a char/text field with PostgreSQL.

Backwards incompatible changes in 2.0

Removed support for bytestrings in some places

To support native Python 2 strings, older Django versions had to accept both bytestings and Unicodes strings. Now that Python 2 support is dropped, bytestings should only be encountered around input/output boundaries (handling of binary fields or HTTP streams, for example). You might have to update your code to limit bytestring usage to a minimum, as Django no longer accepts bytestings in certain code paths. Python’s `-b` option may help detect that mistake in your code.

For example, `reverse()` now uses `str()` instead of `force_text()` to coerce the `args` and `kwargs` it receives, prior to their placement in the URL. For bytestings, this creates a string with an undesired `b` prefix as well.
as additional quotes (\texttt{str(b\textquotesingle foo\textquotesingle)} is "b\textquotesingle foo\textquotesingle"). To adapt, call \texttt{decode()} on the bytestring before passing it to \texttt{reverse()}.

**Database backend API**

This section describes changes that may be needed in third-party database backends.

- The \texttt{DatabaseOperations.datetime_cast_date_sql()}, \texttt{datetime_cast_time_sql()}, \texttt{datetime_trunc_sql()}, \texttt{datetime_extract_sql()}, and \texttt{date_interval_sql()} methods now return only the SQL to perform the operation instead of SQL and a list of parameters.

- Third-party database backends should add a \texttt{DatabaseWrapper.display_name} attribute with the name of the database that your backend works with. Django may use it in various messages, such as in system checks.

- The first argument of \texttt{SchemaEditor\_alter_column_type_sql()} is now \texttt{model} rather than \texttt{table}.

- The first argument of \texttt{SchemaEditor\_create_index_name()} is now \texttt{table_name} rather than \texttt{model}.

- To enable \texttt{FOR UPDATE OF} support, set \texttt{DatabaseFeatures.has_select_for_update_of = True}. If the database requires that the arguments to \texttt{OF} be columns rather than tables, set \texttt{DatabaseFeatures.select_for_update_of_column = True}.

- To enable support for \textit{Window} expressions, set \texttt{DatabaseFeatures.supports_over_clause} to \texttt{True}. You may need to customize the \texttt{DatabaseOperations.window_start_rows_start_end()} and/or \texttt{window_start_range_start_end()} methods.

- Third-party database backends should add a \texttt{DatabaseOperations.cast_char_field_without_max_length} attribute with the database data type that will be used in the \texttt{Cast} function for a \texttt{CharField} if the \texttt{max_length} argument isn’t provided.

- The first argument of \texttt{DatabaseCreation\_clone_test_db()} and \texttt{get_test_db_clone_settings()} is now \texttt{suffix} rather than \texttt{number} (in case you want to rename the signatures in your backend for consistency). \texttt{django.test} also now passes those values as strings rather than as integers.

- Third-party database backends should add a \texttt{DatabaseIntrospection.get_sequences()} method based on the stub in \texttt{BaseDatabaseIntrospection}.

**Dropped support for Oracle 11.2**

The end of upstream support for Oracle 11.2 is Dec. 2020. Django 1.11 will be supported until April 2020 which almost reaches this date. Django 2.0 officially supports Oracle 12.1+.
**Default MySQL isolation level is read committed**

MySQL’s default isolation level, repeatable read, may cause data loss in typical Django usage. To prevent that and for consistency with other databases, the default isolation level is now read committed. You can use the `DATABASES` setting to use a different isolation level, if needed.

**AbstractUser.last_name max_length increased to 150**

A migration for `django.contrib.auth.models.User.last_name` is included. If you have a custom user model inheriting from `AbstractUser`, you’ll need to generate and apply a database migration for your user model.

If you want to preserve the 30 character limit for last names, use a custom form:

```python
from django.contrib.auth.forms import UserChangeForm

class MyUserChangeForm(UserChangeForm):
    last_name = forms.CharField(max_length=30, required=False)
```

If you wish to keep this restriction in the admin when editing users, set `UserAdmin.form` to use this form:

```python
from django.contrib.auth.admin import UserAdmin
from django.contrib.auth.models import User

class MyUserAdmin(UserAdmin):
    form = MyUserChangeForm

admin.site.unregister(User)
admin.site.register(User, MyUserAdmin)
```

**QuerySet.reverse() and last() are prohibited after slicing**

Calling `QuerySet.reverse()` or `last()` on a sliced queryset leads to unexpected results due to the slice being applied after reordering. This is now prohibited, e.g.:

```python
>>> Model.objects.all()[2].reverse()
Traceback (most recent call last):
...
TypeError: Cannot reverse a query once a slice has been taken.
```
Form fields no longer accept optional arguments as positional arguments

To help prevent runtime errors due to incorrect ordering of form field arguments, optional arguments of built-in form fields are no longer accepted as positional arguments. For example:

```python
forms.IntegerField(25, 10)
```

raises an exception and should be replaced with:

```python
forms.IntegerField(max_value=25, min_value=10)
```

call_command() validates the options it receives

call_command() now validates that the argument parser of the command being called defines all of the options passed to call_command().

For custom management commands that use options not created using parser.add_argument(), add a stealth_options attribute on the command:

```python
class MyCommand(BaseCommand):
    stealth_options = ('option_name', ...)
```

Indexes no longer accept positional arguments

For example:

```python
models.Index([‘headline’, ‘-pub_date’], ‘index_name’)
```

raises an exception and should be replaced with:

```python
models.Index(fields=[‘headline’, ‘-pub_date’], name=’index_name’)
```

Foreign key constraints are now enabled on SQLite

This will appear as a backwards-incompatible change (IntegrityError: FOREIGN KEY constraint failed) if attempting to save an existing model instance that’s violating a foreign key constraint.

Foreign keys are now created with DEFERRABLE INITIALLY DEFERRED instead of DEFERRABLE IMMEDIATE. Thus, tables may need to be rebuilt to recreate foreign keys with the new definition, particularly if you’re using a pattern like this:
from django.db import transaction

with transaction.atomic():
    Book.objects.create(author_id=1)
    Author.objects.create(id=1)

If you don’t recreate the foreign key as `DEFERRED`, the first `create()` would fail now that foreign key constraints are enforced.

Backup your database first! After upgrading to Django 2.0, you can then rebuild tables using a script similar to this:

```python
from django.apps import apps
from django.db import connection

for app in apps.get_app_configs():
    for model in app.get_models(include_auto_created=True):
        if model._meta.managed and not (model._meta.proxy or model._meta.swapped):
            for base in model.__bases__:
                if hasattr(base, '_meta'):
                    base._meta.local_many_to_many = []
            model._meta.local_many_to_many = []
            with connection.schema_editor() as editor:
                editor._remake_table(model)
```

This script hasn’t received extensive testing and needs adaption for various cases such as multiple databases. Feel free to contribute improvements.

In addition, because of a table alteration limitation of SQLite, it’s prohibited to perform `RenameModel` and `RenameField` operations on models or fields referenced by other models in a transaction. In order to allow migrations containing these operations to be applied, you must set the `Migration.atomic` attribute to `False`.

**Miscellaneous**

- The `SessionAuthenticationMiddleware` class is removed. It provided no functionality since session authentication is unconditionally enabled in Django 1.10.

- The default HTTP error handlers (handler404, etc.) are now callables instead of dotted Python path strings. Django favors callable references since they provide better performance and debugging experience.

- `RedirectView` no longer silences `NoReverseMatch` if the `pattern_name` doesn’t exist.

- When `USE_L10N` is off, `FloatField` and `DecimalField` now respect `DECIMAL_SEPARATOR` and `THOUSAND_SEPARATOR` during validation. For example, with the settings:
an input of "1.345" is now converted to 1345 instead of 1.345.

- Subclasses of `AbstractBaseUser` are no longer required to implement `get_short_name()` and `get_full_name()`. (The base implementations that raise `NotImplementedError` are removed.) `django.contrib.admin` uses these methods if implemented but doesn’t require them. Third-party apps that use these methods may want to adopt a similar approach.

- The `FIRST_DAY_OF_WEEK` and `NUMBER_GROUPING` format settings are now kept as integers in JavaScript and JSON i18n view outputs.

- `assertNumQueries()` now ignores connection configuration queries. Previously, if a test opened a new database connection, those queries could be included as part of the `assertNumQueries()` count.

- The default size of the Oracle test tablespace is increased from 20M to 50M and the default autoextend size is increased from 10M to 25M.

- To improve performance when streaming large result sets from the database, `QuerySet.iterator()` now fetches 2000 rows at a time instead of 100. The old behavior can be restored using the `chunk_size` parameter. For example:

  ```python
  Book.objects.iterator(chunk_size=100)
  ```

- Providing unknown package names in the `packages` argument of the `JavaScriptCatalog` view now raises `ValueError` instead of passing silently.

- A model instance’s primary key now appears in the default `Model.__str__()` method, e.g. `Question object (1)`.

- `makemigrations` now detects changes to the model field `limit_choices_to` option. Add this to your existing migrations or accept an auto-generated migration for fields that use it.

- Performing queries that require `automatic spatial transformations` now raises `NotImplementedError` on MySQL instead of silently using non-transformed geometries.

- `django.core.exceptions.DjangoRuntimeWarning` is removed. It was only used in the cache backend as an intermediate class in `CacheKeyWarning`’s inheritance of `RuntimeWarning`.

- Renamed `BaseExpression._output_field` to `output_field`. You may need to update custom expressions.

- In older versions, forms and formsets combine their `Media` with widget `Media` by concatenating the two. The combining now tries to preserve the relative order of elements in each list. `MediaOrderConflictWarning` is issued if the order can’t be preserved.
• `django.contrib.gis.gdal.OGRException` is removed. It’s been an alias for `GDALException` since Django 1.8.

• Support for GEOS 3.3.x is dropped.

• The way data is selected for `GeometryField` is changed to improve performance, and in raw SQL queries, those fields must now be wrapped in `connection.ops.select`. See the Raw queries note in the GIS tutorial for an example.

Features deprecated in 2.0

**context argument of** `Field.from_db_value()` **and** `Expression.convert_value()`

The `context` argument of `Field.from_db_value()` and `Expression.convert_value()` is unused as it’s always an empty dictionary. The signature of both methods is now:

```
(self, value, expression, connection)
```

instead of:

```
(self, value, expression, connection, context)
```

Support for the old signature in custom fields and expressions remains until Django 3.0.

Miscellaneous

• The `django.db.backends.postgresql_psycopg2` module is deprecated in favor of `django.db.backends.postgresql`. It’s been an alias since Django 1.9. This only affects code that imports from the module directly. The `DATABASES` setting can still use `'django.db.backends.postgresql_psycopg2'`, though you can simplify that by using the `'django.db.backends.postgresql'` name added in Django 1.9.

• `django.shortcuts.render_to_response()` is deprecated in favor of `django.shortcuts.render()`. `render()` takes the same arguments except that it also requires a `request`.

• The `DEFAULT_CONTENT_TYPE` setting is deprecated. It doesn’t interact well with third-party apps and is obsolete since HTML5 has mostly superseded XHTML.

• `HttpRequest.xreadlines()` is deprecated in favor of iterating over the request.

• The `field_name` keyword argument to `QuerySet.earliest()` and `QuerySet.latest()` is deprecated in favor of passing the field names as arguments. Write `.earliest('pub_date')` instead of `.earliest(field_name='pub_date')`. 
Features removed in 2.0

These features have reached the end of their deprecation cycle and are removed in Django 2.0.

See Features deprecated in 1.9 for details on these changes, including how to remove usage of these features.

- The weak argument to `django.dispatch.signals.Signal.disconnect()` is removed.
- `django.db.backends.base.BaseDatabaseOperations.check_aggregate_support()` is removed.
- The `django.forms.extras` package is removed.
- The `assignment_tag` helper is removed.
- The host argument to `SimpleTestCase assertsRedirects()` is removed. The compatibility layer which allows absolute URLs to be considered equal to relative ones when the path is identical is also removed.
- `Field.rel` and `Field.remote_field.to` are removed.
- The on_delete argument for `ForeignKey` and `OneToOneField` is now required in models and migrations. Consider squashing migrations so that you have fewer of them to update.
- `django.db.models.fields.add_lazy_relation()` is removed.
- When time zone support is enabled, database backends that don’t support time zones no longer convert aware datetimes to naive values in UTC anymore when such values are passed as parameters to SQL queries executed outside of the ORM, e.g. with `cursor.execute()`.
- `django.contrib.auth.tests.utils.skipIfCustomUser()` is removed.
- The `GeoManager` and `GeoQuerySet` classes are removed.
- The `django.contrib.gis.geoip` module is removed.
- The `supports_recursion` check for template loaders is removed from:
  - `django.template.engine.Engine.find_template()`
  - `django.template.loader_tags.ExtendsNode.find_template()`
  - `django.template.loaders.base.Loader.supports_recursion()`
  - `django.template.loaders.cached.Loader.supports_recursion()`
- The `load_template` and `load_template_sources` template loader methods are removed.
- The `template_dirs` argument for template loaders is removed:
  - `django.template.loaders.base.Loader.get_template()`
  - `django.template.loaders.cached.Loader.cache_key()`
  - `django.template.loaders.cached.Loader.get_template()`
  - `django.template.loaders.cached.Loader.get_template_sources()`
Django Documentation, Release 4.2.dev20220706084552

- django.template.loaders.filesystem.Loader.get_template_sources()
- django.template.loaders.base.Loader.__call__() is removed.
- Support for custom error views that don’t accept an exception parameter is removed.
- The mime_type attribute of django.utils.feedgenerator.Atom1Feed and django.utils.feedgenerator.RssFeed is removed.
- The app_name argument to include() is removed.
- Support for passing a 3-tuple (including admin.site.urls) as the first argument to include() is removed.
- Support for setting a URL instance namespace without an application namespace is removed.
- Field._get_val_from_obj() is removed.
- django.template.loaders.eggs.Loader is removed.
- The current_app parameter to the contrib.auth function-based views is removed.
- The callable_obj keyword argument to SimpleTestCase.assertRaisesMessage() is removed.
- Support for the allow_tags attribute on ModelAdmin methods is removed.
- The enclosure keyword argument to SyndicationFeed.add_item() is removed.

See Features deprecated in 1.10 for details on these changes.

- The makemigrations --exit option is removed.
- Support for direct assignment to a reverse foreign key or many-to-many relation is removed.
- The get_srid() and set_srid() methods of django.contrib.gis.geos.GEOSGeometry are removed.
- The get_x(), set_x(), get_y(), set_y(), get_z(), and set_z() methods of django.contrib.gis.geos.Point are removed.
- The get_coords() and set_coords() methods of django.contrib.gis.geos.Point are removed.
- The cascaded_union property of django.contrib.gis.geos.MultiPolygon is removed.
- django.utils.functional.allow_lazy() is removed.
- The shell --plain option is removed.
- The django.core.urlresolvers module is removed in favor of its new location, django.urls.
- CommaSeparatedIntegerField is removed, except for support in historical migrations.
- The template Context.has_key() method is removed.
- Support for the django.core.files.storage.Storage.accessed_time(), created_time(), and modified_time() methods is removed.
• Support for query lookups using the model name when `Meta.default_related_name` is set is removed.

• The MySQL `__search` lookup is removed.

• The shim for supporting custom related manager classes without a `_apply_rel_filters()` method is removed.

• Using `User.is_authenticated()` and `User.is_anonymous()` as methods rather than properties is no longer supported.

• The `Model._meta.virtual_fields` attribute is removed.

• The keyword arguments `virtual_only` in `Field.contribute_to_class()` and `virtual` in `Model._meta.add_field()` are removed.

• The `javascript_catalog()` and `json_catalog()` views are removed.

• `django.contrib.gis.utils.precision_wkt()` is removed.

• In multi-table inheritance, implicit promotion of a `OneToOneField` to a `parent_link` is removed.

• Support for `Widget._format_value()` is removed.

• `FileField` methods `get_directory_name()` and `get_filename()` are removed.

• The `mark_for_escaping()` function and the classes it uses: `EscapeData`, `EscapeBytes`, `EscapeText`, `EscapeString`, and `EscapeUnicode` are removed.

• The `escape` filter now uses `django.utils.html.conditional_escape()`.

• `Manager.use_for_related_fields` is removed.

• Model `Manager` inheritance follows MRO inheritance rules. The requirement to use `Meta.manager_inheritance_from_future` to opt-in to the behavior is removed.

• Support for old-style middleware using `settings.MIDDLEWARE_CLASSES` is removed.

### 9.1.10 1.11 release

**Django 1.11.29 release notes**

March 4, 2020

Django 1.11.29 fixes a security issue in 1.11.28.
**CVE-2020-9402**: Potential SQL injection via `tolerance` parameter in GIS functions and aggregates on Oracle

GIS functions and aggregates on Oracle were subject to SQL injection, using a suitably crafted `tolerance`.

**Django 1.11.28 release notes**

February 3, 2020

Django 1.11.28 fixes a security issue in 1.11.27.

**CVE-2020-7471**: Potential SQL injection via `StringAgg(delimiter)`

`StringAgg` aggregation function was subject to SQL injection, using a suitably crafted `delimiter`.

**Django 1.11.27 release notes**

December 18, 2019

Django 1.11.27 fixes a security issue and a data loss bug in 1.11.26.

**CVE-2019-19844**: Potential account hijack via password reset form

By submitting a suitably crafted email address making use of Unicode characters, that compared equal to an existing user email when lower-cased for comparison, an attacker could be sent a password reset token for the matched account.

In order to avoid this vulnerability, password reset requests now compare the submitted email using the stricter, recommended algorithm for case-insensitive comparison of two identifiers from Unicode Technical Report 36, section 2.11.2(B)(2). Upon a match, the email containing the reset token will be sent to the email address on record rather than the submitted address.

**Bugfixes**

- Fixed a data loss possibility in `SplitArrayField`. When using with `ArrayField(BooleanField())`, all values after the first `True` value were marked as checked instead of preserving passed values (#31073).
Django 1.11.26 release notes

November 4, 2019

Django 1.11.26 fixes a regression in 1.11.25.

Bugfixes

• Fixed a crash when using a contains, contained_by, has_key, has_keys, or has_any_keys lookup on django.contrib.postgres.fields.JSONField, if the right or left hand side of an expression is a key transform (#30826).

Django 1.11.25 release notes

October 1, 2019

Django 1.11.25 fixes a regression in 1.11.23.

Bugfixes

• Fixed a crash when filtering with a Subquery() annotation of a queryset containing django.contrib.postgres.fields.JSONField or HStoreField (#30769).

Django 1.11.24 release notes

September 2, 2019

Django 1.11.24 fixes a regression in 1.11.23.

Bugfixes

• Fixed crash of KeyTransform() for django.contrib.postgres.fields.JSONField and HStoreField when using on expressions with params (#30672).

Django 1.11.23 release notes

August 1, 2019

Django 1.11.23 fixes security issues in 1.11.22.

9.1. Final releases
**CVE-2019-14232: Denial-of-service possibility in django.utils.text.Truncator**

If `django.utils.text.Truncator`'s `chars()` and `words()` methods were passed the `html=True` argument, they were extremely slow to evaluate certain inputs due to a catastrophic backtracking vulnerability in a regular expression. The `chars()` and `words()` methods are used to implement the `truncatechars_html` and `truncatewords_html` template filters, which were thus vulnerable.

The regular expressions used by `Truncator` have been simplified in order to avoid potential backtracking issues. As a consequence, trailing punctuation may now at times be included in the truncated output.

**CVE-2019-14233: Denial-of-service possibility in strip_tags()**

Due to the behavior of the underlying `HTMLParser`, `django.utils.html.strip_tags()` would be extremely slow to evaluate certain inputs containing large sequences of nested incomplete HTML entities. The `strip_tags()` method is used to implement the corresponding `striptags` template filter, which was thus also vulnerable.

`strip_tags()` now avoids recursive calls to `HTMLParser` when progress removing tags, but necessarily incomplete HTML entities, stops being made.

Remember that absolutely NO guarantee is provided about the results of `strip_tags()` being HTML safe. So NEVER mark safe the result of a `strip_tags()` call without escaping it first, for example with `django.utils.html.escape()`.

**CVE-2019-14234: SQL injection possibility in key and index lookups for JSONField/HStoreField**

Key and index lookups for `django.contrib.postgres.fields.JSONField` and key lookups for `HStoreField` were subject to SQL injection, using a suitably crafted dictionary, with dictionary expansion, as the `**kwargs` passed to `QuerySet.filter()`.

**CVE-2019-14235: Potential memory exhaustion in django.utils.encoding.uri_to_iri()**

If passed certain inputs, `django.utils.encoding.uri_to_iri()` could lead to significant memory usage due to excessive recursion when re-percent-encoding invalid UTF-8 octet sequences.

`uri_to_iri()` now avoids recursion when re-percent-encoding invalid UTF-8 octet sequences.
Django 1.11.22 release notes

July 1, 2019

Django 1.11.22 fixes a security issue in 1.11.21.

**CVE-2019-12781: Incorrect HTTP detection with reverse-proxy connecting via HTTPS**

When deployed behind a reverse-proxy connecting to Django via HTTPS, `django.http.HttpRequest.scheme` would incorrectly detect client requests made via HTTP as using HTTPS. This entails incorrect results for `is_secure()`, and `build_absolute_uri()`, and that HTTP requests would not be redirected to HTTPS in accordance with `SECURE_SSL_REDIRECT`.

HttpRequest.scheme now respects `SECURE_PROXY_SSL_HEADER`, if it is configured, and the appropriate header is set on the request, for both HTTP and HTTPS requests.

If you deploy Django behind a reverse-proxy that forwards HTTP requests, and that connects to Django via HTTPS, be sure to verify that your application correctly handles code paths relying on `scheme`, `is_secure()`, `build_absolute_uri()`, and `SECURE_SSL_REDIRECT`.

Django 1.11.21 release notes

June 3, 2019

Django 1.11.21 fixes a security issue in 1.11.20.

**CVE-2019-12308: AdminURLFieldWidget XSS**

The clickable “Current URL” link generated by `AdminURLFieldWidget` displayed the provided value without validating it as a safe URL. Thus, an unvalidated value stored in the database, or a value provided as a URL query parameter payload, could result in an clickable JavaScript link.

`AdminURLFieldWidget` now validates the provided value using `URLValidator` before displaying the clickable link. You may customize the validator by passing a `validator_class` kwarg to `AdminURLFieldWidget.__init__()`, e.g. when using `formfield_overrides`.

Django 1.11.20 release notes

February 11, 2019

Django 1.11.20 fixes a packaging error in 1.11.19.
Bugfixes

- Corrected packaging error from 1.11.19 (#30175).

Django 1.11.19 release notes

February 11, 2019

Django 1.11.19 fixes a security issue in 1.11.18.

CVE-2019-6975: Memory exhaustion in django.utils.numberformat.format()

If django.utils.numberformat.format() –used by contrib.admin as well as the floatformat, filesizeformat, and intcomma templates filters –received a Decimal with a large number of digits or a large exponent, it could lead to significant memory usage due to a call to '{:f}'.format().

To avoid this, decimals with more than 200 digits are now formatted using scientific notation.

Django 1.11.18 release notes

January 4, 2019

Django 1.11.18 fixes a security issue in 1.11.17.

CVE-2019-3498: Content spoofing possibility in the default 404 page

An attacker could craft a malicious URL that could make spoofed content appear on the default page generated by the django.views.defaults.page_not_found() view.

The URL path is no longer displayed in the default 404 template and the request_path context variable is now quoted to fix the issue for custom templates that use the path.

Django 1.11.17 release notes

December 3, 2018

Django 1.11.17 fixes several bugs in 1.11.16 and adds compatibility with Python 3.7.
Bugfixes

• Prevented repetitive calls to `geos_version_tuple()` in the `WKBWriter` class in an attempt to fix a random crash involving `LooseVersion` since Django 1.11.14 (#29959).

Django 1.11.16 release notes

October 1, 2018

Django 1.11.16 fixes a data loss bug in 1.11.15.

Bugfixes

• Fixed a race condition in `QuerySet.update_or_create()` that could result in data loss (#29499).

Django 1.11.15 release notes

August 1, 2018

Django 1.11.15 fixes a security issue in 1.11.14.

CVE-2018-14574: Open redirect possibility in `CommonMiddleware`

If the `CommonMiddleware` and the `APPEND_SLASH` setting are both enabled, and if the project has a URL pattern that accepts any path ending in a slash (many content management systems have such a pattern), then a request to a maliciously crafted URL of that site could lead to a redirect to another site, enabling phishing and other attacks.

`CommonMiddleware` now escapes leading slashes to prevent redirects to other domains.

Django 1.11.14 release notes

July 2, 2018

Django 1.11.14 fixes several bugs in 1.11.13.
Bugfixes

- Fixed `WKBWriter.write()` and `write_hex()` for empty polygons on GEOS 3.6.1+ (#29460).
- Fixed a regression in Django 1.10 that could result in large memory usage when making edits using `ModelAdmin.list_editable` (#28462).

Django 1.11.13 release notes

May 1, 2018

Django 1.11.13 fixes several bugs in 1.11.12.

Bugfixes

- Fixed a regression in Django 1.11.8 where altering a field with a unique constraint may drop and rebuild more foreign keys than necessary (#29193).
- Fixed crashes in `django.contrib.admindocs` when a view is a callable object, such as `django.contrib.syndication.views.Feed` (#29296).
- Fixed a regression in Django 1.11.12 where `QuerySet.values()` or `values_list()` after combining an annotated and unannotated queryset with `union()`, `difference()`, or `intersection()` crashed due to mismatching columns (#29286).

Django 1.11.12 release notes

April 2, 2018

Django 1.11.12 fixes two bugs in 1.11.1.

Bugfixes

- Fixed a regression in Django 1.11.8 where combining two annotated `values_list()` querysets with `union()`, `difference()`, or `intersection()` crashed due to mismatching columns (#29229).
- Fixed a regression in Django 1.11 where an empty choice could be initially selected for the `SelectMultiple` and `CheckboxSelectMultiple` widgets (#29273).
Django 1.11.11 release notes

March 6, 2018

Django 1.11.11 fixes two security issues in 1.11.10.

**CVE-2018-7536: Denial-of-service possibility in urlize and urlizetrunc template filters**

The `django.utils.html.urlize()` function was extremely slow to evaluate certain inputs due to catastrophic backtracking vulnerabilities in two regular expressions. The `urlize()` function is used to implement the `urlize` and `urlizetrunc` template filters, which were thus vulnerable.

The problematic regular expressions are replaced with parsing logic that behaves similarly.

**CVE-2018-7537: Denial-of-service possibility in truncatechars_html and truncatewords_html template filters**

If `django.utils.text.Truncator`’s `chars()` and `words()` methods were passed the `html=True` argument, they were extremely slow to evaluate certain inputs due to a catastrophic backtracking vulnerability in a regular expression. The `chars()` and `words()` methods are used to implement the `truncatechars_html` and `truncatewords_html` template filters, which were thus vulnerable.

The backtracking problem in the regular expression is fixed.

Django 1.11.10 release notes

February 1, 2018

Django 1.11.10 fixes a security issue and several bugs in 1.11.9.

**CVE-2018-6188: Information leakage in AuthenticationForm**

A regression in Django 1.11.8 made `AuthenticationForm` run its `confirm_login_allowed()` method even if an incorrect password is entered. This can leak information about a user, depending on what messages `confirm_login_allowed()` raises. If `confirm_login_allowed()` isn’t overridden, an attacker enter an arbitrary username and see if that user has been set to `is_active=False`. If `confirm_login_allowed()` is overridden, more sensitive details could be leaked.

This issue is fixed with the caveat that `AuthenticationForm` can no longer raise the “This account is inactive.” error if the authentication backend rejects inactive users (the default authentication backend, `ModelBackend`, has done that since Django 1.10). This issue will be revisited for Django 2.1 as a fix to address the caveat will likely be too invasive for inclusion in older versions.
Bugfixes

- Fixed incorrect foreign key nullification if a model has two foreign keys to the same model and a target model is deleted (#29016).
- Fixed a regression where contrib.auth.authenticate() crashes if an authentication backend doesn’t accept request and a later one does (#29071).
- Fixed crash when entering an invalid uuid in ModelAdmin.raw_id_fields (#29094).

Django 1.11.9 release notes

January 1, 2018

Django 1.11.9 fixes several bugs in 1.11.8.

Bugfixes

- Fixed a regression in Django 1.11 that added newlines between MultiWidget’s subwidgets (#28890).
- Fixed incorrect class-based model index name generation for models with quoted db_table (#28876).
- Fixed incorrect foreign key constraint name for models with quoted db_table (#28876).
- Fixed a regression in caching of a GenericForeignKey when the referenced model instance uses more than one level of multi-table inheritance (#28856).

Django 1.11.8 release notes

December 2, 2017

Django 1.11.8 fixes several bugs in 1.11.7.

Bugfixes

- Reallowed, following a regression in Django 1.10, AuthenticationForm to raise the inactive user error when using ModelBackend (#28645).
- Added support for QuerySet.values() and values_list() for union(), difference(), and intersection() queries (#28781).
- Fixed incorrect index name truncation when using a namespace db_table (#28792).
- Made QuerySet.iterator() use server-side cursors on PostgreSQL after values() and values_list() (#28817).
• Fixed crash on SQLite and MySQL when ordering by a filtered subquery that uses nulls_first or nulls_last (#28848).
• Made query lookups for CICCharField, CIEmailField, and CITextField use a citext cast (#28702).
• Fixed a regression in caching of a GenericForeignKey when the referenced model instance uses multi-table inheritance (#28856).
• Fixed “Cannot change column ‘x’: used in a foreign key constraint” crash on MySQL with a sequence of AlterField and/or RenameField operations in a migration (#28305).

Django 1.11.7 release notes

November 1, 2017
Django 1.11.7 fixes several bugs in 1.11.6.

Bugfixes

• Prevented cache.get_or_set() from caching None if the default argument is a callable that returns None (#28601).
• Fixed the Basque DATE_FORMAT string (#28710).
• Made QuerySet.reverse() affect nulls_first and nulls_last (#28722).
• Fixed unquoted table names in Subquery SQL when using OuterRef (#28689).

Django 1.11.6 release notes

October 5, 2017
Django 1.11.6 fixes several bugs in 1.11.5.

Bugfixes

• Made the CharField form field convert whitespace-only values to the empty_value when strip is enabled (#28555).
• Fixed crash when using the name of a model’s autogenerated primary key (id) in an Index’s fields (#28597).
• Fixed a regression in Django 1.9 where a custom view error handler such as handler404 that accesses csrf_token could cause CSRF verification failures on other pages (#28488).
Django 1.11.5 release notes

September 5, 2017

Django 1.11.5 fixes a security issue and several bugs in 1.11.4.

CVE-2017-12794: Possible XSS in traceback section of technical 500 debug page

In older versions, HTML autoescaping was disabled in a portion of the template for the technical 500 debug page. Given the right circumstances, this allowed a cross-site scripting attack. This vulnerability shouldn’t affect most production sites since you shouldn’t run with `DEBUG = True` (which makes this page accessible) in your production settings.

Bug fixes

- Fixed GEOS version parsing if the version has a commit hash at the end (new in GEOS 3.6.2) (#28441).
- Added compatibility for `cx_Oracle` 6 (#28498).
- Fixed select widget rendering when option values are tuples (#28502).
- Django 1.11 inadvertently changed the sequence and trigger naming scheme on Oracle. This causes errors on INSERTs for some tables if `'use_returning_into': False` is in the OPTIONS part of DATABASES. The pre-1.11 naming scheme is now restored. Unfortunately, it necessarily requires an update to Oracle tables created with Django 1.11.[1-4]. Use the upgrade script in #28451 comment 8 to update sequence and trigger names to use the pre-1.11 naming scheme.
- Added POST request support to `LogoutView`, for equivalence with the function-based `logout()` view (#28513).
- Omitted `pages_per_range` from `BrinIndex.deconstruct()` if it’s `None` (#25809).
- Fixed a regression where `SelectDateWidget` localized the years in the select box (#28530).
- Fixed a regression in 1.11.4 where `runserver` crashed with non-Unicode system encodings on Python 2 + Windows (#28487).
- Fixed a regression in Django 1.10 where changes to a `ManyToManyField` weren’t logged in the admin change history (#27998) and prevented `ManyToManyField` initial data in model forms from being affected by subsequent model changes (#28543).
- Fixed non-deterministic results or an `AssertionError` crash in some queries with multiple joins (#26522).
- Fixed a regression in `contrib.auth`’s `login()` and `logout()` views where they ignored positional arguments (#28550).
Django 1.11.4 release notes

August 1, 2017

Django 1.11.4 fixes several bugs in 1.11.3.

Bugfixes

- Fixed a regression in 1.11.3 on Python 2 where non-ASCII format values for date/time widgets results in an empty value in the widget’s HTML (#28355).
- Fixed QuerySet.union() and difference() when combining with a queryset raising EmptyResultSet (#28378).
- Fixed a regression in pickling of LazyObject on Python 2 when the wrapped object doesn’t have __reduce__() (#28389).
- Fixed crash in runserver’s autoreload with Python 2 on Windows with non-str environment variables (#28174).
- Corrected Field.has_changed() to return False for disabled form fields: BooleanField, MultipleChoiceField, MultiValueField, FileField, ModelChoiceField, and ModelMultipleChoiceField.
- Fixed QuerySet.count() for union(), difference(), and intersection() queries. (#28399).
- Fixed ClearableFileInput rendering as a subwidget of MultiWidget (#28414). Custom clearable_file_input.html widget templates will need to adapt for the fact that context values checkbox_name, checkbox_id, is_initial, input_text, initial_text, and clear_checkbox_label are now attributes of widget rather than appearing in the top-level context.
- Fixed queryset crash when using a GenericRelation to a proxy model (#28418).

Django 1.11.3 release notes

July 1, 2017

Django 1.11.3 fixes several bugs in 1.11.2.
Bugfixes

- Removed an incorrect deprecation warning about a missing `renderer` argument if a `Widget.render()` method accepts `**kwargs` (#28265).
- Fixed a regression causing `Model.__init__()` to crash if a field has an instance only descriptor (#28269).
- Fixed an incorrect `DisallowedModelAdminLookup` exception when using a nested reverse relation in `list_filter` (#28262).
- Fixed admin’s `FieldListFilter.get_queryset()` crash on invalid input (#28202).
- Fixed invalid HTML for a required `AdminFileWidget` (#28278).
- Fixed model initialization to set the name of class-based model indexes for models that only inherit `models.Model` (#28282).
- Fixed crash in admin’s inlines when a model has an inherited non-editable primary key (#27967).
- Fixed `QuerySet.union()`, `intersection()`, and `difference()` when combining with an `EmptyQuerySet` (#28293).
- Prevented `Paginator`’s unordered object list warning from evaluating a `QuerySet` (#28284).
- Fixed the value of `redirect_field_name` in `LoginView`’s template context. It’s now an empty string (as it is for the original function-based `login()` view) if the corresponding parameter isn’t sent in a request (in particular, when the login page is accessed directly) (#28229).
- Prevented attribute values in the `django/forms/widgets/attrs.html` template from being localized so that numeric attributes (e.g. `max` and `min`) of `NumberInput` work correctly (#28303).
- Removed casting of the option value to a string in the template context of the `CheckboxSelectMultiple`, `NullBooleanSelect`, `RadioSelect`, `SelectMultiple`, and `Select` widgets (#28176). In Django 1.11.1, casting was added in Python to avoid localization of numeric values in Django templates, but this made some use cases more difficult. Casting is now done in the template using the `|stringformat:'s'` filter.
- Prevented a primary key alteration from adding a foreign key constraint if `db_constraint=False` (#28298).
- Fixed `UnboundLocalError` crash in `RenameField` with nonexistent field (#28350).
- Fixed a regression preventing a model field’s `limit_choices_to` from being evaluated when a `ModelForm` is instantiated (#28345).
Django 1.11.2 release notes

June 1, 2017

Django 1.11.2 adds a minor feature and fixes several bugs in 1.11.1. Also, the latest string translations from Transifex are incorporated.

Minor feature

The new `LiveServerTestCase.port` attribute reallows the use case of binding to a specific port following the `bind to port zero` change in Django 1.11.

Bugfixes

- Added detection for GDAL 2.1 and 2.0, and removed detection for unsupported versions 1.7 and 1.8 (#28181).
- Changed `contrib.gis` to raise `ImproperlyConfigured` rather than `GDALException` if `gdal` isn’t installed, to allow third-party apps to catch that exception (#28178).
- Fixed `django.utils.http.is_safe_url()` crash on invalid IPv6 URLs (#28142).
- Fixed regression causing pickling of model fields to crash (#28188).
- Fixed `django.contrib.auth.authenticate()` when multiple authentication backends don’t accept a positional `request` argument (#28207).
- Fixed introspection of index field ordering on PostgreSQL (#28197).
- Fixed a regression where `Model._state.adding` wasn’t set correctly on multi-table inheritance parent models after saving a child model (#28210).
- Allowed `DjangoJSONEncoder` to serialize `django.utils.deprecation.CallableBool` (#28230).
- Relaxed the validation added in Django 1.11 of the fields in the `defaults` argument of `QuerySet.get_or_create()` and `update_or_create()` to reallow settable model properties (#28222).
- Fixed `MultipleObjectMixinpaginate_queryset()` crash on Python 2 if the `InvalidPage` message contains non-ASCII (#28204).
- Prevented `Subquery` from adding an unnecessary `CAST` which resulted in invalid SQL (#28199).
- Corrected detection of GDAL 2.1 on Windows (#28181).
- Made date-based generic views return a 404 rather than crash when given an out of range date (#28209).
- Fixed a regression where `file_move_safe()` crashed when moving files to a CIFS mount (#28170).
- Moved the `ImageField` file extension validation added in Django 1.11 from the model field to the form field to reallow the use case of storing images without an extension (#28242).
Django 1.11.1 release notes

May 6, 2017

Django 1.11.1 adds a minor feature and fixes several bugs in 1.11.

Allowed disabling server-side cursors on PostgreSQL

The change in Django 1.11 to make `QuerySet.iterator()` use server-side cursors on PostgreSQL prevents running Django with PgBouncer in transaction pooling mode. To realow that, use the `DISABLE_SERVER_SIDE_CURSORS` setting in `DATABASES`.

See Transaction pooling and server-side cursors for more discussion.

Bugfixes

- Made migrations respect Index’s name argument. If you created a named index with Django 1.11, `makemigrations` will create a migration to recreate the index with the correct name (#28051).
- Fixed a crash when using a `__icontains` lookup on a `ArrayField` (#28038).
- Fixed a crash when using a two-tuple in `EmailAddress`’s attachments argument (#28042).
- Fixed `QuerySet.filter()` crash when it references the name of a `OneToOneField` primary key (#28047).
- Fixed empty POST data table appearing instead of “No POST data” in HTML debug page (#28079).
- Restored `BoundField` without any choices evaluating to True (#28058).
- Prevented `SessionBase.cycle_key()` from losing session data if `_session_cache` isn’t populated (#28066).
- Fixed layout of `ReadOnlyPasswordHashWidget` (used in the admin’s user change page) (#28097).
- Allowed prefetch call on managers with custom `ModelIterable` subclasses (#28096).
- Fixed change password link in the `contrib.auth` admin for el, es_MX, and pt translations (#28100).
- Restored the output of the class attribute in the `<ul>` of widgets that use the `multiple_input.html` template. This fixes `ModelAdmin.radio_fields` with `admin.HORIZONTAL` (#28059).
- Fixed crash in `BaseGeometryWidget.subwidgets()` (#28039).
- Fixed exception reraising in ORM query execution when `cursor.execute()` fails and the subsequent `cursor.close()` also fails (#28091).
- Fixed a regression where `CheckboxSelectMultiple`, `NullBooleanSelect`, `RadioSelect`, `SelectMultiple`, and `Select` localized option values (#28075).
- Corrected the stack level of unordered queryset pagination warnings (#28109).
- Fixed a regression causing incorrect queries for __in subquery lookups when models use ForeignKey.
  to_field (#28101).
- Fixed crash when overriding the template of django.views.static.directory_index() (#28122).
- Fixed a regression in formset min_num validation with unchanged forms that have initial data (#28130).
- Prepared for cx_Oracle 6.0 support (#28138).
- Updated the contrib.postgres SplitArrayWidget to use template-based widget rendering (#28040).
- Fixed crash in BaseGeometryWidget.get_context() when overriding existing attrs (#28105).
- Prevented AddIndex and RemoveIndex from mutating model state (#28043).
- Prevented migrations from dropping database indexes from Meta.indexes when changing Field.
  db_index to False (#28052).
- Fixed a regression in choice ordering in form fields with grouped and non-grouped options (#28157).
- Fixed crash in BaseInlineFormSet._construct_form() when using save_as_new (#28159).
- Fixed a regression where Model._state.db wasn’t set correctly on multi-table inheritance parent
  models after saving a child model (#28166).
- Corrected the return type of ArrayField(CITextField()) values retrieved from the database (#28161).
- Fixed QuerySet.prefetch_related() crash when fetching relations in nested Prefetch objects
  (#27554).
- Prevented hiding GDAL errors if it’s not installed when using contrib.gis (#28160). (It’s a required
  dependency as of Django 1.11.)
- Fixed a regression causing __in lookups on a foreign key to fail when using the foreign key’s parent
  model as the lookup value (#28175).

**Django 1.11 release notes**

April 4, 2017

Welcome to Django 1.11!

These release notes cover the new features, as well as some backwards incompatible changes you’ll want to
be aware of when upgrading from Django 1.10 or older versions. We’ve begun the deprecation process for
some features.

See the How to upgrade Django to a newer version guide if you’re updating an existing project.

Django 1.11 is designated as a long-term support release. It will receive security updates for at least three
years after its release. Support for the previous LTS, Django 1.8, will end in April 2018.
Python compatibility

Django 1.11 requires Python 2.7, 3.4, 3.5, 3.6, or 3.7 (as of 1.11.17). We highly recommend and only officially support the latest release of each series.

The Django 1.11.x series is the last to support Python 2. The next major release, Django 2.0, will only support Python 3.4+.

Deprecating warnings are no longer loud by default

Unlike older versions of Django, Django’s own deprecation warnings are no longer displayed by default. This is consistent with Python’s default behavior.

This change allows third-party apps to support both Django 1.11 LTS and Django 1.8 LTS without having to add code to avoid deprecation warnings.

Following the release of Django 2.0, we suggest that third-party app authors drop support for all versions of Django prior to 1.11. At that time, you should be able run your package’s tests using python -Wd so that deprecation warnings do appear. After making the deprecation warning fixes, your app should be compatible with Django 2.0.

What’s new in Django 1.11

Class-based model indexes

The new django.db.models.indexes module contains classes which ease creating database indexes. Indexes are added to models using the Meta.indexes option.

The Index class creates a b-tree index, as if you used db_index on the model field or index_together on the model Meta class. It can be subclassed to support different index types, such as GinIndex. It also allows defining the order (ASC/DESC) for the columns of the index.

Template-based widget rendering

To ease customizing widgets, form widget rendering is now done using the template system rather than in Python. See The form rendering API.

You may need to adjust any custom widgets that you’ve written for a few backwards incompatible changes.
Subquery expressions

The new Subquery and Exists database expressions allow creating explicit subqueries. Subqueries may refer to fields from the outer queryset using the OuterRef class.

Minor features

django.contrib.admin

- ModelAdmin.date_hierarchy can now reference fields across relations.
- The new ModelAdmin.get_exclude() hook allows specifying the exclude fields based on the request or model instance.
- The popup_response.html template can now be overridden per app, per model, or by setting the ModelAdmin.popup_response_template attribute.

django.contrib.auth

- The default iteration count for the PBKDF2 password hasher is increased by 20%.
- The LoginView and LogoutView class-based views supersede the deprecated login() and logout() function-based views.
- The PasswordChangeView, PasswordChangeDoneView, PasswordResetView, PasswordResetDoneView, PasswordResetConfirmView, and PasswordResetCompleteView class-based views supersede the deprecated password_change(), password_change_done(), password_reset(), password_reset_done(), password_reset_confirm(), and password_reset_complete() function-based views.
- The new post_reset_login attribute for PasswordResetConfirmView allows automatically logging in a user after a successful password reset. If you have multiple AUTHENTICATION_BACKENDS configured, use the post_reset_login_backend attribute to choose which one to use.
- To avoid the possibility of leaking a password reset token via the HTTP Referer header (for example, if the reset page includes a reference to CSS or JavaScript hosted on another domain), the PasswordResetConfirmView (but not the deprecated password_reset_confirm() function-based view) stores the token in a session and redirects to itself to present the password change form to the user without the token in the URL.
- update_session_auth_hash() now rotates the session key to allow a password change to invalidate stolen session cookies.
- The new success_url_allowed_hosts attribute for LoginView and LogoutView allows specifying a set of hosts that are safe for redirecting after login and logout.
- Added password validators `help_text` to `UserCreationForm`.
- The `HttpRequest` is now passed to `authenticate()` which in turn passes it to the authentication backend if it accepts a `request` argument.
- The `user_login_failed()` signal now receives a `request` argument.
- `PasswordResetForm` supports custom user models that use an email field named something other than `'email'`. Set `CustomUser.EMAIL_FIELD` to the name of the field.
- `get_user_model()` can now be called at import time, even in modules that define models.

**django.contrib.contenttypes**

- When stale content types are detected in the `remove_stale_contenttypes` command, there’s now a list of related objects such as `auth.Permissions` that will also be deleted. Previously, only the content types were listed (and this prompt was after `migrate` rather than in a separate command).

**django.contrib.gis**

- The new `GEOSGeometry.from_gml()` and `OGRGeometry.from_gml()` methods allow creating geometries from GML.
- Added support for the `dwithin` lookup on SpatiaLite.
- The `Area` function, `Distance` function, and distance lookups now work with geodetic coordinates on SpatiaLite.
- The OpenLayers-based form widgets now use `OpenLayers.js` from `https://cdnjs.cloudflare.com` which is more suitable for production use than the old `https://openlayers.org/` source. They are also updated to use OpenLayers 3.
- PostGIS migrations can now change field dimensions.
- Added the ability to pass the `size`, `shape`, and `offset` parameters when creating `GDALRaster` objects.
- Added SpatiaLite support for the `IsValid` function, `MakeValid` function, and `isvalid` lookup.
- Added Oracle support for the `AsGML` function, `BoundingCircle` function, `IsValid` function, and `isvalid` lookup.
django.contrib.postgres

- The new distinct argument for `StringAgg` determines if concatenated values will be distinct.
- The new `GinIndex` and `BrinIndex` classes allow creating GIN and BRIN indexes in the database.
- `django.contrib.postgres.fields.JSONField` accepts a new `encoder` parameter to specify a custom class to encode data types not supported by the standard encoder.
- The new `CIText` mixin and `CITextExtension` migration operation allow using PostgreSQL’s citext extension for case-insensitive lookups. Three fields are provided: `CICharField`, `CIEmailField`, and `CITextField`.
- The new `JSONBAgg` allows aggregating values as a JSON array.
- The `HStoreField` (model field) and `HStoreField` (form field) allow storing null values.

Cache

- Memcached backends now pass the contents of `OPTIONS` as keyword arguments to the client constructors, allowing for more advanced control of client behavior. See the cache arguments documentation for examples.
- Memcached backends now allow defining multiple servers as a comma-delimited string in `LOCATION`, for convenience with third-party services that use such strings in environment variables.

CSRF

- Added the `CSRF_USE_SESSIONS` setting to allow storing the CSRF token in the user’s session rather than in a cookie.

Database backends

- Added the `skip_locked` argument to `QuerySet.select_for_update()` on PostgreSQL 9.5+ and Oracle to execute queries with `FOR UPDATE SKIP LOCKED`.
- Added the `TEST['TEMPLATE']` setting to let PostgreSQL users specify a template for creating the test database.
- `QuerySet.iterator()` now uses server-side cursors on PostgreSQL. This feature transfers some of the worker memory load (used to hold query results) to the database and might increase database memory usage.
- Added MySQL support for the `isolation_level` option in `OPTIONS` to allow specifying the transaction isolation level. To avoid possible data loss, it’s recommended to switch from MySQL’s default level, repeatable read, to read committed.
• Added support for cx_Oracle 5.3.

Email

• Added the EMAIL_USE_LOCALTIME setting to allow sending SMTP date headers in the local time zone rather than in UTC.

• EmailMessage.attach() and attach_file() now fall back to MIME type application/octet-stream when binary content that can’t be decoded as UTF-8 is specified for a text/* attachment.

File Storage

• To make it wrappable by io.TextIOWrapper, File now has the readable(), writable(), and seekable() methods.

Forms

• The new empty_value attribute on CharField, EmailField, RegexField, SlugField, and URLField allows specifying the Python value to use to represent “empty”.

• The new Form.get_initial_for_field() method returns initial data for a form field.

Internationalization

• Number formatting and the NUMBER_GROUPING setting support non-uniform digit grouping.

Management Commands

• The new loaddata --exclude option allows excluding models and apps while loading data from fixtures.

• The new diffsettings --default option allows specifying a settings module other than Django’s default settings to compare against.

• app_labels arguments now limit the showmigrations --plan output.
Migrations

- Added support for serialization of `uuid.UUID` objects.

Models

- Added support for callable values in the `defaults` argument of `QuerySet.update_or_create()` and `get_or_create()`.
- `ImageField` now has a default `validate_image_file_extension` validator. (This validator moved to the form field in Django 1.11.2.)
- Added support for time truncation to `Trunc` functions.
- Added the `ExtractWeek` function to extract the week from `DateField` and `DateTimeField` and exposed it through the `week` lookup.
- Added the `TruncTime` function to truncate `DateTimeField` to its time component and exposed it through the `time` lookup.
- Added support for expressions in `QuerySet.values()` and `values_list()`.
- Added support for query expressions on lookups that take multiple arguments, such as `range`.
- You can now use the `unique=True` option with `FileField`.
- Added the `nulls_first` and `nulls_last` parameters to `Expression.asc()` and `desc()` to control the ordering of null values.
- The new F expression `bitleftshift()` and `bitrightshift()` methods allow bitwise shift operations.
- Added `QuerySet.union()`, `intersection()`, and `difference()`.

Requests and Responses

- Added `QueryDict.fromkeys()`.
- `CommonMiddleware` now sets the `Content-Length` response header for non-streaming responses.
- Added the `SECURE_HSTS_PRELOAD` setting to allow appending the `preload` directive to the `Strict-Transport-Security` header.
- `ConditionalGetMiddleware` now adds the ETag header to responses.
Serialization

- The new `django.core.serializers.base.Serializer.stream_class` attribute allows subclasses to customize the default stream.
- The encoder used by the `JSON serializer` can now be customized by passing a `cls` keyword argument to the `serializers.serialize()` function.
- `DjangoJSONEncoder` now serializes `timedelta` objects (used by `DurationField`).

Templates

- `mark_safe()` can now be used as a decorator.
- The `Jinja2` template backend now supports context processors by setting the `'context_processors'` option in `OPTIONS`.
- The `regroup` tag now returns `namedtuples` instead of dictionaries so you can unpack the group object directly in a loop, e.g. `{% for grouper, list in regrouped %}`.
- Added a `resetcycle` template tag to allow resetting the sequence of the `cycle` template tag.
- You can now specify specific directories for a particular `filesystem.Loader`.

Tests

- Added `DiscoverRunner.get_test_runner_kwargs()` to allow customizing the keyword arguments passed to the test runner.
- Added the `test --debug-mode` option to help troubleshoot test failures by setting the `DEBUG` setting to `True`.
- The new `django.test.utils.setup_databases()` (moved from `django.test.runner`) and `teardown_databases()` functions make it easier to build custom test runners.
- Added support for `unittest.TestCase.subTest()`'s when using the `test --parallel` option.
- `DiscoverRunner` now runs the system checks at the start of a test run. Override the `DiscoverRunner.run_checks()` method if you want to disable that.
Validators

- Added `FileExtensionValidator` to validate file extensions and `validate_image_file_extension` to validate image files.

Backwards incompatible changes in 1.11

django.contrib.gis

- To simplify the codebase and because it’s easier to install than when `contrib.gis` was first released, GDAL is now a required dependency for GeoDjango. In older versions, it’s only required for SQLite.
- `contrib.gis.maps` is removed as it interfaces with a retired version of the Google Maps API and seems to be unmaintained. If you’re using it, let us know.
- The `GEOSGeometry` equality operator now also compares SRID.
- The OpenLayers-based form widgets now use OpenLayers 3, and the `gis/openlayers.html` and `gis/openlayers-osm.html` templates have been updated. Check your project if you subclass these widgets or extend the templates. Also, the new widgets work a bit differently than the old ones. Instead of using a toolbar in the widget, you click to draw, click and drag to move the map, and click and drag a point/vertex/corner to move it.
- Support for SpatiaLite < 4.0 is dropped.
- Support for GDAL 1.7 and 1.8 is dropped.
- The widgets in `contrib.gis.forms.widgets` and the admin’s `OpenLayersWidget` use the form rendering API rather than `loader.render_to_string()`. If you’re using a custom widget template, you’ll need to be sure your form renderer can locate it. For example, you could use the `TemplatesSetting` renderer.

django.contrib.staticfiles

- `collectstatic` may now fail during post-processing when using a hashed static files storage if a reference loop exists (e.g. 'foo.css' references 'bar.css' which itself references 'foo.css') or if the chain of files referencing other files is too deep to resolve in several passes. In the latter case, increase the number of passes using `ManifestStaticFilesStorage.max_post_process_passes`.
- When using `ManifestStaticFilesStorage`, static files not found in the manifest at runtime now raise a `ValueError` instead of returning an unchanged path. You can revert to the old behavior by setting `ManifestStaticFilesStorage.manifest_strict` to `False`. 
Database backend API

This section describes changes that may be needed in third-party database backends.

• The `DatabaseOperations.time_trunc_sql()` method is added to support `TimeField` truncation. It accepts a `lookup_type` and `field_name` arguments and returns the appropriate SQL to truncate the given time field `field_name` to a time object with only the given specificity. The `lookup_type` argument can be either 'hour', 'minute', or 'second'.

• The `DatabaseOperations.datetime_cast_time_sql()` method is added to support the `time` lookup. It accepts a `field_name` and `tzname` arguments and returns the SQL necessary to cast a datetime value to time value.

• To enable `FOR UPDATE SKIP LOCKED` support, set `DatabaseFeatures.has_select_for_update_skip_locked = True`.

• The new `DatabaseFeatures.supports_index_column_ordering` attribute specifies if a database allows defining ordering for columns in indexes. The default value is True and the `DatabaseIntrospection.get_constraints()` method should include an 'orders' key in each of the returned dictionaries with a list of 'ASC' and/or 'DESC' values corresponding to the ordering of each column in the index.

• `inspectdb` no longer calls `DatabaseIntrospection.get_indexes()` which is deprecated. Custom database backends should ensure all types of indexes are returned by `DatabaseIntrospection.get_constraints()`.

• Renamed the `ignores_quoted_identifier_case` feature to `ignores_table_name_case` to more accurately reflect how it is used.

• The `name` keyword argument is added to the `DatabaseWrapper.create_cursor(self, name=None)` method to allow usage of server-side cursors on backends that support it.

Dropped support for PostgreSQL 9.2 and PostGIS 2.0

Upstream support for PostgreSQL 9.2 ends in September 2017. As a consequence, Django 1.11 sets PostgreSQL 9.3 as the minimum version it officially supports.

Support for PostGIS 2.0 is also removed as PostgreSQL 9.2 is the last version to support it.

Also, the minimum supported version of psycopg2 is increased from 2.4.5 to 2.5.4.
LiveServerTestCase binds to port zero

Rather than taking a port range and iterating to find a free port, LiveServerTestCase binds to port zero and relies on the operating system to assign a free port. The DJANGO_LIVE_TEST_SERVER_ADDRESS environment variable is no longer used, and as it’s also no longer used, the manage.py test --liveserver option is removed.

If you need to bind LiveServerTestCase to a specific port, use the port attribute added in Django 1.11.2.

Protection against insecure redirects in django.contrib.auth and i18n views

LoginView, LogoutView (and the deprecated function-based equivalents), and set_language() protect users from being redirected to non-HTTPS next URLs when the app is running over HTTPS.

QuerySet.get_or_create() and update_or_create() validate arguments

To prevent typos from passing silently, get_or_create() and update_or_create() check that their arguments are model fields. This should be backwards-incompatible only in the fact that it might expose a bug in your project.

pytz is a required dependency and support for settings.TIME_ZONE = None is removed

To simplify Django’s timezone handling, pytz is now a required dependency. It’s automatically installed along with Django.

Support for settings.TIME_ZONE = None is removed as the behavior isn’t commonly used and is questionably useful. If you want to automatically detect the timezone based on the system timezone, you can use tzlocal:

```python
from tzlocal import get_localzone

TIME_ZONE = get_localzone().zone
```

This works similar to settings.TIME_ZONE = None except that it also sets os.environ['TZ']. Let us know if there’s a use case where you find you can’t adapt your code to set a TIME_ZONE.

9.1. Final releases
HTML changes in admin templates

<p class="help"> is replaced with a <div> tag to allow including lists inside help text.

Read-only fields are wrapped in <div class="readonly"> instead of <p> to allow any kind of HTML as the field’s content.

Changes due to the introduction of template-based widget rendering

Some undocumented classes in django.forms.widgets are removed:

- SubWidget
- RendererMixin, ChoiceFieldRenderer, RadioFieldRenderer, CheckboxFieldRenderer
- ChoiceInput, RadioChoiceInput, CheckboxChoiceInput

The undocumented Select.render_option() method is removed.

The Widget.format_output() method is removed. Use a custom widget template instead.

Some widget values, such as <select> options, are now localized if settings.USE_L10N=True. You could revert to the old behavior with custom widget templates that uses the localize template tag to turn off localization.

**django.template.backends.django.Template.render() prohibits non-dict context**

For compatibility with multiple template engines, django.template.backends.django.Template.render() (returned from high-level template loader APIs such as loader.get_template()) must receive a dictionary of context rather than Context or RequestContext. If you were passing either of the two classes, pass a dictionary instead – doing so is backwards-compatible with older versions of Django.

Model state changes in migration operations

To improve the speed of applying migrations, rendering of related models is delayed until an operation that needs them (e.g. RunPython). If you have a custom operation that works with model classes or model instances from the from_state argument in database_forwards() or database_backwards(), you must render model states using the clear_delayed_apps_cache() method as described in writing your own migration operation.
Server-side cursors on PostgreSQL

The change to make `QuerySet.iterator()` use server-side cursors on PostgreSQL prevents running Django with PgBouncer in transaction pooling mode. To realow that, use the `DISABLE_SERVER_SIDE_CURSORS` setting (added in Django 1.11.1) in `DATABASES`.

See Transaction pooling and server-side cursors for more discussion.

Miscellaneous

- If no items in the feed have a `pubdate` or `updatedate` attribute, `SyndicationFeed.latest_post_date()` now returns the current UTC date/time, instead of a datetime without any timezone information.
- CSRF failures are logged to the `django.security.csrf` logger instead of `django.request`.
- `ALLOWED_HOSTS` validation is no longer disabled when running tests. If your application includes tests with custom host names, you must include those host names in `ALLOWED_HOSTS`. See Tests and multiple host names.
- Using a foreign key’s id (e.g. `field_id`) in `ModelAdmin.list_display` displays the related object’s ID. Remove the `_id` suffix if you want the old behavior of the string representation of the object.
- In model forms, `CharField` with `null=True` now saves `NULL` for blank values instead of empty strings.
- On Oracle, `Model.validate_unique()` no longer checks empty strings for uniqueness as the database interprets the value as `NULL`.
- If you subclass `AbstractUser` and override `clean()`, be sure it calls `super()`. `BaseUserManager.normalize_email()` is called in a new `AbstractUser.clean()` method so that normalization is applied in cases like model form validation.
- `EmailField` and `URLField` no longer accept the `strip` keyword argument. Remove it because it doesn’t have an effect in older versions of Django as these fields always strip whitespace.
- The `checked` and `selected` attribute rendered by form widgets now uses HTML5 boolean syntax rather than XHTML’s `checked='checked'` and `selected='selected'`.
- `RelatedManager.add()`, `remove()`, `clear()`, and `set()` now clear the `prefetch_related()` cache.
- To prevent possible loss of saved settings, `setup_test_environment()` now raises an exception if called a second time before calling `teardown_test_environment()`.
- The undocumented `DateTimeAwareJSONEncoder` alias for `DjangoJSONEncoder` (renamed in Django 1.0) is removed.
- The `cached template loader` is now enabled if `OPTIONS['loaders']` isn’t specified and `OPTIONS['debug']` is `False` (the latter option defaults to the value of `DEBUG`). This could be backwards-incompatible if you have some template tags that aren’t thread safe.
• The prompt for stale content type deletion no longer occurs after running the migrate command. Use the new remove_stale_contenttypes command instead.

• The admin’s widget for IntegerField uses type="number" rather than type="text".

• Conditional HTTP headers are now parsed and compared according to the RFC 7232 Conditional Requests specification rather than the older RFC 2616.

• patch_response_headers() no longer adds a Last-Modified header. According to the RFC 7234#section-4.2.2, this header is useless alongside other caching headers that provide an explicit expiration time, e.g. Expires or Cache-Control. UpdateCacheMiddleware and add_never_cache_headers() call patch_response_headers() and therefore are also affected by this change.

• In the admin templates, <p class="help"> is replaced with a <div> tag to allow including lists inside help text.

• ConditionalGetMiddleware no longer sets the Date header as web servers set that header. It also no longer sets the Content-Length header as this is now done by CommonMiddleware.

If you have a middleware that modifies a response’s content and appears before CommonMiddleware in the MIDDLEWARE or MIDDLEWARE_CLASSES settings, you must reorder your middleware so that responses aren’t modified after Content-Length is set, or have the response modifying middleware reset the Content-Length header.

• get_model() and get_models() now raise AppRegistryNotReady if they’re called before models of all applications have been loaded. Previously they only required the target application’s models to be loaded and thus could return models without all their relations set up. If you need the old behavior of get_model(), set the require_ready argument to False.

• The unused BaseCommand.can_import_settings attribute is removed.

• The undocumented django.utils.functional.lazy_property is removed.

• For consistency with non-multipart requests, MultiPartParser.parse() now leaves request.POST immutable. If you’re modifying that QueryDict, you must now first copy it, e.g. request.POST.copy().

• Support for cx_Oracle < 5.2 is removed.

• Support for IPython < 1.0 is removed from the shell command.

• The signature of private API Widget.build_attrs() changed from extra_attrs=None, **kwargs to base_attrs, extra_attrs=None.

• File-like objects (e.g., StringIO and BytesIO) uploaded to an ImageField using the test client now require a name attribute with a value that passes the validate_image_file_extension validator. See the note in Client.post().

• FileField now moves rather than copies the file it receives. With the default file upload settings, files larger than FILE_UPLOAD_MAX_MEMORY_SIZE now have the same permissions as temporary files (often
0o600) rather than the system’s standard umask (often 0o6644). Set the `FILE_UPLOAD_PERMISSIONS` if you need the same permission regardless of file size.

Features deprecated in 1.11

`models.permalink()` decorator

Use `django.urls.reverse()` instead. For example:

```python
from django.db import models

class MyModel(models.Model):
    ...

    @models.permalink
    def url(self):
        return ('guitarist_detail', [self.slug])
```

becomes:

```python
from django.db import models
from django.urls import reverse

class MyModel(models.Model):
    ...

    def url(self):
        return reverse('guitarist_detail', args=[self.slug])
```

Miscellaneous

- `contrib.auth`’s `login()` and `logout()` function-based views are deprecated in favor of new class-based views `LoginView` and `LogoutView`.
- The unused `extra_context` parameter of `contrib.auth.views.logout_then_login()` is deprecated.
- `contrib.auth`’s `password_change()`, `password_change_done()`, `password_reset()`, `password_reset_done()`, `password_reset_confirm()`, and `password_reset_complete()` function-based views are deprecated in favor of new class-based views `PasswordChangeView`, `PasswordChangeDoneView`, `PasswordResetView`, `PasswordResetDoneView`, `PasswordResetConfirmView`, and `PasswordResetCompleteView`.
- `django.test.runner.setup_databases()` is moved to `django.test.utils.setup_databases()`.
  The old location is deprecated.
• `django.utils.translation.string_concat()` is deprecated in favor of `django.utils.text.format_lazy()`. `string_concat(*strings)` can be replaced by `format_lazy('{}' * len(strings), *strings).

• For the PyLibMCCache cache backend, passing `pylibmc` behavior settings as top-level attributes of `OPTIONS` is deprecated. Set them under a `behaviors` key within `OPTIONS` instead.

• The `host` parameter of `django.utils.http.is_safe_url()` is deprecated in favor of the new `allowed_hosts` parameter.

• Silencing exceptions raised while rendering the `{% include %}` template tag is deprecated as the behavior is often more confusing than helpful. In Django 2.1, the exception will be raised.

• `DatabaseIntrospection.get_indexes()` is deprecated in favor of `DatabaseIntrospection.get_constraints()`.

• `authenticate()` now passes a `request` argument to the `authenticate()` method of authentication backends. Support for methods that don’t accept `request` as the first positional argument will be removed in Django 2.1.

• The `USE_ETAGS` setting is deprecated in favor of `ConditionalGetMiddleware` which now adds the ETag header to responses regardless of the setting. `CommonMiddleware` and `django.utils.cache.patch_response_headers()` will no longer set ETags when the deprecation ends.

• `Model._meta.has_auto_field` is deprecated in favor of checking if `Model._meta.auto_field` is not `None`.

• Using regular expression groups with `iLmsu#` in `url()` is deprecated. The only group that’s useful is `(?i)` for case-insensitive URLs, however, case-insensitive URLs aren’t a good practice because they create multiple entries for search engines, for example. An alternative solution could be to create a `handler404` that looks for uppercase characters in the URL and redirects to a lowercase equivalent.

• The `renderer` argument is added to the `Widget.render()` method. Methods that don’t accept that argument will work through a deprecation period.

9.1.11 1.10 release

Django 1.10.8 release notes

September 5, 2017

Django 1.10.8 fixes a security issue in 1.10.7.
CVE-2017-12794: Possible XSS in traceback section of technical 500 debug page

In older versions, HTML autoescaping was disabled in a portion of the template for the technical 500 debug page. Given the right circumstances, this allowed a cross-site scripting attack. This vulnerability shouldn’t affect most production sites since you shouldn’t run with \texttt{DEBUG = True} (which makes this page accessible) in your production settings.

Django 1.10.7 release notes

April 4, 2017

Django 1.10.7 fixes two security issues and a bug in 1.10.6.

CVE-2017-7233: Open redirect and possible XSS attack via user-supplied numeric redirect URLs

Django relies on user input in some cases (e.g. \texttt{django.contrib.auth.views.login()} and \texttt{i18n}) to redirect the user to an “on success” URL. The security check for these redirects (namely \texttt{django.utils.http.is_safe_url()}) considered some numeric URLs (e.g. \texttt{http:999999999}) “safe” when they shouldn’t be.

Also, if a developer relies on \texttt{is_safe_url()} to provide safe redirect targets and puts such a URL into a link, they could suffer from an XSS attack.

CVE-2017-7234: Open redirect vulnerability in \texttt{django.views.static.serve()}

A maliciously crafted URL to a Django site using the \texttt{serve()} view could redirect to any other domain. The view no longer does any redirects as they don’t provide any known, useful functionality.

Note, however, that this view has always carried a warning that it is not hardened for production use and should be used only as a development aid.

Bugfixes

- Made admin’s \texttt{RelatedFieldWidgetWrapper} use the wrapped widget’s \texttt{value\_omitted\_from\_data()} method (#27905).
- Fixed model form \texttt{default fallback} for \texttt{SelectMultiple} (#27993).
Django 1.10.6 release notes

March 1, 2017

Django 1.10.6 fixes several bugs in 1.10.5.

Bugfixes

- Fixed `ClearableFileInput`’s “Clear” checkbox on model form fields where the model field has a default (#27805).
- Fixed `RequestDataTooBig` and `TooManyFieldsSent` exceptions crashing rather than generating a bad request response (#27820).
- Fixed a crash on Oracle and PostgreSQL when subtracting `DurationField` or `IntegerField` from `DateField` (#27828).
- Fixed query expression date subtraction accuracy on PostgreSQL for differences larger than a month (#27856).
- Fixed a `GDALException` raised by `GDALClose` on GDAL $\geq$ 2.0 (#27479).

Django 1.10.5 release notes

January 4, 2017

Django 1.10.5 fixes several bugs in 1.10.4.

Bugfixes

- Fixed a crash in the debug view if `request.user` can’t be retrieved, such as if the database is unavailable (#27567).
- Fixed occasional missing plural forms in `JavaScriptCatalog` (#27418).
- Fixed a regression in the `timesince` and `timeuntil` filters that caused incorrect results for dates in a leap year (#27637).
- Fixed a regression where `collectstatic` overwrote newer files in remote storages (#27658).
Django 1.10.4 release notes

December 1, 2016

Django 1.10.4 fixes several bugs in 1.10.3.

**Bugfixes**

- Quoted the Oracle test user’s password in queries to fix the “ORA-00922: missing or invalid option” error when the password starts with a number or special character (#27420).
- Fixed incorrect `app_label`/`model_name` arguments for `allow_migrate()` in `makemigrations` migration consistency checks (#27461).
- Made `Model.delete(keep_parents=True)` preserve parent reverse relationships in multi-table inheritance (#27407).
- Fixed a `QuerySet.update()` crash on SQLite when updating a `DateTimeField` with an F() expression and a `timedelta` (#27544).
- Prevented `LocaleMiddleware` from redirecting on URLs that should return 404 when using `prefix_default_language=False` (#27402).
- Prevented an unnecessary index from being created on an InnoDB `ForeignKey` when the field was added after the model was created (#27558).

Django 1.10.3 release notes

November 1, 2016

Django 1.10.3 fixes two security issues and several bugs in 1.10.2.

**User with hardcoded password created when running tests on Oracle**

When running tests with an Oracle database, Django creates a temporary database user. In older versions, if a password isn’t manually specified in the database settings `TEST` dictionary, a hardcoded password is used. This could allow an attacker with network access to the database server to connect.

This user is usually dropped after the test suite completes, but not when using the `manage.py test --keepdb` option or if the user has an active session (such as an attacker’s connection).

A randomly generated password is now used for each test run.
DNS rebinding vulnerability when DEBUG=True

Older versions of Django don’t validate the Host header against settings.ALLOWED_HOSTS when settings.DEBUG=True. This makes them vulnerable to a DNS rebinding attack.

While Django doesn’t ship a module that allows remote code execution, this is at least a cross-site scripting vector, which could be quite serious if developers load a copy of the production database in development or connect to some production services for which there’s no development instance, for example. If a project uses a package like the django-debug-toolbar, then the attacker could execute arbitrary SQL, which could be especially bad if the developers connect to the database with a superuser account.

settings.ALLOWED_HOSTS is now validated regardless of DEBUG. For convenience, if ALLOWED_HOSTS is empty and DEBUG=True, the following variations of localhost are allowed ['localhost', '127.0.0.1', '::1']. If your local settings file has your production ALLOWED_HOSTS value, you must now omit it to get those fallback values.

Bugfixes

- Allowed User.is_authenticated and User.is_anonymous properties to be tested for set membership (#27309).
- Fixed a performance regression when running migrate in projects with RenameModel operations (#27279).
- Added model_name to the allow_migrate() calls in makemigrations (#27200).
- Made the JavaScriptCatalog view respect the packages argument; previously it was ignored (#27374).
- Fixed QuerySet.bulk_create() on PostgreSQL when the number of objects is a multiple plus one of batch_size (#27385).
- Prevented i18n_patterns() from using too much of the URL as the language to fix a use case for prefix_default_language=False (#27063).
- Replaced a possibly incorrect redirect from SessionMiddleware when a session is destroyed in a concurrent request with a SuspiciousOperation to indicate that the request can’t be completed (#27363).

Django 1.10.2 release notes

October 1, 2016

Django 1.10.2 fixes several bugs in 1.10.1.
Bugfixes

- Fixed a crash in MySQL database validation where `SELECT @@sql_mode` doesn’t return a result (#27180).
- Allowed combining `contrib.postgres.search.SearchQuery` with more than one `&` or `|` operators (#27143).
- Disabled system check for URL patterns beginning with a ‘/’ when `APPEND_SLASH=False` (#27238).
- Fixed model form default fallback for `CheckboxSelectMultiple`, `MultiWidget`, `FileInput`, `SplitDateTimeWidget`, `SelectDateWidget`, and `SplitArrayWidget` (#27186). Custom widgets affected by this issue should implement `value_omitted_from_data()`.
- Fixed a crash in `runserver` logging during a “Broken pipe” error (#27271).
- Fixed a regression where unchanged localized date/time fields were listed as changed in the admin’s model history messages (#27302).

Django 1.10.1 release notes

September 1, 2016

Django 1.10.1 fixes several bugs in 1.10.

Bugfixes

- Fixed a crash in MySQL connections where `SELECT @@SQL_AUTO_IS_NULL` doesn’t return a result (#26991).
- Allowed `User.is_authenticated` and `User.is_anonymous` properties to be compared using `==`, `!=`, and `|` (#26988, #27154).
- Removed the broken `BaseCommand.usage()` method which was for `optparse` support (#27000).
- Fixed a checks framework crash with an empty `Meta.default_permissions` (#26997).
- Fixed a regression in the number of queries when using `RadioSelect` with a `ModelChoiceField` form field (#27001).
- Fixed a crash if `request.META['CONTENT_LENGTH']` is an empty string (#27005).
- Fixed the `isnull` lookup on a `ForeignKey` with its `to_field` pointing to a `CharField` or pointing to a `CharField` defined with `primary_key=True` (#26983).
- Prevented the `migrate` command from raising `InconsistentMigrationHistory` in the presence of unapplied squashed migrations (#27004).
- Fixed a regression in `Client.force_login()` which required specifying a `backend` rather than automatically using the first one if multiple backends are configured (#27027).
- Made `QuerySet.bulk_create()` properly initialize model instances on backends, such as PostgreSQL, that support returning the IDs of the created records so that many-to-many relationships can be used on the new objects (#27026).
- Fixed crash of `django.views.static.serve()` with `show_indexes` enabled (#26973).
- Fixed `ClearableFileInput` to avoid the required HTML attribute when initial data exists (#27037).
- Fixed annotations with database functions when combined with lookups on PostGIS (#27014).
- Reallowed the `{% for %}` tag to unpack any iterable (#27058).
- Made `makemigrations` skip inconsistent history checks on non-default databases if database routers aren’t in use or if no apps can be migrated to the database (#27054, #27110, #27142).
- Removed duplicated managers in `Model._meta.managers` (#27073).
- Fixed `contrib.admindocs` crash when a view is in a class, such as some of the admin views (#27018).
- Reverted a few admin checks that checked `field.many_to_many` back to `isinstance(field, models.ManyToManyField)` since it turned out the checks weren’t suitable to be generalized like that (#26998).
- Added the database alias to the `InconsistentMigrationHistory` message raised by `makemigrations` and `migrate` (#27089).
- Fixed the creation of `ContentType` and `Permission` objects for models of applications without migrations when calling the `migrate` command with no migrations to apply (#27044).
- Included the already applied migration state changes in the `Apps` instance provided to the `pre_migrate` signal receivers to allow `ContentType` renaming to be performed on model rename (#27100).
- Reallowed subclassing `UserCreationForm` without `USERNAME_FIELD` in `Meta.fields` (#27111).
- Fixed a regression in model forms where model fields with a `default` that didn’t appear in POST data no longer used the `default` (#27039).

**Django 1.10 release notes**

August 1, 2016

Welcome to Django 1.10!

These release notes cover the new features, as well as some backwards incompatible changes you’ll want to be aware of when upgrading from Django 1.9 or older versions. We’ve dropped some features that have reached the end of their deprecation cycle, and we’ve begun the deprecation process for some features.

See the How to upgrade Django to a newer version guide if you’re updating an existing project.
Python compatibility

Like Django 1.9, Django 1.10 requires Python 2.7, 3.4, or 3.5. We highly recommend and only officially support the latest release of each series.

What’s new in Django 1.10

Full text search for PostgreSQL

django.contrib.postgres now includes a collection of database functions to allow the use of the full text search engine. You can search across multiple fields in your relational database, combine the searches with other lookups, use different language configurations and weightings, and rank the results by relevance.

It also now includes trigram support, using the trigram_similar lookup, and the TrigramSimilarity and TrigramDistance expressions.

New-style middleware

A new style of middleware is introduced to solve the lack of strict request/response layering of the old-style of middleware described in DEP 0005. You’ll need to adapt old, custom middleware and switch from the MIDDLEWARE_CLASSES setting to the new MIDDLEWARE setting to take advantage of the improvements.

Official support for Unicode usernames

The User model in django.contrib.auth originally only accepted ASCII letters and numbers in usernames. Although it wasn’t a deliberate choice, Unicode characters have always been accepted when using Python 3.

The username validator now explicitly accepts Unicode characters by default on Python 3 only.

Custom user models may use the new ASCIIUsernameValidator or UnicodeUsernameValidator.

Minor features

django.contrib.admin

- For sites running on a subpath, the default URL for the "View site" link at the top of each admin page will now point to request.META['SCRIPT_NAME'] if set, instead of /.
- The success message that appears after adding or editing an object now contains a link to the object’s change form.
• All inline JavaScript is removed so you can enable the Content-Security-Policy HTTP header if you wish.

• The new `InlineModelAdmin.classes` attribute allows specifying classes on inline fieldsets. Inlines with a `collapse` class will be initially collapsed and their header will have a small “show” link.

• If a user doesn’t have the add permission, the `object-tools` block on a model’s changelist will now be rendered (without the add button). This makes it easier to add custom tools in this case.

• The `LogEntry` model now stores change messages in a JSON structure so that the message can be dynamically translated using the current active language. A new `LogEntry.get_change_message()` method is now the preferred way of retrieving the change message.

• Selected objects for fields in `ModelAdmin.raw_id_fields` now have a link to object’s change form.

• Added “No date” and “Has date” choices for `DateFieldListFilter` if the field is nullable.

• The jQuery library embedded in the admin is upgraded from version 2.1.4 to 2.2.3.

`django.contrib.auth`

• Added support for the Argon2 password hash. It’s recommended over PBKDF2, however, it’s not the default as it requires a third-party library.

• The default iteration count for the PBKDF2 password hasher has been increased by 25%. This backwards compatible change will not affect users who have subclassed `django.contrib.auth.hashers.PBKDF2PasswordHasher` to change the default value.

• The `django.contrib.auth.views.logout()` view sends “no-cache” headers to prevent an issue where Safari caches redirects and prevents a user from being able to log out.

• Added the optional `backend` argument to `django.contrib.auth.views.login()` to allow using it without credentials.

• The new `LOGOUT_REDIRECT_URL` setting controls the redirect of the `django.contrib.auth.views.logout()` view, if the view doesn’t get a `next_page` argument.

• The new `redirect_authenticated_user` parameter for the `django.contrib.auth.views.login()` view allows redirecting authenticated users visiting the login page.

• The new `AllowAllUsersModelBackend` and `AllowAllUsersRemoteUserBackend` ignore the value of `User.is_active`, while `ModelBackend` and `RemoteUserBackend` now reject inactive users.
django.contrib.gis

- **Distance lookups** now accept expressions as the distance value parameter.
- The new `GEOSGeometry.unary_union` property computes the union of all the elements of this geometry.
- Added the `GEOSGeometry.covers()` binary predicate.
- Added the `GDALBand.statistics()` method and `mean` and `std` attributes.
- Added support for the `MakeLine` aggregate and `GeoHash` function on SpatiaLite.
- Added support for the `Difference`, `Intersection`, and `SymDifference` functions on MySQL.
- Added support for instantiating empty GEOS geometries.
- The new `trim` and `precision` properties of `WKTWriter` allow controlling output of the fractional part of the coordinates in WKT.
- Added the `LineString.closed` and `MultiLineString.closed` properties.
- The `GeoJSON serializer` now outputs the primary key of objects in the `properties` dictionary if specific fields aren’t specified.
- The ability to replicate input data on the `GDALBand.data()` method was added. Band data can now be updated with repeated values efficiently.
- Added database functions `IsValid` and `MakeValid`, as well as the `isvalid` lookup, all for PostGIS. This allows filtering and repairing invalid geometries on the database side.
- Added raster support for all spatial lookups.

django.contrib.postgres

- For convenience, `HStoreField` now casts its keys and values to strings.

django.contrib.sessions

- The `clearsessions` management command now removes file-based sessions.
django.contrib.sites

- The `Site` model now supports natural keys.

django.contrib.staticfiles

- The `static` template tag now uses `django.contrib.staticfiles` if it’s in `INSTALLED_APPS`. This is especially useful for third-party apps which can now always use `{% load static %}` (instead of `{% load staticfiles %}` or `{% load static from staticfiles %}`) and not worry about whether or not the `staticfiles` app is installed.

- You can more easily customize the `collectstatic --ignore` option with a custom AppConfig.

Cache

- The file-based cache backend now uses the highest pickling protocol.

CSRF

- The default `CSRF_FAILURE_VIEW`, `views.csrf.csrf_failure()` now accepts an optional `template_name` parameter, defaulting to `'403_csrf.html'`, to control the template used to render the page.

- To protect against BREACH attacks, the CSRF protection mechanism now changes the form token value on every request (while keeping an invariant secret which can be used to validate the different tokens).

Database backends

- Temporal data subtraction was unified on all backends.

- If the database supports it, backends can set `DatabaseFeatures.can_return_ids_from_bulk_insert=True` and implement `DatabaseOperations.fetch_returned_insert_ids()` to set primary keys on objects created using `QuerySet.bulk_create()`.

- Added keyword arguments to the `as_sql()` methods of various expressions (Func, When, Case, and OrderBy) to allow database backends to customize them without mutating `self`, which isn’t safe when using different database backends. See the `arg_joiner` and `**extra_context` parameters of `Func.as_sql()` for an example.
File Storage

- Storage backends now present a timezone-aware API with new methods `get_accessed_time()`, `get_created_time()`, and `get_modified_time()`. They return a timezone-aware `datetime` if `USE_TZ` is `True` and a naive `datetime` in the local timezone otherwise.

- The new `Storage.generate_filename()` method makes it easier to implement custom storages that don’t use the `os.path` calls previously in `FileField`.

Forms

- Form and widget `Media` is now served using `django.contrib.staticfiles` if installed.

- The `<input>` tag rendered by `CharField` now includes a `minlength` attribute if the field has a `min_length`.

- Required form fields now have the `required` HTML attribute. Set the new `Form.use_required_attribute` attribute to `False` to disable it. The `required` attribute isn’t included on forms of formsets because the browser validation may not be correct when adding and deleting formsets.

Generic Views

- The `View` class can now be imported from `django.views`.

Internationalization

- The `i18n_patterns()` helper function can now be used in a root URLConf specified using `request.urlconf`.

- By setting the new `prefix_default_language` parameter for `i18n_patterns()` to `False`, you can allow accessing the default language without a URL prefix.

- `set_language()` now returns a 204 status code (No Content) for AJAX requests when there is no `next` parameter in `POST` or `GET`.

- The `JavaScriptCatalog` and `JSONCatalog` class-based views supersede the deprecated `javascript_catalog()` and `json_catalog()` function-based views. The new views are almost equivalent to the old ones except that by default the new views collect all JavaScript strings in the `djangojs` translation domain from all installed apps rather than only the JavaScript strings from `LOCALE_PATHS`. 
Management Commands

- `call_command()` now returns the value returned from the `command.handle()` method.
- The new `check --fail-level` option allows specifying the message level that will cause the command to exit with a non-zero status.
- The new `makemigrations --check` option makes the command exit with a non-zero status when model changes without migrations are detected.
- `makemigrations` now displays the path to the migration files that it generates.
- The `shell --interface` option now accepts python to force use of the “plain” Python interpreter.
- The new `shell --command` option lets you run a command as Django and exit, instead of opening the interactive shell.
- Added a warning to `dumpdata` if a proxy model is specified (which results in no output) without its concrete parent.
- The new `BaseCommand.requires_migrations_checks` attribute may be set to `True` if you want your command to print a warning, like `runserver` does, if the set of migrations on disk don’t match the migrations in the database.
- To assist with testing, `call_command()` now accepts a command object as the first argument.
- The `shell` command supports tab completion on systems using `libedit`, e.g. macOS.
- The `inspectdb` command lets you choose what tables should be inspected by specifying their names as arguments.

Migrations

- Added support for serialization of `enum.Enum` objects.
- Added the `elidable` argument to the `RunSQL` and `RunPython` operations to allow them to be removed when squashing migrations.
- Added support for non-atomic migrations by setting the `atomic` attribute on a `Migration`.
- The `migrate` and `makemigrations` commands now check for a consistent migration history. If they find some unapplied dependencies of an applied migration, `InconsistentMigrationHistory` is raised.
- The `pre_migrate()` and `post_migrate()` signals now dispatch their migration plan and apps.
Models

- Reverse foreign keys from proxy models are now propagated to their concrete class. The reverse relation attached by a `ForeignKey` pointing to a proxy model is now accessible as a descriptor on the proxied model class and may be referenced in queryset filtering.

- The new `Field.rel_db_type()` method returns the database column data type for fields such as `ForeignKey` and `OneToOneField` that point to another field.

- The `arity` class attribute is added to `Func`. This attribute can be used to set the number of arguments the function accepts.

- Added `BigAutoField` which acts much like an `AutoField` except that it is guaranteed to fit numbers from 1 to \(9223372036854775807\).

- `QuerySet.in_bulk()` may be called without any arguments to return all objects in the queryset.

- `related_query_name` now supports app label and class interpolation using the `%(app_label)s` and `%(class)s` strings.

- Allowed overriding model fields inherited from abstract base classes.

- The `prefetch_related_objects()` function is now a public API.

- `QuerySet.bulk_create()` sets the primary key on objects when using PostgreSQL.

- Added the `Cast` database function.

- A proxy model may now inherit multiple proxy models that share a common non-abstract parent class.

- Added `Extract` functions to extract datetime components as integers, such as year and hour.

- Added `Trunc` functions to truncate a date or datetime to a significant component. They enable queries like sales-per-day or sales-per-hour.

- `Model.__init__()` now sets values of virtual fields from its keyword arguments.

- The new `Meta.base_manager_name` and `Meta.default_manager_name` options allow controlling the `_base_manager` and `_default_manager`, respectively.

Requests and Responses

- Added `request.user` to the debug view.

- Added `HttpResponse` methods `readable()` and `seekable()` to make an instance a stream-like object and allow wrapping it with `io.TextIOWrapper`.

- Added the `HttpRequest.content_type` and `content_params` attributes which are parsed from the `CONTENT_TYPE` header.

9.1. Final releases
The parser for `request.COOKIES` is simplified to better match the behavior of browsers. `request.COOKIES` may now contain cookies that are invalid according to RFC 6265 but are possible to set via `document.cookie`.

**Serialization**

- The `django.core.serializers.json.DjangoJSONEncoder` now knows how to serialize lazy strings, typically used for translatable content.

**Templates**

- Added the `autoescape` option to the `DjangoTemplates` backend and the `Engine` class.
- Added the `is` and `is not` comparison operators to the `if` tag.
- Allowed `dictsort` to order a list of lists by an element at a specified index.
- The `debug()` context processor contains queries for all database aliases instead of only the default alias.
- Added relative path support for string arguments of the `extends` and `include` template tags.

**Tests**

- To better catch bugs, `TestCase` now checks deferrable database constraints at the end of each test.
- Tests and test cases can be marked with `tags` and run selectively with the new `test --tag` and `test --exclude-tag` options.
- You can now login and use sessions with the test client even if `django.contrib.sessions` is not in `INSTALLED_APPS`.

**URLs**

- An addition in `django.setup()` allows URL resolving that happens outside of the request/response cycle (e.g. in management commands and standalone scripts) to take `FORCE_SCRIPT_NAME` into account when it is set.
Validators

- **URLValidator** now limits the length of domain name labels to 63 characters and the total length of domain names to 253 characters per RFC 1034.

- **int_list_validator()** now accepts an optional `allow_negative` boolean parameter, defaulting to `False`, to allow negative integers.

Backwards incompatible changes in 1.10

Warning: In addition to the changes outlined in this section, be sure to review the Features removed in 1.10 for the features that have reached the end of their deprecation cycle and therefore been removed. If you haven’t updated your code within the deprecation timeline for a given feature, its removal may appear as a backwards incompatible change.

Database backend API

- GIS’s **AreaField** uses an unspecified underlying numeric type that could in practice be any numeric Python type. `decimal.Decimal` values retrieved from the database are now converted to `float` to make it easier to combine them with values used by the GIS libraries.

- In order to enable temporal subtraction you must set the `supports_temporal_subtraction` database feature flag to `True` and implement the `DatabaseOperations.subtract_temporals()` method. This method should return the SQL and parameters required to compute the difference in microseconds between the `lhs` and `rhs` arguments in the datatype used to store `DurationField`.

**select_related() prohibits non-relational fields for nested relations**

Django 1.8 added validation for non-relational fields in `select_related()`:

```
>>> Book.objects.select_related('title')
Traceback (most recent call last):
  ...
FieldError: Non-relational field given in select_related: 'title'
```

But it didn’t prohibit nested non-relation fields as it does now:

```
>>> Book.objects.select_related('author__name')
Traceback (most recent call last):
  ...
FieldError: Non-relational field given in select_related: 'name'
```
_meta.get_fields() returns consistent reverse fields for proxy models

Before Django 1.10, the get_fields() method returned different reverse fields when called on a proxy model compared to its proxied concrete class. This inconsistency was fixed by returning the full set of fields pointing to a concrete class or one of its proxies in both cases.

AbstractUser.username max_length increased to 150

A migration for django.contrib.auth.models.User.username is included. If you have a custom user model inheriting from AbstractUser, you’ll need to generate and apply a database migration for your user model.

We considered an increase to 254 characters to more easily allow the use of email addresses (which are limited to 254 characters) as usernames but rejected it due to a MySQL limitation. When using the utf8mb4 encoding (recommended for proper Unicode support), MySQL can only create unique indexes with 191 characters by default. Therefore, if you need a longer length, please use a custom user model.

If you want to preserve the 30 character limit for usernames, use a custom form when creating a user or changing usernames:

```python
from django.contrib.auth.forms import UserCreationForm

class MyUserCreationForm(UserCreationForm):
    username = forms.CharField(
        max_length=30,
        help_text='Required. 30 characters or fewer. Letters, digits and @/./+/-/_ only.',
    )
```

If you wish to keep this restriction in the admin, set UserAdmin.add_form to use this form:

```python
from django.contrib.auth.admin import UserAdmin as BaseUserAdmin
from django.contrib.auth.models import User

class UserAdmin(BaseUserAdmin):
    add_form = MyUserCreationForm

admin.site.unregister(User)
admin.site.register(User, UserAdmin)
```
Dropped support for PostgreSQL 9.1

Upstream support for PostgreSQL 9.1 ends in September 2016. As a consequence, Django 1.10 sets PostgreSQL 9.2 as the minimum version it officially supports.

**runserver output goes through logging**

Request and response handling of the `runserver` command is sent to the `django.server` logger instead of to `sys.stderr`. If you disable Django’s logging configuration or override it with your own, you’ll need to add the appropriate logging configuration if you want to see that output:

```python
'formatters': {
    'django.server': {
        '()': 'django.utils.log.ServerFormatter',
        'format': '[%(server_time)s] %(message)s',
    },
},
'handlers': {
    'django.server': {
        'level': 'INFO',
        'class': 'logging.StreamHandler',
        'formatter': 'django.server',
    },
},
'loggers': {
    'django.server': {
        'handlers': ['django.server'],
        'level': 'INFO',
        'propagate': False,
    },
}
```
auth.CustomUser and auth.ExtensionUser test models were removed

Since the introduction of migrations for the contrib apps in Django 1.8, the tables of these custom user test models were not created anymore making them unusable in a testing context.

Apps registry is no longer auto-populated when unpickling models outside of Django

The apps registry is no longer auto-populated when unpickling models. This was added in Django 1.7.2 as an attempt to allow unpickling models outside of Django, such as in an RQ worker, without calling django.setup(), but it creates the possibility of a deadlock. To adapt your code in the case of RQ, you can provide your own worker script that calls django.setup().

Removed null assignment check for non-null foreign key fields

In older versions, assigning None to a non-nullable ForeignKey or OneToOneField raised ValueError('Cannot assign None: "model.field" does not allow null values.'). For consistency with other model fields which don’t have a similar check, this check is removed.

Removed weak password hashers from the default PASSWORD_HASHERS setting

Django 0.90 stored passwords as unsalted MD5. Django 0.91 added support for salted SHA1 with automatic upgrade of passwords when a user logs in. Django 1.4 added PBKDF2 as the default password hasher.

If you have an old Django project with MD5 or SHA1 (even salted) encoded passwords, be aware that these can be cracked fairly easily with today’s hardware. To make Django users acknowledge continued use of weak hashers, the following hashers are removed from the default PASSWORD_HASHERS setting:

```python
'django.contrib.auth.hashers.SHA1PasswordHasher'
'django.contrib.auth.hashers.MD5PasswordHasher'
'django.contrib.auth.hashers.UnsaltedSHA1PasswordHasher'
'django.contrib.auth.hashers.UnsaltedMD5PasswordHasher'
'django.contrib.auth.hashers.CryptPasswordHasher'
```

Consider using a wrapped password hasher to strengthen the hashes in your database. If that’s not feasible, add the PASSWORD_HASHERS setting to your project and add back any hashers that you need.

You can check if your database has any of the removed hashers like this:

```python
from django.contrib.auth import get_user_model
User = get_user_model()
# Unsalted MD5/SHA1:
```
User.objects.filter(password__startswith='md5$$')
User.objects.filter(password__startswith='sha1$$')
# Salted MD5/SHA1:
User.objects.filter(password__startswith='md5$').exclude(password__startswith='md5$$')
User.objects.filter(password__startswith='sha1$').exclude(password__startswith='sha1$$')
# Crypt hasher:
User.objects.filter(password__startswith='crypt$$')

from django.db.models import CharField
from django.db.models.functions import Length
CharField.register_lookup(Length)
# Unsalted MD5 passwords might not have an 'md5$$' prefix:
User.objects.filter(password__length=32)

Field.get_prep_lookup() and Field.get_db_prep_lookup() methods are removed

If you have a custom field that implements either of these methods, register a custom lookup for it. For example:

class MyField(Field):
   ...

class MyFieldExact(Exact):
   def get_prep_lookup(self):
      # do_custom_stuff_for_myfield
      ....

MyField.register_lookup(MyFieldExact)

django.contrib.gis

- Support for SpatiaLite < 3.0 and GEOS < 3.3 is dropped.
- The add_postgis_srs() backwards compatibility alias for django.contrib.gis.utils.add_srs_entry() is removed.
- On Oracle/GIS, the Area aggregate function now returns a float instead of decimal.Decimal. (It’s still wrapped in a measure of square meters.)
• The default GEOSGeometry representation (WKT output) is trimmed by default. That is, instead of POINT (23.0000000000000000 5.5000000000000000), you’ll get POINT (23 5.5).

Maximum size of a request body and the number of GET/POST parameters is limited

Two new settings help mitigate denial-of-service attacks via large requests:

• DATA_UPLOAD_MAX_MEMORY_SIZE limits the size that a request body may be. File uploads don’t count toward this limit.
• DATA_UPLOAD_MAX_NUMBER_FIELDS limits the number of GET/POST parameters that are parsed.

Applications that receive unusually large form posts may need to tune these settings.

Miscellaneous

• The repr() of a QuerySet is wrapped in <QuerySet> to disambiguate it from a plain list when debugging.
• utils.version.get_version() returns PEP 440 compliant release candidate versions (e.g. ‘1.10rc1’ instead of ‘1.10c1’).
• CSRF token values are now required to be strings of 64 alphanumerics; values of 32 alphanumerics, as set by older versions of Django by default, are automatically replaced by strings of 64 characters. Other values are considered invalid. This should only affect developers or users who replace these tokens.
• The LOGOUT_URL setting is removed as Django hasn’t made use of it since pre-1.0. If you use it in your project, you can add it to your project’s settings. The default value was ‘/accounts/logout/’.
• Objects with a close() method such as files and generators passed to HttpResponse are now closed immediately instead of when the WSGI server calls close() on the response.
• A redundant transaction.atomic() call in QuerySet.update_or_create() is removed. This may affect query counts tested by TransactionTestCase.assertNumQueries().
• Support for skip_validation in BaseCommand.execute(**options) is removed. Use skip_checks (added in Django 1.7) instead.
• loaddata now raises a CommandError instead of showing a warning when the specified fixture file is not found.
• Instead of directly accessing the LogEntry.change_message attribute, it’s now better to call the LogEntry.get_change_message() method which will provide the message in the current language.
• The default error views now raise TemplateDoesNotExist if a nonexistent template_name is specified.
• The unused choices keyword argument of the Select and SelectMultiple widgets’ render() method is removed. The choices argument of the render_options() method is also removed, making selected_choices the first argument.
• Tests that violate deferrable database constraints will now error when run on a database that supports deferrable constraints.

• Built-in management commands now use indexing of keys in options, e.g. `options['verbosity']`, instead of `options.get()` and no longer perform any type coercion. This could be a problem if you’re calling commands using `Command.execute()` (which bypasses the argument parser that sets a default value) instead of `call_command()`. Instead of calling `Command.execute()`, pass the command object as the first argument to `call_command()`.

• `ModelBackend` and `RemoteUserBackend` now reject inactive users. This means that inactive users can’t login and will be logged out if they are switched from `is_active=True` to `False`. If you need the previous behavior, use the new `AllowAllUsersModelBackend` or `AllowAllUsersRemoteUserBackend` in `AUTHENTICATION_BACKENDS` instead.

• In light of the previous change, the test client’s `login()` method no longer always rejects inactive users but instead delegates this decision to the authentication backend. `force_login()` also delegates the decision to the authentication backend, so if you’re using the default backends, you need to use an active user.

• `django.views.i18n.set_language()` may now return a 204 status code for AJAX requests.

• The `base_field` attribute of `RangeField` is now a type of field, not an instance of a field. If you have created a custom subclass of `RangeField`, you should change the `base_field` attribute.

• Middleware classes are now initialized when the server starts rather than during the first request.

• If you override `is_authenticated()` or `is_anonymous()` in a custom user model, you must convert them to attributes or properties as described in the deprecation note.

• When using `ModelAdmin.save_as=True`, the “Save as new” button now redirects to the change view for the new object instead of to the model’s changelist. If you need the previous behavior, set the new `ModelAdmin.save_as_continue` attribute to `False`.

• Required form fields now have the `required` HTML attribute. Set the `Form.use_required_attribute` attribute to `False` to disable it. You could also add the `novalidate` attribute to `<form>` if you don’t want browser validation. To disable the `required` attribute on custom widgets, override the `Widget.use_required_attribute()` method.

• The WSGI handler no longer removes content of responses from HEAD requests or responses with a `status_code` of 100-199, 204, or 304. Most web servers already implement this behavior. Responses retrieved using the Django test client continue to have these “response fixes” applied.

• `Model.__init__()` now receives `django.db.models.DEFERRED` as the value of deferred fields.

• The `Model._deferred` attribute is removed as dynamic model classes when using `QuerySet.defer()` and `only()` is removed.

• `Storage.save()` no longer replaces ‘\’ with ‘/’. This behavior is moved to `FileSystemStorage` since this is a storage specific implementation detail. Any Windows user with a custom storage implementation that relies on this behavior will need to implement it in the custom storage’s `save()` method.
- Private `FileField` methods `get_directory_name()` and `get_filename()` are no longer called (and are now deprecated) which is a backwards incompatible change for users overriding those methods on custom fields. To adapt such code, override `FileField.generate_filename()` or `Storage.generate_filename()` instead. It might be possible to use `upload_to` also.

- The subject of mail sent by `AdminEmailHandler` is no longer truncated at 989 characters. If you were counting on a limited length, truncate the subject yourself.

- Private expressions `django.db.models.expressions.Date` and `DateTime` are removed. The new `Trunc` expressions provide the same functionality.

- The `_base_manager` and `_default_manager` attributes are removed from model instances. They remain accessible on the model class.

- Accessing a deleted field on a model instance, e.g. after `del obj.field`, reloads the field’s value instead of raising `AttributeError`.

- If you subclass `AbstractBaseUser` and override `clean()`, be sure it calls `super()`. `AbstractBaseUser.normalize_username()` is called in a new `AbstractBaseUser.clean()` method.

- Private API `django.forms.models.model_to_dict()` returns a queryset rather than a list of primary keys for `ManyToManyField`.

- If `django.contrib.staticfiles` is installed, the `static` template tag uses the `staticfiles` storage to construct the URL rather than simply joining the value with `STATIC_ROOT`. The new approach encodes the URL, which could be backwards-incompatible in cases such as including a fragment in a path, e.g. `{% static 'img.svg#fragment' %}`, since the # is encoded as `%23`. To adapt, move the fragment outside the template tag: `{% static 'img.svg' %}#fragment`.

- When `USE_L10N` is True, localization is now applied for the `date` and `time` filters when no format string is specified. The `DATE_FORMAT` and `TIME_FORMAT` specifiers from the active locale are used instead of the settings of the same name.

### Features deprecated in 1.10

#### Direct assignment to a reverse foreign key or many-to-many relation

Instead of assigning related objects using direct assignment:

```python
>>> new_list = [obj1, obj2, obj3]
>>> e.related_set = new_list
```

Use the `set()` method added in Django 1.9:

```python
>>> e.related_set.set([obj1, obj2, obj3])
```

This prevents confusion about an assignment resulting in an implicit save.
Non-timezone-aware Storage API

The old, non-timezone-aware methods `accessed_time()`, `created_time()`, and `modified_time()` are deprecated in favor of the new `get_*_time()` methods.

Third-party storage backends should implement the new methods and mark the old ones as deprecated. Until then, the new `get_*_time()` methods on the base `Storage` class convert `datetimes` from the old methods as required and emit a deprecation warning as they do so.

Third-party storage backends may retain the old methods as long as they wish to support earlier versions of Django.

django.contrib.gis

- The `get_srid()` and `set_srid()` methods of `GEOSGeometry` are deprecated in favor of the `srid` property.
- The `get_x()`, `set_x()`, `get_y()`, `set_y()`, `get_z()`, and `set_z()` methods of `Point` are deprecated in favor of the `x`, `y`, and `z` properties.
- The `get_coords()` and `set_coords()` methods of `Point` are deprecated in favor of the `tuple` property.
- The `cascaded_union` property of `MultiPolygon` is deprecated in favor of the `unary_union` property.
- The `django.contrib.gis.utils.precision_wkt()` function is deprecated in favor of `WKTWriter`.

CommaSeparatedIntegerField model field

CommaSeparatedIntegerField is deprecated in favor of `CharField` with the `validate_comma_separated_integer_list()` validator:

```python
from django.core.validators import validate_comma_separated_integer_list
from django.db import models

class MyModel(models.Model):
    numbers = models.CharField(..., validators=[validate_comma_separated_integer_list])
```

If you’re using Oracle, `CharField` uses a different database field type (`NVARCHAR2`) than CommaSeparatedIntegerField (`VARCHAR2`). Depending on your database settings, this might imply a different encoding, and thus a different length (in bytes) for the same contents. If your stored values are longer than the 4000 byte limit of `NVARCHAR2`, you should use `TextField` (`NCLOB`) instead. In this case, if you have any queries that group by the field (e.g. annotating the model with an aggregation or using `distinct()`) you’ll need to change them (to defer the field).
Using a model name as a query lookup when `default_related_name` is set

Assume the following models:

```python
from django.db import models

class Foo(models.Model):
    pass

class Bar(models.Model):
    foo = models.ForeignKey(Foo)

    class Meta:
        default_related_name = 'bars'
```

In older versions, `default_related_name` couldn’t be used as a query lookup. This is fixed and support for the old lookup name is deprecated. For example, since `default_related_name` is set in model `Bar`, instead of using the model name `bar` as the lookup:

```python
>>> bar = Bar.objects.get(pk=1)
>>> Foo.objects.get(bar=bar)
```

use the `default_related_name` `bars`:

```python
>>> Foo.objects.get(bars=bar)
```

__search query lookup

The `search` lookup, which supports MySQL only and is extremely limited in features, is deprecated. Replace it with a custom lookup:

```python
from django.db import models

class Search(models.Lookup):
    lookup_name = 'search'

    def as_mysql(self, compiler, connection):
        lhs, lhs_params = self.process_lhs(compiler, connection)
        rhs, rhs_params = self.process_rhs(compiler, connection)
        params = lhs_params + rhs_params
        return 'MATCH (%s) AGAINST (%s IN BOOLEAN MODE)' % (lhs, rhs), params

models.CharField.register_lookup(Search)
models.TextField.register_lookup(Search)
```
Using `User.is_authenticated()` and `User.is_anonymous()` as methods

The `is_authenticated()` and `is_anonymous()` methods of `AbstractBaseUser` and `AnonymousUser` classes are now properties. They will still work as methods until Django 2.0, but all usage in Django now uses attribute access.

For example, if you use `AuthenticationMiddleware` and want to know whether the user is currently logged-in you would use:

```python
if request.user.is_authenticated:
    ... # Do something for logged-in users.
else:
    ... # Do something for anonymous users.
```

instead of `request.user.is_authenticated()`.

This change avoids accidental information leakage if you forget to call the method, e.g.:

```python
if request.user.is_authenticated:
    return sensitive_information
```

If you override these methods in a custom user model, you must change them to properties or attributes.

Django uses a `CallableBool` object to allow these attributes to work as both a property and a method. Thus, until the deprecation period ends, you cannot compare these properties using the `is` operator. That is, the following won’t work:

```python
if request.user.is_authenticated is True:
    ...
```

Custom manager classes available through `prefetch_related` must define a `_apply_rel_filters()` method

If you defined a custom manager class available through `prefetch_related()` you must make sure it defines a `_apply_rel_filters()` method.

This method must accept a `QuerySet` instance as its single argument and return a filtered version of the queryset for the model instance the manager is bound to.
The “escape” half of django.utils.safestring

The mark_for_escaping() function and the classes it uses: EscapeData, EscapeBytes, EscapeText, EscapeString, and EscapeUnicode are deprecated.

As a result, the “lazy” behavior of the escape filter (where it would always be applied as the last filter no matter where in the filter chain it appeared) is deprecated. The filter will change to immediately apply conditional_escape() in Django 2.0.

Manager.use_for_related_fields and inheritance changes

Manager.use_for_related_fields is deprecated in favor of setting Meta.base_manager_name on the model.

Model Manager inheritance will follow MRO inheritance rules in Django 2.0, changing the current behavior where managers defined on non-abstract base classes aren’t inherited by child classes. A deprecating warning with instructions on how to adapt your code is raised if you have any affected managers. You’ll either redefine a manager from an abstract model on the child class to override the manager from the concrete model, or you’ll set the model’s Meta.manager_inheritance_from_future=True option to opt-in to the new inheritance behavior.

During the deprecation period, use_for_related_fields will be honored and raise a warning, even if a base_manager_name is set. This allows third-party code to preserve legacy behavior while transitioning to the new API. The warning can be silenced by setting silence_use_for_related_fields_deprecation=True on the manager.

Miscellaneous

- The makemigrations --exit option is deprecated in favor of the makemigrations --check option.
- django.utils.functional.allow_lazy() is deprecated in favor of the new keep_lazy() function which can be used with a more natural decorator syntax.
- The shell --plain option is deprecated in favor of -i python or --interface python.
- Importing from the django.core.urlresolvers module is deprecated in favor of its new location, django.urls.
- The template Context.has_key() method is deprecated in favor of in.
- The private attribute virtual_fields of Model._meta is deprecated in favor of private_fields.
- The private keyword arguments virtual_only in Field.contribute_to_class() and virtual in Model._meta.add_field() are deprecated in favor of private_only and private, respectively.
- The javascript_catalog() and json_catalog() views are deprecated in favor of class-based views JavaScriptCatalog and JSONCatalog.
In multi-table inheritance, implicit promotion of a OneToOneField to a parent_link is deprecated. Add parent_link=True to such fields.

The private API Widget._format_value() is made public and renamed to format_value(). The old name will work through a deprecation period.

Private FileField methods get_directory_name() and get_filename() are deprecated in favor of performing this work in Storage.generate_filename().

Old-style middleware that uses settings.MIDDLEWARE_CLASSES are deprecated. Adapt old, custom middleware and use the new MIDDLEWARE setting.

**Features removed in 1.10**

These features have reached the end of their deprecation cycle and are removed in Django 1.10. See Features deprecated in 1.8 for details, including how to remove usage of these features.

- Support for calling a SQLCompiler directly as an alias for calling its quote_name_unless_alias method is removed.

- The cycle and firstof template tags are removed from the future template tag library.

- django.conf.urls.patterns() is removed.

- Support for the prefix argument to django.conf.urls.i18n.i18n_patterns() is removed.

- SimpleTestCase.urls is removed.

- Using an incorrect count of unpacked values in the for template tag raises an exception rather than failing silently.

- The ability to reverse() URLs using a dotted Python path is removed.

- The ability to use a dotted Python path for the LOGIN_URL and LOGIN_REDIRECT_URL settings is removed.

- Support for optparse is dropped for custom management commands.

- The class django.core.management.NoArgsCommand is removed.

- django.core.context_processors module is removed.

- django.db.models.sql.aggregates module is removed.

- django.contrib.gis.db.models.sql.aggregates module is removed.

- The following methods and properties of django.db.sql.query.Query are removed:
  - Properties: aggregates and aggregate_select
  - Methods: add_aggregate, set_aggregate_mask, and append_aggregate_mask.

- django.template.resolve_variable is removed.
• The following private APIs are removed from `django.db.models.options.Options (Model._meta):
  - `get_field_by_name`
  - `get_all_field_names`
  - `get_fields_with_model`
  - `get_concrete_fields_with_model`
  - `get_m2m_with_model`
  - `get_all_related_objects`
  - `get_all_related_objects_with_model`
  - `get_all_related_many_to_many_objects`
  - `get_all_related_m2m_objects_with_model`

• The `error_message` argument of `django.forms.RegexField` is removed.

• The unordered list filter no longer supports old style lists.

• Support for string `view` arguments to `url()` is removed.

• The backward compatible shim to rename `django.forms.Form._has_changed()` to `has_changed()` is removed.

• The `removetags` template filter is removed.

• The `remove_tags()` and `strip_entities()` functions in `django.utils.html` is removed.

• The `is_admin_site` argument to `django.contrib.auth.views.password_reset()` is removed.

• `django.db.models.field.subclassing.SubfieldBase` is removed.

• `django.utils.checksums` is removed.

• The `original_content_type_id` attribute on `django.contrib.admin.helpers.InlineAdminForm` is removed.

• The backwards compatibility shim to allow `FormMixin.get_form()` to be defined with no default value for its `form_class` argument is removed.

• The following settings are removed, and you must upgrade to the `TEMPLATES` setting:
  - `ALLOWED_INCLUDE_ROOTS`
  - `TEMPLATE_CONTEXT_PROCESSORS`
  - `TEMPLATE_DEBUG`
  - `TEMPLATE_DIRS`
  - `TEMPLATE_LOADERS`
  - `TEMPLATE_STRING_IF_INVALID`
• The backwards compatibility alias `django.template.loader.BaseLoader` is removed.

• Django template objects returned by `get_template()` and `select_template()` no longer accept a `Context` in their `render()` method.

• Template response APIs enforce the use of `dict` and backend-dependent template objects instead of `Context` and `Template` respectively.

• The `current_app` parameter for the following function and classes is removed:
  - `django.shortcuts.render()`
  - `django.template.Context()`
  - `django.template.RequestContext()`
  - `django.template.response.TemplateResponse()`

• The dictionary and `context_instance` parameters for the following functions are removed:
  - `django.shortcuts.render()`
  - `django.shortcuts.render_to_response()`
  - `django.template.loader.render_to_string()`

• The `dirs` parameter for the following functions is removed:
  - `django.template.loader.get_template()`
  - `django.template.loader.select_template()`
  - `django.shortcuts.render()`
  - `django.shortcuts.render_to_response()`

• Session verification is enabled regardless of whether or not `'django.contrib.auth.middleware.SessionAuthenticationMiddleware' is in MIDDLEWARE_CLASSES. `SessionAuthenticationMiddleware` no longer has any purpose and can be removed from MIDDLEWARE_CLASSES. It’s kept as a stub until Django 2.0 as a courtesy for users who don’t read this note.

• Private attribute `django.db.models.Field.related` is removed.

• The `--list` option of the `migrate` management command is removed.

• The `ssi` template tag is removed.

• Support for the `=` comparison operator in the `if` template tag is removed.

• The backwards compatibility shims to allow `Storage.get_available_name()` and `Storage.save()` to be defined without a `max_length` argument are removed.

• Support for the legacy `%(<foo>)s` syntax in `ModelFormMixin.success_url` is removed.
- GeoQuerySet aggregate methods `collect()`, `extent()`, `extent3d()`, `make_line()`, and `unionagg()` are removed.
- The ability to specify `ContentType.name` when creating a content type instance is removed.
- Support for the old signature of `allow_migrate` is removed.
- Support for the syntax of `{% cycle %}` that uses comma-separated arguments is removed.
- The warning that `Signer` issued when given an invalid separator is now a `ValueError`.

### 9.1.12 1.9 release

**Django 1.9.13 release notes**

April 4, 2017

Django 1.9.13 fixes two security issues and a bug in 1.9.12. This is the final release of the 1.9.x series.

**CVE-2017-7233: Open redirect and possible XSS attack via user-supplied numeric redirect URLs**

Django relies on user input in some cases (e.g. `django.contrib.auth.views.login()` and `i18n`) to redirect the user to an “on success” URL. The security check for these redirects (namely `django.utils.http.is_safe_url()`) considered some numeric URLs (e.g. `http://999999999`) “safe” when they shouldn’t be.

Also, if a developer relies on `is_safe_url()` to provide safe redirect targets and puts such a URL into a link, they could suffer from an XSS attack.

**CVE-2017-7234: Open redirect vulnerability in `django.views.static.serve()`**

A maliciously crafted URL to a Django site using the `serve()` view could redirect to any other domain. The view no longer does any redirects as they don’t provide any known, useful functionality.

Note, however, that this view has always carried a warning that it is not hardened for production use and should be used only as a development aid.

**Bugfixes**

- Fixed a regression in the `timesince` and `timeuntil` filters that caused incorrect results for dates in a leap year (#27637).
Django 1.9.12 release notes

December 1, 2016

Django 1.9.12 fixes a regression in 1.9.11.

Bugfixes

- Quoted the Oracle test user’s password in queries to fix the “ORA-00922: missing or invalid option” error when the password starts with a number or special character (#27420).

Django 1.9.11 release notes

November 1, 2016

Django 1.9.11 fixes two security issues in 1.9.10.

User with hardcoded password created when running tests on Oracle

When running tests with an Oracle database, Django creates a temporary database user. In older versions, if a password isn’t manually specified in the database settings TEST dictionary, a hardcoded password is used. This could allow an attacker with network access to the database server to connect.

This user is usually dropped after the test suite completes, but not when using the manage.py test --keepdb option or if the user has an active session (such as an attacker’s connection).

A randomly generated password is now used for each test run.

DNS rebinding vulnerability when DEBUG=True

Older versions of Django don’t validate the Host header against settings.ALLOWED_HOSTS when settings.DEBUG=True. This makes them vulnerable to a DNS rebinding attack.

While Django doesn’t ship a module that allows remote code execution, this is at least a cross-site scripting vector, which could be quite serious if developers load a copy of the production database in development or connect to some production services for which there’s no development instance, for example. If a project uses a package like the django-debug-toolbar, then the attacker could execute arbitrary SQL, which could be especially bad if the developers connect to the database with a superuser account.

settings.ALLOWED_HOSTS is now validated regardless of DEBUG. For convenience, if ALLOWED_HOSTS is empty and DEBUG=True, the following variations of localhost are allowed ['localhost', '127.0.0.1', '::1']. If your local settings file has your production ALLOWED_HOSTS value, you must now omit it to get those fallback values.
Django 1.9.10 release notes

September 26, 2016

Django 1.9.10 fixes a security issue in 1.9.9.

CSRF protection bypass on a site with Google Analytics

An interaction between Google Analytics and Django’s cookie parsing could allow an attacker to set arbitrary cookies leading to a bypass of CSRF protection.

The parser for `request.COOKIES` is simplified to better match the behavior of browsers and to mitigate this attack. `request.COOKIES` may now contain cookies that are invalid according to RFC 6265 but are possible to set via `document.cookie`.

Django 1.9.9 release notes

August 1, 2016

Django 1.9.9 fixes several bugs in 1.9.8.

Bugfixes

- Fixed invalid HTML in template postmortem on the debug page (#26938).
- Fixed some GIS database function crashes on MySQL 5.7 (#26657).

Django 1.9.8 release notes

July 18, 2016

Django 1.9.8 fixes a security issue and several bugs in 1.9.7.

XSS in admin’s add/change related popup

Unsafe usage of JavaScript’s `Element.innerHTML` could result in XSS in the admin’s add/change related popup. `Element.textContent` is now used to prevent execution of the data.

The debug view also used `innerHTML`. Although a security issue wasn’t identified there, out of an abundance of caution it’s also updated to use `textContent`.
Bugfixes

- Fixed missing `varchar/text_pattern_ops` index on `CharField` and `TextField` respectively when using `AddField` on PostgreSQL (#26889).
- Fixed `makemessages` crash on Python 2 with non-ASCII file names (#26897).

Django 1.9.7 release notes

June 4, 2016

Django 1.9.7 fixes several bugs in 1.9.6.

Bugfixes

- Removed the need for the `request` context processor on the admin login page to fix a regression in 1.9 (#26558).
- Fixed translation of password validators’ `help_text` in forms (#26544).
- Fixed a regression causing the cached template loader to crash when using lazy template names (#26603).
- Fixed `on_commit` callbacks execution order when callbacks make transactions (#26627).
- Fixed `HStoreField` to raise a `ValidationError` instead of crashing on non-dictionary JSON input (#26672).
- Fixed `dbshell` crash on PostgreSQL with an empty database name (#26698).
- Fixed a regression in queries on a `OneToOneField` that has `to_field` and `primary_key=True` (#26667).

Django 1.9.6 release notes

May 2, 2016

Django 1.9.6 fixes several bugs in 1.9.5.

Bugfixes

- Added support for relative path redirects to the test client and to `SimpleTestCase assertRedirects()` because Django 1.9 no longer converts redirects to absolute URIs (#26428).
- Fixed `TimeField` microseconds round-tripping on MySQL and SQLite (#26498).
- Prevented `makemigrations` from generating infinite migrations for a model field that references a `functools.partial` (#26475).
• Fixed a regression where `SessionBase.pop()` returned `None` rather than raising a `KeyError` for non-existent values (#26520).

• Fixed a regression causing the cached template loader to crash when using template names starting with a dash (#26536).

• Restored conversion of an empty string to null when saving values of `GenericIPAddressField` on SQLite and MySQL (#26557).

• Fixed a `makemessages` regression where temporary `.py` extensions were leaked in source file paths (#26341).

Django 1.9.5 release notes

April 1, 2016
Django 1.9.5 fixes several bugs in 1.9.4.

Bugfixes

• Made `MultiPartParser` ignore filenames that normalize to an empty string to fix crash in `MemoryFileUploadHandler` on specially crafted user input (#26325).

• Fixed a race condition in `BaseCache.get_or_set()` (#26332). It now returns the `default` value instead of `False` if there’s an error when trying to add the value to the cache.

• Fixed data loss on SQLite where `DurationField` values with fractional seconds could be saved as `None` (#26324).

• The forms in `contrib.auth` no longer strip trailing and leading whitespace from the password fields (#26334). The change requires users who set their password to something with such whitespace after a site updated to Django 1.9 to reset their password. It provides backwards-compatibility for earlier versions of Django.

• Fixed a memory leak in the cached template loader (#26306).

• Fixed a regression that caused `collectstatic --clear` to fail if the storage doesn’t implement `path()` (#26297).

• Fixed a crash when using a reverse lookup with a subquery when a `ForeignKey` has a `to_field` set to something other than the primary key (#26373).

• Fixed a regression in `CommonMiddleware` that caused spurious warnings in logs on requests missing a trailing slash (#26293).

• Restored the functionality of the admin’s `raw_id_fields` in `list_editable` (#26387).

• Fixed a regression with abstract model inheritance and explicit parent links (#26413).
• Fixed a migrations crash on SQLite when renaming the primary key of a model containing a `ForeignKey` to 'self' (#26384).

• Fixed `JSONField` inadvertently escaping its contents when displaying values after failed form validation (#25532).

Django 1.9.4 release notes

March 5, 2016

Django 1.9.4 fixes a regression on Python 2 in the 1.9.3 security release where `utils.http.is_safe_url()` crashes on bytestring URLs (#26308).

Django 1.9.3 release notes

March 1, 2016

Django 1.9.3 fixes two security issues and several bugs in 1.9.2.

CVE-2016-2512: Malicious redirect and possible XSS attack via user-supplied redirect URLs containing basic auth

Django relies on user input in some cases (e.g. `django.contrib.auth.views.login()` and i18n) to redirect the user to a “on success” URL. The security check for these redirects (namely `django.utils.http.is_safe_url()`) considered some URLs with basic authentication credentials “safe” when they shouldn’t be.

For example, a URL like `http://mysite.example.com\@attacker.com` would be considered safe if the request’s host is `http://mysite.example.com`, but redirecting to this URL sends the user to `attacker.com`. Also, if a developer relies on `is_safe_url()` to provide safe redirect targets and puts such a URL into a link, they could suffer from an XSS attack.

CVE-2016-2513: User enumeration through timing difference on password hasher work factor upgrade

In each major version of Django since 1.6, the default number of iterations for the `PBKDF2PasswordHasher` and its subclasses has increased. This improves the security of the password as the speed of hardware increases, however, it also creates a timing difference between a login request for a user with a password encoded in an older number of iterations and login request for a nonexistent user (which runs the default hasher’s default number of iterations since Django 1.6).

This only affects users who haven’t logged in since the iterations were increased. The first time a user logs in after an iterations increase, their password is updated with the new iterations and there is no longer a timing difference.
The new `BasePasswordHasher.harden_runtime()` method allows hashers to bridge the runtime gap between the work factor (e.g. iterations) supplied in existing encoded passwords and the default work factor of the hasher. This method is implemented for `PBKDF2PasswordHasher` and `BCryptPasswordHasher`. The number of rounds for the latter hasher hasn’t changed since Django 1.4, but some projects may subclass it and increase the work factor as needed.

A warning will be emitted for any third-party password hashers that don’t implement a `harden_runtime()` method.

If you have different password hashes in your database (such as SHA1 hashes from users who haven’t logged in since the default hasher switched to PBKDF2 in Django 1.4), the timing difference on a login request for these users may be even greater and this fix doesn’t remedy that difference (or any difference when changing hashers). You may be able to upgrade those hashes to prevent a timing attack for that case.

**Bugfixes**

- Skipped URL checks (new in 1.9) if the `ROOT_URLCONF` setting isn’t defined (#26155).
- Fixed a crash on PostgreSQL that prevented using `TIME_ZONE=None` and `USE_TZ=False` (#26177).
- Added system checks for query name clashes of hidden relationships (#26162).
- Fixed a regression for cases where `ForeignKey.get_extra_descriptor_filter()` returned a `Q` object (#26153).
- Fixed regression with an `__in=qs` lookup for a `ForeignKey` with `to_field` set (#26196).
- Made `forms.FileField` and `utils.translation.lazy_number()` picklable (#26212).
- Fixed `RangeField` and `ArrayField` serialization with `None` values (#26215).
- Fixed a crash when filtering by a `Decimal` in `RawQuery` (#26219).
- Reallowed dashes in top-level domain names of URLs checked by `URLValidator` to fix a regression in Django 1.8 (#26204).
- Fixed some crashing deprecation shims in `SimpleTemplateResponse` that regressed in Django 1.9 (#26253).
- Fixed `BoundField` to reallow slices of subwidgets (#26267).
- Changed the admin’s “permission denied” message in the login template to use `get_username` instead of `username` to support custom user models (#26231).
- Fixed a crash when passing a nonexistent template name to the cached template loader’s `load_template()` method (#26280).
- Prevented `ContentTypeManager` instances from sharing their cache (#26286).
- Reverted a change in Django 1.9.2 (#25858) that prevented relative lazy relationships defined on abstract models to be resolved according to their concrete model’s `app_label` (#26186).
Django 1.9.2 release notes

February 1, 2016

Django 1.9.2 fixes a security regression in 1.9 and several bugs in 1.9.1. It also makes a small backwards incompatible change that hopefully doesn’t affect any users.

Security issue: User with “change” but not “add” permission can create objects for ModelAdmin’s with save_as=True

If a ModelAdmin uses save_as=True (not the default), the admin provides an option when editing objects to “Save as new”. A regression in Django 1.9 prevented that form submission from raising a “Permission Denied” error for users without the “add” permission.

Backwards incompatible change: .py-tpl files rewritten in project/app templates

The addition of some Django template language syntax to the default app template in Django 1.9 means those files now have some invalid Python syntax. This causes difficulties for packaging systems that unconditionally byte-compile *.py files.

To remedy this, a .py-tpl suffix is now used for the project and app template files included in Django. The .py-tpl suffix is replaced with .py by the startproject and startapp commands. For example, a template with the filename manage.py-tpl will be created as manage.py.

Please file a ticket if you have a custom project template containing .py-tpl files and find this behavior problematic.

Bugfixes

- Fixed a regression in ConditionalGetMiddleware causing If-None-Match checks to always return HTTP 200 (#26024).
- Fixed a regression that caused the “user-tools” items to display on the admin’s logout page (#26035).
- Fixed a crash in the translations system when the current language has no translations (#26046).
- Fixed a regression that caused the incorrect day to be selected when opening the admin calendar widget for timezones from GMT+0100 to GMT+1200 (#24980).
- Fixed a regression in the admin’s edit related model popup that caused an escaped value to be displayed in the select dropdown of the parent window (#25997).
- Fixed a regression in 1.8.8 causing incorrect index handling in migrations on PostgreSQL when adding db_index=True or unique=True to a CharField or TextField that already had the other specified, or when removing one of them from a field that had both, or when adding unique=True to a field already listed in unique_together (#26034).
• Fixed a regression where defining a relation on an abstract model’s field using a string model name without an app_label no longer resolved that reference to the abstract model’s app if using that model in another application (#25858).

• Fixed a crash when destroying an existing test database on MySQL or PostgreSQL (#26096).

• Fixed CSRF cookie check on POST requests when USE_X_FORWARDED_PORT=True (#26094).

• Fixed a queryset.order_by() crash when ordering by a relational field of a ManyToManyField through model (#26092).

• Fixed a regression that caused an exception when making database queries on SQLite with more than 2000 parameters when DEBUG is True on distributions that increase the SQLITE_MAX_VARIABLE_NUMBER compile-time limit to over 2000, such as Debian (#26063).

• Fixed a crash when using a reverse OneToOneField in ModelAdmin.readonly_fields (#26060).

• Fixed a crash when calling the migrate command in a test case with the available_apps attribute pointing to an application with migrations disabled using the MIGRATION_MODULES setting (#26135).

• Restored the ability for testing and debugging tools to determine the template from which a node came from, even during template inheritance or inclusion. Prior to Django 1.9, debugging tools could access the template origin from the node via Node.token.source[0]. This was an undocumented, private API. The origin is now available directly on each node using the Node.origin attribute (#25848).

• Fixed a regression in Django 1.8.5 that broke copying a SimpleLazyObject with copy.copy() (#26122).

• Always included geometry_field in the GeoJSON serializer output regardless of the fields parameter (#26138).

• Fixed the contrib.gis map widgets when using USE_THOUSAND_SEPARATOR=True (#20415).

• Made invalid forms display the initial of values of their disabled fields (#26129).

Django 1.9.1 release notes

January 2, 2016

Django 1.9.1 fixes several bugs in 1.9.

Bugfixes

• Fixed BaseCache.get_or_set() with the DummyCache backend (#25840).

• Fixed a regression in FormMixin causing forms to be validated twice (#25548, #26018).

• Fixed a system check crash with nested ArrayFields (#25867).

• Fixed a state bug when migrating a SeparateDatabaseAndState operation backwards (#25896).
• Fixed a regression in `CommonMiddleware` causing If-None-Match checks to always return HTTP 200 (#25900).
• Fixed missing `varchar/text_pattern_ops` index on `CharField` and `TextField` respectively when using `AlterField` on PostgreSQL (#25412).
• Fixed admin’s delete confirmation page’s summary counts of related objects (#25883).
• Added `from __future__ import unicode_literals` to the default `apps.py` created by `startapp` on Python 2 (#25909). Add this line to your own `apps.py` files created using Django 1.9 if you want your migrations to work on both Python 2 and Python 3.
• Prevented `QuerySet.delete()` from crashing on MySQL when querying across relations (#25882).
• Fixed evaluation of zero-length slices of `QuerySet.values()` (#25894).
• Fixed a state bug when using an `AlterModelManagers` operation (#25852).
• Fixed `TypedChoiceField` change detection with nullable fields (#25942).
• Fixed incorrect timezone warnings in custom admin templates that don’t have a `data-admin-utc-offset` attribute in the `body` tag. (#25845).
• Fixed a regression which prevented using a language not in Django’s default language list (`LANGUAGES`) (#25915).
• Avoided hiding some exceptions, like an invalid `INSTALLED_APPS` setting, behind `AppRegistryNotReady` when starting `runserver` (#25510). This regression appeared in 1.8.5 as a side effect of fixing #24704 and by mistake the fix wasn’t applied to the stable/1.9.x branch.
• Fixed `migrate --fake-initial` detection of many-to-many tables (#25922).
• Restored the functionality of the admin’s `list_editable` add and change buttons (#25903).
• Fixed `isnull` query lookup for `ForeignObject` (#25972).
• Fixed a regression in the admin which ignored line breaks in read-only fields instead of converting them to `<br>` (#25465).
• Fixed incorrect object reference in `SingleObjectMixin.get_context_object_name()` (#26006).
• Made `loaddata` skip disabling and enabling database constraints when it doesn’t load any fixtures (#23372).
• Restored `contrib.auth` hashers compatibility with `py-bcrypt` (#26016).
• Fixed a crash in `QuerySet.values()/values_list()` after an `annotate()` and `order_by()` when `values()/values_list()` includes a field not in the `order_by()` (#25316).
Django 1.9 release notes

Welcome to Django 1.9!

These release notes cover the new features, as well as some backwards incompatible changes you’ll want to be aware of when upgrading from Django 1.8 or older versions. We’ve dropped some features that have reached the end of their deprecation cycle, and we’ve begun the deprecation process for some features.

See the How to upgrade Django to a newer version guide if you’re updating an existing project.

Python compatibility

Django 1.9 requires Python 2.7, 3.4, or 3.5. We highly recommend and only officially support the latest release of each series.

The Django 1.8 series is the last to support Python 3.2 and 3.3.

What’s new in Django 1.9

Performing actions after a transaction commit

The new on_commit() hook allows performing actions after a database transaction is successfully committed. This is useful for tasks such as sending notification emails, creating queued tasks, or invalidating caches.

This functionality from the django-transaction-hooks package has been integrated into Django.

Password validation

Django now offers password validation to help prevent the usage of weak passwords by users. The validation is integrated in the included password change and reset forms and is simple to integrate in any other code. Validation is performed by one or more validators, configured in the new AUTH_PASSWORD_VALIDATORS setting.

Four validators are included in Django, which can enforce a minimum length, compare the password to the user’s attributes like their name, ensure passwords aren’t entirely numeric, or check against an included list of common passwords. You can combine multiple validators, and some validators have custom configuration options. For example, you can choose to provide a custom list of common passwords. Each validator provides a help text to explain its requirements to the user.

By default, no validation is performed and all passwords are accepted, so if you don’t set AUTH_PASSWORD_VALIDATORS, you will not see any change. In new projects created with the default startproject template, a simple set of validators is enabled. To enable basic validation in the included auth forms for your project, you could set, for example:
See Password validation for more details.

Permission mixins for class-based views

Django now ships with the mixins AccessMixin, LoginRequiredMixin, PermissionRequiredMixin, and UserPassesTestMixin to provide the functionality of the django.contrib.auth.decorators for class-based views. These mixins have been taken from, or are at least inspired by, the django-braces project.

There are a few differences between Django’s and django-braces’ implementation, though:

- The raise_exception attribute can only be True or False. Custom exceptions or callables are not supported.
- The handle_no_permission() method does not take a request argument. The current request is available in self.request.
- The custom test_func() of UserPassesTestMixin does not take a user argument. The current user is available in self.request.user.
- The permission_required attribute supports a string (defining one permission) or a list/tuple of strings (defining multiple permissions) that need to be fulfilled to grant access.
- The new permission_denied_message attribute allows passing a message to the PermissionDenied exception.
**New styling for contrib.admin**

The admin sports a modern, flat design with new SVG icons which look perfect on HiDPI screens. It still provides a fully-functional experience to YUI’s A-grade browsers. Older browser may experience varying levels of graceful degradation.

**Running tests in parallel**

The *test* command now supports a `--parallel` option to run a project’s tests in multiple processes in parallel.

Each process gets its own database. You must ensure that different test cases don’t access the same resources. For instance, test cases that touch the filesystem should create a temporary directory for their own use.

This option is enabled by default for Django’s own test suite provided:

- the OS supports it (all but Windows)
- the database backend supports it (all the built-in backends but Oracle)

**Minor features**

django.contrib.admin

- Admin views now have `model_admin` or `admin_site` attributes.
- The URL of the admin change view has been changed (was at /admin/<app>/<model>/<pk>/ by default and is now at /admin/<app>/<model>/<pk>/change/). This should not affect your application unless you have hardcoded admin URLs. In that case, replace those links by reversing admin URLs instead. Note that the old URL still redirects to the new one for backwards compatibility, but it may be removed in a future version.
- `ModelAdmin.get_list_select_related()` was added to allow changing the `select_related()` values used in the admin’s changelist query based on the request.
- The `available_apps` context variable, which lists the available applications for the current user, has been added to the `AdminSite.each_context()` method.
- `AdminSite.empty_value_display` and `ModelAdmin.empty_value_display` were added to override the display of empty values in admin change list. You can also customize the value for each field.
- Added jQuery events when an inline form is added or removed on the change form page.
- The time picker widget includes a ‘6 p.m’ option for consistency of having predefined options every 6 hours.
- JavaScript slug generation now supports Romanian characters.
django.contrib.admindocs

- The model section of the admindocs now also describes methods that take arguments, rather than ignoring them.

django.contrib.auth

- The default iteration count for the PBKDF2 password hasher has been increased by 20%. This backwards compatible change will not affect users who have subclassed django.contrib.auth.hashers.PBKDF2PasswordHasher to change the default value.
- The BCryptSHA256PasswordHasher will now update passwords if its rounds attribute is changed.
- AbstractBaseUser and BaseUserManager were moved to a new django.contrib.auth.base_user module so that they can be imported without including django.contrib.auth in INSTALLED_APPS (doing so raised a deprecation warning in older versions and is no longer supported in Django 1.9).
- The permission argument of permission_required() accepts all kinds of iterables, not only list and tuples.
- The new PersistentRemoteUserMiddleware makes it possible to use REMOTE_USER for setups where the header is only populated on login pages instead of every request in the session.
- The django.contrib.auth.views.password_reset() view accepts an extra_email_context parameter.

django.contrib.contenttypes

- It’s now possible to use order_with_respect_to with a GenericForeignKey.

django.contrib.gis

- All GeoQuerySet methods have been deprecated and replaced by equivalent database functions. As soon as the legacy methods have been replaced in your code, you should even be able to remove the special GeoManager from your GIS-enabled classes.
- The GDAL interface now supports instantiating file-based and in-memory GDALRaster objects from raw data. Setters for raster properties such as projection or pixel values have been added.
- For PostGIS users, the new RasterField allows storing GDALRaster objects. It supports automatic spatial index creation and reprojection when saving a model. It does not yet support spatial querying.
- The new GDALRaster.warp() method allows warping a raster by specifying target raster properties such as origin, width, height, or pixel size (among others).

9.1. Final releases
The new `GDALRaster.transform()` method allows transforming a raster into a different spatial reference system by specifying a target `srid`.

The new `GeoIP2` class allows using MaxMind’s GeoLite2 databases which includes support for IPv6 addresses.

The default OpenLayers library version included in widgets has been updated from 2.13 to 2.13.1.

django.contrib.postgres

- Added support for the `rangefield.contained_by` lookup for some built in fields which correspond to the range fields.
- Added `django.contrib.postgres.fields.JSONField`.
- Added PostgreSQL specific aggregation functions.
- Added the `TransactionNow` database function.

django.contrib.sessions

- The session model and `SessionStore` classes for the `db` and `cached_db` backends are refactored to allow a custom database session backend to build upon them. See Extending database-backed session engines for more details.

django.contrib.sites

- `get_current_site()` now handles the case where `request.get_host()` returns `domain:port`, e.g. `example.com:80`. If the lookup fails because the host does not match a record in the database and the host has a port, the port is stripped and the lookup is retried with the domain part only.

django.contrib.syndication

- Support for multiple enclosures per feed item has been added. If multiple enclosures are defined on a RSS feed, an exception is raised as RSS feeds, unlike Atom feeds, do not support multiple enclosures per feed item.
Cache

- `django.core.cache.backends.base.BaseCache` now has a `get_or_set()` method.
- `django.views.decorators.cache.never_cache()` now sends more persuasive headers (added `no-cache, no-store, must-revalidate` to `Cache-Control`) to better prevent caching. This was also added in Django 1.8.8.

CSRF

- The request header’s name used for CSRF authentication can be customized with `CSRF_HEADER_NAME`.
- The CSRF referer header is now validated against the `CSRF_COOKIE_DOMAIN` setting if set. See How it works for details.
- The new `CSRF_TRUSTED_ORIGINS` setting provides a way to allow cross-origin unsafe requests (e.g. POST) over HTTPS.

Database backends

- The PostgreSQL backend (`django.db.backends.postgresql_psycopg2`) is also available as `django.db.backends.postgresql`. The old name will continue to be available for backwards compatibility.

File Storage

- `Storage.get_valid_name()` is now called when the `upload_to` is a callable.
- `File` now has the `seekable()` method when using Python 3.

Forms

- `ModelForm` accepts the new `Meta` option `field_classes` to customize the type of the fields. See Overriding the default fields for details.
- You can now specify the order in which form fields are rendered with the `field_order` attribute, the `field_order` constructor argument, or the `order_fields()` method.
- A form prefix can be specified inside a form class, not only when instantiating a form. See Prefixes for forms for details.
- You can now specify keyword arguments that you want to pass to the constructor of forms in a formset.
- `SlugField` now accepts an `allow_unicode` argument to allow Unicode characters in slugs.
- `CharField` now accepts a `strip` argument to strip input data of leading and trailing whitespace. As this defaults to `True` this is different behavior from previous releases.
• Form fields now support the `disabled` argument, allowing the field widget to be displayed disabled by browsers.

• It’s now possible to customize bound fields by overriding a field’s `get_bound_field()` method.

Generic Views

• Class-based views generated using `as_view()` now have `view_class` and `view_initkwargs` attributes.

• `method_decorator()` can now be used with a list or tuple of decorators. It can also be used to decorate classes instead of methods.

Internationalization

• The `django.views.i18n.set_language()` view now properly redirects to translated URLs, when available.

• The `django.views.i18n.javascript_catalog()` view now works correctly if used multiple times with different configurations on the same page.

• The `django.utils.timezone.make_aware()` function gained an `is_dst` argument to help resolve ambiguous times during DST transitions.

• You can now use locale variants supported by gettext. These are usually used for languages which can be written in different scripts, for example Latin and Cyrillic (e.g. `be@latin`).

• Added the `django.views.i18n.json_catalog()` view to help build a custom client-side i18n library upon Django translations. It returns a JSON object containing a translations catalog, formatting settings, and a plural rule.

• Added the `name_translated` attribute to the object returned by the `get_language_info` template tag. Also added a corresponding template filter: `language_name_translated`.

• You can now run `compilemessages` from the root directory of your project and it will find all the app message files that were created by `makemessages`.

• `makemessages` now calls `xgettext` once per locale directory rather than once per translatable file. This speeds up localization builds.

• `blocktrans` supports assigning its output to a variable using `asvar`.

• Two new languages are available: Colombian Spanish and Scottish Gaelic.
Management Commands

- The new `sendtestemail` command lets you send a test email to easily confirm that email sending through Django is working.

- To increase the readability of the SQL code generated by `sqlmigrate`, the SQL code generated for each migration operation is preceded by the operation’s description.

- The `dumpdata` command output is now deterministically ordered. Moreover, when the `--output` option is specified, it also shows a progress bar in the terminal.

- The `createcachetable` command now has a `--dry-run` flag to print out the SQL rather than execute it.

- The `startapp` command creates an `apps.py` file. Since it doesn’t use `default_app_config` (a discouraged API), you must specify the app config’s path, e.g. `'polls.apps.PollsConfig'`, in `INSTALLED_APPS` for it to be used (instead of just `'polls'`).

- When using the PostgreSQL backend, the `dbshell` command can connect to the database using the password from your settings file (instead of requiring it to be manually entered).

- The `django` package may be run as a script, i.e. `python -m django`, which will behave the same as `django-admin`.

- Management commands that have the `--noinput` option now also take `--no-input` as an alias for that option.

Migrations

- Initial migrations are now marked with an `initial = True` class attribute which allows `migrate --fake-initial` to more easily detect initial migrations.

- Added support for serialization of `functools.partial` and `LazyObject` instances.

- When supplying `None` as a value in `MIGRATION_MODULES`, Django will consider the app an app without migrations.

- When applying migrations, the “Rendering model states” step that’s displayed when running `migrate` with verbosity 2 or higher now computes only the states for the migrations that have already been applied. The model states for migrations being applied are generated on demand, drastically reducing the amount of required memory.

  However, this improvement is not available when unapplying migrations and therefore still requires the precomputation and storage of the intermediate migration states.

  This improvement also requires that Django no longer supports mixed migration plans. Mixed plans consist of a list of migrations where some are being applied and others are being unapplied. This was never officially supported and never had a public API that supports this behavior.
• The `squashmigrations` command now supports specifying the starting migration from which migrations will be squashed.

Models

• `QuerySet.bulk_create()` now works on proxy models.

• Database configuration gained a `TIME_ZONE` option for interacting with databases that store datetimes in local time and don’t support time zones when `USE_TZ` is True.

• Added the `RelatedManager.set()` method to the related managers created by `ForeignKey`, `GenericForeignKey`, and `ManyToManyField`.

• The `add()` method on a reverse foreign key now has a `bulk` parameter to allow executing one query regardless of the number of objects being added rather than one query per object.

• Added the `keep_parents` parameter to `Model.delete()` to allow deleting only a child’s data in a model that uses multi-table inheritance.

• `Model.delete()` and `QuerySet.delete()` return the number of objects deleted.

• Added a system check to prevent defining both `Meta.ordering` and `order_with_respect_to` on the same model.

• `Date and time` lookups can be chained with other lookups (such as `exact`, `gt`, `lt`, etc.). For example: `Entry.objects.filter(pub_date__month__gt=6)`.

• Time lookups (hour, minute, second) are now supported by `TimeField` for all database backends. Support for backends other than SQLite was added but undocumented in Django 1.7.

• You can specify the `output_field` parameter of the `Avg` aggregate in order to aggregate over non-numeric columns, such as `DurationField`.

• Added the `date` lookup to `DateTimeField` to allow querying the field by only the date portion.

• Added the `Greatest` and `Least` database functions.

• Added the `Now` database function, which returns the current date and time.

• `Transform` is now a subclass of `Func()` which allows `Transforms` to be used on the right hand side of an expression, just like regular `Funcs`. This allows registering some database functions like `Length`, `Lower`, and `Upper` as transforms.

• `SlugField` now accepts an `allow_unicode` argument to allow Unicode characters in slugs.

• Added support for referencing annotations in `QuerySet.distinct()`.

• `connection.queries` shows queries with substituted parameters on SQLite.

• `Query expressions` can now be used when creating new model instances using `save()`, `create()`, and `bulk_create()`.
Requests and Responses

- Unless `HttpResponse.reason_phrase` is explicitly set, it now is determined by the current value of `HttpResponse.status_code`. Modifying the value of `status_code` outside of the constructor will also modify the value of `reason_phrase`.
- The debug view now shows details of chained exceptions on Python 3.
- The default 40x error views now accept a second positional parameter, the exception that triggered the view.
- View error handlers now support `TemplateResponse`, commonly used with class-based views.
- Exceptions raised by the `render()` method are now passed to the `process_exception()` method of each middleware.
- Request middleware can now set `HttpRequest.urlconf` to `None` to revert any changes made by previous middleware and return to using the `ROOT_URLCONF`.
- The `DISALLOWED_USER_AGENTS` check in `CommonMiddleware` now raises a `PermissionDenied` exception as opposed to returning an `HttpResponseForbidden` so that `handler403` is invoked.
- Added `HttpRequest.get_port()` to fetch the originating port of the request.
- Added the `json_dumps_params` parameter to `JsonResponse` to allow passing keyword arguments to the `json.dumps()` call used to generate the response.
- The `BrokenLinkEmailsMiddleware` now ignores 404s when the referer is equal to the requested URL. To circumvent the empty referer check already implemented, some web bots set the referer to the requested URL.

Templates

- Template tags created with the `simple_tag()` helper can now store results in a template variable by using the `as` argument.
- Added a `Context.setdefault()` method.
- The `django.template` logger was added and includes the following messages:
  - A `DEBUG` level message for missing context variables.
  - A `WARNING` level message for uncaught exceptions raised during the rendering of an `{% include %}` when debug mode is off (helpful since `{% include %}` silences the exception and returns an empty string).
- The `firstof` template tag supports storing the output in a variable using ‘as’.
- `Context.update()` can now be used as a context manager.
- Django template loaders can now extend templates recursively.
- The debug page template postmortem now include output from each engine that is installed.

- Debug page integration for custom template engines was added.

- The *DjangoTemplates* backend gained the ability to register libraries and builtins explicitly through the template OPTIONS.

- The timesince and timeuntil filters were improved to deal with leap years when given large time spans.

- The include tag now caches parsed templates objects during template rendering, speeding up reuse in places such as for loops.

**Tests**

- Added the json() method to test client responses to give access to the response body as JSON.

- Added the force_login() method to the test client. Use this method to simulate the effect of a user logging into the site while skipping the authentication and verification steps of login().

**URLs**

- Regular expression lookahead assertions are now allowed in URL patterns.

- The application namespace can now be set using an app_name attribute on the included module or object. It can also be set by passing a 2-tuple of (list of patterns), (application namespace) as the first argument to include().

- System checks have been added for common URL pattern mistakes.

**Validators**

- Added django.core.validators.int_list_validator() to generate validators of strings containing integers separated with a custom character.

- EmailValidator now limits the length of domain name labels to 63 characters per RFC 1034.

- Added validate_unicode_slug() to validate slugs that may contain Unicode characters.
Backwards incompatible changes in 1.9

Warning: In addition to the changes outlined in this section, be sure to review the Features removed in 1.9 for the features that have reached the end of their deprecation cycle and therefore been removed. If you haven’t updated your code within the deprecation timeline for a given feature, its removal may appear as a backwards incompatible change.

Database backend API

- A couple of new tests rely on the ability of the backend to introspect column defaults (returning the result as Field.default). You can set the can_introspect_default database feature to False if your backend doesn’t implement this. You may want to review the implementation on the backends that Django includes for reference (#24245).

- Registering a global adapter or converter at the level of the DB-API module to handle time zone information of datetime values passed as query parameters or returned as query results on databases that don’t support time zones is discouraged. It can conflict with other libraries.

  The recommended way to add a time zone to datetime values fetched from the database is to register a converter for DateTimeField in DatabaseOperations.get_db_converters().

  The needs_datetime_string_cast database feature was removed. Database backends that set it must register a converter instead, as explained above.

- The DatabaseOperations.value_to_db_<type>() methods were renamed to adapt_<type>field_value() to mirror the convert_<type>field_value() methods.

- To use the new date lookup, third-party database backends may need to implement the DatabaseOperations.datetime_cast_date_sql() method.

- The DatabaseOperations.time_extract_sql() method was added. It calls the existing date_extract_sql() method. This method is overridden by the SQLite backend to add time lookups (hour, minute, second) to TimeField, and may be needed by third-party database backends.

- The DatabaseOperations.datetime_cast_sql() method (not to be confused with DatabaseOperations.datetime_cast_date_sql() mentioned above) has been removed. This method served to format dates on Oracle long before 1.0, but hasn’t been overridden by any core backend in years and hasn’t been called anywhere in Django’s code or tests.

- In order to support test parallelization, you must implement the DatabaseCreation._clone_test_db() method and set DatabaseFeatures.can_clone_databases = True. You may have to adjust DatabaseCreation.get_test_db_clone_settings().
Default settings that were tuples are now lists

The default settings in django.conf.global_settings were a combination of lists and tuples. All settings that were formerly tuples are now lists.

**is_usable attribute on template loaders is removed**

Django template loaders previously required an is_usable attribute to be defined. If a loader was configured in the template settings and this attribute was False, the loader would be silently ignored. In practice, this was only used by the egg loader to detect if setuptools was installed. The is_usable attribute is now removed and the egg loader instead fails at runtime if setuptools is not installed.

**Related set direct assignment**

Direct assignment of related objects in the ORM used to perform a clear() followed by a call to add(). This caused needlessly large data changes and prevented using the m2m_changed signal to track individual changes in many-to-many relations.

Direct assignment now relies on the new set() method on related managers which by default only processes changes between the existing related set and the one that’s newly assigned. The previous behavior can be restored by replacing direct assignment by a call to set() with the keyword argument clear=True.

ModelForm, and therefore ModelAdmin, internally rely on direct assignment for many-to-many relations and as a consequence now use the new behavior.

**Filesystem-based template loaders catch more specific exceptions**

When using the filesystem.Loader or app_directories.Loader template loaders, earlier versions of Django raised a TemplateDoesNotExist error if a template source existed but was unreadable. This could happen under many circumstances, such as if Django didn’t have permissions to open the file, or if the template source was a directory. Now, Django only silences the exception if the template source does not exist. All other situations result in the original IOError being raised.

**HTTP redirects no longer forced to absolute URIs**

Relative redirects are no longer converted to absolute URIs. RFC 2616 required the Location header in redirect responses to be an absolute URI, but it has been superseded by RFC 7231 which allows relative URIs in Location, recognizing the actual practice of user agents, almost all of which support them.

Consequently, the expected URLs passed to assertRedirects should generally no longer include the scheme and domain part of the URLs. For example, self.assertRedirects(response, "http://testserver/"
some-url/’) should be replaced by `self.assertRedirects(response, ’/some-url/’) (unless the redirection specifically contained an absolute URL).

In the rare case that you need the old behavior (discovered with an ancient version of Apache with mod_scgi that interprets a relative redirect as an “internal redirect”), you can restore it by writing a custom middleware:

```python
class LocationHeaderFix(object):
    def process_response(self, request, response):
        if 'Location' in response:
            response['Location'] = request.build_absolute_uri(response['Location'])
        return response
```

**Dropped support for PostgreSQL 9.0**

Upstream support for PostgreSQL 9.0 ended in September 2015. As a consequence, Django 1.9 sets 9.1 as the minimum PostgreSQL version it officially supports.

**Dropped support for Oracle 11.1**

Upstream support for Oracle 11.1 ended in August 2015. As a consequence, Django 1.9 sets 11.2 as the minimum Oracle version it officially supports.

**Bulk behavior of `add()` method of related managers**

To improve performance, the `add()` methods of the related managers created by `ForeignKey` and `GenericForeignKey` changed from a series of `Model.save()` calls to a single `QuerySet.update()` call. The change means that `pre_save` and `post_save` signals aren’t sent anymore. You can use the `bulk=False` keyword argument to revert to the previous behavior.

**Template LoaderOrigin and StringOrigin are removed**

In previous versions of Django, when a template engine was initialized with `debug` as `True`, an instance of `django.template.loader.LoaderOrigin` or `django.template.base.StringOrigin` was set as the origin attribute on the template object. These classes have been combined into `Origin` and is now always set regardless of the engine debug setting. For a minimal level of backwards compatibility, the old class names will be kept as aliases to the new `Origin` class until Django 2.0.
Changes to the default logging configuration

To make it easier to write custom logging configurations, Django’s default logging configuration no longer defines `django.request` and `django.security` loggers. Instead, it defines a single `django` logger, filtered at the `INFO` level, with two handlers:

- `console`: filtered at the `INFO` level and only active if `DEBUG=True`.
- `mail_admins`: filtered at the `ERROR` level and only active if `DEBUG=False`.

If you aren’t overriding Django’s default logging, you should see minimal changes in behavior, but you might see some new logging to the `runserver` console, for example.

If you are overriding Django’s default logging, you should check to see how your configuration merges with the new defaults.

HttpRequest details in error reporting

It was redundant to display the full details of the `HttpRequest` each time it appeared as a stack frame variable in the HTML version of the debug page and error email. Thus, the HTTP request will now display the same standard representation as other variables (`repr(request)`). As a result, the `ExceptionReporterFilter.get_request_repr()` method and the undocumented `django.http.build_request_repr()` function were removed.

The contents of the text version of the email were modified to provide a traceback of the same structure as in the case of AJAX requests. The traceback details are rendered by the `ExceptionReporter.get_traceback_text()` method.

Removal of time zone aware global adapters and converters for datetimes

Django no longer registers global adapters and converters for managing time zone information on `datetime` values sent to the database as query parameters or read from the database in query results. This change affects projects that meet all the following conditions:

- The `USE_TZ` setting is `True`.
- The database is SQLite, MySQL, Oracle, or a third-party database that doesn’t support time zones. In doubt, you can check the value of `connection.features.supports_timezones`.
- The code queries the database outside of the ORM, typically with `cursor.execute(sql, params)`.

If you’re passing aware `datetime` parameters to such queries, you should turn them into naive datetimes in UTC:

```python
from django.utils import timezone
param = timezone.make_naive(param, timezone.utc)
```
If you fail to do so, the conversion will be performed as in earlier versions (with a deprecation warning) up until Django 1.11. Django 2.0 won’t perform any conversion, which may result in data corruption.

If you’re reading `datetime` values from the results, they will be naive instead of aware. You can compensate as follows:

```python
from django.utils import timezone
value = timezone.make_aware(value, timezone.utc)
```

You don’t need any of this if you’re querying the database through the ORM, even if you’re using `raw()` queries. The ORM takes care of managing time zone information.

**Template tag modules are imported when templates are configured**

The `DjangoTemplates` backend now performs discovery on installed template tag modules when instantiated. This update enables libraries to be provided explicitly via the 'libraries' key of `OPTIONS` when defining a `DjangoTemplates` backend. Import or syntax errors in template tag modules now fail early at instantiation time rather than when a template with a `{% load %}` tag is first compiled.

**`django.template.base.add_to_builtins()` is removed**

Although it was a private API, projects commonly used `add_to_builtins()` to make template tags and filters available without using the `{% load %}` tag. This API has been formalized. Projects should now define built-in libraries via the 'builtins' key of `OPTIONS` when defining a `DjangoTemplates` backend.

**`simple_tag` now wraps tag output in `conditional_escape`**

In general, template tags do not autoescape their contents, and this behavior is documented. For tags like `inclusion_tag`, this is not a problem because the included template will perform autoescaping. For `assignment_tag()`, the output will be escaped when it is used as a variable in the template.

For the intended use cases of `simple_tag`, however, it is very easy to end up with incorrect HTML and possibly an XSS exploit. For example:

```python
@register.simple_tag(takes_context=True)
def greeting(context):
    return "Hello {0}!".format(context['request'].user.first_name)
```

In older versions of Django, this will be an XSS issue because `user.first_name` is not escaped.

In Django 1.9, this is fixed: if the template context has `autoescape=True` set (the default), then `simple_tag` will wrap the output of the tag function with `conditional_escape()`.

To fix your `simple_tags`, it is best to apply the following practices:
• Any code that generates HTML should use either the template system or `format_html()`.
• If the output of a `simple_tag` needs escaping, use `escape()` or `conditional_escape()`.
• If you are absolutely certain that you are outputting HTML from a trusted source (e.g., a CMS field that stores HTML entered by admins), you can mark it as such using `mark_safe()`.

Tags that follow these rules will be correct and safe whether they are run on Django 1.9+ or earlier.

**Paginator.page_range**

`Paginator.page_range` is now an iterator instead of a list.

In versions of Django previous to 1.8, `Paginator.page_range` returned a list in Python 2 and a `range` in Python 3. Django 1.8 consistently returned a list, but an iterator is more efficient.

Existing code that depends on list specific features, such as indexing, can be ported by converting the iterator into a list using `list()`.

**Implicit QuerySet `__in` lookup removed**

In earlier versions, queries such as:

```python
Model.objects.filter(related_id=RelatedModel.objects.all())
```

would implicitly convert to:

```python
Model.objects.filter(related_id__in=RelatedModel.objects.all())
```

resulting in SQL like "related_id IN (SELECT id FROM ...)."

This implicit `__in` no longer happens so the "IN" SQL is now "=" , and if the subquery returns multiple results, at least some databases will throw an error.

**contrib.admin browser support**

The admin no longer supports Internet Explorer 8 and below, as these browsers have reached end-of-life.

CSS and images to support Internet Explorer 6 and 7 have been removed. PNG and GIF icons have been replaced with SVG icons, which are not supported by Internet Explorer 8 and earlier.

The jQuery library embedded in the admin has been upgraded from version 1.11.2 to 2.1.4. jQuery 2.x has the same API as jQuery 1.x, but does not support Internet Explorer 6, 7, or 8, allowing for better performance and a smaller file size. If you need to support IE8 and must also use the latest version of Django, you can override the admin’s copy of jQuery with your own by creating a Django application with this structure:
SyntaxError when installing Django setuptools 5.5.x

When installing Django 1.9 or 1.9.1 with setuptools 5.5.x, you’ll see:

```
Compiling django/conf/app_template/apps.py ...
  File "django/conf/app_template/apps.py", line 4
    class {{ camel_case_app_name }}Config(AppConfig):
    ~
SyntaxError: invalid syntax

Compiling django/conf/app_template/models.py ...
  File "django/conf/app_template/models.py", line 1
    {{ unicode_literals }}from django.db import models
    ~
SyntaxError: invalid syntax
```

It’s safe to ignore these errors (Django will still install just fine), but you can avoid them by upgrading setuptools to a more recent version. If you’re using pip, you can upgrade pip using `python -m pip install -U pip` which will also upgrade setuptools. This is resolved in later versions of Django as described in the Django 1.9.2 release notes.

Miscellaneous

- The jQuery static files in `contrib.admin` have been moved into a `vendor/jquery` subdirectory.
- The text displayed for null columns in the admin changelist `list_display` cells has changed from `(None)` (or its translated equivalent) to `-` (a dash).
- `django.http.responses.REASON_PHRASES` and `django.core.handlers.wsgi.STATUS_CODE_TEXT` have been removed. Use Python’s Standard Library instead: `http.client.responses` for Python 3 and `httplib.responses` for Python 2.
- `ValuesQuerySet` and `ValuesListQuerySet` have been removed.
- The `admin/base.html` template no longer sets `window.__admin_media_prefix__` or `window.__admin_utc_offset__`. Image references in JavaScript that used that value to construct absolute URLs have been moved to CSS for easier customization. The UTC offset is stored on a data attribute of the `<body>` tag.
- `CommaSeparatedIntegerField` validation has been refined to forbid values like ",", ",1", and ",1,,2".
• Form initialization was moved from the `ProcessFormView.get()` method to the new `FormMixin.get_context_data()` method. This may be backwards incompatible if you have overridden the `get_context_data()` method without calling `super()`.

• Support for PostGIS 1.5 has been dropped.

• The `django.contrib.sites.models.Site.domain` field was changed to be `unique`.

• In order to enforce test isolation, database queries are not allowed by default in `SimpleTestCase` tests anymore. You can disable this behavior by setting the `allow_database_queries` class attribute to `True` on your test class.

• `ResolverMatch.app_name` was changed to contain the full namespace path in the case of nested namespaces. For consistency with `ResolverMatch.namespace`, the empty value is now an empty string instead of `None`.

• For security hardening, session keys must be at least 8 characters.

• Private function `django.utils.functional.total_ordering()` has been removed. It contained a workaround for a `functools.total_ordering()` bug in Python versions older than 2.7.3.

• XML serialization (either through `dumpdata` or the syndication framework) used to output any characters it received. Now if the content to be serialized contains any control characters not allowed in the XML 1.0 standard, the serialization will fail with a `ValueError`.

• `CharField` now strips input of leading and trailing whitespace by default. This can be disabled by setting the new `strip` argument to `False`.

• Template text that is translated and uses two or more consecutive percent signs, e.g. "%%", may have a new `msgid` after `makemessages` is run (most likely the translation will be marked fuzzy). The new `msgid` will be marked "#, python-format".

• If neither `request.current_app` nor `Context.current_app` are set, the `url` template tag will now use the namespace of the current request. Set `request.current_app` to `None` if you don’t want to use a namespace hint.

• The `SILENCED_SYSTEM_CHECKS` setting now silences messages of all levels. Previously, messages of `ERROR` level or higher were printed to the console.

• The `FlatPage.enable_comments` field is removed from the `FlatPageAdmin` as it’s unused by the application. If your project or a third-party app makes use of it, create a custom `ModelAdmin` to add it back.

• The return value of `setup_databases()` and the first argument of `teardown_databases()` changed. They used to be `(old_names, mirrors)` tuples. Now they’re just the first item, `old_names`.

• By default `LiveServerTestCase` attempts to find an available port in the 8081-8179 range instead of just trying port 8081.

• The system checks for `ModelAdmin` now check instances rather than classes.
• The private API to apply mixed migration plans has been dropped for performance reasons. Mixed plans consist of a list of migrations where some are being applied and others are being unapplied.

• The related model object descriptor classes in `django.db.models.fields.related` (private API) are moved from the `related` module to `related_descriptors` and renamed as follows:
  - `ReverseSingleRelatedObjectDescriptor` is `ForwardManyToOneDescriptor`
  - `SingleRelatedObjectDescriptor` is `ReverseOneToOneDescriptor`
  - `ForeignRelatedObjectsDescriptor` is `ReverseManyToManyDescriptor`
  - `ManyRelatedObjectsDescriptor` is `ManyToManyDescriptor`

• If you implement a custom `handler404` view, it must return a response with an HTTP 404 status code. Use `HttpResponseNotFound` or pass `status=404` to the `HttpResponse`. Otherwise, `APPEND_SLASH` won’t work correctly with `DEBUG=False`.

**Features deprecated in 1.9**

`assignment_tag()`

Django 1.4 added the `assignment_tag` helper to ease the creation of template tags that store results in a template variable. The `simple_tag()` helper has gained this same ability, making the `assignment_tag` obsolete. Tags that use `assignment_tag` should be updated to use `simple_tag`.

`{% cycle %}` syntax with comma-separated arguments

The `cycle` tag supports an inferior old syntax from previous Django versions:

```
{% cycle row1,row2,row3 %}
```

Its parsing caused bugs with the current syntax, so support for the old syntax will be removed in Django 1.10 following an accelerated deprecation.

**ForeignKey and OneToOneField on_delete argument**

In order to increase awareness about cascading model deletion, the `on_delete` argument of `ForeignKey` and `OneToOneField` will be required in Django 2.0.

Update models and existing migrations to explicitly set the argument. Since the default is `models.CASCADE`, add `on_delete=models.CASCADE` to all `ForeignKey` and `OneToOneField` that don’t use a different option. You can also pass it as the second positional argument if you don’t care about compatibility with older versions of Django.
Field.rel changes

Field.rel and its methods and attributes have changed to match the related fields API. The Field.rel attribute is renamed to remote_field and many of its methods and attributes are either changed or renamed. The aim of these changes is to provide a documented API for relation fields.

GeoManager and GeoQuerySet custom methods

All custom GeoQuerySet methods (area(), distance(), gml(), ...) have been replaced by equivalent geographic expressions in annotations (see in new features). Hence the need to set a custom GeoManager to GIS-enabled models is now obsolete. As soon as your code doesn’t call any of the deprecated methods, you can simply remove the objects = GeoManager() lines from your models.

Template loader APIs have changed

Django template loaders have been updated to allow recursive template extending. This change necessitated a new template loader API. The old load_template() and load_template_sources() methods are now deprecated. Details about the new API can be found in the template loader documentation.

Passing a 3-tuple or an app_name to include()

The instance namespace part of passing a tuple as an argument to include() has been replaced by passing the namespace argument to include(). For example:

```python
polls_patterns = [
    url(...),
]

urlpatterns = [
    url(r'^polls/', include((polls_patterns, 'polls', 'author-polls'))),
]
```

becomes:

```python
polls_patterns = ([
    url(...),
], 'polls')  # 'polls' is the app_name

urlpatterns = [
    url(r'^polls/', include(polls_patterns, namespace='author-polls')),
]```
The `app_name` argument to `include()` has been replaced by passing a 2-tuple (as above), or passing an object or module with an `app_name` attribute (as below). If the `app_name` is set in this new way, the `namespace` argument is no longer required. It will default to the value of `app_name`. For example, the URL patterns in the tutorial are changed from:

**Listing 1: mysite/urls.py**

```python
urlpatterns = [
    url(r'^polls/', include('polls.urls', namespace="polls")),
    ...
]
```

to:

**Listing 2: mysite/urls.py**

```python
urlpatterns = [
    url(r'^polls/', include('polls.urls')),  # 'namespace="polls"' removed
    ...
]
```

**Listing 3: polls/urls.py**

```python
app_name = 'polls'  # added
urlpatterns = [...]  # added
```

This change also means that the old way of including an `AdminSite` instance is deprecated. Instead, pass `admin.site.urls` directly to `django.conf.urls.url()`.
Listing 4: urls.py

```python
from django.conf.urls import url
from django.contrib import admin

urlpatterns = [
    url(r'^admin/', admin.site.urls),
]
```

**URL application namespace required if setting an instance namespace**

In the past, an instance namespace without an application namespace would serve the same purpose as the application namespace, but it was impossible to reverse the patterns if there was an application namespace with the same name. Includes that specify an instance namespace require that the included URLconf sets an application namespace.

**current_app parameter to contrib.auth views**

All views in `django.contrib.auth.views` have the following structure:

```python
def view(request, ..., current_app=None, ...):
    ...

    if current_app is not None:
        request.current_app = current_app

    return TemplateResponse(request, template_name, context)
```

As of Django 1.8, `current_app` is set on the `request` object. For consistency, these views will require the caller to set `current_app` on the `request` instead of passing it in a separate argument.

**django.contrib.gis.geoip**

The `django.contrib.gis.geoip2` module supersedes `django.contrib.gis.geoip`. The new module provides a similar API except that it doesn’t provide the legacy GeoIP-Python API compatibility methods.
## Miscellaneous

- The weak argument to `django.dispatch.signals.Signal.disconnect()` has been deprecated as it has no effect.

- The `check_aggregate_support()` method of `django.db.backends.base.BaseDatabaseOperations` has been deprecated and will be removed in Django 2.0. The more general `check_expression_support()` should be used instead.

- `django.forms.extras` is deprecated. You can find `SelectDateWidget` in `django.forms.widgets` (or simply `django.forms`) instead.

- Private API `django.db.models.fields.add_lazy_relation()` is deprecated.

- The `django.contrib.auth.tests.utils.skipIfCustomUser()` decorator is deprecated. With the test discovery changes in Django 1.6, the tests for `django.contrib` apps are no longer run as part of the user’s project. Therefore, the `@skipIfCustomUser` decorator is no longer needed to decorate tests in `django.contrib.auth`.

- If you customized some error handlers, the view signatures with only one request parameter are deprecated. The views should now also accept a second exception positional parameter.

- The `django.utils.feedgenerator.Atom1Feed.mime_type` and `django.utils.feedgenerator.RssFeed.mime_type` attributes are deprecated in favor of `content_type`.

- `Signer` now issues a warning if an invalid separator is used. This will become an exception in Django 1.10.

- `django.db.models.Field._get_val_from_obj()` is deprecated in favor of `Field.value_from_object()`.

- `django.template.loaders.eggs.Loader` is deprecated as distributing applications as eggs is not recommended.

- The `callable_obj` keyword argument to `SimpleTestCase.assertRaisesMessage()` is deprecated. Pass the callable as a positional argument instead.

- The `allow_tags` attribute on methods of `ModelAdmin` has been deprecated. Use `format_html()`, `format_html_join()`, or `mark_safe()` when constructing the method’s return value instead.

- The `enclosure` keyword argument to `SyndicationFeed.add_item()` is deprecated. Use the new `enclosures` argument which accepts a list of `Enclosure` objects instead of a single one.

Features removed in 1.9

These features have reached the end of their deprecation cycle and are removed in Django 1.9. See Features deprecated in 1.7 for details, including how to remove usage of these features.

- `django.utils.dictconfig` is removed.
- `django.utils.importlib` is removed.
- `django.utils.tzinfo` is removed.
- `django.utils.unittest` is removed.
- The `syncdb` command is removed.
- `django.db.models.signals.pre_syncdb` and `django.db.models.signals.post_syncdb` is removed.
- Support for `allow_syncdb` on database routers is removed.
- Automatic syncing of apps without migrations is removed. Migrations are compulsory for all apps unless you pass the `migrate --run-syncdb` option.
- The SQL management commands for apps without migrations, `sql`, `sqlall`, `sqlclear`, `sqldropindexes`, and `sqlindexes`, are removed.
- Support for automatic loading of `initial_data` fixtures and initial SQL data is removed.
- All models need to be defined inside an installed application or declare an explicit `app_label`. Furthermore, it isn’t possible to import them before their application is loaded. In particular, it isn’t possible to import models inside the root package of an application.
- The model and form `IPAddressField` is removed. A stub field remains for compatibility with historical migrations.
- `AppCommand.handle_app()` is no longer supported.
- `RequestSite` and `get_current_site()` are no longer importable from `django.contrib.sites.models`.
- FastCGI support via the `runfcgi` management command is removed.
- `django.utils.datastructures.SortedDict` is removed.
- `ModelAdmin.declared_fieldsets` is removed.
- The `util` modules that provided backwards compatibility are removed:
  - `django.contrib.admin.util`
  - `django.contrib.gis.db.backends.util`
  - `django.db.backends.util`
  - `django.forms.util`
- `ModelAdmin.get_formsets` is removed.
• The backward compatible shims introduced to rename the `BaseMemcachedCache._get_memcache_timeout()` method to `get_backend_timeout()` is removed.
• The `--natural` and `-n` options for `dumpdata` are removed.
• The `use_natural_keys` argument for `serializers.serialize()` is removed.
• Private API `django.forms.forms.get_declared_fields()` is removed.
• The ability to use a `SplitDateTimeWidget` with `DateTimeField` is removed.
• The `WSGIRequest.REQUEST` property is removed.
• The class `django.utils.datastructures.MergeDict` is removed.
• The zh-cn and zh-tw language codes are removed.
• The internal `django.utils.functional.memoize()` is removed.
• `django.core.cache.get_cache` is removed.
• `django.db.models.loading` is removed.
• Passing callable arguments to querysets is no longer possible.
• `BaseCommand.requires_model_validation` is removed in favor of `requires_system_check`. Admin validators is replaced by admin checks.
• The `ModelAdmin.validator_class` and `default_validator_class` attributes are removed.
• `ModelAdmin.validate()` is removed.
• `django.db.backends.DatabaseValidation.validate_field` is removed in favor of the `check_field` method.
• The `validate` management command is removed.
• `django.utils.module_loading.import_by_path` is removed in favor of `django.utils.module_loading.import_string`.
• `ssi` and `url` template tags are removed from the `future` template tag library.
• `django.utils.text.javascript_quote()` is removed.
• Database test settings as independent entries in the database settings, prefixed by `TEST_`, are no longer supported.
• The `cache_choices` option to `ModelChoiceField` and `ModelMultipleChoiceField` is removed.
• The default value of the `RedirectView.permanent` attribute has changed from `True` to `False`.
• `django.contrib.sitemaps.FlatPageSitemap` is removed in favor of `django.contrib.flatpages.sitemaps.FlatPageSitemap`.
• Private API `django.test.utils.TestTemplateLoader` is removed.
• The `django.contrib.contenttypes.generic` module is removed.
9.1.13 1.8 release

Django 1.8.19 release notes

March 6, 2018
Django 1.8.19 fixes two security issues in 1.8.18.

CVE-2018-7536: Denial-of-service possibility in urlize and urlizetrunc template filters

The django.utils.html.urlize() function was extremely slow to evaluate certain inputs due to a catastrophic backtracking vulnerability in a regular expression. The urlize() function is used to implement the urlize and urlizetrunc template filters, which were thus vulnerable.

The problematic regular expression is replaced with parsing logic that behaves similarly.

CVE-2018-7537: Denial-of-service possibility in truncatechars_html and truncatewords_html template filters

If django.utils.text.Truncator’s chars() and words() methods were passed the html=True argument, they were extremely slow to evaluate certain inputs due to a catastrophic backtracking vulnerability in a regular expression. The chars() and words() methods are used to implement the truncatechars_html and truncatewords_html template filters, which were thus vulnerable.

The backtracking problem in the regular expression is fixed.

Django 1.8.18 release notes

April 4, 2017
Django 1.8.18 fixes two security issues in 1.8.17.

CVE-2017-7233: Open redirect and possible XSS attack via user-supplied numeric redirect URLs

Django relies on user input in some cases (e.g. django.contrib.auth.views.login() and i18n) to redirect the user to an “on success” URL. The security check for these redirects (namely django.utils.http.is_safe_url()) considered some numeric URLs (e.g. http:999999999) “safe” when they shouldn’t be.

Also, if a developer relies on is_safe_url() to provide safe redirect targets and puts such a URL into a link, they could suffer from an XSS attack.
CVE-2017-7234: Open redirect vulnerability in `django.views.static.serve()`

A maliciously crafted URL to a Django site using the `serve()` view could redirect to any other domain. The view no longer does any redirects as they don’t provide any known, useful functionality.

Note, however, that this view has always carried a warning that it is not hardened for production use and should be used only as a development aid.

Django 1.8.17 release notes

December 1, 2016

Django 1.8.17 fixes a regression in 1.8.16.

Bugfixes

- Quoted the Oracle test user’s password in queries to fix the “ORA-00922: missing or invalid option” error when the password starts with a number or special character (#27420).

Django 1.8.16 release notes

November 1, 2016

Django 1.8.16 fixes two security issues in 1.8.15.

User with hardcoded password created when running tests on Oracle

When running tests with an Oracle database, Django creates a temporary database user. In older versions, if a password isn’t manually specified in the database settings `TEST` dictionary, a hardcoded password is used. This could allow an attacker with network access to the database server to connect.

This user is usually dropped after the test suite completes, but not when using the `manage.py test --keepdb` option or if the user has an active session (such as an attacker’s connection).

A randomly generated password is now used for each test run.
DNS rebinding vulnerability when `DEBUG=True`

Older versions of Django don’t validate the Host header against `settings.ALLOWED_HOSTS` when `settings.DEBUG=True`. This makes them vulnerable to a DNS rebinding attack.

While Django doesn’t ship a module that allows remote code execution, this is at least a cross-site scripting vector, which could be quite serious if developers load a copy of the production database in development or connect to some production services for which there’s no development instance, for example. If a project uses a package like the `django-debug-toolbar`, then the attacker could execute arbitrary SQL, which could be especially bad if the developers connect to the database with a superuser account.

`settings.ALLOWED_HOSTS` is now validated regardless of `DEBUG`. For convenience, if `ALLOWED_HOSTS` is empty and `DEBUG=True`, the following variations of localhost are allowed: `['localhost', '127.0.0.1', '::1']`. If your local settings file has your production `ALLOWED_HOSTS` value, you must now omit it to get those fallback values.

**Django 1.8.15 release notes**

September 26, 2016

Django 1.8.15 fixes a security issue in 1.8.14.

**CSRF protection bypass on a site with Google Analytics**

An interaction between Google Analytics and Django’s cookie parsing could allow an attacker to set arbitrary cookies leading to a bypass of CSRF protection.

The parser for `request.COOKIES` is simplified to better match the behavior of browsers and to mitigate this attack. `request.COOKIES` may now contain cookies that are invalid according to RFC 6265 but are possible to set via `document.cookie`.

**Django 1.8.14 release notes**

July 18, 2016

Django 1.8.14 fixes a security issue and a bug in 1.8.13.
XSS in admin’s add/change related popup

Unsafe usage of JavaScript’s `Element.innerHTML` could result in XSS in the admin’s add/change related popup. `Element.textContent` is now used to prevent execution of the data.

The debug view also used `innerHTML`. Although a security issue wasn’t identified there, out of an abundance of caution it’s also updated to use `textContent`.

Bugfixes

- Fixed missing `varchar/text_pattern_ops` index on `CharField` and `TextField` respectively when using `AddField` on PostgreSQL (#26889).

Django 1.8.13 release notes

May 2, 2016

Django 1.8.13 fixes several bugs in 1.8.12.

Bugfixes

- Fixed `TimeField` microseconds round-tripping on MySQL and SQLite (#26498).
- Restored conversion of an empty string to null when saving values of `GenericIPAddressField` on SQLite and MySQL (#26557).

Django 1.8.12 release notes

April 1, 2016

Django 1.8.12 fixes several bugs in 1.8.11.

Bugfixes

- Made `MultiPartParser` ignore filenames that normalize to an empty string to fix crash in `MemoryFileUploadHandler` on specially crafted user input (#26325).
- Fixed data loss on SQLite where `DurationField` values with fractional seconds could be saved as `None` (#26324).
- Restored the functionality of the admin’s `raw_id_fields` in `list_editable` (#26387).
Django 1.8.11 release notes

March 5, 2016

Django 1.8.11 fixes a regression on Python 2 in the 1.8.10 security release where `utils.http.is_safe_url()` crashes on bytestring URLs (#26308).

Django 1.8.10 release notes

March 1, 2016

Django 1.8.10 fixes two security issues and several bugs in 1.8.9.

CVE-2016-2512: Malicious redirect and possible XSS attack via user-supplied redirect URLs containing basic auth

Django relies on user input in some cases (e.g. `django.contrib.auth.views.login()` and `i18n`) to redirect the user to an “on success” URL. The security check for these redirects (namely `django.utils.http.is_safe_url()`) considered some URLs with basic authentication credentials “safe” when they shouldn’t be.

For example, a URL like `http://mysite.example.com\@attacker.com` would be considered safe if the request’s host is `http://mysite.example.com`, but redirecting to this URL sends the user to `attacker.com`. Also, if a developer relies on `is_safe_url()` to provide safe redirect targets and puts such a URL into a link, they could suffer from an XSS attack.

CVE-2016-2513: User enumeration through timing difference on password hasher work factor upgrade

In each major version of Django since 1.6, the default number of iterations for the `PBKDF2PasswordHasher` and its subclasses has increased. This improves the security of the password as the speed of hardware increases, however, it also creates a timing difference between a login request for a user with a password encoded in an older number of iterations and login request for a nonexistent user (which runs the default hasher’s default number of iterations since Django 1.6).

This only affects users who haven’t logged in since the iterations were increased. The first time a user logs in after an iterations increase, their password is updated with the new iterations and there is no longer a timing difference.

The new `BasePasswordHasher.harden_runtime()` method allows hashers to bridge the runtime gap between the work factor (e.g. iterations) supplied in existing encoded passwords and the default work factor of the hasher. This method is implemented for `PBKDF2PasswordHasher` and `BCryptPasswordHasher`. The number of rounds for the latter hasher hasn’t changed since Django 1.4, but some projects may subclass it and increase the work factor as needed.
A warning will be emitted for any third-party password hashers that don’t implement a `harden_runtime()` method.

If you have different password hashes in your database (such as SHA1 hashes from users who haven’t logged in since the default hasher switched to PBKDF2 in Django 1.4), the timing difference on a login request for these users may be even greater and this fix doesn’t remedy that difference (or any difference when changing hashers). You may be able to upgrade those hashes to prevent a timing attack for that case.

**Bugfixes**

- Fixed a crash on PostgreSQL that prevented using `TIME_ZONE=None` and `USE_TZ=False` (#26177).
- Added system checks for query name clashes of hidden relationships (#26162).
- Made `forms.FileField` and `utils.translation.lazy_number()` picklable (#26212).
- Fixed `RangeField` and `ArrayField` serialization with `None` values (#26215).
- Reallowed dashes in top-level domain names of URLs checked by `URLValidator` to fix a regression in Django 1.8 (#26204).
- Fixed `BoundField` to reallow slices of subwidgets (#26267).
- Prevented `ContentTypeManager` instances from sharing their cache (#26286).

**Django 1.8.9 release notes**

February 1, 2016

Django 1.8.9 fixes several bugs in 1.8.8.

**Bugfixes**

- Fixed a regression that caused the “user-tools” items to display on the admin’s logout page (#26035).
- Fixed a crash in the translations system when the current language has no translations (#26046).
- Fixed a regression that caused the incorrect day to be selected when opening the admin calendar widget for timezones from GMT+0100 to GMT+1200 (#24980).
- Fixed a regression in 1.8.8 causing incorrect index handling in migrations on PostgreSQL when adding `db_index=True` or `unique=True` to a `CharField` or `TextField` that already had the other specified, or when removing one of them from a field that had both, or when adding `unique=True` to a field already listed in `unique_together` (#26034).
- Fixed a crash when using an `__in` lookup inside a `Case` expression (#26071).
- Fixed a crash when using a reverse `OneToOneField` in `ModelAdmin.readonly_fields` (#26060).
• Fixed a regression in Django 1.8.5 that broke copying a SimpleLazyObject with copy.copy() (#26122).
• Fixed the contrib.gis map widgets when using USE_THOUSAND_SEPARATOR=True (#20415).

Django 1.8.8 release notes

January 2, 2016

Django 1.8.8 fixes several bugs in 1.8.7.

Python 3.2 users, please be advised that we’ve decided to drop support for Python 3.2 in Django 1.8.x at the end of 2016. We won’t break things intentionally after that, but we won’t test subsequent releases against Python 3.2 either. Upstream support for Python 3.2 ends February 2016 so we don’t find much value in providing security updates for a version of Python that could be insecure. To read more about the decision and to let us know if this will be problematic for you, please read the django-developers thread.

Bugfixes

• Fixed incorrect unique_together field name generation by inspectdb (#25274).
• Corrected __len query lookup on ArrayField for empty arrays (#25772).
• Restored the ability to use custom formats from formats.py with django.utils.formats.get_format() and the date template filter (#25812).
• Fixed a state bug when migrating a SeparateDatabaseAndState operation backwards (#25896).
• Fixed missing varchar/text_pattern_ops index on CharField and TextField respectively when using AlterField on PostgreSQL (#25412).
• Fixed a state bug when using an AlterModelManagers operation (#25852).
• Fixed a regression which prevented using a language not in Django’s default language list (LANGUAGES) (#25915).
• django.views.decorators.cache.never_cache() now sends more persuasive headers (added no-cache, no-store, must-revalidate to Cache-Control) to better prevent caching (#13008). This fixes a problem where a page refresh in Firefox cleared the selected entries in the admin’s filter_horizontal and filter_vertical widgets, which could result in inadvertent data loss if a user didn’t notice that and then submitted the form (#22955).
• Fixed a regression in the admin which ignored line breaks in read-only fields instead of converting them to <br> (#25465).
• Made loaddata skip disabling and enabling database constraints when it doesn’t load any fixtures (#23372).
• Fixed a crash in QuerySet.values()/values_list() after an annotate() and order_by() when values()/values_list() includes a field not in the order_by() (#25316).
Django 1.8.7 release notes

November 24, 2015

Django 1.8.7 fixes a security issue and several bugs in 1.8.6.

Additionally, Django’s vendored version of six, `django.utils.six`, has been upgraded to the latest release (1.10.0).

Fixed settings leak possibility in date template filter

If an application allows users to specify an unvalidated format for dates and passes this format to the `date` filter, e.g. `{% last_updated|date:user_date_format %}`, then a malicious user could obtain any secret in the application’s settings by specifying a settings key instead of a date format, e.g. "SECRET_KEY" instead of "j/m/Y".

To remedy this, the underlying function used by the `date` template filter, `django.utils.formats.get_format()`, now only allows accessing the date/time formatting settings.

Bugfixes

- Fixed a crash of the debug view during the autumn DST change when `USE_TZ` is `False` and `pytz` is installed.
- Fixed a regression in 1.8.6 that caused database routers without an `allow_migrate()` method to crash (#25686).
- Fixed a regression in 1.8.6 by restoring the ability to use `Manager` objects for the `queryset` argument of `ModelChoiceField` (#25683).
- Fixed a regression in 1.8.6 that caused an application with South migrations in the `migrations` directory to fail (#25618).
- Fixed a data loss possibility with `Prefetch` if `to_attr` is set to a `ManyToManyField` (#25693).
- Fixed a regression in 1.8 by making `gettext()` once again return UTF-8 bytestrings on Python 2 if the input is a bytestring (#25720).
- Fixed serialization of `DateRangeField` and `DateTimeRangeField` (#24937).
- Fixed the exact lookup of `ArrayField` (#25666).
- Fixed `Model.refresh_from_db()` updating of `ForeignKey` fields with `on_delete=models.SET_NULL` (#25715).
- Fixed a duplicate query regression in 1.8 on proxied model deletion (#25685).
- Fixed `set_FOO_order()` crash when the `ForeignKey` of a model with `order_with_respect_to` references a model with a `OneToOneField` primary key (#25786).
• Fixed incorrect validation for `PositiveIntegerField` and `PositiveSmallIntegerField` on MySQL resulting in values greater than 4294967295 or 65535, respectively, passing validation and being silently truncated by the database (#25767).

Django 1.8.6 release notes

November 4, 2015

Django 1.8.6 adds official support for Python 3.5 and fixes several bugs in 1.8.5.

Bugfixes

• Fixed a regression causing `ModelChoiceField` to ignore `prefetch_related()` on its queryset (#25496).
• Allowed `mode=memory` in SQLite test database name if supported (#12118).
• Fixed system check crash on `ForeignKey` to abstract model (#25503).
• Fixed incorrect queries when you have multiple `ManyToManyField` on different models that have the same field name, point to the same model, and have their reverse relations disabled (#25545).
• Allowed filtering over a `RawSQL` annotation (#25506).
• Made the `Concat` database function idempotent on SQLite (#25517).
• Avoided a confusing stack trace when starting `runserver` with an invalid `INSTALLED_APPS` setting (#25510). This regression appeared in 1.8.5 as a side effect of fixing #24704.
• Made deferred models use their proxied model’s `_meta.apps` for caching and retrieval (#25563). This prevents any models generated in data migrations using `QuerySet.defer()` from leaking to test and application code.
• Fixed a typo in the name of the `strictly_above` PostGIS lookup (#25592).
• Fixed crash with `contrib.postgres.forms.SplitArrayField` and `IntegerField` on invalid value (#25597).
• Added a helpful error message when Django and South migrations exist in the same directory (#25618).
• Fixed a regression in `URLValidator` that allowed URLs with consecutive dots in the domain section (like `http://example..com/`) to pass (#25620).
• Fixed a crash with `GenericRelation` and `BaseModelAdmin.to_field_allowed` (#25622).
Django 1.8.5 release notes

October 3, 2015

Django 1.8.5 fixes several bugs in 1.8.4.

Bugfixes

- Made the development server’s autoreload more robust (#24704).
- Fixed `AssertionError` in some delete queries with a model containing a field that is both a foreign and primary key (#24951).
- Fixed `AssertionError` in some complex queries (#24525).
- Fixed a migrations crash with `GenericForeignKey` (#25040).
- Made `translation.override()` clear the overridden language when a translation isn’t initially active (#25295).
- Fixed crash when using a value in `ModelAdmin.list_display` that clashed with a reverse field on the model (#25299).
- Fixed autocompletion for options of non-`argparse` management commands (#25372).
- Alphabetized ordering of imports in `from django.db import migrations, models` statement in newly created migrations (#25384).
- Fixed migrations crash on MySQL when adding a text or a blob field with an unhashable default (#25393).
- Changed `Count` queries to execute `COUNT(*)` instead of `COUNT('*')` as versions of Django before 1.8 did (#25377). This may fix a performance regression on some databases.
- Fixed custom queryset chaining with `values()` and `values_list()` (#20625).
- Moved the unsaved model instance assignment data loss check on reverse relations to `Model.save()` (#25160).
- Readded inline foreign keys to form instances when validating model formsets (#25431).
- Allowed using ORM write methods after disabling autocommit with `set_autocommit(False)` (#24921).
- Fixed the `manage.py test --keepdb` option on Oracle (#25421).
- Fixed incorrect queries with multiple many-to-many fields on a model with the same ‘to’ model and with `related_name` set to ‘+’ (#24505, #25486).
- Fixed pickling a `SimpleLazyObject` wrapping a model (#25389).
Django 1.8.4 release notes

August 18, 2015

Django 1.8.4 fixes a security issue and several bugs in 1.8.3.

Denial-of-service possibility in logout() view by filling session store

Previously, a session could be created when anonymously accessing the django.contrib.auth.views.logout() view (provided it wasn’t decorated with login_required() as done in the admin). This could allow an attacker to easily create many new session records by sending repeated requests, potentially filling up the session store or causing other users’ session records to be evicted.

The SessionMiddleware has been modified to no longer create empty session records, including when SESSION_SAVE_EVERY_REQUEST is active.

Bugfixes

- Added the ability to serialize values from the newly added UUIDField (#25019).
- Added a system check warning if the old TEMPLATE_* settings are defined in addition to the new TEMPLATES setting.
- Fixed QuerySet.raw() so InvalidQuery is not raised when using the db_column name of a ForeignKey field with primary_key=True (#12768).
- Prevented an exception in TestCase.setUpTestData() from leaking the transaction (#25176).
- Fixed has_changed() method in contrib.postgres.forms.HStoreField (#25215, #25233).
- Fixed the recording of squashed migrations when running the migrate command (#25231).
- Moved the unsaved model instance assignment data loss check to Model.save() to allow easier usage of in-memory models (#25160).
- Prevented varchar_patterns_ops and text_patterns_ops indexes for ArrayField (#25180).

Django 1.8.3 release notes

July 8, 2015

Django 1.8.3 fixes several security issues and bugs in 1.8.2.

Also, django.utils.deprecation.RemovedInDjango20Warning was renamed to RemovedInDjango10Warning as the version roadmap was revised to 1.9, 1.10, 1.11 (LTS), 2.0 (drops Python 2 support). For backwards compatibility, RemovedInDjango20Warning remains as an importable alias.
Denial-of-service possibility by filling session store

In previous versions of Django, the session backends created a new empty record in the session storage anytime `request.session` was accessed and there was a session key provided in the request cookies that didn’t already have a session record. This could allow an attacker to easily create many new session records simply by sending repeated requests with unknown session keys, potentially filling up the session store or causing other users’ session records to be evicted.

The built-in session backends now create a session record only if the session is actually modified; empty session records are not created. Thus this potential DoS is now only possible if the site chooses to expose a session-modifying view to anonymous users.

As each built-in session backend was fixed separately (rather than a fix in the core sessions framework), maintainers of third-party session backends should check whether the same vulnerability is present in their backend and correct it if so.

Header injection possibility since validators accept newlines in input

Some of Django’s built-in validators (EmailValidator, most seriously) didn’t prohibit newline characters (due to the usage of $ instead of \Z in the regular expressions). If you use values with newlines in HTTP response or email headers, you can suffer from header injection attacks. Django itself isn’t vulnerable because HttpResponse and the mail sending utilities in django.core.mail prohibit newlines in HTTP and SMTP headers, respectively. While the validators have been fixed in Django, if you’re creating HTTP responses or email messages in other ways, it’s a good idea to ensure that those methods prohibit newlines as well. You might also want to validate that any existing data in your application doesn’t contain unexpected newlines.

`validate_ipv4_address()`, `validate_slug()`, and `URLValidator` are also affected, however, as of Django 1.6 the GenericIPAddressField, IPAddressField, SlugField, and URLField form fields which use these validators all strip the input, so the possibility of newlines entering your data only exists if you are using these validators outside of the form fields.

The undocumented, internally unused `validate_integer()` function is now stricter as it validates using a regular expression instead of simply casting the value using `int()` and checking if an exception was raised.

Denial-of-service possibility in URL validation

`URLValidator` included a regular expression that was extremely slow to evaluate against certain invalid inputs. This regular expression has been simplified and optimized.
Bugfixes

- Fixed `BaseRangeField.prepare_value()` to use each `base_field`'s `prepare_value()` method (#24841).
- Fixed crash during `makemigrations` if a migrations module either is missing `__init__.py` or is a file (#24848).
- Fixed `QuerySet.exists()` returning incorrect results after annotation with `Count()` (#24835).
- Corrected `HStoreField.has_changed()` (#24844).
- Reverted an optimization to the CSRF template context processor which caused a regression (#24836).
- Fixed a regression which caused template context processors to overwrite variables set on a `RequestContext` after it’s created (#24847).
- Prevented the loss of `null/not null` column properties during field renaming of MySQL databases (#24817).
- Fixed a crash when using a reverse one-to-one relation in `ModelAdmin.list_display` (#24851).
- Fixed quoting of SQL when renaming a field to `AutoField` in PostgreSQL (#24892).
- Fixed lack of unique constraint when changing a field from `primary_key=True` to `unique=True` (#24893).
- Fixed queryset pickling when using `prefetch_related()` after deleting objects (#24831).
- Allowed using `choices` longer than 1 day with `DurationField` (#24897).
- Fixed a crash when loading squashed migrations from two apps with a dependency between them, where the dependent app’s replaced migrations are partially applied (#24895).
- Fixed recording of applied status for squashed (replacement) migrations (#24628).
- Fixed queryset annotations when using `Case` expressions with `exclude()` (#24833).
- Corrected join promotion for multiple `Case` expressions. Annotating a query with multiple `Case` expressions could unexpectedly filter out results (#24924).
- Fixed usage of transforms in subqueries (#24744).
- Fixed `SimpleTestCase.assertRaisesMessage()` on Python 2.7.10 (#24903).
- Provided better backwards compatibility for the `verbosity` argument in `optparse` management commands by casting it to an integer (#24769).
- Fixed `prefetch_related()` on databases other than PostgreSQL for models using UUID primary keys (#24912).
- Fixed removing `unique_together` constraints on MySQL (#24972).
• Fixed crash when uploading images with MIME types that Pillow doesn’t detect, such as bitmap, in forms.ImageField (#24948).

• Fixed a regression when deleting a model through the admin that has a GenericRelation with a related_query_name (#24940).

• Reallowed non-ASCII values for ForeignKey.related_name on Python 3 by fixing the false positive system check (#25016).

• Fixed inline forms that use a parent object that has a UUIDField primary key and a child object that has an AutoField primary key (#24958).

• Fixed a regression in the unordered_list template filter on certain inputs (#25031).

• Fixed a regression in URLValidator that invalidated Punycode TLDs (#25059).

• Improved pyinotify runserver polling (#23882).

Django 1.8.2 release notes

May 20, 2015

Django 1.8.2 fixes a security issue and several bugs in 1.8.1.

Fixed session flushing in the cached_db backend

A change to session.flush() in the cached_db session backend in Django 1.8 mistakenly sets the session key to an empty string rather than None. An empty string is treated as a valid session key and the session cookie is set accordingly. Any users with an empty string in their session cookie will use the same session store. session.flush() is called by django.contrib.auth.logout() and, more seriously, by django.contrib.auth.login() when a user switches accounts. If a user is logged in and logs in again to a different account (without logging out) the session is flushed to avoid reuse. After the session is flushed (and its session key becomes '') the account details are set on the session and the session is saved. Any users with an empty string in their session cookie will now be logged into that account.

Bugfixes

• Fixed check for template engine alias uniqueness (#24685).

• Fixed crash when reusing the same Case instance in a query (#24752).

• Corrected join promotion for Case expressions. For example, annotating a query with a Case expression could unexpectedly filter out results (#24766).

• Fixed negated Q objects in expressions. Cases like Case(When(~Q(friends__age__lte=30))) tried to generate a subquery which resulted in a crash (#24705).
• Fixed incorrect GROUP BY clause generation on MySQL when the query’s model has a self-referential foreign key (#24748).

• Implemented `ForeignKey.get_db_prep_value()` so that `ForeignKeys` pointing to `UUIDField` and inheritance on models with `UUIDField` primary keys work correctly (#24698, #24712).

• Fixed `isnull` lookup for `HStoreField` (#24751).

• Fixed a MySQL crash when a migration removes a combined index (unique_together or index_together) containing a foreign key (#24757).

• Fixed session cookie deletion when using `SESSION_COOKIE_DOMAIN` (#24799).

• On PostgreSQL, when no access is granted for the `postgres` database, Django now falls back to the default database when it normally requires a “no database” connection (#24791).

• Fixed display of `contrib.admin`’s `ForeignKey` widget when it’s used in a row with other fields (#24784).

Django 1.8.1 release notes

May 1, 2015

Django 1.8.1 fixes several bugs in 1.8 and includes some optimizations in the migrations framework.

Bugfixes

• Added support for serializing `timedelta` objects in migrations (#24566).

• Restored proper parsing of the `testserver` command’s positional arguments (fixture names) (#24571).

• Prevented `TypeError` in translation functions `check_for_language()` and `get_language_bidi()` when translations are deactivated (#24569).

• Fixed `squashmigrations` command when using `SeparateDatabaseAndState` (#24278).

• Stripped microseconds from `datetime` values when using an older version of the MySQLdb DB API driver as it does not support fractional seconds (#24584).

• Fixed a migration crash when altering `ManyToManyField`s (#24513).

• Fixed a crash with `QuerySet.update()` on foreign keys to one-to-one fields (#24578).

• Fixed a regression in the model detail view of `admindocs` when a model has a reverse foreign key relation (#24624).

• Prevented arbitrary file inclusions in `admindocs` (#24625).

• Fixed a crash with `QuerySet.update()` on foreign keys to instances with `uuid` primary keys (#24611).

• Fixed database introspection with SQLite 3.8.9 (released April 8, 2015) (#24637).
- Updated `urlpatterns` examples generated by `startproject` to remove usage of referencing views by dotted path in `django.conf.urls.url()` which is deprecated in Django 1.8 (#24635).

- Fixed queries where an expression was referenced in `order_by()`, but wasn’t part of the select clause. An example query is `qs.annotate(foo=F('field')).values('pk').order_by('foo')` (#24615).

- Fixed a database table name quoting regression (#24605).

- Prevented the loss of `null/not null` column properties during field alteration of MySQL databases (#24595).

- Fixed JavaScript path of `contrib.admin`’s related field widget when using alternate static file storages (#24655).

- Fixed a migration crash when adding new relations to models (#24573).

- Fixed a migration crash when applying migrations with model managers on Python 3 that were generated on Python 2 (#24701).

- Restored the ability to use iterators as queryset filter arguments (#24719).

- Fixed a migration crash when renaming the target model of a many-to-many relation (#24725).

- Removed flushing of the test database with `test --keepdb`, which prevented apps with data migrations from using the option (#24729).

- Fixed `makemessages` crash in some locales (#23271).

- Fixed help text positioning of `contrib.admin` fields that use the `ModelAdmin.filter_horizontal` and `filter_vertical` options (#24676).

- Fixed `AttributeError: function 'GDALAllRegister' not found` error when initializing `contrib.gis` on Windows.

**Optimizations**

- Changed `ModelState` to deepcopy fields instead of deconstructing and reconstructing (#24591). This speeds up the rendering of model states and reduces memory usage when running `manage.py migrate` (although other changes in this release may negate any performance benefits).

**Django 1.8 release notes**

April 1, 2015

Welcome to Django 1.8!

These release notes cover the new features, as well as some backwards incompatible changes you’ll want to be aware of when upgrading from Django 1.7 or older versions. We’ve also begun the deprecation process for some features, and some features have reached the end of their deprecation process and have been removed.
See the How to upgrade Django to a newer version guide if you’re updating an existing project.

Django 1.8 has been designated as Django’s second long-term support release. It will receive security updates for at least three years after its release. Support for the previous LTS, Django 1.4, will end 6 months from the release date of Django 1.8.

**Python compatibility**

Django 1.8 requires Python 2.7, 3.2, 3.3, 3.4, or 3.5. We highly recommend and only officially support the latest release of each series.

Django 1.8 is the first release to support Python 3.5.

Due to the end of upstream support for Python 3.2 in February 2016, we won’t test Django 1.8.x on Python 3.2 after the end of 2016.

**What’s new in Django 1.8**

**Model._meta API**

Django now has a formalized API for `Model._meta`, providing an officially supported way to retrieve fields and filter fields based on their attributes.

The `Model._meta` object has been part of Django since the days of pre-0.96 “Magic Removal”—it just wasn’t an official, stable API. In recognition of this, we’ve endeavored to maintain backwards-compatibility with the old API endpoint where possible. However, API endpoints that aren’t part of the new official API have been deprecated and will eventually be removed.

**Multiple template engines**

Django 1.8 defines a stable API for integrating template backends. It includes built-in support for the Django template language and for [Jinja2](https://palletsprojects.com/p/jinja/). It supports rendering templates with multiple engines within the same project. Learn more about the new features in the topic guide and check the upgrade instructions in older versions of the documentation.

**Security enhancements**

Several features of the [django-secure](https://django-secure.readthedocs.io/) third-party library have been integrated into Django. `django.middleware.security.SecurityMiddleware` provides several security enhancements to the request/response cycle. The new `check --deploy` option allows you to check your production settings file for ways to increase the security of your site.
New PostgreSQL specific functionality

Django now has a module with extensions for PostgreSQL specific features, such as `ArrayField`, `HStoreField`, Range Fields, and `unaccent` lookup. A full breakdown of the features is available in the documentation.

New data types

- Django now has a `UUIDField` for storing universally unique identifiers. It is stored as the native uuid data type on PostgreSQL and as a fixed length character field on other backends. There is a corresponding form field.
- Django now has a `DurationField` for storing periods of time - modeled in Python by `timedelta`. It is stored in the native `interval` data type on PostgreSQL, as an `INTERVAL DAY(9) TO SECOND(6)` on Oracle, and as a `bigint` of microseconds on other backends. Date and time related arithmetic has also been improved on all backends. There is a corresponding form field.

Query Expressions, Conditional Expressions, and Database Functions

Query Expressions allow you to create, customize, and compose complex SQL expressions. This has enabled annotate to accept expressions other than aggregates. Aggregates are now able to reference multiple fields, as well as perform arithmetic, similar to `F()` objects. `order_by()` has also gained the ability to accept expressions.

Conditional Expressions allow you to use `if ... elif ... else` logic within queries.

A collection of database functions is also included with functionality such as `Coalesce`, `Concat`, and `Substr`.

TestCase data setup

`TestCase` has been refactored to allow for data initialization at the class level using transactions and savepoints. Database backends which do not support transactions, like MySQL with the MyISAM storage engine, will still be able to run these tests but won’t benefit from the improvements. Tests are now run within two nested `atomic()` blocks: one for the whole class and one for each test.

- The class method `TestCase.setUpTestData()` adds the ability to set up test data at the class level. Using this technique can speed up the tests as compared to using `setUp()`.
- Fixture loading within `TestCase` is now performed once for the whole `TestCase`.
Minor features

django.contrib.admin

- `ModelAdmin` now has a `has_module_permission()` method to allow limiting access to the module on the admin index page.
- `InlineModelAdmin` now has an attribute `show_change_link` that supports showing a link to an inline object’s change form.
- Use the new `django.contrib.admin.RelatedOnlyFieldListFilter` in `ModelAdmin.list_filter` to limit the `list_filter` choices to foreign objects which are attached to those from the `ModelAdmin`.
- The `ModelAdmin.delete_view()` displays a summary of objects to be deleted on the deletion confirmation page.
- The jQuery library embedded in the admin has been upgraded to version 1.11.2.
- You can now specify `AdminSite.site_url` in order to display a link to the front-end site.
- You can now specify `ModelAdmin.show_full_result_count` to control whether or not the full count of objects should be displayed on a filtered admin page.
- The `AdminSite.password_change()` method now has an `extra_context` parameter.
- You can now control who may login to the admin site by overriding only `AdminSite.has_permission()` and `AdminSite.login_form`. The `base.html` template has a new block `usertools` which contains the user-specific header. A new context variable `has_permission`, which gets its value from `has_permission()`, indicates whether the user may access the site.
- Foreign key dropdowns now have buttons for changing or deleting related objects using a popup.

django.contrib.admindocs

- reStructuredText is now parsed in model docstrings.

django.contrib.auth

- Authorization backends can now raise `PermissionDenied` in `has_perm()` and `has_module_perms()` to short-circuit permission checking.
- `PasswordResetForm` now has a method `send_mail()` that can be overridden to customize the mail to be sent.
- The `max_length` of `Permission.name` has been increased from 50 to 255 characters. Please run the database migration.
- `USERNAME_FIELD` and `REQUIRED_FIELDS` now supports `ForeignKeys`. 
• The default iteration count for the PBKDF2 password hasher has been increased by 33%. This backwards compatible change will not affect users who have subclassed `django.contrib.auth.hashers.PBKDF2PasswordHasher` to change the default value.

django.contrib.gis

• A new GeoJSON serializer is now available.

• It is now allowed to include a subquery as a geographic lookup argument, for example `City.objects.filter(point__within=Country.objects.filter(continent='Africa').values('mpoly'))`.

• The SpatiaLite backend now supports `Collect` and `Extent` aggregates when the database version is 3.0 or later.

• The PostGIS 2 `CREATE EXTENSION postgis` and the SpatiaLite `SELECT InitSpatialMetaData` initialization commands are now automatically run by `migrate`.

• The GDAL interface now supports retrieving properties of raster (image) data file.

• Compatibility shims for `SpatialRefSys` and `GeometryColumns` changed in Django 1.2 have been removed.

• All GDAL-related exceptions are now raised with `GDALException`. The former `OGRException` has been kept for backwards compatibility but should not be used any longer.

django.contrib.sessions

• Session cookie is now deleted after `flush()` is called.

django.contrib.sitemaps

• The new `Sitemap.i18n` attribute allows you to generate a sitemap based on the `LANGUAGES` setting.

django.contrib.sites

• `get_current_site()` will now lookup the current site based on `request.get_host()` if the `SITE_ID` setting is not defined.

• The default `Site` created when running `migrate` now respects the `SITE_ID` setting (instead of always using pk=1).
Cache

- The `incr()` method of the `django.core.cache.backends.locmem.LocMemCache` backend is now thread-safe.

Cryptography

- The `max_age` parameter of the `django.core.signing.TimestampSigner.unsign()` method now also accepts a `datetime.timedelta` object.

Database backends

- The MySQL backend no longer strips microseconds from `datetime` values as MySQL 5.6.4 and up supports fractional seconds depending on the declaration of the datetime field (when `DATETIME` includes fractional precision greater than 0). New datetime database columns created with Django 1.8 and MySQL 5.6.4 and up will support microseconds. See the MySQL database notes for more details.
- The MySQL backend no longer creates explicit indexes for foreign keys when using the InnoDB storage engine, as MySQL already creates them automatically.
- The Oracle backend no longer defines the `connection_persists_old_columns` feature as `True`. Instead, Oracle will now include a cache busting clause when getting the description of a table.

Email

- Email backends now support the context manager protocol for opening and closing connections.
- The SMTP email backend now supports `keyfile` and `certfile` authentication with the `EMAIL_SSL_CERTFILE` and `EMAIL_SSL_KEYFILE` settings.
- The SMTP `EmailBackend` now supports setting the `timeout` parameter with the `EMAIL_TIMEOUT` setting.
- `EmailMessage` and `EmailMultiAlternatives` now support the `reply_to` parameter.

File Storage

- `Storage.get_available_name()` and `Storage.save()` now take a `max_length` argument to implement storage-level maximum filename length constraints. Filenames exceeding this argument will get truncated. This prevents a database error when appending a unique suffix to a long filename that already exists on the storage. See the deprecation note about adding this argument to your custom storage classes.
Forms

- Form widgets now render attributes with a value of True or False as HTML5 boolean attributes.
- The new `has_error()` method allows checking if a specific error has happened.
- If `required_css_class` is defined on a form, then the `<label>` tags for required fields will have this class present in its attributes.
- The rendering of non-field errors in unordered lists (<ul>) now includes `nonfield` in its list of classes to distinguish them from field-specific errors.
- `Field` now accepts a `label_suffix` argument, which will override the form’s `label_suffix`. This enables customizing the suffix on a per-field basis—previously it wasn’t possible to override a form’s `label_suffix` while using shortcuts such as `{{ form.as_p }}` in templates.
- `SelectDateWidget` now accepts an `empty_label` argument, which will override the top list choice label when `DateField` is not required.
- After an `ImageField` has been cleaned and validated, the `UploadedFile` object will have an additional `image` attribute containing the Pillow `Image` instance used to check if the file was a valid image. It will also update `UploadedFile.content_type` with the image’s content type as determined by Pillow.
- You can now pass a callable that returns an iterable of choices when instantiating a `ChoiceField`.

Generic Views

- Generic views that use `MultipleObjectMixin` may now specify the ordering applied to the `queryset` by setting `ordering` or overriding `get_ordering()`.
- The new `SingleObjectMixin.query_pk_and_slug` attribute allows changing the behavior of `get_object()` so that it’ll perform its lookup using both the primary key and the slug.
- The `get_form()` method doesn’t require a `form_class` to be provided anymore. If not provided `form_class` defaults to `get_form_class()`.
- Placeholders in `ModelFormMixin.success_url` now support the Python `str.format()` syntax. The legacy `{<foo>}` syntax is still supported but will be removed in Django 1.10.

Internationalization

- `FORMAT_MODULE_PATH` can now be a list of strings representing module paths. This allows importing several format modules from different reusable apps. It also allows overriding those custom formats in your main Django project.
Logging

- The `django.utils.log.AdminEmailHandler` class now has a `send_mail()` method to make it more subclass friendly.

Management Commands

- Database connections are now always closed after a management command called from the command line has finished doing its job.
- Commands from alternate package formats like eggs are now also discovered.
- The new `dumpdata --output` option allows specifying a file to which the serialized data is written.
- The new `makemessages --exclude` and `compilemessages --exclude` options allow excluding specific locales from processing.
- `compilemessages` now has a `--use-fuzzy` or `-f` option which includes fuzzy translations into compiled files.
- The `loaddata --ignorenonexistent` option now ignores data for models that no longer exist.
- `runserver` now uses daemon threads for faster reloading.
- `inspectdb` now outputs `Meta.unique_together`. It is also able to introspect `AutoField` for MySQL and PostgreSQL databases.
- When calling management commands with options using `call_command()`, the option name can match the command line option name (without the initial dashes) or the final option destination variable name, but in either case, the resulting option received by the command is now always the `dest` name specified in the command option definition (as long as the command uses the `argparse` module).
- The `dbshell` command now supports MySQL’s optional SSL certificate authority setting (`--ssl-ca`).
- The new `makemigrations --name` allows giving the migration(s) a custom name instead of a generated one.
- The `loaddata` command now prevents repeated fixture loading. If `FIXTURE_DIRS` contains duplicates or a default fixture directory path (app_name/fixtures), an exception is raised.
- The new `makemigrations --exit` option allows exiting with an error code if no migrations are created.
- The new `showmigrations` command allows listing all migrations and their dependencies in a project.
Middleware

- The `CommonMiddleware.response_redirect_class` attribute allows you to customize the redirects issued by the middleware.
- A debug message will be logged to the `django.request` logger when a middleware raises a `MiddlewareNotUsed` exception in `DEBUG` mode.

Migrations

- The `RunSQL` operation can now handle parameters passed to the SQL statements.
- It is now possible to have migrations (most probably data migrations) for applications without models.
- Migrations can now serialize model managers as part of the model state.
- A generic mechanism to handle the deprecation of model fields was added.
- The `RunPython.noop()` and `RunSQL.noop` class method/attribute were added to ease in making `RunPython` and `RunSQL` operations reversible.
- The migration operations `RunPython` and `RunSQL` now call the `allow_migrate()` method of database routers. The router can use the newly introduced `app_label` and `hints` arguments to make a routing decision. To take advantage of this feature you need to update the router to the new `allow_migrate` signature, see the deprecation section for more details.

Models

- Django now logs at most 9000 queries in `connections.queries`, in order to prevent excessive memory usage in long-running processes in debug mode.
- There is now a model `Meta` option to define a default related name for all relational fields of a model.
- Pickling models and querysets across different versions of Django isn’t officially supported (it may work, but there’s no guarantee). An extra variable that specifies the current Django version is now added to the pickled state of models and querysets, and Django raises a `RuntimeWarning` when these objects are unpickled in a different version than the one in which they were pickled.
- Added `Model.from_db()` which Django uses whenever objects are loaded using the ORM. The method allows customizing model loading behavior.
- `extra(select={...})` now allows you to escape a literal `%s` sequence using `%%s`.
- Custom Lookups can now be registered using a decorator pattern.
- The new `Transform.bilateral` attribute allows creating bilateral transformations. These transformations are applied to both `lhs` and `rhs` when used in a lookup expression, providing opportunities for more sophisticated lookups.
• SQL special characters (, %, _) are now escaped properly when a pattern lookup (e.g. contains, startswith, etc.) is used with an F() expression as the right-hand side. In those cases, the escaping is performed by the database, which can lead to somewhat complex queries involving nested REPLACE function calls.

• You can now refresh model instances by using `Model.refresh_from_db()`.

• You can now get the set of deferred fields for a model using `Model.get_deferred_fields()`.

• Model field default’s are now used when primary key field’s are set to `None`.

Signals

• Exceptions from the (receiver, exception) tuples returned by `Signal.send_robust()` now have their traceback attached as a `__traceback__` attribute.

• The `environ` argument, which contains the WSGI environment structure from the request, was added to the `request_started` signal.

• You can now import the `setting_changed()` signal from `django.core.signals` to avoid loading `django.test` in non-test situations. Django no longer does so itself.

System Check Framework

• `register` can now be used as a function.

Templates

• `urlize` now supports domain-only links that include characters after the top-level domain (e.g. djangoproject.com/ and djangoproject.com/download/).

• `urlize` doesn’t treat exclamation marks at the end of a domain or its query string as part of the URL (the URL in e.g. 'djangoproject.com! is djangoproject.com)

• Added a `locmem.Loader` class that loads Django templates from a Python dictionary.

• The `now` tag can now store its output in a context variable with the usual syntax: `{% now 'j n Y' as varname %}`.
Requests and Responses

- WSGIRequest now respects paths starting with //.
- The HttpRequest.build_absolute_uri() method now handles paths starting with // correctly.
- If DEBUG is True and a request raises a SuspiciousOperation, the response will be rendered with a detailed error page.
- The query_string argument of QueryDict is now optional, defaulting to None, so a blank QueryDict can now be instantiated with QueryDict() instead of QueryDict(None) or QueryDict('').
- The GET and POST attributes of an HttpRequest object are now QueryDicts rather than dictionaries, and the FILES attribute is now a MultiValueDict. This brings this class into line with the documentation and with WSGIRequest.
- The HttpResponse.charset attribute was added.
- WSGIRequestHandler now follows RFC in converting URI to IRI, using uri_to_iri().
- The HttpRequest.get_full_path() method now escapes unsafe characters from the path portion of a Uniform Resource Identifier (URI) properly.
- HttpResponse now implements a few additional methods like getvalue() so that instances can be used as stream objects.
- The new HttpResponse.setdefault() method allows setting a header unless it has already been set.
- You can use the new FileResponse to stream files.
- The condition() decorator for conditional view processing now supports the If-unmodified-since header.

Tests

- The RequestFactory.trace() and Client.trace() methods were implemented, allowing you to create TRACE requests in your tests.
- The count argument was added to assertTemplateUsed(). This allows you to assert that a template was rendered a specific number of times.
- The new assertJSONNotEqual() assertion allows you to test that two JSON fragments are not equal.
- Added options to the test command to preserve the test database (--keepdb), to run the test cases in reverse order (--reverse), and to enable SQL logging for failing tests (--debug-sql).
- Added the resolver_match attribute to test client responses.
- Added several settings that allow customization of test tablespace parameters for Oracle: DATAFILE, DATAFILE_TMP, DATAFILE_MAXSIZE and DATAFILE_TMP_MAXSIZE.
- The override_settings() decorator can now affect the master router in DATABASE_ROUTERS.
• Added test client support for file uploads with file-like objects.

• A shared cache is now used when testing with an SQLite in-memory database when using Python 3.4+ and SQLite 3.7.13+. This allows sharing the database between threads.

Validators

• URLValidator now supports IPv6 addresses, Unicode domains, and URLs containing authentication data.

Backwards incompatible changes in 1.8

Warning: In addition to the changes outlined in this section, be sure to review the deprecation plan for any features that have been removed. If you haven’t updated your code within the deprecation timeline for a given feature, its removal may appear as a backwards incompatible change.

Related object operations are run in a transaction

Some operations on related objects such as add() or direct assignment ran multiple data modifying queries without wrapping them in transactions. To reduce the risk of data corruption, all data modifying methods that affect multiple related objects (i.e. add(), remove(), clear(), and direct assignment) now perform their data modifying queries from within a transaction, provided your database supports transactions.

This has one backwards incompatible side effect, signal handlers triggered from these methods are now executed within the method’s transaction and any exception in a signal handler will prevent the whole operation.

Assigning unsaved objects to relations raises an error

Note: To more easily allow in-memory usage of models, this change was reverted in Django 1.8.4 and replaced with a check during model.save(). For example:

```python
>>> book = Book.objects.create(name="Django")
>>> book.author = Author(name="John")
>>> book.save()
Traceback (most recent call last):
  ...
ValueError: save() prohibited to prevent data loss due to unsaved related object ‘author’.
```

A similar check on assignment to reverse one-to-one relations was removed in Django 1.8.5.
Assigning unsaved objects to a `ForeignKey`, `GenericForeignKey`, and `OneToOneField` now raises a `ValueError`.

Previously, the assignment of an unsaved object would be silently ignored. For example:

```python
>>> book = Book.objects.create(name="Django")
>>> book.author = Author(name="John")
>>> book.author.save()
>>> book.save()

>>> Book.objects.get(name="Django")
>>> book.author
```

Now, an error will be raised to prevent data loss:

```python
>>> book.author = Author(name="john")
Traceback (most recent call last):
...
ValueError: Cannot assign "<Author: John>": "Author" instance isn't saved in the database.
```

If you require allowing the assignment of unsaved instances (the old behavior) and aren’t concerned about the data loss possibility (e.g. you never save the objects to the database), you can disable this check by using the `ForeignKey.allow_unsaved_instance_assignment` attribute. (This attribute was removed in 1.8.4 as it’s no longer relevant.)

**Management commands that only accept positional arguments**

If you have written a custom management command that only accepts positional arguments and you didn’t specify the `args` command variable, you might get an error like `Error: unrecognized arguments: ...`, as variable parsing is now based on `argparse` which doesn’t implicitly accept positional arguments. You can make your command backwards compatible by simply setting the `args` class variable. However, if you don’t have to keep compatibility with older Django versions, it’s better to implement the new `add_arguments()` method as described in How to create custom django-admin commands.

**Custom test management command arguments through test runner**

The method to add custom arguments to the `test` management command through the test runner has changed. Previously, you could provide an `option_list` class variable on the test runner to add more arguments (à la `optparse`). Now to implement the same behavior, you have to create an `add_arguments(cls, parser)` class method on the test runner and call `parser.add_argument` to add any custom arguments, as `parser` is now an `argparse.ArgumentParser` instance.
Model check ensures auto-generated column names are within limits specified by database

A field name that’s longer than the column name length supported by a database can create problems. For example, with MySQL you’ll get an exception trying to create the column, and with PostgreSQL the column name is truncated by the database (you may see a warning in the PostgreSQL logs).

A model check has been introduced to better alert users to this scenario before the actual creation of database tables.

If you have an existing model where this check seems to be a false positive, for example on PostgreSQL where the name was already being truncated, simply use `db_column` to specify the name that’s being used.

The check also applies to the columns generated in an implicit `ManyToManyField.through` model. If you run into an issue there, use `through` to create an explicit model and then specify `db_column` on its column(s) as needed.

Query relation lookups now check object types

Querying for model lookups now checks if the object passed is of correct type and raises a `ValueError` if not. Previously, Django didn’t care if the object was of correct type; it just used the object’s related field attribute (e.g. `id`) for the lookup. Now, an error is raised to prevent incorrect lookups:

```python
>>> book = Book.objects.create(name="Django")
>>> book = Book.objects.filter(author=book)
Traceback (most recent call last):
  ...
ValueError: Cannot query "<Book: Django>": Must be "Author" instance.
```

`select_related()` now checks given fields

`select_related()` now validates that the given fields actually exist. Previously, nonexistent fields were silently ignored. Now, an error is raised:

```python
>>> book = Book.objects.select_related('nonexistent_field')
Traceback (most recent call last):
  ...
FieldError: Invalid field name(s) given in select_related: 'nonexistent_field'
```

The validation also makes sure that the given field is relational:

```python
>>> book = Book.objects.select_related('name')
Traceback (most recent call last):
  ...
FieldError: Non-relational field given in select_related: 'name'
```
Default EmailField.max_length increased to 254

The old default 75 character max_length was not capable of storing all possible RFC3696/5321-compliant email addresses. In order to store all possible valid email addresses, the max_length has been increased to 254 characters. You will need to generate and apply database migrations for your affected models (or add max_length=75 if you wish to keep the length on your current fields). A migration for django.contrib.auth.models.User.email is included.

Support for PostgreSQL versions older than 9.0

The end of upstream support periods was reached in July 2014 for PostgreSQL 8.4. As a consequence, Django 1.8 sets 9.0 as the minimum PostgreSQL version it officially supports.

This also includes dropping support for PostGIS 1.3 and 1.4 as these versions are not supported on versions of PostgreSQL later than 8.4.

Django also now requires the use of Psycopg2 version 2.4.5 or higher (or 2.5+ if you want to use django.contrib.postgres).

Support for MySQL versions older than 5.5

The end of upstream support periods was reached in January 2012 for MySQL 5.0 and December 2013 for MySQL 5.1. As a consequence, Django 1.8 sets 5.5 as the minimum MySQL version it officially supports.

Support for Oracle versions older than 11.1

The end of upstream support periods was reached in July 2010 for Oracle 9.2, January 2012 for Oracle 10.1, and July 2013 for Oracle 10.2. As a consequence, Django 1.8 sets 11.1 as the minimum Oracle version it officially supports.

Specific privileges used instead of roles for tests on Oracle

Earlier versions of Django granted the CONNECT and RESOURCE roles to the test user on Oracle. These roles have been deprecated, so Django 1.8 uses the specific underlying privileges instead. This changes the privileges required of the main user for running tests (unless the project is configured to avoid creating a test user). The exact privileges required now are detailed in Oracle notes.
AbstractUser.last_login allows null values

The AbstractUser.last_login field now allows null values. Previously, it defaulted to the time when the user was created which was misleading if the user never logged in. If you are using the default user (django.contrib.auth.models.User), run the database migration included in contrib.auth.

If you are using a custom user model that inherits from AbstractUser, you’ll need to run makemigrations and generate a migration for your app that contains that model. Also, if wish to set last_login to NULL for users who haven’t logged in, you can run this query:

```python
from django.db import models
from django.contrib.auth import get_user_model
from django.contrib.auth.models import AbstractBaseUser

UserModel = get_user_model()
if issubclass(UserModel, AbstractBaseUser):
    UserModel._default_manager.filter(
        last_login=models.F('dateJoined')
    ).update(last_login=None)
```

django.contrib.gis

- Support for GEOS 3.1 and GDAL 1.6 has been dropped.
- Support for SpatiaLite < 2.4 has been dropped.
- GIS-specific lookups have been refactored to use the django.db.models.Lookup API.
- The default str representation of GEOSGeometry objects has been changed from WKT to EWKT format (including the SRID). As this representation is used in the serialization framework, that means that dumpdata output will now contain the SRID value of geometry objects.

Priority of context processors for TemplateResponse brought in line with render

The TemplateResponse constructor is designed to be a drop-in replacement for the render() function. However, it had a slight incompatibility, in that for TemplateResponse, context data from the passed in context dictionary could be shadowed by context data returned from context processors, whereas for render it was the other way around. This was a bug, and the behavior of render is more appropriate, since it allows the globally defined context processors to be overridden locally in the view. If you were relying on the fact context data in a TemplateResponse could be overridden using a context processor, you will need to change your code.
Overriding setUpClass / tearDownClass in test cases

The decorators `override_settings()` and `modify_settings()` now act at the class level when used as class decorators. As a consequence, when overriding `setUpClass()` or `tearDownClass()`, the `super` implementation should always be called.

Removal of `django.contrib.formtools`

The `formtools contrib` app has been moved to a separate package and the relevant documentation pages have been updated or removed.

The new package is available on GitHub and on PyPI.

Database connection reloading between tests

Django previously closed database connections between each test within a `TestCase`. This is no longer the case as Django now wraps the whole `TestCase` within a transaction. If some of your tests relied on the old behavior, you should have them inherit from `TransactionTestCase` instead.

Cleanup of the `django.template` namespace

If you’ve been relying on private APIs exposed in the `django.template` module, you may have to import them from `django.template.base` instead.

Also private APIs `django.template.base.compile_string()`, `django.template.loader.find_template()`, and `django.template.loader.get_template_from_string()` were removed.

model attribute on private model relations

In earlier versions of Django, on a model with a reverse foreign key relationship (for example), `model._meta.get_all_related_objects()` returned the relationship as a `django.db.models.related.RelatedObject` with the `model` attribute set to the source of the relationship. Now, this method returns the relationship as `django.db.models.fields.related.ManyToOneRel` (private API `RelatedObject` has been removed), and the `model` attribute is set to the target of the relationship instead of the source. The source model is accessible on the `related_model` attribute instead.

Consider this example from the tutorial in Django 1.8:

```python
>>> p = Poll.objects.get(pk=1)
>>> p._meta.get_all_related_objects()
[<ManyToOneRel: polls.choice>]
>>> p._meta.get_all_related_objects()[0].model
```

(continues on next page)
and compare it to the behavior on older versions:

```python
>>> p._meta.get_all_related_objects()
[<RelatedObject: polls:choice related to poll>]
```

To access the source model, you can use a pattern like this to write code that will work with both Django 1.8 and older versions:

```python
for relation in opts.get_all_related_objects():
    to_model = getattr(relation, 'related_model', relation.model)
```

Also note that `get_all_related_objects()` is deprecated in 1.8.

**Database backend API**

The following changes to the database backend API are documented to assist those writing third-party backends in updating their code:

- **BaseDatabaseXXX** classes have been moved to `django.db.backends.base`. Please import them from the new locations:

  ```python
  from django.db.backends.base.base import BaseDatabaseWrapper
  from django.db.backends.base.client import BaseDatabaseClient
  from django.db.backends.base.creation import BaseDatabaseCreation
  from django.db.backends.base.features import BaseDatabaseFeatures
  from django.db.backends.base.introspection import BaseDatabaseIntrospection
  from django.db.backends.base.introspection import FieldInfo, TableInfo
  from django.db.backends.base.operations import BaseDatabaseOperations
  from django.db.backends.base.schema import BaseDatabaseSchemaEditor
  from django.db.backends.base.validation import BaseDatabaseValidation
  ```

- The `data_types`, `data_types_suffix`, and `data_type_check_constraints` attributes have moved from the `DatabaseCreation` class to `DatabaseWrapper`.

- The `SQLCompiler.as_sql()` method now takes a subquery parameter (#24164).

- The `BaseDatabaseOperations.date_interval_sql()` method now only takes a `timedelta` parameter.
django.contrib.admin

- AdminSite no longer takes an app_name argument and its app_name attribute has been removed. The application name is always admin (as opposed to the instance name which you can still customize using AdminSite(name=...)).

- The ModelAdmin.get_object() method (private API) now takes a third argument named from_field in order to specify which field should match the provided object_id.

- The ModelAdmin.response_delete() method now takes a second argument named obj_id which is the serialized identifier used to retrieve the object before deletion.

Default autoescaping of functions in django.template.defaultfilters

In order to make built-in template filters that output HTML “safe by default” when calling them in Python code, the following functions in django.template.defaultfilters have been changed to automatically escape their input value:

- join
- linebreaks
- linebreaks_filter
- linenumbers
- unordered_list
- urlize
- urlizetrunc

You can revert to the old behavior by specifying autoescape=False if you are passing trusted content. This change doesn’t have any effect when using the corresponding filters in templates.

Miscellaneous

- connections.queries is now a read-only attribute.

- Database connections are considered equal only if they’re the same object. They aren’t hashable any more.

- GZipMiddleware used to disable compression for some content types when the request is from Internet Explorer, in order to work around a bug in IE6 and earlier. This behavior could affect performance on IE7 and later. It was removed.

- URLField.to_python no longer adds a trailing slash to pathless URLs.

- The length template filter now returns 0 for an undefined variable, rather than an empty string.
• ForeignKey.default_error_message['invalid'] has been changed from '%(model)s instance with pk %(pk)r does not exist.' to '%(model)s instance with %(field)s %(value)r does not exist.' If you are using this message in your own code, please update the list of interpolated parameters. Internally, Django will continue to provide the pk parameter in params for backwards compatibility.

• UserCreationForm.error_messages['duplicate_username'] is no longer used. If you wish to customize that error message, override it on the form using the 'unique' key in Meta. error_messages['username'] or, if you have a custom form field for 'username', using the 'unique' key in its error_messages argument.

• The block usertools in the base.html template of django.contrib.admin now requires the has_permission context variable to be set. If you have any custom admin views that use this template, update them to pass AdminSite.has_permission() as this new variable’s value or simply include AdminSite.each_context(request) in the context.

• Internal changes were made to the ClearableFileInput widget to allow more customization. The undocumented url_markup_template attribute was removed in favor of template_with_initial.

• For consistency with other major vendors, the en_GB locale now has Monday as the first day of the week.

• Seconds have been removed from any locales that had them in TIME_FORMAT, DATETIME_FORMAT, or SHORT_DATETIME_FORMAT.

• The default max size of the Oracle test tablespace has increased from 300M (or 200M, before 1.7.2) to 500M.

• reverse() and reverse_lazy() now return Unicode strings instead of bytestrings.

• The CacheClass shim has been removed from all cache backends. These aliases were provided for backwards compatibility with Django 1.3. If you are still using them, please update your project to use the real class name found in the BACKEND key of the CACHES setting.

• By default, call_command() now always skips the check framework (unless you pass it skip_checks=False).

• When iterating over lines, File now uses universal newlines. The following are recognized as ending a line: the Unix end-of-line convention '\n', the Windows convention '\r\n', and the old Macintosh convention '\r'.

• The Memcached cache backends MemcachedCache and PyLibMCCache will delete a key if set() fails. This is necessary to ensure the cache_db session store always fetches the most current session data.

• Private APIs override_template_loaders and override_with_test_loader in django.test.utils were removed. Override TEMPLATES with override_settings instead.

• Warnings from the MySQL database backend are no longer converted to exceptions when DEBUG is True.
HttpRequest now has a simplified repr (e.g. `<WSGIRequest: GET '/somepath/'>`). This won’t change the behavior of the SafeExceptionReporterFilter class.

Class-based views that use ModelFormMixin will raise an ImproperlyConfigured exception when both the fields and form_class attributes are specified. Previously, fields was silently ignored.

When following redirects, the test client now raises RedirectCycleError if it detects a loop or hits a maximum redirect limit (rather than passing silently).

Translatable strings set as the default parameter of the field are cast to concrete strings later, so the return type of Field.get_default() is different in some cases. There is no change to default values which are the result of a callable.

GenericIPAddressField.empty_strings_allowed is now False. Database backends that interpret empty strings as null (only Oracle among the backends that Django includes) will no longer convert null values back to an empty string. This is consistent with other backends.

When the BaseCommand.leave_locale_alone attribute is False, translations are now deactivated instead of forcing the “en-us” locale. In the case your models contained non-English strings and you counted on English translations to be activated in management commands, this will not happen any longer. It might be that new database migrations are generated (once) after migrating to 1.8.

django.utils.translation.get_language() now returns None instead of LANGUAGE_CODE when translations are temporarily deactivated.

When a translation doesn’t exist for a specific literal, the fallback is now taken from the LANGUAGE_CODE language (instead of from the untranslated msgid message).

The name field of django.contrib.contenttypes.models.ContentType has been removed by a migration and replaced by a property. That means it’s not possible to query or filter a ContentType by this field any longer.

Be careful if you upgrade to Django 1.8 and skip Django 1.7. If you run manage.py migrate --fake, this migration will be skipped and you’ll see a RuntimeError: Error creating new content types. exception because the name column won’t be dropped from the database. Use manage.py migrate --fake-initial to fake only the initial migration instead.

The new migrate --fake-initial option allows faking initial migrations. In 1.7, initial migrations were always automatically faked if all tables created in an initial migration already existed.

An app without migrations with a ForeignKey to an app with migrations may now result in a foreign key constraint error when migrating the database or running tests. In Django 1.7, this could fail silently and result in a missing constraint. To resolve the error, add migrations to the app without them.
Features deprecated in 1.8

Selected methods in `django.db.models.options.Options`

As part of the formalization of the `Model._meta` API (from the `django.db.models.options.Options` class), a number of methods have been deprecated and will be removed in Django 1.10:

- `get_all_field_names()`
- `get_all_related_objects()`
- `get_all_related_objects_with_model()`
- `get_all_related_many_to_many_objects()`
- `get_all_related_m2m_objects_with_model()`
- `get_concrete_fields_with_model()`
- `get_field_by_name()`
- `get_fields_with_model()`
- `get_m2m_with_model()`

Loading cycle and firstof template tags from future library

Django 1.6 introduced `{% load cycle from future %}` and `{% load firstof from future %}` syntax for forward compatibility of the `cycle` and `firstof` template tags. This syntax is now deprecated and will be removed in Django 1.10. You can simply remove the `{% load ... from future %}` tags.

`django.conf.urls.patterns()`

In the olden days of Django, it was encouraged to reference views as strings in `urlpatterns`:

```python
urlpatterns = patterns('',
    url('^$', 'myapp.views.myview'),
)
```

and Django would magically import `myapp.views.myview` internally and turn the string into a real function reference. In order to reduce repetition when referencing many views from the same module, the `patterns()` function takes a required initial `prefix` argument which is prepended to all views-as-strings in that set of `urlpatterns`:

```python
urlpatterns = patterns('myapp.views',
    url('^$', 'myview'),
)
```
In the modern era, we have updated the tutorial to instead recommend importing your views module and referencing your view functions (or classes) directly. This has a number of advantages, all deriving from the fact that we are using normal Python in place of “Django String Magic” : the errors when you mistype a view name are less obscure, IDEs can help with autocompletion of view names, etc.

So these days, the above use of the prefix arg is much more likely to be written (and is better written) as:

```python
from myapp import views

urlpatterns = patterns('',
    url('^$', views.myview),
    url('^other/$', views(otherview),
)
```

Thus `patterns()` serves little purpose and is a burden when teaching new users (answering the newbie’s question “why do I need this empty string as the first argument to `patterns()`?”). For these reasons, we are deprecating it. Updating your code is as simple as ensuring that `urlpatterns` is a list of `django.conf.urls.url()` instances. For example:

```python
from django.conf.urls import url
from myapp import views

urlpatterns = [
    url('^$', views.myview),
    url('^other/$', views.otherview),
]
```

**Passing a string as view to `django.conf.urls.url()`**

Related to the previous item, referencing views as strings in the `url()` function is deprecated. Pass the callable view as described in the previous section instead.
Template-related settings

As a consequence of the multiple template engines refactor, several settings are deprecated in favor of `TEMPLATES`:

- `ALLOWED_INCLUDE_ROOTS`
- `TEMPLATE_CONTEXT_PROCESSORS`
- `TEMPLATE_DEBUG`
- `TEMPLATE_DIRS`
- `TEMPLATE_LOADERS`
- `TEMPLATE_STRING_IF_INVALID`

`django.core.context_processors`

Built-in template context processors have been moved to `django.template.context_processors`.

`django.test.SimpleTestCase.urls`

The attribute `SimpleTestCase.urls` for specifying URLconf configuration in tests has been deprecated and will be removed in Django 1.10. Use `@override_settings(ROOT_URLCONF=...)` instead.

`prefix argument to i18n_patterns()`

Related to the previous item, the `prefix` argument to `django.conf.urls.i18n.i18n_patterns()` has been deprecated. Simply pass a list of `django.conf.urls.url()` instances instead.

Using an incorrect count of unpacked values in the `for` template tag

Using an incorrect count of unpacked values in `for` tag will raise an exception rather than fail silently in Django 1.10.

Passing a dotted path to `reverse()` and `url`

Reversing URLs by Python path is an expensive operation as it causes the path being reversed to be imported. This behavior has also resulted in a security issue. Use named URL patterns for reversing instead.

If you are using `django.contrib.sitemaps`, add the `name` argument to the `url` that references `django.contrib.sitemaps.views.sitemap()`:
from django.contrib.sitemaps.views import sitemap

url(r'^sitemap\..xml$', sitemap, {'sitemaps': sitemaps},
    name='django.contrib.sitemaps.views.sitemap')

to ensure compatibility when reversing by Python path is removed in Django 1.10.

Similarly for GIS sitemaps, add name='django.contrib.gis.sitemaps.views.kml' or name='django.contrib.gis.sitemaps.views.kmz'.

If you are using a Python path for the LOGIN_URL or LOGIN_REDIRECT_URL setting, use the name of the url() instead.

**Aggregate methods and modules**

The django.db.models.sql.aggregates and django.contrib.gis.db.models.sql.aggregates modules (both private API), have been deprecated as django.db.models.aggregates and django.contrib.gis.db.models.aggregates are now also responsible for SQL generation. The old modules will be removed in Django 1.10.

If you were using the old modules, see Query Expressions for instructions on rewriting custom aggregates using the new stable API.

The following methods and properties of django.db.models.sql.query.Query have also been deprecated and the backwards compatibility shims will be removed in Django 1.10:

- Query.aggregates, replaced by annotations.
- Query.aggregate_select, replaced by annotation_select.
- Query.add_aggregate(), replaced by add_annotation().
- Query.set_aggregate_mask(), replaced by set_annotation_mask().
- Query.append_aggregate_mask(), replaced by append_annotation_mask().

**Extending management command arguments through Command.option_list**

Management commands now use argparse instead of optparse to parse command-line arguments passed to commands. This also means that the way to add custom arguments to commands has changed: instead of extending the option_list class list, you should now override the add_arguments() method and add arguments through argparse.add_argument(). See this example for more details.
**django.core.management.NoArgsCommand**

The class **NoArgsCommand** is now deprecated and will be removed in Django 1.10. Use **BaseCommand** instead, which takes no arguments by default.

**Listing all migrations in a project**

The **--list** option of the **migrate** management command is deprecated and will be removed in Django 1.10. Use **showmigrations** instead.

**cache_choices option of ModelChoiceField and ModelMultipleChoiceField**

**ModelChoiceField** and **ModelMultipleChoiceField** took an undocumented, untested option **cache_choices**. This cached querysets between multiple renderings of the same **Form** object. This option is subject to an accelerated deprecation and will be removed in Django 1.9.

**django.template.resolve_variable()**

The function has been informally marked as “Deprecated” for some time. Replace **resolve_variable(path, context)** with **django.template.Variable(path).resolve(context)**.

**django.contrib.webdesign**

It provided the **lorem** template tag which is now included in the built-in tags. Simply remove 'django.contrib.webdesign' from **INSTALLED_APPS** and `{% load webdesign %}` from your templates.

**error_message argument to django.forms.RegexField**

It provided backwards compatibility for pre-1.0 code, but its functionality is redundant. Use **Field.error_messages[‘invalid’]** instead.

**Old unordered_list syntax**

An older (pre-1.0), more restrictive and verbose input format for the **unordered_list** template filter has been deprecated:

```
```

Using the new syntax, this becomes:
django.forms.Field._has_changed()

Rename this method to `has_changed()` by removing the leading underscore. The old name will still work until Django 1.10.

django.utils.html.remove_tags() and removetags template filter

django.utils.html.remove_tags() as well as the template filter removetags have been deprecated as they cannot guarantee safe output. Their existence is likely to lead to their use in security-sensitive contexts where they are not actually safe.

The unused and undocumented `django.utils.html.strip_entities()` function has also been deprecated.

`is_admin_site` argument to `django.contrib.auth.views.password_reset()`

It’s a legacy option that should no longer be necessary.

SubfieldBase

django.db.models.fields.subclassing.SubfieldBase has been deprecated and will be removed in Django 1.10. Historically, it was used to handle fields where type conversion was needed when loading from the database, but it was not used in `.values()` calls or in aggregates. It has been replaced with `from_db_value()`.

The new approach doesn’t call the `to_python()` method on assignment as was the case with SubfieldBase. If you need that behavior, reimplement the Creator class from Django’s source code in your project.

django.utils.checksums

The `django.utils.checksums` module has been deprecated and will be removed in Django 1.10. The functionality it provided (validating checksum using the Luhn algorithm) was undocumented and not used in Django. The module has been moved to the `django-localflavor` package (version 1.1+).
**InlineAdminForm.original_content_type_id**

The `original_content_type_id` attribute on `InlineAdminForm` has been deprecated and will be removed in Django 1.10. Historically, it was used to construct the "view on site" URL. This URL is now accessible using the `absolute_url` attribute of the form.

**django.views.generic.edit.FormMixin.get_form()’s form_class argument**

FormMixin subclasses that override the `get_form()` method should make sure to provide a default value for the `form_class` argument since it’s now optional.

**Rendering templates loaded by get_template() with a Context**

The return type of `get_template()` has changed in Django 1.8: instead of a `django.template.Template`, it returns a `Template` instance whose exact type depends on which backend loaded it.

Both classes provide a `render()` method, however, the former takes a `django.template.Context` as an argument while the latter expects a `dict`. This change is enforced through a deprecation path for Django templates.

All this also applies to `select_template()`.

**Template and Context classes in template responses**

Some methods of `SimpleTemplateResponse` and `TemplateResponse` accepted `django.template.Context` and `django.template.Template` objects as arguments. They should now receive `dict` and backend-dependent template objects respectively.

This also applies to the return types if you have subclassed either template response class.

Check the template response API documentation for details.

**current_app argument of template-related APIs**

The following functions and classes will no longer accept a `current_app` parameter to set an URL namespace in Django 1.10:

- `django.shortcuts.render()`
- `django.template.Context()`
- `django.template.RequestContext()`
- `django.template.response.TemplateResponse()`
Set `request.current_app` instead, where `request` is the first argument to these functions or classes. If you’re using a plain `Context`, use a `RequestContext` instead.

**dictionary and context_instance arguments of rendering functions**

The following functions will no longer accept the `dictionary` and `context_instance` parameters in Django 1.10:

- `django.shortcuts.render()`
- `django.shortcuts.render_to_response()`
- `django.template.loader.render_to_string()`

Use the `context` parameter instead. When `dictionary` is passed as a positional argument, which is the most common idiom, no changes are needed.

If you’re passing a `Context` in `context_instance`, pass a `dict` in the `context` parameter instead. If you’re passing a `RequestContext`, pass the request separately in the `request` parameter.

**dirs argument of template-finding functions**

The following functions will no longer accept a `dirs` parameter to override `TEMPLATE_DIRS` in Django 1.10:

- `django.template.loader.get_template()`
- `django.template.loader.select_template()`
- `django.shortcuts.render()`
- `django.shortcuts.render_to_response()`

The parameter didn’t work consistently across different template loaders and didn’t work for included templates.

`django.template.loader.BaseLoader`

`django.template.loader.BaseLoader` was renamed to `django.template.loaders.base.Loader`. If you’ve written a custom template loader that inherits `BaseLoader`, you must inherit `Loader` instead.
django.test.utils.TestTemplateLoader

Private API `django.test.utils.TestTemplateLoader` is deprecated in favor of `django.template.loaders.locmem.Loader` and will be removed in Django 1.9.

**Support for the max_length argument on custom Storage classes**

Storage subclasses should add `max_length=None` as a parameter to `get_available_name()` and/or `save()` if they override either method. Support for storages that do not accept this argument will be removed in Django 1.10.

qn replaced by compiler

In previous Django versions, various internal ORM methods (mostly `as_sql` methods) accepted a `qn` (for “quote name”) argument, which was a reference to a function that quoted identifiers for sending to the database. In Django 1.8, that argument has been renamed to `compiler` and is now a full `SQLCompiler` instance. For backwards-compatibility, calling a `SQLCompiler` instance performs the same name-quoting that the `qn` function used to. However, this backwards-compatibility shim is immediately deprecated: you should rename your `qn` arguments to `compiler`, and call `compiler.quote_name_unless_alias(...)` where you previously called `qn(...).

Default value of RedirectView.permanent

The default value of the `RedirectView.permanent` attribute will change from `True` to `False` in Django 1.9.

Using AuthenticationMiddleware without SessionAuthenticationMiddleware

django.contrib.auth.middleware.SessionAuthenticationMiddleware was added in Django 1.7. In Django 1.7.2, its functionality was moved to `auth.get_user()` and, for backwards compatibility, enabled only if `'django.contrib.auth.middleware.SessionAuthenticationMiddleware' appears in `MIDDLEWARE_CLASSES`.

In Django 1.10, session verification will be enabled regardless of whether or not `SessionAuthenticationMiddleware` is enabled (at which point `SessionAuthenticationMiddleware` will have no significance). You can add it to your `MIDDLEWARE_CLASSES` sometime before then to opt-in. Please read the upgrade considerations first.
django.contrib.sitemaps.FlatPageSitemap

django.contrib.sitemaps.FlatPageSitemap has moved to django.contrib.flatpages.sitemaps. FlatPageSitemap. The old import location is deprecated and will be removed in Django 1.9.

**Model Field.related**

Private attribute `django.db.models.Field.related` is deprecated in favor of `Field.rel`. The latter is an instance of `django.db.models.fields.related.ForeignObjectRel` which replaces `django.db.models.related.RelatedObject`. The `django.db.models.related` module has been removed and the `Field.related` attribute will be removed in Django 1.10.

**ssi template tag**

The `ssi` template tag allows files to be included in a template by absolute path. This is of limited use in most deployment situations, and the `include` tag often makes more sense. This tag is now deprecated and will be removed in Django 1.10.

**= as comparison operator in if template tag**

Using a single equals sign with the `{% if %}` template tag for equality testing was undocumented and untested. It’s now deprecated in favor of `==`.

**%(<foo>)s syntax in ModelFormMixin.success_url**

The legacy `%(<foo>)s` syntax in `ModelFormMixin.success_url` is deprecated and will be removed in Django 1.10.

**GeoQuerySet aggregate methods**

The `collect()`, `extent()`, `extent3d()`, `make_line()`, and `unionagg()` aggregate methods are deprecated and should be replaced by their function-based aggregate equivalents (`Collect`, `Extent`, `Extent3D`, `MakeLine`, and `Union`).
Signature of the allow_migrate router method

The signature of the allow_migrate() method of database routers has changed from allow_migrate(db, model) to allow_migrate(db, app_label, model_name=None, **hints).

When model_name is set, the value that was previously given through the model positional argument may now be found inside the hints dictionary under the key 'model'.

After switching to the new signature the router will also be called by the RunPython and RunSQL operations.

Features removed in 1.8

These features have reached the end of their deprecation cycle and are removed in Django 1.8. See Features deprecated in 1.6 for details, including how to remove usage of these features.

- django.contrib.comments is removed.
- The following transaction management APIs are removed:
  - TransactionMiddleware
  - the decorators and context managers autocommit, commit_on_success, and commit_manually, defined in django.db.transaction
  - the functions commit_unless_managed and rollback_unless_managed, also defined in django.db.transaction
  - the TRANSACTIONS_MANAGED setting
- The cycle and firstof template tags auto-escape their arguments.
- The SEND_BROKEN_LINK_EMAILS setting is removed.
- django.middleware.doc.XViewMiddleware is removed.
- The Model._meta.module_name alias is removed.
- The backward compatible shims introduced to rename get_query_set and similar query-set methods are removed. This affects the following classes: BaseModelAdmin, ChangeList, BaseCommentNode, GenericForeignKey, Manager, SingleRelatedObjectDescriptor and ReverseSingleRelatedObjectDescriptor.
- The backward compatible shims introduced to rename the attributes ChangeList.root_query_set and ChangeList.query_set are removed.
- django.views.defaults.shortcut and django.conf.urls.shortcut are removed.
- Support for the Python Imaging Library (PIL) module is removed.
- The following private APIs are removed:
  - django.db.backend
- `django.db.close_connection()`
- `django.db.backends.creation.BaseDatabaseCreation.set_autocommit()`
- `django.db.transaction.is_managed()`
- `django.db.transaction.managed()`

- `django.forms.widgets.RadioInput` is removed.

- The module `django.test.simple` and the class `django.test.simple.DjangoTestSuiteRunner` are removed.

- The module `django.test._doctest` is removed.

- The `CACHE_MIDDLEWARE_ANONYMOUS_ONLY` setting is removed. This change affects both `django.middleware.cache.CacheMiddleware` and `django.middleware.cache.UpdateCacheMiddleware` despite the lack of a deprecation warning in the latter class.

- Usage of the hard-coded Hold down “Control”, or “Command” on a Mac, to select more than one string to override or append to user-provided `help_text` in forms for `ManyToMany` model fields is no longer performed by Django anymore either at the model or forms layer.

- The `Model._meta.get_(add|change|delete)_permission` methods are removed.

- The session key `django_language` is no longer read for backwards compatibility.

- Geographic Sitemaps are removed (`django.contrib.gis.sitemaps.views.index` and `django.contrib.gis.sitemaps.views.sitemap`).

- `django.utils.html.fix_ampersands`, the `fix_ampersands` template filter, and `django.utils.html.clean_html` are removed.

9.1.14 1.7 release

Django 1.7.11 release notes

November 24, 2015

Django 1.7.11 fixes a security issue and a data loss bug in 1.7.10.

Fixed settings leak possibility in date template filter

If an application allows users to specify an unvalidated format for dates and passes this format to the `date` filter, e.g. `{{ last_updated|date:user_date_format }}`, then a malicious user could obtain any secret in the application’s settings by specifying a settings key instead of a date format. e.g. "SECRET_KEY" instead of "j/m/Y".

To remedy this, the underlying function used by the `date` template filter, `django.utils.formats.get_format()`, now only allows accessing the date/time formatting settings.
Bugfixes

• Fixed a data loss possibility with `Prefetch` if `to_attr` is set to a `ManyToManyField` (#25693).

Django 1.7.10 release notes

August 18, 2015
Django 1.7.10 fixes a security issue in 1.7.9.

Denial-of-service possibility in `logout()` view by filling session store

Previously, a session could be created when anonymously accessing the `django.contrib.auth.views.logout()` view (provided it wasn’t decorated with `login_required()` as done in the admin). This could allow an attacker to easily create many new session records by sending repeated requests, potentially filling up the session store or causing other users’ session records to be evicted.

The `SessionMiddleware` has been modified to no longer create empty session records, including when `SESSION_SAVE_EVERY_REQUEST` is active.

Additionally, the `contrib.sessions.backends.base.SessionBase.flush()` and `cache_db.SessionStore.flush()` methods have been modified to avoid creating a new empty session. Maintainers of third-party session backends should check if the same vulnerability is present in their backend and correct it if so.

Django 1.7.9 release notes

July 8, 2015
Django 1.7.9 fixes several security issues and bugs in 1.7.8.

Denial-of-service possibility by filling session store

In previous versions of Django, the session backends created a new empty record in the session storage any-time `request.session` was accessed and there was a session key provided in the request cookies that didn’t already have a session record. This could allow an attacker to easily create many new session records simply by sending repeated requests with unknown session keys, potentially filling up the session store or causing other users’ session records to be evicted.

The built-in session backends now create a session record only if the session is actually modified; empty session records are not created. Thus this potential DoS is now only possible if the site chooses to expose a session-modifying view to anonymous users.
As each built-in session backend was fixed separately (rather than a fix in the core sessions framework), maintainers of third-party session backends should check whether the same vulnerability is present in their backend and correct it if so.

**Header injection possibility since validators accept newlines in input**

Some of Django’s built-in validators (`EmailValidator`, most seriously) didn’t prohibit newline characters (due to the usage of $ instead of \Z in the regular expressions). If you use values with newlines in HTTP response or email headers, you can suffer from header injection attacks. Django itself isn’t vulnerable because `HttpResponse` and the mail sending utilities in `django.core.mail` prohibit newlines in HTTP and SMTP headers, respectively. While the validators have been fixed in Django, if you’re creating HTTP responses or email messages in other ways, it’s a good idea to ensure that those methods prohibit newlines as well. You might also want to validate that any existing data in your application doesn’t contain unexpected newlines.

`validate_ipv4_address()`, `validate_slug()`, and `URLValidator` are also affected, however, as of Django 1.6 the `GenericIPAddressField`, `IPAddressField`, `SlugField`, and `URLField` form fields which use these validators all strip the input, so the possibility of newlines entering your data only exists if you are using these validators outside of the form fields.

The undocumented, internally unused `validate_integer()` function is now stricter as it validates using a regular expression instead of simply casting the value using `int()` and checking if an exception was raised.

**Bugfixes**

- Prevented the loss of null/not null column properties during field renaming of MySQL databases (#24817).
- Fixed `SimpleTestCase.assertRaisesMessage()` on Python 2.7.10 (#24903).

**Django 1.7.8 release notes**

May 1, 2015

Django 1.7.8 fixes:

- Database introspection with SQLite 3.8.9 (released April 8, 2015) (#24637).
- A database table name quoting regression in 1.7.2 (#24605).
- The loss of null/not null column properties during field alteration of MySQL databases (#24595).
Django 1.7.7 release notes

March 18, 2015

Django 1.7.7 fixes several bugs and security issues in 1.7.6.

Denial-of-service possibility with strip_tags()

Last year strip_tags() was changed to work iteratively. The problem is that the size of the input it’s processing can increase on each iteration which results in an infinite loop in strip_tags(). This issue only affects versions of Python that haven’t received a bugfix in HTMLParser; namely Python < 2.7.7 and 3.3.5. Some operating system vendors have also backported the fix for the Python bug into their packages of earlier versions.

To remedy this issue, strip_tags() will now return the original input if it detects the length of the string it’s processing increases. Remember that absolutely NO guarantee is provided about the results of strip_tags() being HTML safe. So NEVER mark safe the result of a strip_tags() call without escaping it first, for example with escape().

Mitigated possible XSS attack via user-supplied redirect URLs

Django relies on user input in some cases (e.g. django.contrib.auth.views.login() and i18n) to redirect the user to an “on success” URL. The security checks for these redirects (namely django.utils.http.is_safe_url()) accepted URLs with leading control characters and so considered URLs like \x08javascript:... safe. This issue doesn’t affect Django currently, since we only put this URL into the Location response header and browsers seem to ignore JavaScript there. Browsers we tested also treat URLs prefixed with control characters such as %08//example.com as relative paths so redirection to an unsafe target isn’t a problem either.

However, if a developer relies on is_safe_url() to provide safe redirect targets and puts such a URL into a link, they could suffer from an XSS attack as some browsers such as Google Chrome ignore control characters at the start of a URL in an anchor href.

Bugfixes

- Fixed renaming of classes in migrations where renaming a subclass would cause incorrect state to be recorded for objects that referenced the superclass (#24354).
- Stopped writing migration files in dry run mode when merging migration conflicts. When makemigrations --merge is called with verbosity=3 the migration file is written to stdout (#24427).
Django 1.7.6 release notes

March 9, 2015

Django 1.7.6 fixes a security issue and several bugs in 1.7.5.

Mitigated an XSS attack via properties in ModelAdmin.readonly_fields

The ModelAdmin.readonly_fields attribute in the Django admin allows displaying model fields and model attributes. While the former were correctly escaped, the latter were not. Thus untrusted content could be injected into the admin, presenting an exploitation vector for XSS attacks.

In this vulnerability, every model attribute used in readonly_fields that is not an actual model field (e.g. a property) will fail to be escaped even if that attribute is not marked as safe. In this release, autoescaping is now correctly applied.

Bugfixes

- Fixed crash when coercing ManyRelatedManager to a string (#24352).
- Fixed a bug that prevented migrations from adding a foreign key constraint when converting an existing field to a foreign key (#24447).

Django 1.7.5 release notes

February 25, 2015

Django 1.7.5 fixes several bugs in 1.7.4.

Bugfixes

- Reverted a fix that prevented a migration crash when unapplying contrib.contenttypes’s or contrib.auth’s first migration (#24075) due to severe impact on the test performance (#24251) and problems in multi-database setups (#24298).
- Fixed a regression that prevented custom fields inheriting from ManyToManyField from being recognized in migrations (#24236).
- Fixed crash in contrib.sites migrations when a default database isn’t used (#24332).
- Added the ability to set the isolation level on PostgreSQL with psycopg2 ≥ 2.4.2 (#24318). It was advertised as a new feature in Django 1.6 but it didn’t work in practice.
- Formats for the Azerbaijani locale (az) have been added.

9.1. Final releases
Django 1.7.4 release notes

January 27, 2015

Django 1.7.4 fixes several bugs in 1.7.3.

Bugfixes

- Fixed a migration crash when unapplying contrib.contenttypes's or contrib.auth's first migration (#24075).
- Made the migration’s RenameModel operation rename ManyToManyField tables (#24135).
- Fixed a migration crash on MySQL when migrating from a OneToOneField to a ForeignKey (#24163).
- Prevented the static.serve view from producing ResourceWarnings in certain circumstances (security fix regression, #24193).
- Fixed schema check for ManyToManyField to look for internal type instead of checking class instance, so you can write custom m2m-like fields with the same behavior. (#24104).

Django 1.7.3 release notes

January 13, 2015

Django 1.7.3 fixes several security issues and bugs in 1.7.2.

WSGI header spoofing via underscore/dash conflation

When HTTP headers are placed into the WSGI environ, they are normalized by converting to uppercase, converting all dashes to underscores, and prepending HTTP_. For instance, a header X-Auth-User would become HTTP_X_AUTH_USER in the WSGI environ (and thus also in Django’s request.META dictionary).

Unfortunately, this means that the WSGI environ cannot distinguish between headers containing dashes and headers containing underscores: X-Auth-User and X-Auth_User both become HTTP_X_AUTH_USER. This means that if a header is used in a security-sensitive way (for instance, passing authentication information along from a front-end proxy), even if the proxy carefully strips any incoming value for X-Auth-User, an attacker may be able to provide an X-Auth_User header (with underscore) and bypass this protection.

In order to prevent such attacks, both Nginx and Apache 2.4+ strip all headers containing underscores from incoming requests by default. Django’s built-in development server now does the same. Django’s development server is not recommended for production use, but matching the behavior of common production servers reduces the surface area for behavior changes during deployment.
Mitigated possible XSS attack via user-supplied redirect URLs

Django relies on user input in some cases (e.g. `django.contrib.auth.views.login()` and i18n) to redirect the user to an “on success” URL. The security checks for these redirects (namely `django.utils.http.is_safe_url()`) didn’t strip leading whitespace on the tested URL and as such considered URLs like `javascript:...` safe. If a developer relied on `is_safe_url()` to provide safe redirect targets and put such a URL into a link, they could suffer from a XSS attack. This bug doesn’t affect Django currently, since we only put this URL into the `Location` response header and browsers seem to ignore JavaScript there.

Denial-of-service attack against `django.views.static.serve`

In older versions of Django, the `django.views.static.serve()` view read the files it served one line at a time. Therefore, a big file with no newlines would result in memory usage equal to the size of that file. An attacker could exploit this and launch a denial-of-service attack by simultaneously requesting many large files. This view now reads the file in chunks to prevent large memory usage.

Note, however, that this view has always carried a warning that it is not hardened for production use and should be used only as a development aid. Now may be a good time to audit your project and serve your files in production using a real front-end web server if you are not doing so.

Database denial-of-service with `ModelMultipleChoiceField`

Given a form that uses `ModelMultipleChoiceField` and `show_hidden_initial=True` (not a documented API), it was possible for a user to cause an unreasonable number of SQL queries by submitting duplicate values for the field’s data. The validation logic in `ModelMultipleChoiceField` now deduplicates submitted values to address this issue.

Bugfixes

- The default iteration count for the PBKDF2 password hasher has been increased by 25%. This part of the normal major release process was inadvertently omitted in 1.7. This backwards compatible change will not affect users who have subclassed `django.contrib.auth.hashers.PBKDF2PasswordHasher` to change the default value.
- Fixed a crash in the CSRF middleware when handling non-ASCII referer header (#23815).
- Fixed a crash in the `django.contrib.auth.redirect_to_login` view when passing a `reverse_lazy()` result on Python 3 (#24097).
- Added correct formats for Greek (el) (#23967).
- Fixed a migration crash when unapplying a migration where multiple operations interact with the same model (#24110).
Django 1.7.2 release notes

January 2, 2015

Django 1.7.2 fixes several bugs in 1.7.1.
Additionally, Django’s vendored version of six, `django.utils.six`, has been upgraded to the latest release (1.9.0).

Bugfixes

- Fixed migration’s renaming of auto-created many-to-many tables when changing `Meta.db_table` (#23630).
- Fixed a migration crash when adding an explicit `id` field to a model on SQLite (#23702).
- Added a warning for duplicate models when a module is reloaded. Previously a `RuntimeError` was raised every time two models clashed in the app registry. (#23621).
- Prevented `flush` from loading initial data for migrated apps (#23699).
- Fixed a `makemessages` regression in 1.7.1 when `STATIC_ROOT` has the default `None` value (#23717).
- Added GeoDjango compatibility with `mysqlclient` database driver.
- Fixed MySQL 5.6+ crash with `GeometryField` in migrations (#23719).
- Fixed a migration crash when removing a field that is referenced in `AlterIndexTogether` or `AlterUniqueTogether` (#23614).
- Updated the first day of the week in the Ukrainian locale to Monday.
- Added support for transactional spatial metadata initialization on `SpatiaLite 4.1+` (#23152).
- Fixed a migration crash that prevented changing a nullable field with a default to non-nullable with the same default (#23738).
- Fixed a migration crash when adding `GeometryField` with `blank=True` on PostGIS (#23731).
- Allowed usage of `DateTimeField()` as `Transform.output_field` (#23420).
- Fixed a migration serializing bug involving `float("nan")` and `float("inf")` (#23770).
- Fixed a regression where custom form fields having a `queryset` attribute but no `limit_choices_to` could not be used in a `ModelForm` (#23795).
- Fixed a custom field type validation error with MySQL backend when `db_type` returned `None` (#23761).
- Fixed a migration crash when a field is renamed that is part of an `index_together` (#23859).
- Fixed `squashmigrations` to respect the `--no-optimize` parameter (#23799).
- Made `RenameModel` reversible (#2248)
• Avoided unnecessary rollbacks of migrations from other apps when migrating backwards (#23410).
• Fixed a rare query error when using deeply nested subqueries (#23605).
• Fixed a crash in migrations when deleting a field that is part of a index/unique_together constraint (#23794).
• Fixed django.core.files.File.__repr__() when the file’s name contains Unicode characters (#23888).
• Added missing context to the admin’s delete_selected view that prevented custom site header, etc. from appearing (#23898).
• Fixed a regression with dynamically generated inlines and allowed field references in the admin (#23754).
• Fixed an infinite loop bug for certain cyclic migration dependencies, and made the error message for cyclic dependencies much more helpful.
• Added missing index_together handling for SQLite (#23880).
• Fixed a crash when RunSQL SQL content was collected by the schema editor, typically when using sqlmigrate (#23909).
• Fixed a regression in contrib.admin add/change views which caused some ModelAdmin methods to receive the incorrect obj value (#23934).
• Fixed runserver crash when socket error message contained Unicode characters (#23946).
• Fixed serialization of type when adding a deconstruct() method (#23950).
• Prevented the django.contrib.auth.middleware.SessionAuthenticationMiddleware from setting a "Vary: Cookie" header on all responses (#23939).
• Fixed a crash when adding blank=True to TextField() on MySQL (#23920).
• Fixed index creation by the migration infrastructure, particularly when dealing with PostgreSQL specific {text|varchar}_pattern_ops indexes (#23954).
• Fixed bug in makemigrations that created broken migration files when dealing with multiple table inheritance and inheriting from more than one model (#23956).
• Fixed a crash when a MultiValueField has invalid data (#23674).
• Fixed a crash in the admin when using “Save as new” and also deleting a related inline (#23857).
• Always converted related_name to text (Unicode), since that is required on Python 3 for interpolation. Removed conversion of related_name to text in migration deconstruction (#23455 and #23982).
• Enlarged the sizes of tablespaces which are created by default for testing on Oracle (the main tablespace was increased from 200M to 300M and the temporary tablespace from 100M to 150M). This was required to accommodate growth in Django’s own test suite (#23969).
• Fixed timesince filter translations in Korean (#23989).
• Fixed the SQLite SchemaEditor to properly add defaults in the absence of a user specified default. For example, a CharField with blank=True didn’t set existing rows to an empty string which resulted in a crash when adding the NOT NULL constraint (#23987).

• makemigrations no longer prompts for a default value when adding TextField() or CharField() without a default (#23405).

• Fixed a migration crash when adding order_with_respect_to to a table with existing rows (#23983).

• Restored the pre_migrate signal if all apps have migrations (#23975).

• Made admin system checks run for custom AdminSites (#23497).

• Ensured the app registry is fully populated when unpickling models. When an external script (like a queueing infrastructure) reloads pickled models, it could crash with an AppRegistryNotReady exception (#24007).

• Added quoting to field indexes in the SQL generated by migrations to prevent a crash when the index name requires it (#24015).

• Added datetime.time support to migrations questioner (#23998).

• Fixed admindocs crash on apps installed as eggs (#23525).

• Changed migrations autodetector to generate an AlterModelOptions operation instead of DeleteModel and CreateModel operations when changing Meta.managed. This prevents data loss when changing managed from False to True and vice versa (#24037).

• Enabled the sqlsequencereset command on apps with migrations (#24054).

• Added tablespace SQL to apps with migrations (#24051).

• Corrected contrib.sites default site creation in a multiple database setup (#24000).

• Restored support for objects that aren’t str or bytes in django.utils.safestring.mark_for_escaping() on Python 3.

• Supported strings escaped by third-party libraries with the __html__ convention in the template engine (#23831).

• Prevented extraneous DROP DEFAULT SQL in migrations (#23581).

• Restored the ability to use more than five levels of subqueries (#23758).

• Fixed crash when ValidationError is initialized with a ValidationError that is initialized with a dictionary (#24008).

• Prevented a crash on apps without migrations when running migrate --list (#23366).
Django 1.7.1 release notes

October 22, 2014

Django 1.7.1 fixes several bugs in 1.7.

Bug fixes

- Allowed related many-to-many fields to be referenced in the admin (#23604).
- Added a more helpful error message if you try to migrate an app without first creating the contenttypes table (#22411).
- Modified migrations dependency algorithm to avoid possible infinite recursion.
- Fixed a UnicodeDecodeError when the flush error message contained Unicode characters (#22882).
- Reinstated missing CHECK SQL clauses which were omitted on some backends when not using migrations (#23416).
- Fixed serialization of type objects in migrations (#22951).
- Allowed inline and hidden references to admin fields (#23431).
- The @deconstructible decorator now fails with a ValueError if the decorated object cannot automatically be imported (#23418).
- Fixed a typo in an inlineformset_factory() error message that caused a crash (#23451).
- Restored the ability to use ABSOLUTE_URL_OVERRIDES with the 'auth.User' model (#11775). As a side effect, the setting now adds a get_absolute_url() method to any model that appears in ABSOLUTE_URL_OVERRIDES but doesn’t define get_absolute_url().
- Avoided masking some ImportError exceptions during application loading (#22920).
- Empty index_together or unique_together model options no longer results in infinite migrations (#23452).
- Fixed crash in contrib.sitemaps if lastmod returned a date rather than a datetime (#23403).
- Allowed migrations to work with app_labels that have the same last part (e.g. django.contrib.auth and vendor.auth) (#23483).
- Restored the ability to deepcopy F objects (#23492).
- Formats for Welsh (cy) and several Chinese locales (zh_CN, zh_Hans, zh_Hant and zh_TW) have been added. Formats for Macedonian have been fixed (trailing dot removed, #23532).
- Added quoting of constraint names in the SQL generated by migrations to prevent crash with uppercase characters in the name (#23065).
• Fixed renaming of models with a self-referential many-to-many field (ManyToManyField('self')) (#23503).

• Added the `get_extra()`, `get_max_num()`, and `get_min_num()` hooks to `GenericInlineModelAdmin` (#23539).

• Made `migrations.RunSQL` no longer require percent sign escaping. This is now consistent with `cursor.execute()` (#23426).

• Made the `SERIALIZE` entry in the `TEST` dictionary usable (#23421).

• Fixed bug in migrations that prevented foreign key constraints to unmanaged models with a custom primary key (#23415).

• Added `SchemaEditor` for MySQL GIS backend so that spatial indexes will be created for apps with migrations (#23538).

• Added `SchemaEditor` for Oracle GIS backend so that spatial metadata and indexes will be created for apps with migrations (#23537).

• Coerced the `related_name` model field option to Unicode during migration generation to generate migrations that work with both Python 2 and 3 (#23455).

• Fixed `MigrationWriter` to handle built-in types without imports (#23560).

• Fixed `deepcopy` on `ErrorList` (#23594).

• Made the `admindocs` view to browse view details check if the view specified in the URL exists in the URLConf. Previously it was possible to import arbitrary packages from the Python path. This was not considered a security issue because `admindocs` is only accessible to staff users (#23601).

• Fixed `UnicodeDecodeError` crash in `AdminEmailHandler` with non-ASCII characters in the request (#23593).

• Fixed missing `get_or_create` and `update_or_create` on related managers causing `IntegrityError` (#23611).

• Made `urlsafe_base64_decode()` return the proper type (bytestring) on Python 3 (#23333).

• `makemigrations` can now serialize timezone-aware values (#23365).

• Added a prompt to the migrations questioner when removing the null constraint from a field to prevent an `IntegrityError` on existing NULL rows (#23609).

• Fixed generic relations in `ModelAdmin.list_filter` (#23616).

• Restored RFC compliance for the SMTP backend on Python 3 (#23063).

• Fixed a crash while parsing cookies containing invalid content (#23638).

• The system check framework now raises error models.E020 when the class method `Model.check()` is unreachable (#23615).
• Made the Oracle test database creation drop the test user in the event of an unclean exit of a previous
test run (#23649).
• Fixed makemigrations to detect changes to Meta.db_table (#23629).
• Fixed a regression when feeding the Django test client with an empty data string (#21740).
• Fixed a regression in makemessages where static files were unexpectedly ignored (#23583).

Django 1.7 release notes

September 2, 2014

Welcome to Django 1.7!

These release notes cover the new features, as well as some backwards incompatible changes you’ll want to
be aware of when upgrading from Django 1.6 or older versions. We’ve begun the deprecation process for
some features, and some features have reached the end of their deprecation process and have been removed.

Python compatibility

Django 1.7 requires Python 2.7, 3.2, 3.3, or 3.4. We highly recommend and only officially support the latest
release of each series.

The Django 1.6 series is the last to support Python 2.6. Django 1.7 is the first release to support Python 3.4.
This change should affect only a small number of Django users, as most operating-system vendors today are
shipping Python 2.7 or newer as their default version. If you’re still using Python 2.6, however, you’ll need
to stick to Django 1.6 until you can upgrade your Python version. Per our support policy, Django 1.6 will
continue to receive security support until the release of Django 1.8.

What’s new in Django 1.7

Schema migrations

Django now has built-in support for schema migrations. It allows models to be updated, changed, and deleted
by creating migration files that represent the model changes and which can be run on any development,
staging or production database.

Migrations are covered in their own documentation, but a few of the key features are:
• syncdb has been deprecated and replaced by migrate. Don’t worry - calls to syncdb will still work as
  before.
• A new makemigrations command provides an easy way to autodetect changes to your models and
  make migrations for them.
django.db.models.signals.pre_syncdb and django.db.models.signals.post_syncdb have been deprecated, to be replaced by `pre_migrate` and `post_migrate` respectively. These new signals have slightly different arguments. Check the documentation for details.

- The `allow_syncdb` method on database routers is now called `allow_migrate`, but still performs the same function. Routers with `allow_syncdb` methods will still work, but that method name is deprecated and you should change it as soon as possible (nothing more than renaming is required).

- `initial_data` fixtures are no longer loaded for apps with migrations; if you want to load initial data for an app, we suggest you create a migration for your application and define a `RunPython` or `RunSQL` operation in the `operations` section of the migration.

- Test rollback behavior is different for apps with migrations; in particular, Django will no longer emulate rollbacks on non-transactional databases or inside `TransactionTestCase` unless specifically requested.

- It is not advised to have apps without migrations depend on (have a `ForeignKey` or `ManyToManyField` to) apps with migrations.

**App-loading refactor**

Historically, Django applications were tightly linked to models. A singleton known as the “app cache” dealt with both installed applications and models. The models module was used as an identifier for applications in many APIs.

As the concept of Django applications matured, this code showed some shortcomings. It has been refactored into an “app registry” where models modules no longer have a central role and where it’s possible to attach configuration data to applications.

Improvements thus far include:

- Applications can run code at startup, before Django does anything else, with the `ready()` method of their configuration.

- Application labels are assigned correctly to models even when they’re defined outside of `models.py`. You don’t have to set `app_label` explicitly any more.

- It is possible to omit `models.py` entirely if an application doesn’t have any models.

- Applications can be relabeled with the `label` attribute of application configurations, to work around label conflicts.

- The name of applications can be customized in the admin with the `verbose_name` of application configurations.

- The admin automatically calls `autodiscover()` when Django starts. You can consequently remove this line from your URLconf.

- Django imports all application configurations and models as soon as it starts, through a deterministic and straightforward process. This should make it easier to diagnose import issues such as import loops.
**New method on Field subclasses**

To help power both schema migrations and to enable easier addition of composite keys in future releases of Django, the `Field` API now has a new required method: `deconstruct()`.

This method takes no arguments, and returns a tuple of four items:

- **name**: The field’s attribute name on its parent model, or `None` if it is not part of a model
- **path**: A dotted, Python path to the class of this field, including the class name.
- **args**: Positional arguments, as a list
- **kwargs**: Keyword arguments, as a dict

These four values allow any field to be serialized into a file, as well as allowing the field to be copied safely, both essential parts of these new features.

This change should not affect you unless you write custom Field subclasses; if you do, you may need to reimplement the `deconstruct()` method if your subclass changes the method signature of `__init__` in any way. If your field just inherits from a built-in Django field and doesn’t override `__init__`, no changes are necessary.

If you do need to override `deconstruct()`, a good place to start is the built-in Django fields (`django/db/models/fields/__init__.py`) as several fields, including `DecimalField` and `DateField`, override it and show how to call the method on the superclass and simply add or remove extra arguments.

This also means that all arguments to fields must themselves be serializable; to see what we consider serializable, and to find out how to make your own classes serializable, read the migration serialization documentation.

**Calling custom QuerySet methods from the Manager**

Historically, the recommended way to make reusable model queries was to create methods on a custom `Manager` class. The problem with this approach was that after the first method call, you’d get back a `QuerySet` instance and couldn’t call additional custom manager methods.

Though not documented, it was common to work around this issue by creating a custom `QuerySet` so that custom methods could be chained; but the solution had a number of drawbacks:

- The custom `QuerySet` and its custom methods were lost after the first call to `values()` or `values_list()`.

- Writing a custom `Manager` was still necessary to return the custom `QuerySet` class and all methods that were desired on the `Manager` had to be proxied to the `QuerySet`. The whole process went against the DRY principle.

The `QuerySet.as_manager()` class method can now directly create `Manager` with `QuerySet` methods:
```python
class FoodQuerySet(models.QuerySet):
    def pizzas(self):
        return self.filter(kind='pizza')
    
    def vegetarian(self):
        return self.filter(vegetarian=True)

class Food(models.Model):
    kind = models.CharField(max_length=50)
    vegetarian = models.BooleanField(default=False)
    objects = FoodQuerySet.as_manager()

Food.objects.pizzas().vegetarian()
```

### Using a custom manager when traversing reverse relations

It is now possible to specify a custom manager when traversing a reverse relationship:

```python
class Blog(models.Model):
    pass

class Entry(models.Model):
    blog = models.ForeignKey(Blog)

    objects = models.Manager()  # Default Manager
    entries = EntryManager()    # Custom Manager

b = Blog.objects.get(id=1)
b.entry_set(manager='entries').all()
```

### New system check framework

We’ve added a new **System check framework** for detecting common problems (like invalid models) and providing hints for resolving those problems. The framework is extensible so you can add your own checks for your own apps and libraries.

To perform system checks, you use the **check** management command. This command replaces the older **validate** management command.
New Prefetch object for advanced prefetch_related operations.

The new Prefetch object allows customizing prefetch operations.

You can specify the QuerySet used to traverse a given relation or customize the storage location of prefetch results.

This enables things like filtering prefetched relations, calling select_related() from a prefetched relation, or prefetching the same relation multiple times with different querysets. See prefetch_related() for more details.

Admin shortcuts support time zones

The “today” and “now” shortcuts next to date and time input widgets in the admin are now operating in the current timezone. Previously, they used the browser timezone, which could result in saving the wrong value when it didn’t match the current timezone on the server.

In addition, the widgets now display a help message when the browser and server time zone are different, to clarify how the value inserted in the field will be interpreted.

Using database cursors as context managers

Prior to Python 2.7, database cursors could be used as a context manager. The specific backend’s cursor defined the behavior of the context manager. The behavior of magic method lookups was changed with Python 2.7 and cursors were no longer usable as context managers.

Django 1.7 allows a cursor to be used as a context manager. That is, the following can be used:

```python
with connection.cursor() as c:
    c.execute(...)```

instead of:

```python
c = connection.cursor()
try:
    c.execute(...)
finally:
    c.close()```
Custom lookups

It is now possible to write custom lookups and transforms for the ORM. Custom lookups work just like Django’s built-in lookups (e.g. `lte`, `icontains`) while transforms are a new concept.

The `django.db.models.Lookup` class provides a way to add lookup operators for model fields. As an example it is possible to add `day_lte` operator for `DateFields`.

The `django.db.models.Transform` class allows transformations of database values prior to the final lookup. For example it is possible to write a `year` transform that extracts year from the field’s value. Transforms allow for chaining. After the `year` transform has been added to `DateField` it is possible to filter on the transformed value, for example `qs.filter(author__birthdate__year__lte=1981)`.

For more information about both custom lookups and transforms refer to the custom lookups documentation.

Improvements to Form error handling

`Form.add_error()`

Previously there were two main patterns for handling errors in forms:

- Raising a `ValidationError` from within certain functions (e.g. `Field.clean()`, `Form.clean_<fieldname>()`, or `Form.clean()` for non-field errors.)
- Fiddling with `Form._errors` when targeting a specific field in `Form.clean()` or adding errors from outside of a “clean” method (e.g. directly from a view).

Using the former pattern was straightforward since the form can guess from the context (i.e. which method raised the exception) where the errors belong and automatically process them. This remains the canonical way of adding errors when possible. However the latter was fiddly and error-prone, since the burden of handling edge cases fell on the user.

The new `add_error()` method allows adding errors to specific form fields from anywhere without having to worry about the details such as creating instances of `django.forms.utils.ErrorList` or dealing with `Form.cleaned_data`. This new API replaces manipulating `Form._errors` which now becomes a private API.

See Cleaning and validating fields that depend on each other for an example using `Form.add_error()`.

Error metadata

The `ValidationError` constructor accepts metadata such as error `code` or `params` which are then available for interpolating into the error message (see Raising `ValidationError` for more details); however, before Django 1.7 those metadata were discarded as soon as the errors were added to `Form.errors`.

`Form.errors` and `django.forms.utils.ErrorList` now store the `ValidationError` instances so these metadata can be retrieved at any time through the new `Form.errors.as_data` method.
The retrieved `ValidationError` instances can then be identified thanks to their error code which enables things like rewriting the error’s message or writing custom logic in a view when a given error is present. It can also be used to serialize the errors in a custom format such as XML.

The new `Form.errors.as_json()` method is a convenience method which returns error messages along with error codes serialized as JSON. `as_json()` uses `as_data()` and gives an idea of how the new system could be extended.

**Error containers and backward compatibility**

Heavy changes to the various error containers were necessary in order to support the features above, specifically `Form.errors`, `django.forms.utils.ErrorList`, and the internal storages of `ValidationError`. These containers which used to store error strings now store `ValidationError` instances and public APIs have been adapted to make this as transparent as possible, but if you’ve been using private APIs, some of the changes are backwards incompatible; see `ValidationError` constructor and internal storage for more details.

**Minor features**

`django.contrib.admin`

- You can now implement `site_header`, `site_title`, and `index_title` attributes on a custom `AdminSite` in order to easily change the admin site’s page title and header text. No more needing to override templates!
- Buttons in `django.contrib.admin` now use the `border-radius` CSS property for rounded corners rather than GIF background images.
- Some admin templates now have app-<app_name> and model-<model_name> classes in their <body> tag to allow customizing the CSS per app or per model.
- The admin changelist cells now have a field-<field_name> class in the HTML to enable style customizations.
- The admin’s search fields can now be customized per-request thanks to the new `django.contrib.admin.ModelAdmin.get_search_fields()` method.
- The `ModelAdmin.get_fields()` method may be overridden to customize the value of `ModelAdmin.fields`.
- In addition to the existing `admin.site.register` syntax, you can use the new `register()` decorator to register a `ModelAdmin`.
- You may specify `ModelAdmin.list_display_links = None` to disable links on the change list page grid.
• You may now specify `ModelAdmin.view_on_site` to control whether or not to display the “View on site” link.

• You can specify a descending ordering for a `ModelAdmin.list_display` value by prefixing the `admin_order_field` value with a hyphen.

• The `ModelAdmin.get_changeform_initial_data()` method may be overridden to define custom behavior for setting initial change form data.

django.contrib.auth

• Any **kwargs passed to `email_user()` are passed to the underlying `send_mail()` call.

• The `permission_required()` decorator can take a list of permissions as well as a single permission.

• You can override the new `AuthenticationForm.confirm_login_allowed()` method to more easily customize the login policy.

• `django.contrib.auth.views.password_reset()` takes an optional `html_email_template_name` parameter used to send a multipart HTML email for password resets.

• The `AbstractBaseUser.get_session_auth_hash()` method was added and if your `AUTH_USER_MODEL` inherits from `AbstractBaseUser`, changing a user’s password now invalidates old sessions if the `django.contrib.auth.middleware.SessionAuthenticationMiddleware` is enabled. See `Session invalidation on password change` for more details.

django.contrib.formtools

• Calls to `WizardView.done()` now include a `form_dict` to allow easier access to forms by their step name.

django.contrib.gis

• The default OpenLayers library version included in widgets has been updated from 2.11 to 2.13.

• Prepared geometries now also support the `crosses`, `disjoint`, `overlaps`, `touches` and `within` predicates, if GEOS 3.3 or later is installed.
django.contrib.messages

- The backends for `django.contrib.messages` that use cookies, will now follow the `SESSION_COOKIE_SECURE` and `SESSION_COOKIE_HTTPONLY` settings.
- The `messages` context processor now adds a dictionary of default levels under the name `DEFAULT_MESSAGE_LEVELS`.
- `Message` objects now have a `level_tag` attribute that contains the string representation of the message level.

django.contrib.redirects

- `RedirectFallbackMiddleware` has two new attributes (``response_gone_class`` and ``response_redirect_class``) that specify the types of `HttpResponse` instances the middleware returns.

django.contrib.sessions

- The "django.contrib.sessions.backends.cached_db" session backend now respects `SESSION_CACHE_ALIAS`. In previous versions, it always used the default cache.

django.contrib.sitemaps

- The `sitemap framework` now makes use of `lastmod` to set a Last-Modified header in the response. This makes it possible for the `ConditionalGetMiddleware` to handle conditional GET requests for sitemaps which set `lastmod`.

django.contrib.sites

- The new `django.contrib.sites.middleware.CurrentSiteMiddleware` allows setting the current site on each request.

django.contrib.staticfiles

- The static files storage classes may be subclassed to override the permissions that collected static files and directories receive by setting the `file_permissions_mode` and `directory_permissions_mode` parameters. See `collectstatic` for example usage.
- The `CachedStaticFilesStorage` backend gets a sibling class called `ManifestStaticFilesStorage` that doesn’t use the cache system at all but instead a JSON file called `staticfiles.json` for storing...
the mapping between the original file name (e.g. css/styles.css) and the hashed file name (e.g. css/styles.55e7cbb9ba48.css). The staticfiles.json file is created when running the collectstatic management command and should be a less expensive alternative for remote storages such as Amazon S3.

See the ManifestStaticFilesStorage docs for more information.

- findstatic now accepts verbosity flag level 2, meaning it will show the relative paths of the directories it searched. See findstatic for example output.

**django.contrib.syndication**

- The Atom1Feed syndication feed’s updated element now utilizes updateddate instead of pubdate, allowing the published element to be included in the feed (which relies on pubdate).

**Cache**

- Access to caches configured in CACHES is now available via django.core.cache.caches. This dict-like object provides a different instance per thread. It supersedes django.core.cache.get_cache() which is now deprecated.
- If you instantiate cache backends directly, be aware that they aren’t thread-safe any more, as django.core.cache.caches now yields different instances per thread.
- Defining the TIMEOUT argument of the CACHES setting as None will set the cache keys as “non-expiring” by default. Previously, it was only possible to pass timeout=None to the cache backend’s set() method.

**Cross Site Request Forgery**

- The CSRF_COOKIE_AGE setting facilitates the use of session-based CSRF cookies.

**Email**

- send_mail() now accepts an html_message parameter for sending a multipart text/plain and text/html email.
- The SMTP EmailBackend now accepts a timeout parameter.
File Storage

- File locking on Windows previously depended on the PyWin32 package; if it wasn’t installed, file locking failed silently. That dependency has been removed, and file locking is now implemented natively on both Windows and Unix.

File Uploads

- The new `UploadedFile.content_type_extra` attribute contains extra parameters passed to the content-type header on a file upload.

- The new `FILE_UPLOAD_DIRECTORY_PERMISSIONS` setting controls the file system permissions of directories created during file upload, like `FILE_UPLOAD_PERMISSIONS` does for the files themselves.

- The `FileField.upload_to` attribute is now optional. If it is omitted or given `None` or an empty string, a subdirectory won’t be used for storing the uploaded files.

- Uploaded files are now explicitly closed before the response is delivered to the client. Partially uploaded files are also closed as long as they are named file in the upload handler.

- `Storage.get_available_name()` now appends an underscore plus a random 7 character alphanumeric string (e.g. "_x3a1gho"), rather than iterating through an underscore followed by a number (e.g. "_1", "_2", etc.) to prevent a denial-of-service attack. This change was also made in the 1.6.6, 1.5.9, and 1.4.14 security releases.

Forms

- The `<label>` and `<input>` tags rendered by `RadioSelect` and `CheckboxSelectMultiple` when looping over the radio buttons or checkboxes now include `for` and `id` attributes, respectively. Each radio button or checkbox includes an `id_for_label` attribute to output the element’s ID.

- The `<textarea>` tags rendered by `Textarea` now include a `maxlength` attribute if the `TextField` model field has a `max_length`.

- `Field.choices` now allows you to customize the “empty choice” label by including a tuple with an empty string or `None` for the key and the custom label as the value. The default blank option "----------" will be omitted in this case.

- `MultiValueField` allows optional subfields by setting the `require_all_fields` argument to `False`. The `required` attribute for each individual field will be respected, and a new `incomplete` validation error will be raised when any required fields are empty.

- The `clean()` method on a form no longer needs to return `self.cleaned_data`. If it does return a changed dictionary then that will still be used.
After a temporary regression in Django 1.6, it’s now possible again to make `TypedChoiceField` `coerce` method return an arbitrary value.

`SelectDateWidget.months` can be used to customize the wording of the months displayed in the select widget.

The `min_num` and `validate_min` parameters were added to `formset_factory()` to allow validating a minimum number of submitted forms.

The metaclasses used by `Form` and `ModelForm` have been reworked to support more inheritance scenarios. The previous limitation that prevented inheriting from both `Form` and `ModelForm` simultaneously have been removed as long as `ModelForm` appears first in the MRO.

It’s now possible to remove a field from a `Form` when subclassing by setting the name to `None`.

It’s now possible to customize the error messages for `ModelForm`’s `unique`, `unique_for_date`, and `unique_together` constraints. In order to support `unique_together` or any other `NON_FIELD_ERROR`, `ModelForm` now looks for the `NON_FIELD_ERROR` key in the `error_messages` dictionary of the `ModelForm`’s inner `Meta` class. See considerations regarding model’s `error_messages` for more details.

### Internationalization

- The `django.middleware.locale.LocaleMiddleware.response_redirect_class` attribute allows you to customize the redirects issued by the middleware.

- The `LocaleMiddleware` now stores the user’s selected language with the session key `_language`. This should only be accessed using the `LANGUAGE_SESSION_KEY` constant. Previously it was stored with the key `django_language` and the `LANGUAGE_SESSION_KEY` constant did not exist, but keys reserved for Django should start with an underscore. For backwards compatibility `django_language` is still read from in 1.7. Sessions will be migrated to the new key as they are written.

- The `blocktrans` tag now supports a `trimmed` option. This option will remove newline characters from the beginning and the end of the content of the `{% blocktrans %}` tag, replace any whitespace at the beginning and end of a line and merge all lines into one using a space character to separate them. This is quite useful for indenting the content of a `{% blocktrans %}` tag without having the indentation characters end up in the corresponding entry in the `.po` file, which makes the translation process easier.

- When you run `makemessages` from the root directory of your project, any extracted strings will now be automatically distributed to the proper app or project message file. See Localization: how to create language files for details.

- The `makemessages` command now always adds the `--previous` command line flag to the `msgmerge` command, keeping previously translated strings in `.po` files for fuzzy strings.

- The following settings to adjust the language cookie options were introduced: `LANGUAGE_COOKIE_AGE`, `LANGUAGE_COOKIE_DOMAIN` and `LANGUAGE_COOKIE_PATH`. 
• Added Format localization for Esperanto.

Management Commands

• The new --no-color option for django-admin disables the colorization of management command output.

• The new dumpdata --natural-foreign and dumpdata --natural-primary options, and the new use_natural_foreign_keys and use_natural_primary_keys arguments for serializers. serialize(), allow the use of natural primary keys when serializing.

• It is no longer necessary to provide the cache table name or the --database option for the createcachetable command. Django takes this information from your settings file. If you have configured multiple caches or multiple databases, all cache tables are created.

• The runserver command received several improvements:
  – On Linux systems, if pyinotify is installed, the development server will reload immediately when a file is changed. Previously, it polled the filesystem for changes every second. That caused a small delay before reloads and reduced battery life on laptops.
  – In addition, the development server automatically reloads when a translation file is updated, i.e. after running compilemessages.
  – All HTTP requests are logged to the console, including requests for static files or favicon.ico that used to be filtered out.

• Management commands can now produce syntax colored output under Windows if the ANSICON third-party tool is installed and active.

• collectstatic command with symlink option is now supported on Windows NT 6 (Windows Vista and newer).

• Initial SQL data now works better if the sqlparse Python library is installed.

  Note that it’s deprecated in favor of the RunSQL operation of migrations, which benefits from the improved behavior.

Models

• The QuerySet.update_or_create() method was added.

• The new default_permissions model Meta option allows you to customize (or disable) creation of the default add, change, and delete permissions.

• Explicit OneToOneField for Multi-table inheritance are now discovered in abstract classes.

• It is now possible to avoid creating a backward relation for OneToOneField by setting its related_name to '+' or ending it with '+'.
• *F expressions* support the power operator (**).

• The `remove()` and `clear()` methods of the related managers created by `ForeignKey` and `GenericForeignKey` now accept the `bulk` keyword argument to control whether or not to perform operations in bulk (i.e. using `QuerySet.update()`). Defaults to `True`.

• It is now possible to use `None` as a query value for the `iexact` lookup.

• It is now possible to pass a callable as value for the attribute `limit_choices_to` when defining a `ForeignKey` or `ManyToManyField`.

• Calling `only()` and `defer()` on the result of `QuerySet.values()` now raises an error (before that, it would either result in a database error or incorrect data).

• You can use a single list for `index_together` (rather than a list of lists) when specifying a single set of fields.

• Custom intermediate models having more than one foreign key to any of the models participating in a many-to-many relationship are now permitted, provided you explicitly specify which foreign keys should be used by setting the new `ManyToManyField.through_fields` argument.

• Assigning a model instance to a non-relation field will now throw an error. Previously this used to work if the field accepted integers as input as it took the primary key.

• Integer fields are now validated against database backend specific min and max values based on their `internal_type`. Previously model field validation didn’t prevent values out of their associated column data type range from being saved resulting in an integrity error.

• It is now possible to explicitly `order_by()` a relation `_id` field by using its attribute name.

**Signals**

• The `enter` argument was added to the `setting_changed` signal.

• The model signals can be now be connected to using a `str` of the `app_label.ModelName` form – just like related fields – to lazily reference their senders.

**Templates**

• The `Context.push()` method now returns a context manager which automatically calls `pop()` upon exiting the `with` statement. Additionally, `push()` now accepts parameters that are passed to the `dict` constructor used to build the new context level.

• The new `Context.flatten()` method returns a `Context`’s stack as one flat dictionary.

• `Context` objects can now be compared for equality (internally, this uses `Context.flatten()` so the internal structure of each `Context`’s stack doesn’t matter as long as their flattened version is identical).

• The `widthratio` template tag now accepts an "as" parameter to capture the result in a variable.
• The `include` template tag will now also accept anything with a `render()` method (such as a `Template`) as an argument. String arguments will be looked up using `get_template()` as always.

• It is now possible to `include` templates recursively.

• Template objects now have an origin attribute set when `TEMPLATE_DEBUG` is True. This allows template origins to be inspected and logged outside of the `django.template` infrastructure.

• `TypeError` exceptions are no longer silenced when raised during the rendering of a template.

• The following functions now accept a `dirs` parameter which is a list or tuple to override `TEMPLATE_DIRS`:
  
  ```python
  - django.template.loader.get_template()
  - django.template.loader.select_template()
  - django.shortcuts.render()
  - django.shortcuts.render_to_response()
  ```

• The `time` filter now accepts timezone-related format specifiers 'e', 'O', 'T' and 'Z' and is able to digest time-zone-aware `datetime` instances performing the expected rendering.

• The `cache` tag will now try to use the cache called “template.fragments” if it exists and fall back to using the default cache otherwise. It also now accepts an optional using keyword argument to control which cache it uses.

• The new `truncatechars_html` filter truncates a string to be no longer than the specified number of characters, taking HTML into account.

Requests and Responses

• The new `HttpRequest.scheme` attribute specifies the scheme of the request (http or https normally).

• The shortcut `redirect()` now supports relative URLs.

• The new `JsonResponse` subclass of `HttpResponse` helps easily create JSON-encoded responses.

Tests

• `DiscoverRunner` has two new attributes, `test_suite` and `test_runner`, which facilitate overriding the way tests are collected and run.

• The `fetch_redirect_response` argument was added to `assertRedirects()`. Since the test client can’t fetch externals URLs, this allows you to use `assertRedirects` with redirects that aren’t part of your Django app.

• Correct handling of scheme when making comparisons in `assertRedirects()`.
• The `secure` argument was added to all the request methods of `Client`. If `True`, the request will be made through HTTPS.

• `assertNumQueries()` now prints out the list of executed queries if the assertion fails.

• The `WSGIRequest` instance generated by the test handler is now attached to the `django.test.Response.wsgi_request` attribute.

• The database settings for testing have been collected into a dictionary named `TEST`.

Utilities

• Improved `strip_tags()` accuracy (but it still cannot guarantee an HTML-safe result, as stated in the documentation).

Validators

• `RegexValidator` now accepts the optional `flags` and Boolean `inverse_match` arguments. The `inverse_match` attribute determines if the `ValidationError` should be raised when the regular expression pattern matches (`True`) or does not match (`False`, by default) the provided value. The `flags` attribute sets the flags used when compiling a regular expression string.

• `URLValidator` now accepts an optional `schemes` argument which allows customization of the accepted URI schemes (instead of the defaults `http(s)` and `ftp(s)`).

• `validate_email()` now accepts addresses with IPv6 literals, like `example@[2001:db8::1]`, as specified in RFC 5321.

Backwards incompatible changes in 1.7

Warning: In addition to the changes outlined in this section, be sure to review the deprecation plan for any features that have been removed. If you haven’t updated your code within the deprecation timeline for a given feature, its removal may appear as a backwards incompatible change.

allow_syncdb / allow_migrate

While Django will still look at `allow_syncdb` methods even though they should be renamed to `allow_migrate`, there is a subtle difference in which models get passed to these methods.

For apps with migrations, `allow_migrate` will now get passed `historical models`, which are special versioned models without custom attributes, methods or managers. Make sure your `allow_migrate` methods are only referring to fields or other items in `model._meta`. 
**initial_data**

Apps with migrations will not load `initial_data` fixtures when they have finished migrating. Apps without migrations will continue to load these fixtures during the phase of `migrate` which emulates the old `syncdb` behavior, but any new apps will not have this support.

Instead, you are encouraged to load initial data in migrations if you need it (using the `RunPython` operation and your model classes); this has the added advantage that your initial data will not need updating every time you change the schema.

Additionally, like the rest of Django’s old `syncdb` code, `initial_data` has been started down the deprecation path and will be removed in Django 1.9.

**deconstruct() and serializability**

Django now requires all Field classes and all of their constructor arguments to be serializable. If you modify the constructor signature in your custom Field in any way, you’ll need to implement a `deconstruct()` method; we’ve expanded the custom field documentation with instructions on implementing this method.

The requirement for all field arguments to be serializable means that any custom class instances being passed into Field constructors - things like custom Storage subclasses, for instance - need to have a `deconstruct` method defined on them as well, though Django provides a handy class decorator that will work for most applications.

**App-loading changes**

**Start-up sequence**

Django 1.7 loads application configurations and models as soon as it starts. While this behavior is more straightforward and is believed to be more robust, regressions cannot be ruled out. See Troubleshooting for solutions to some problems you may encounter.

**Standalone scripts**

If you’re using Django in a plain Python script — rather than a management command — and you rely on the `DJANGO_SETTINGS_MODULE` environment variable, you must now explicitly initialize Django at the beginning of your script with:

```
>>> import django
>>> django.setup()
```

Otherwise, you will hit an `AppRegistryNotReady` exception.
WSGI scripts

Until Django 1.3, the recommended way to create a WSGI application was:

```python
import django.core.handlers.wsgi
application = django.core.handlers.wsgi.WSGIHandler()
```

In Django 1.4, support for WSGI was improved and the API changed to:

```python
from django.core.wsgi import get_wsgi_application
application = get_wsgi_application()
```

If you’re still using the former style in your WSGI script, you need to upgrade to the latter, or you will hit an `AppRegistryNotReady` exception.

App registry consistency

It is no longer possible to have multiple installed applications with the same label. In previous versions of Django, this didn’t always work correctly, but didn’t crash outright either.

If you have two apps with the same label, you should create an `AppConfig` for one of them and override its `label` there. You should then adjust your code wherever it references this application or its models with the old label.

It isn’t possible to import the same model twice through different paths any more. As of Django 1.6, this may happen only if you’re manually putting a directory and a subdirectory on `PYTHONPATH`. Refer to the section on the new project layout in the 1.4 release notes for migration instructions.

You should make sure that:

- All models are defined in applications that are listed in `INSTALLED_APPS` or have an explicit `app_label`.
- Models aren’t imported as a side-effect of loading their application. Specifically, you shouldn’t import models in the root module of an application nor in the module that define its configuration class.

Django will enforce these requirements as of version 1.9, after a deprecation period.

Subclassing AppCommand

Subclasses of `AppCommand` must now implement a `handle_app_config()` method instead of `handle_app()`. This method receives an `AppConfig` instance instead of a models module.
Introspecting applications

Since `INSTALLED_APPS` now supports application configuration classes in addition to application modules, you should review code that accesses this setting directly and use the app registry (`django.apps.apps`) instead.

The app registry has preserved some features of the old app cache. Even though the app cache was a private API, obsolete methods and arguments will be removed through a standard deprecation path, with the exception of the following changes that take effect immediately:

- `get_model` raises `LookupError` instead of returning `None` when no model is found.
- The `only_installed` argument of `get_model` and `get_models` no longer exists, nor does the `seed_cache` argument of `get_model`.

Management commands and order of `INSTALLED_APPS`

When several applications provide management commands with the same name, Django loads the command from the application that comes first in `INSTALLED_APPS`. Previous versions loaded the command from the application that came last.

This brings discovery of management commands in line with other parts of Django that rely on the order of `INSTALLED_APPS`, such as static files, templates, and translations.

Validation`Error constructor and internal storage`

The behavior of the `ValidationError` constructor has changed when it receives a container of errors as an argument (e.g. a list or an `ErrorList`):

- It converts any strings it finds to instances of `ValidationError` before adding them to its internal storage.
- It doesn’t store the given container but rather copies its content to its own internal storage; previously the container itself was added to the `ValidationError` instance and used as internal storage.

This means that if you access the `ValidationError` internal storages, such as `error_list`; `error_dict`; or the return value of `update_error_dict()` you may find instances of `ValidationError` where you would have previously found strings.

Also if you directly assigned the return value of `update_error_dict()` to `Form._errors` you may inadvertently add `list` instances where `ErrorList` instances are expected. This is a problem because unlike a simple `list`, an `ErrorList` knows how to handle instances of `ValidationError`.

Most use-cases that warranted using these private APIs are now covered by the newly introduced `Form.add_error()` method:
# Old pattern:
try:
    # ...
except ValidationError as e:
    self._errors = e.update_error_dict(self._errors)

# New pattern:
try:
    # ...
except ValidationError as e:
    self.add_error(None, e)

If you need both Django <= 1.6 and 1.7 compatibility you can’t use `Form.add_error()` since it wasn’t available before Django 1.7, but you can use the following workaround to convert any list into `ErrorList`:

```python
try:
    # ...
except ValidationError as e:
    self._errors = e.update_error_dict(self._errors)

# Additional code to ensure `ErrorDict` is exclusively composed of `ErrorList` instances.
for field, error_list in self._errors.items():
    if not isinstance(error_list, self.error_class):
        self._errors[field] = self.error_class(error_list)
```

**Behavior of LocMemCache regarding pickle errors**

An inconsistency existed in previous versions of Django regarding how pickle errors are handled by different cache backends. `django.core.cache.backends.locmem.LocMemCache` used to fail silently when such an error occurs, which is inconsistent with other backends and leads to cache-specific errors. This has been fixed in Django 1.7, see #21200 for more details.

**Cache keys are now generated from the request’s absolute URL**

Previous versions of Django generated cache keys using a request’s path and query string but not the scheme or host. If a Django application was serving multiple subdomains or domains, cache keys could collide. In Django 1.7, cache keys vary by the absolute URL of the request including scheme, host, path, and query string. For example, the URL portion of a cache key is now generated from `https://www.example.com/path/to/?key=val` rather than `/path/to/?key=val`. The cache keys generated by Django 1.7 will be different from the keys generated by older versions of Django. After upgrading to Django 1.7, the first request to any previously cached URL will be a cache miss.
Passing None to Manager.db_manager()

In previous versions of Django, it was possible to use `db_manager(using=None)` on a model manager instance to obtain a manager instance using default routing behavior, overriding any manually specified database routing. In Django 1.7, a value of `None` passed to `db_manager` will produce a router that retains any manually assigned database routing—the manager will not be reset. This was necessary to resolve an inconsistency in the way routing information cascaded over joins. See #13724 for more details.

pytz may be required

If your project handles datetimes before 1970 or after 2037 and Django raises a `ValueError` when encountering them, you will have to install `pytz`. You may be affected by this problem if you use Django’s time zone-related date formats or `django.contrib.syndication`.

remove() and clear() methods of related managers

The `remove()` and `clear()` methods of the related managers created by `ForeignKey`, `GenericForeignKey`, and `ManyToManyField` suffered from a number of issues. Some operations ran multiple data modifying queries without wrapping them in a transaction, and some operations didn’t respect default filtering when it was present (i.e. when the default manager on the related model implemented a custom `get_queryset()`). Fixing the issues introduced some backward incompatible changes:

- The default implementation of `remove()` for `ForeignKey` related managers changed from a series of `Model.save()` calls to a single `QuerySet.update()` call. The change means that `pre_save` and `post_save` signals aren’t sent anymore. You can use the `bulk=False` keyword argument to revert to the previous behavior.

- The `remove()` and `clear()` methods for `GenericForeignKey` related managers now perform bulk delete. The `Model.delete()` method isn’t called on each instance anymore. You can use the `bulk=False` keyword argument to revert to the previous behavior.

- The `remove()` and `clear()` methods for `ManyToManyField` related managers perform nested queries when filtering is involved, which may or may not be an issue depending on your database and your data itself. See this note for more details.
Admin login redirection strategy

Historically, the Django admin site passed the request from an unauthorized or unauthenticated user directly to the login view, without HTTP redirection. In Django 1.7, this behavior changed to conform to a more traditional workflow where any unauthorized request to an admin page will be redirected (by HTTP status code 302) to the login page, with the next parameter set to the referring path. The user will be redirected there after a successful login.

Note also that the admin login form has been updated to not contain the this_is_the_login_form field (now unused) and the ValidationError code has been set to the more regular invalid_login key.

select_for_update() requires a transaction

Historically, queries that use select_for_update() could be executed in autocommit mode, outside of a transaction. Before Django 1.6, Django’s automatic transactions mode allowed this to be used to lock records until the next write operation. Django 1.6 introduced database-level autocommit; since then, execution in such a context voids the effect of select_for_update(). It is, therefore, assumed now to be an error and raises an exception.

This change was made because such errors can be caused by including an app which expects global transactions (e.g. ATOMIC_REQUESTS set to True), or Django’s old autocommit behavior, in a project which runs without them; and further, such errors may manifest as data-corruption bugs. It was also made in Django 1.6.3.

This change may cause test failures if you use select_for_update() in a test class which is a subclass of TransactionTestCase rather than TestCase.

Contrib middleware removed from default MIDDLEWARE_CLASSES

The app-loading refactor deprecated using models from apps which are not part of the INSTALLED_APPS setting. This exposed an incompatibility between the default INSTALLED_APPS and MIDDLEWARE_CLASSES in the global defaults (django.conf.global_settings). To bring these settings in sync and prevent deprecation warnings when doing things like testing reusable apps with minimal settings, SessionMiddleware, AuthenticationMiddleware, and MessageMiddleware were removed from the defaults. These classes will still be included in the default settings generated by startproject. Most projects will not be affected by this change but if you were not previously declaring the MIDDLEWARE_CLASSES in your project settings and relying on the global default you should ensure that the new defaults are in line with your project’s needs. You should also check for any code that accesses django.conf.global_settings.MIDDLEWARE_CLASSES directly.
Miscellaneous

- The `django.core.files.uploadhandler.FileUploadHandler.new_file()` method is now passed an additional `content_type_extra` parameter. If you have a custom `FileUploadHandler` that implements `new_file()`, be sure it accepts this new parameter.

- `ModelFormSets` no longer delete instances when `save(commit=False)` is called. See `can_delete` for instructions on how to manually delete objects from deleted forms.

- Loading empty fixtures emits a `RuntimeWarning` rather than raising `CommandError`.

- `django.contrib.staticfiles.views.serve()` will now raise an `Http404` exception instead of `ImproperlyConfigured` when `DEBUG` is False. This change removes the need to conditionally add the view to your root URLConf, which in turn makes it safe to reverse by name. It also removes the ability for visitors to generate spurious HTTP 500 errors by requesting static files that don’t exist or haven’t been collected yet.

- The `django.db.models.Model.__eq__()` method is now defined in a way where instances of a proxy model and its base model are considered equal when primary keys match. Previously only instances of exact same class were considered equal on primary key match.

- The `django.db.models.Model.__eq__()` method has changed such that two `Model` instances without primary key values won’t be considered equal (unless they are the same instance).

- The `django.db.models.Model.__hash__()` method will now raise `TypeError` when called on an instance without a primary key value. This is done to avoid mutable `__hash__` values in containers.

- `AutoField` columns in SQLite databases will now be created using the `AUTOINCREMENT` option, which guarantees monotonic increments. This will cause primary key numbering behavior to change on SQLite, becoming consistent with most other SQL databases. This will only apply to newly created tables. If you have a database created with an older version of Django, you will need to migrate it to take advantage of this feature. For example, you could do the following:
  1) Use `dumpdata` to save your data.
  2) Rename the existing database file (keep it as a backup).
  3) Run `migrate` to create the updated schema.
  4) Use `loaddata` to import the fixtures you exported in (1).

- `django.contrib.auth.models(AbstractUser) no longer defines a `get_absolute_url()` method. The old definition returned `"/users/%s/" % urlquote(self.username)` which was arbitrary since applications may or may not define such a url in `urlpatterns`. Define a `get_absolute_url()` method on your own custom user object or use `ABSOLUTE_URL_OVERRIDES` if you want a URL for your user.

- The static asset-serving functionality of the `django.test.LiveServerTestCase` class has been simplified: Now it’s only able to serve content already present in `STATIC_ROOT` when tests are run. The ability to transparently serve all the static assets (similarly to what one gets with `DEBUG =
True at development-time) has been moved to a new class that lives in the staticfiles application (the one actually in charge of such feature): django.contrib.staticfiles.testing. StaticLiveServerTestCase. In other words, LiveServerTestCase itself is less powerful but at the same time has less magic.

Rationale behind this is removal of dependency of non-contrib code on contrib applications.

- The old cache URI syntax (e.g. "locmem:///") is no longer supported. It still worked, even though it was not documented or officially supported. If you’re still using it, please update to the current CACHES syntax.

- The default ordering of Form fields in case of inheritance has changed to follow normal Python MRO. Fields are now discovered by iterating through the MRO in reverse with the topmost class coming last. This only affects you if you relied on the default field ordering while having fields defined on both the current class and on a parent Form.

- The required argument of SelectDateWidget has been removed. This widget now respects the form field’s is_required attribute like other widgets.

- Widget.is_hidden is now a read-only property, getting its value by introspecting the presence of input_type == 'hidden'.

- select_related() now chains in the same way as other similar calls like prefetch_related. That is, select_related('foo', 'bar') is equivalent to select_related('foo').select_related('bar'). Previously the latter would have been equivalent to select_related('bar').

- GeoDjango dropped support for GEOS < 3.1.

- The init_connection_state method of database backends now executes in autocommit mode (unless you set AUTOCOMMIT to False). If you maintain a custom database backend, you should check that method.

- The django.db.backends.BaseDatabaseFeatures.allows_primary_key_0 attribute has been renamed to allows_auto_pk_0 to better describe it. It’s True for all database backends included with Django except MySQL which does allow primary keys with value 0. It only forbids autoincrement primary keys with value 0.

- Shadowing model fields defined in a parent model has been forbidden as this creates ambiguity in the expected model behavior. In addition, clashing fields in the model inheritance hierarchy result in a system check error. For example, if you use multi-inheritance, you need to define custom primary key fields on parent models, otherwise the default id fields will clash. See Multiple inheritance for details.

- django.utils.translation.parse_accept_lang_header() now returns lowercase locales, instead of the case as it was provided. As locales should be treated case-insensitive this allows us to speed up locale detection.

- django.utils.translation.get_language_from_path() and django.utils.translation.trans_real.get_supported_language_variant() now no longer have a supported argument.
• The shortcut view in `django.contrib.contenttypes.views` now supports protocol-relative URLs (e.g. `//example.com`).

• `GenericRelation` now supports an optional `related_query_name` argument. Setting `related_query_name` adds a relation from the related object back to the content type for filtering, ordering and other query operations.

• When running tests on PostgreSQL, the `USER` will need read access to the built-in `postgres` database. This is in lieu of the previous behavior of connecting to the actual non-test database.

• As part of the System check framework, fields, models, and model managers all implement a `check()` method that is registered with the check framework. If you have an existing method called `check()` on one of these objects, you will need to rename it.

• As noted above in the “Cache” section of “Minor Features”, defining the `TIMEOUT` argument of the `CACHES` setting as `None` will set the cache keys as “non-expiring”. Previously, with the memcache backend, a `TIMEOUT` of 0 would set non-expiring keys, but this was inconsistent with the set-and-expire (i.e. no caching) behavior of `set("key", "value", timeout=0)`. If you want non-expiring keys, please update your settings to use `None` instead of 0 as the latter now designates set-and-expire in the settings as well.

• The `sql*` management commands now respect the `allow_migrate()` method of `DATABASE_ROUTERS`. If you have models synced to non-default databases, use the `--database` flag to get SQL for those models (previously they would always be included in the output).

• Decoding the query string from URLs now falls back to the ISO-8859-1 encoding when the input is not valid UTF-8.

• With the addition of the `django.contrib.auth.middleware.SessionAuthenticationMiddleware` to the default project template (pre-1.7.2 only), a database must be created before accessing a page using `runserver`.

• The addition of the `schemes` argument to `URLValidator` will appear as a backwards-incompatible change if you were previously using a custom regular expression to validate schemes. Any scheme not listed in `schemes` will fail validation, even if the regular expression matches the given URL.

Features deprecated in 1.7

django.core.cache.get_cache

django.core.cache.get_cache has been supplanted by `django.core.cache.caches`. 

9.1. Final releases
django.utils.dictconfig/django.utils.importlib

django.utils.dictconfig and django.utils.importlib were copies of respectively logging.config and importlib provided for Python versions prior to 2.7. They have been deprecated.

django.utils.module_loading.import_by_path

The current django.utils.module_loading.import_by_path function catches AttributeError, ImportError, and ValueError exceptions, and re-raises ImproperlyConfigured. Such exception masking makes it needlessly hard to diagnose circular import problems, because it makes it look like the problem comes from inside Django. It has been deprecated in favor of import_string().

django.utils.tzinfo

django.utils.tzinfo provided two tzinfo subclasses, LocalTimezone and FixedOffset. They’ve been deprecated in favor of more correct alternatives provided by django.utils.timezone, django.utils.timezone.get_default_timezone() and django.utils.timezone.get_fixed_timezone().

django.utils.unittest

django.utils.unittest provided uniform access to the unittest2 library on all Python versions. Since unittest2 became the standard library’s unittest module in Python 2.7, and Django 1.7 drops support for older Python versions, this module isn’t useful anymore. It has been deprecated. Use unittest instead.

django.utils.datastructures.SortedDict

As OrderedDict was added to the standard library in Python 2.7, SortedDict is no longer needed and has been deprecated.

The two additional, deprecated methods provided by SortedDict (insert() and value_for_index()) have been removed. If you relied on these methods to alter structures like form fields, you should now treat these OrderedDicts as immutable objects and override them to change their content.

For example, you might want to override MyFormClass.base_fields (although this attribute isn’t considered a public API) to change the ordering of fields for all MyFormClass instances; or similarly, you could override self.fields from inside MyFormClass.__init__(), to change the fields for a particular form instance. For example (from Django itself):

```python
PasswordChangeForm.base_fields = OrderedDict(
    (k, PasswordChangeForm.base_fields[k])
    for k in ['old_password', 'new_password1', 'new_password2']
)
```
Custom SQL location for models package

Previously, if models were organized in a package (myapp/models/) rather than simply myapp/models.py, Django would look for initial SQL data in myapp/models/sql/. This bug has been fixed so that Django will search myapp/sql/ as documented. After this issue was fixed, migrations were added which deprecates initial SQL data. Thus, while this change still exists, the deprecation is irrelevant as the entire feature will be removed in Django 1.9.

Reorganization of django.contrib.sites

django.contrib.sites provides reduced functionality when it isn’t in INSTALLED_APPS. The app-loading refactor adds some constraints in that situation. As a consequence, two objects were moved, and the old locations are deprecated:

- RequestSite now lives in django.contrib.sites.requests.
- get_current_site() now lives in django.contrib.sites.shortcuts.

declared_fieldsets attribute on ModelAdmin

ModelAdmin.declared_fieldsets has been deprecated. Despite being a private API, it will go through a regular deprecation path. This attribute was mostly used by methods that bypassed ModelAdmin. get_fieldsets() but this was considered a bug and has been addressed.

Reorganization of django.contrib.contenttypes

Since django.contrib.contenttypes.generic defined both admin and model related objects, an import of this module could trigger unexpected side effects. As a consequence, its contents were split into contenttypes submodules and the django.contrib.contenttypes.generic module is deprecated:

- GenericForeignKey and GenericRelation now live in fields.
- BaseGenericInlineFormSet and generic_inlineformset_factory() now live in forms.
- GenericInlineModelAdmin, GenericStackedInline and GenericTabularInline now live in admin.
syncdb

The `syncdb` command has been deprecated in favor of the new `migrate` command. `migrate` takes the same arguments as `syncdb` used to plus a few more, so it’s safe to just change the name you’re calling and nothing else.

util modules renamed to utils

The following instances of `util.py` in the Django codebase have been renamed to `utils.py` in an effort to unify all util and utils references:

- `django.contrib.admin.util`
- `django.contrib.gis.db.backends.util`
- `django.db.backends.util`
- `django.forms.util`

get_formsets method on ModelAdmin

`ModelAdmin.get_formsets` has been deprecated in favor of the new `get_formsets_with_inlines()`, in order to better handle the case of selectively showing inlines on a `ModelAdmin`.

IPAddressField

The `django.db.models.IPAddressField` and `django.forms.IPAddressField` fields have been deprecated in favor of `django.db.models.GenericIPAddressField` and `django.forms.GenericIPAddressField`.

BaseMemcachedCache._get_memcache_timeout method

The `BaseMemcachedCache._get_memcache_timeout()` method has been renamed to `get_backend_timeout()`. Despite being a private API, it will go through the normal deprecation.

Natural key serialization options

The `--natural` and `-n` options for `dumpdata` have been deprecated. Use `dumpdata --natural-foreign` instead.

Similarly, the `use_natural_keys` argument for `serializers.serialize()` has been deprecated. Use `use_natural_foreign_keys` instead.
Merging of POST and GET arguments into WSGIRequest.REQUEST

It was already strongly suggested that you use GET and POST instead of REQUEST, because the former are more explicit. The property REQUEST is deprecated and will be removed in Django 1.9.

django.utils.datastructures.MergeDict class

MergeDict exists primarily to support merging POST and GET arguments into a REQUEST property on WSGIRequest. To merge dictionaries, use dict.update() instead. The class MergeDict is deprecated and will be removed in Django 1.9.

Language codes zh-cn, zh-tw and fy-nl

The currently used language codes for Simplified Chinese zh-cn, Traditional Chinese zh-tw and (Western) Frisian fy-nl are deprecated and should be replaced by the language codes zh-hans, zh-hant and fy respectively. If you use these language codes, you should rename the locale directories and update your settings to reflect these changes. The deprecated language codes will be removed in Django 1.9.

django.utils.functional.memoize function

The function memoize is deprecated and should be replaced by the functools.lru_cache decorator (available from Python 3.2 onward).

Django ships a backport of this decorator for older Python versions and it’s available at django.utils.lru_cache.lru_cache. The deprecated function will be removed in Django 1.9.

Geo Sitemaps

Google has retired support for the Geo Sitemaps format. Hence Django support for Geo Sitemaps is deprecated and will be removed in Django 1.8.

Passing callable arguments to queryset methods

Callable arguments for querysets were an undocumented feature that was unreliable. It’s been deprecated and will be removed in Django 1.9.

Callable arguments were evaluated when a queryset was constructed rather than when it was evaluated, thus this feature didn’t offer any benefit compared to evaluating arguments before passing them to queryset and created confusion that the arguments may have been evaluated at query time.
ADMIN_FOR setting

The ADMIN_FOR feature, part of the admin docs, has been removed. You can remove the setting from your configuration at your convenience.

SplitDateTimeWidget with DateTimeField

SplitDateTimeWidget support in DateTimeField is deprecated, use SplitDateTimeWidget with SplitDateTimeField instead.

validate

The validate management command is deprecated in favor of the check command.

django.core.management.BaseCommand

requires_model_validation is deprecated in favor of a new requires_system_checks flag. If the latter flag is missing, then the value of the former flag is used. Defining both requires_system_checks and requires_model_validation results in an error.

The check() method has replaced the old validate() method.

ModelAdmin validators

The ModelAdmin.validator_class and default_validator_class attributes are deprecated in favor of the new checks_class attribute.

The ModelAdmin.validate() method is deprecated in favor of ModelAdmin.check().

The django.contrib.admin.validation module is deprecated.

django.db.backends.DatabaseValidation.validate_field

This method is deprecated in favor of a new check_field method. The functionality required by check_field() is the same as that provided by validate_field(), but the output format is different. Third-party database backends needing this functionality should provide an implementation of check_field().
Loading ssi and url template tags from future library

Django 1.3 introduced `{% load ssi from future %}` and `{% load url from future %}` syntax for forward compatibility of the ssi and url template tags. This syntax is now deprecated and will be removed in Django 1.9. You can simply remove the `{% load ... from future %}` tags.

`django.utils.text.javascript_quote`  

`javascript_quote()` was an undocumented function present in `django.utils.text`. It was used internally in the `javascript_catalog()` view whose implementation was changed to make use of `json.dumps()` instead. If you were relying on this function to provide safe output from untrusted strings, you should use `django.utils.html.escapejs` or the `escapejs` template filter. If all you need is to generate valid JavaScript strings, you can simply use `json.dumps()`.

`fix_ampersands` utils method and template filter

The `django.utils.html.fix_ampersands` method and the `fix_ampersands` template filter are deprecated, as the escaping of ampersands is already taken care of by Django’s standard HTML escaping features. Combining this with `fix_ampersands` would either result in double escaping, or, if the output is assumed to be safe, a risk of introducing XSS vulnerabilities. Along with `fix_ampersands`, `django.utils.html.clean_html` is deprecated, an undocumented function that calls `fix_ampersands`. As this is an accelerated deprecation, `fix_ampersands` and `clean_html` will be removed in Django 1.8.

Reorganization of database test settings

All database settings with a `TEST_` prefix have been deprecated in favor of entries in a `TEST` dictionary in the database settings. The old settings will be supported until Django 1.9. For backwards compatibility with older versions of Django, you can define both versions of the settings as long as they match.

FastCGI support

FastCGI support via the `runfcgi` management command will be removed in Django 1.9. Please deploy your project using WSGI.
Moved objects in contrib.sites

Following the app-loading refator, two objects in django.contrib.sites.models needed to be moved because they must be available without importing django.contrib.sites.models when django.contrib.sites isn’t installed. Import RequestSite from django.contrib.sites.requests and get_current_site() from django.contrib.sites.shortcuts. The old import locations will work until Django 1.9.

django.forms.forms.get_declared_fields()

Django no longer uses this functional internally. Even though it’s a private API, it’ll go through the normal deprecation cycle.

Private Query Lookup APIs

Private APIs django.db.models.sql.where.WhereNode.make_atom() and django.db.models.sql.where.Constraint are deprecated in favor of the new custom lookups API.

Features removed in 1.7

These features have reached the end of their deprecation cycle and are removed in Django 1.7. See Features deprecated in 1.5 for details, including how to remove usage of these features.

- django.utils.simplejson is removed.
- django.utils.itercompat.product is removed.
- INSTALLED_APPS and TEMPLATE_DIRS are no longer corrected from a plain string into a tuple.
- HttpResponse, SimpleTemplateResponse, TemplateResponse, render_to_response(), index(), and sitemap() no longer take a mimetype argument
- HttpResponse immediately consumes its content if it’s an iterator.
- The AUTH_PROFILE_MODULE setting, and the get_profile() method on the User model are removed.
- The cleanup management command is removed.
- The daily_cleanup.py script is removed.
- select_related() no longer has a depth keyword argument.
- The get_warnings_state()/restore_warnings_state() functions from django.test.utils and the save_warnings_state()/restore_warnings_state() django.test.*TestCase are removed.
- The check_for_test_cookie method in AuthenticationForm is removed.
• The version of `django.contrib.auth.views.password_reset_confirm()` that supports base36 encoded user IDs (`django.contrib.auth.views.password_reset_confirm_uidb36`) is removed.

• The `django.utils.encoding.StrAndUnicode` mix-in is removed.

9.1.15 1.6 release

Django 1.6.11 release notes

March 18, 2015

Django 1.6.11 fixes two security issues in 1.6.10.

**Denial-of-service possibility with `strip_tags()`**

Last year `strip_tags()` was changed to work iteratively. The problem is that the size of the input it’s processing can increase on each iteration which results in an infinite loop in `strip_tags()`. This issue only affects versions of Python that haven’t received a bugfix in HTMLParser; namely Python < 2.7.7 and 3.3.5. Some operating system vendors have also backported the fix for the Python bug into their packages of earlier versions.

To remedy this issue, `strip_tags()` will now return the original input if it detects the length of the string it’s processing increases. Remember that absolutely NO guarantee is provided about the results of `strip_tags()` being HTML safe. So NEVER mark safe the result of a `strip_tags()` call without escaping it first, for example with `escape()`.

**Mitigated possible XSS attack via user-supplied redirect URLs**

Django relies on user input in some cases (e.g. `django.contrib.auth.views.login()` and `i18n`) to redirect the user to an “on success” URL. The security checks for these redirects (namely `django.utils.http.is_safe_url()`) accepted URLs with leading control characters and so considered URLs like `%08javascript:...` safe. This issue doesn’t affect Django currently, since we only put this URL into the `Location` response header and browsers seem to ignore JavaScript there. Browsers we tested also treat URLs prefixed with control characters such as `%08//example.com` as relative paths so redirection to an unsafe target isn’t a problem either.

However, if a developer relies on `is_safe_url()` to provide safe redirect targets and puts such a URL into a link, they could suffer from an XSS attack as some browsers such as Google Chrome ignore control characters at the start of a URL in an anchor `href`. 
Django 1.6.10 release notes

January 13, 2015

Django 1.6.10 fixes several security issues in 1.6.9.

WSGI header spoofing via underscore/dash conflation

When HTTP headers are placed into the WSGI environ, they are normalized by converting to uppercase, converting all dashes to underscores, and prepending `HTTP_`. For instance, a header `X-Auth-User` would become `HTTP_X_AUTH_USER` in the WSGI environ (and thus also in Django’s `request.META` dictionary).

Unfortunately, this means that the WSGI environ cannot distinguish between headers containing dashes and headers containing underscores: `X-Auth-User` and `X-Auth_User` both become `HTTP_X_AUTH_USER`. This means that if a header is used in a security-sensitive way (for instance, passing authentication information along from a front-end proxy), even if the proxy carefully strips any incoming value for `X-Auth-User`, an attacker may be able to provide an `X-Auth_User` header (with underscore) and bypass this protection.

In order to prevent such attacks, both Nginx and Apache 2.4+ strip all headers containing underscores from incoming requests by default. Django’s built-in development server now does the same. Django’s development server is not recommended for production use, but matching the behavior of common production servers reduces the surface area for behavior changes during deployment.

Mitigated possible XSS attack via user-supplied redirect URLs

Django relies on user input in some cases (e.g. `django.contrib.auth.views.login()` and `i18n`) to redirect the user to an “on success” URL. The security checks for these redirects (namely `django.utils.http.is_safe_url()`) didn’t strip leading whitespace on the tested URL and as such considered URLs like `javascript:...` safe. If a developer relied on `is_safe_url()` to provide safe redirect targets and put such a URL into a link, they could suffer from a XSS attack. This bug doesn’t affect Django currently, since we only put this URL into the `Location` response header and browsers seem to ignore JavaScript there.

Denial-of-service attack against `django.views.static.serve`

In older versions of Django, the `django.views.static.serve()` view read the files it served one line at a time. Therefore, a big file with no newlines would result in memory usage equal to the size of that file. An attacker could exploit this and launch a denial-of-service attack by simultaneously requesting many large files. This view now reads the file in chunks to prevent large memory usage.

Note, however, that this view has always carried a warning that it is not hardened for production use and should be used only as a development aid. Now may be a good time to audit your project and serve your files in production using a real front-end web server if you are not doing so.
Database denial-of-service with ModelMultipleChoiceField

Given a form that uses ModelMultipleChoiceField and show_hidden_initial=True (not a documented API), it was possible for a user to cause an unreasonable number of SQL queries by submitting duplicate values for the field’s data. The validation logic in ModelMultipleChoiceField now deduplicates submitted values to address this issue.

Django 1.6.9 release notes

January 2, 2015

Django 1.6.9 fixes a regression in the 1.6.6 security release.

Additionally, Django’s vendored version of six, django.utils.six, has been upgraded to the latest release (1.9.0).

Bugfixes

- Fixed a regression with dynamically generated inlines and allowed field references in the admin (#23754).

Django 1.6.8 release notes

October 22, 2014

Django 1.6.8 fixes a couple regressions in the 1.6.6 security release.

Bugfixes

- Allowed related many-to-many fields to be referenced in the admin (#23604).
- Allowed inline and hidden references to admin fields (#23431).

Django 1.6.7 release notes

September 2, 2014

Django 1.6.7 fixes several bugs in 1.6.6, including a regression related to a security fix in that release.
Bugfixes

- Allowed inherited and m2m fields to be referenced in the admin (#23329).
- Fixed a crash when using `QuerySet.defer()` with `select_related()` (#23370).

Django 1.6.6 release notes

August 20, 2014

Django 1.6.6 fixes several security issues and bugs in 1.6.5.

reverse() could generate URLs pointing to other hosts

In certain situations, URL reversing could generate scheme-relative URLs (URLs starting with two slashes), which could unexpectedly redirect a user to a different host. An attacker could exploit this, for example, by redirecting users to a phishing site designed to ask for user’s passwords.

To remedy this, URL reversing now ensures that no URL starts with two slashes (//), replacing the second slash with its URL encoded counterpart (%2F). This approach ensures that semantics stay the same, while making the URL relative to the domain and not to the scheme.

File upload denial-of-service

Before this release, Django’s file upload handing in its default configuration may degrade to producing a huge number of `os.stat()` system calls when a duplicate filename is uploaded. Since `stat()` may invoke IO, this may produce a huge data-dependent slowdown that slowly worsens over time. The net result is that given enough time, a user with the ability to upload files can cause poor performance in the upload handler, eventually causing it to become very slow simply by uploading 0-byte files. At this point, even a slow network connection and few HTTP requests would be all that is necessary to make a site unavailable.

We’ve remedied the issue by changing the algorithm for generating file names if a file with the uploaded name already exists. `Storage.get_available_name()` now appends an underscore plus a random 7 character alphanumeric string (e.g. "_x3a1gho"), rather than iterating through an underscore followed by a number (e.g. "_1", "_2", etc.).
**RemoteUserMiddleware session hijacking**

When using the `RemoteUserMiddleware` and the `RemoteUserBackend`, a change to the `REMOTE_USER` header between requests without an intervening logout could result in the prior user’s session being co-opted by the subsequent user. The middleware now logs the user out on a failed login attempt.

**Data leakage via query string manipulation in contrib.admin**

In older versions of Django it was possible to reveal any field’s data by modifying the “popup” and “to_field” parameters of the query string on an admin change form page. For example, requesting a URL like `/admin/auth/user/?_popup=1&t=password` and viewing the page’s HTML allowed viewing the password hash of each user. While the admin requires users to have permissions to view the change form pages in the first place, this could leak data if you rely on users having access to view only certain fields on a model.

To address the issue, an exception will now be raised if a `to_field` value that isn’t a related field to a model that has been registered with the admin is specified.

**Bugfixes**

- Corrected email and URL validation to reject a trailing dash (#22579).
- Prevented indexes on PostgreSQL virtual fields (#22514).
- Prevented edge case where values of FK fields could be initialized with a wrong value when an inline model formset is created for a relationship defined to point to a field other than the PK (#13794).
- Restored `pre_delete` signals for `GenericRelation` cascade deletion (#22998).
- Fixed transaction handling when specifying non-default database in `createcachetable` and `flush` (#23089).
- Fixed the “ORA-01843: not a valid month” errors when using Unicode with older versions of Oracle server (#20292).
- Restored bug fix for sending Unicode email with Python 2.6.5 and below (#19107).
- Prevented `UnicodeDecodeError` in `runserver` with non-UTF-8 and non-English locale (#23265).
- Fixed JavaScript errors while editing multi-geometry objects in the OpenLayers widget (#23137, #23293).
- Prevented a crash on Python 3 with query strings containing unencoded non-ASCII characters (#22996).
Django 1.6.5 release notes

May 14, 2014

Django 1.6.5 fixes two security issues and several bugs in 1.6.4.

**Issue: Caches may incorrectly be allowed to store and serve private data**

In certain situations, Django may allow caches to store private data related to a particular session and then serve that data to requests with a different session, or no session at all. This can lead to information disclosure and can be a vector for cache poisoning.

When using Django sessions, Django will set a `Vary: Cookie` header to ensure caches do not serve cached data to requests from other sessions. However, older versions of Internet Explorer (most likely only Internet Explorer 6, and Internet Explorer 7 if run on Windows XP or Windows Server 2003) are unable to handle the `Vary` header in combination with many content types. Therefore, Django would remove the header if the request was made by Internet Explorer.

To remedy this, the special behavior for these older Internet Explorer versions has been removed, and the `Vary` header is no longer stripped from the response. In addition, modifications to the `Cache-Control` header for all Internet Explorer requests with a `Content-Disposition` header have also been removed as they were found to have similar issues.

**Issue: Malformed redirect URLs from user input not correctly validated**

The validation for redirects did not correctly validate some malformed URLs, which are accepted by some browsers. This allows a user to be redirected to an unsafe URL unexpectedly.

Django relies on user input in some cases (e.g. `django.contrib.auth.views.login()`, `django.contrib.comments`, and `i18n`) to redirect the user to an “on success” URL. The security checks for these redirects (namely `django.utils.http.is_safe_url()`) did not correctly validate some malformed URLs, such as `http:\\\\djangoproject.com`, which are accepted by some browsers with more liberal URL parsing.

To remedy this, the validation in `is_safe_url()` has been tightened to be able to handle and correctly validate these malformed URLs.

**Bugfixes**

- Made the `year_lookup_bounds_for_datetime_field` Oracle backend method Python 3 compatible (#22551).
- Fixed `pgettext_lazy` crash when receiving bytestring content on Python 2 (#22565).
- Fixed the SQL generated when filtering by a negated `Q` object that contains a `F` object. (#22429).
- Avoided overwriting data fetched by `select_related()` in certain cases which could cause minor performance regressions (#22508).

**Django 1.6.4 release notes**

April 28, 2014

Django 1.6.4 fixes several bugs in 1.6.3.

**Bug fixes**

- Added backwards compatibility support for the `django.contrib.messages` cookie format of Django 1.4 and earlier to facilitate upgrading to 1.6 from 1.4 (#22426).
- Restored the ability to `reverse()` views created using `functools.partial()` (#22486).
- Fixed the `object_id` of the `LogEntry` that’s created after a user password change in the admin (#22515).

**Django 1.6.3 release notes**

April 21, 2014

Django 1.6.3 fixes several bugs in 1.6.2, including three security issues, and makes one backwards-incompatible change:

### Unexpected code execution using `reverse()`

Django’s URL handling is based on a mapping of regex patterns (representing the URLs) to callable views, and Django’s own processing consists of matching a requested URL against those patterns to determine the appropriate view to invoke.

Django also provides a convenience function – `reverse()` – which performs this process in the opposite direction. The `reverse()` function takes information about a view and returns a URL which would invoke that view. Use of `reverse()` is encouraged for application developers, as the output of `reverse()` is always based on the current URL patterns, meaning developers do not need to change other code when making changes to URLs.

One argument signature for `reverse()` is to pass a dotted Python path to the desired view. In this situation, Django will import the module indicated by that dotted path as part of generating the resulting URL. If such a module has import-time side effects, those side effects will occur.

Thus it is possible for an attacker to cause unexpected code execution, given the following conditions:

1. One or more views are present which construct a URL based on user input (commonly, a “next” parameter in a querystring indicating where to redirect upon successful completion of an action).
2. One or more modules are known to an attacker to exist on the server’s Python import path, which perform code execution with side effects on importing.

To remedy this, `reverse()` will now only accept and import dotted paths based on the view-containing modules listed in the project’s URL pattern configuration, so as to ensure that only modules the developer intended to be imported in this fashion can or will be imported.

**Caching of anonymous pages could reveal CSRF token**

Django includes both a caching framework and a system for preventing cross-site request forgery (CSRF) attacks. The CSRF-protection system is based on a random nonce sent to the client in a cookie which must be sent by the client on future requests and, in forms, a hidden value which must be submitted back with the form.

The caching framework includes an option to cache responses to anonymous (i.e., unauthenticated) clients.

When the first anonymous request to a given page is by a client which did not have a CSRF cookie, the cache framework will also cache the CSRF cookie and serve the same nonce to other anonymous clients who do not have a CSRF cookie. This can allow an attacker to obtain a valid CSRF cookie value and perform attacks which bypass the check for the cookie.

To remedy this, the caching framework will no longer cache such responses. The heuristic for this will be:

1. If the incoming request did not submit any cookies, and
2. If the response did send one or more cookies, and
3. If the `Vary: Cookie` header is set on the response, then the response will not be cached.

**MySQL typecasting**

The MySQL database is known to “typecast” on certain queries; for example, when querying a table which contains string values, but using a query which filters based on an integer value, MySQL will first silently coerce the strings to integers and return a result based on that.

If a query is performed without first converting values to the appropriate type, this can produce unexpected results, similar to what would occur if the query itself had been manipulated.

Django’s model field classes are aware of their own types and most such classes perform explicit conversion of query arguments to the correct database-level type before querying. However, three model field classes did not correctly convert their arguments:

- `FilePathField`
- `GenericIPAddressField`
- `IPAddressField`
These three fields have been updated to convert their arguments to the correct types before querying.

Additionally, developers of custom model fields are now warned via documentation to ensure their custom field classes will perform appropriate type conversions, and users of the `raw()` and `extra()` query methods—which allow the developer to supply raw SQL or SQL fragments—will be advised to ensure they perform appropriate manual type conversions prior to executing queries.

**select_for_update() requires a transaction**

Historically, queries that use `select_for_update()` could be executed in autocommit mode, outside of a transaction. Before Django 1.6, Django’s automatic transactions mode allowed this to be used to lock records until the next write operation. Django 1.6 introduced database-level autocommit; since then, execution in such a context voids the effect of `select_for_update()`. It is, therefore, assumed now to be an error and raises an exception.

This change was made because such errors can be caused by including an app which expects global transactions (e.g. `ATOMIC_REQUESTS` set to True), or Django’s old autocommit behavior, in a project which runs without them; and further, such errors may manifest as data-corruption bugs.

This change may cause test failures if you use `select_for_update()` in a test class which is a subclass of `TransactionTestCase` rather than `TestCase`.

**Other bugfixes and changes**

- Content retrieved from the GeoIP library is now properly decoded from its default iso-8859-1 encoding (#21996).
- Fixed `AttributeError` when using `bulk_create()` with `ForeignObject` (#21566).
- Fixed crash of `QuerySets` that use `F() + timedelta()` when their query was compiled more once (#21643).
- Prevented custom `widget` class attribute of `IntegerField` subclasses from being overwritten by the code in their `__init__` method (#22245).
- Improved `strip_tags()` accuracy (but it still cannot guarantee an HTML-safe result, as stated in the documentation).
- Fixed a regression in the `django.contrib.gis` SQL compiler for non-concrete fields (#22250).
- Fixed `ModelAdmin.preserve_filters` when running a site with a URL prefix (#21795).
- Fixed a crash in the `find_command` management utility when the `PATH` environment variable wasn’t set (#22256).
- Fixed `changepassword` on Windows (#22364).
- Avoided shadowing deadlock exceptions on MySQL (#22291).
• Wrapped database exceptions in _set_autocommit (#22321).
• Fixed atomicity when closing a database connection or when the database server disconnects (#21239 and #21202)
• Fixed regression in prefetch_related that caused the related objects query to include an unnecessary join (#21760).

Additionally, Django’s vendored version of six, django.utils.six has been upgraded to the latest release (1.6.1).

Django 1.6.2 release notes

February 6, 2014

This is Django 1.6.2, a bugfix release for Django 1.6. Django 1.6.2 fixes several bugs in 1.6.1:

• Prevented the base geometry object of a prepared geometry to be garbage collected, which could lead to crash Django (#21662).
• Fixed a crash when executing the changepassword command when the user object representation contained non-ASCII characters (#21627).
• The collectstatic command will raise an error rather than default to using the current working directory if STATIC_ROOT is not set. Combined with the --clear option, the previous behavior could wipe anything below the current working directory (#21581).
• Fixed mail encoding on Python 3.3.3+ (#21093).
• Fixed an issue where when settings.DATABASES['default']['AUTOCOMMIT'] = False, the connection wasn’t in autocommit mode but Django pretended it was.
• Fixed a regression in multiple-table inheritance exclude() queries (#21787).
• Added missing items to django.utils.timezone.__all__(#21880).
• Fixed a field misalignment issue with select_related() and model inheritance (#21413).
• Fixed join promotion for negated AND conditions (#21748).
• Oracle database introspection now works with boolean and float fields (#19884).
• Fixed an issue where lazy objects weren’t actually marked as safe when passed through mark_safe() and could end up being double-escaped (#21882).

Additionally, Django’s vendored version of six, django.utils.six has been upgraded to the latest release (1.5.2).
Django 1.6.1 release notes

December 12, 2013

This is Django 1.6.1, a bugfix release for Django 1.6. In addition to the bug fixes listed below, translations submitted since the 1.6 release are also included.

Bug fixes

• Fixed BCryptSHA256PasswordHasher with py-bcrypt and Python 3 (#21398).

• Fixed a regression that prevented a ForeignKey with a hidden reverse manager (related_name ending with ‘+’) from being used as a lookup for prefetch_related (#21410).

• Fixed Queryset.datetimes raising AttributeError in some situations (#21432).

• Fixed ModelBackend raising UnboundLocalError if get_user_model() raised an error (#21439).

• Fixed a regression that prevented editable GenericRelation subclasses from working in ModelForms (#21428).

• Added missing to_python method for ModelMultipleChoiceField which is required in Django 1.6 to properly detect changes from initial values (#21568).

• Fixed django.contrib.humanize translations where the Unicode sequence for the non-breaking space was returned verbatim (#21415).

• Fixed loaddata error when fixture file name contained any dots not related to file extensions (#21457) or when fixture path was relative but located in a subdirectory (#21551).

• Fixed display of inline instances in formsets when parent has 0 for primary key (#21472).

• Fixed a regression where custom querysets for foreign keys were overwritten if ModelAdmin had ordering set (#21405).

• Removed mention of a feature in the --locale/-l option of the makemessages and compilemessages commands that never worked as promised: Support of multiple locale names separated by commas. It’s still possible to specify multiple locales in one run by using the option multiple times (#21488, #17181).

• Fixed a regression that unnecessarily triggered settings configuration when importing get_wsgi_application (#21486).

• Fixed test client logout() method when using the cookie-based session backend (#21448).

• Fixed a crash when a GeometryField uses a non-geometric widget (#21496).

• Fixed password hash upgrade when changing the iteration count (#21535).

• Fixed a bug in the debug view when the URLconf only contains one element (#21530).

• Re-added missing search result count and reset link in changelist admin view (#21510).
• The current language is no longer saved to the session by `LocaleMiddleware` on every response, but rather only after a logout (#21473).

• Fixed a crash when executing `runserver` on non-English systems and when the formatted date in its output contained non-ASCII characters (#21358).

• Fixed a crash in the debug view after an exception occurred on Python \( \geq 3.3 \) (#21443).

• Fixed a crash in `ImageField` on some platforms (Homebrew and RHEL6 reported) (#21355).

• Fixed a regression when using generic relations in `ModelAdmin.list_filter` (#21431).

Django 1.6 release notes

Note: Dedicated to Malcolm Tredinnick

On March 17, 2013, the Django project and the free software community lost a very dear friend and developer. Malcolm was a long-time contributor to Django, a model community member, a brilliant mind, and a friend. His contributions to Django — and to many other open source projects — are nearly impossible to enumerate. Many on the core Django team had their first patches reviewed by him; his mentorship enriched us. His consideration, patience, and dedication will always be an inspiration to us.

This release of Django is for Malcolm.

—The Django Developers

November 6, 2013

Welcome to Django 1.6!

These release notes cover the new features, as well as some backwards incompatible changes you’ll want to be aware of when upgrading from Django 1.5 or older versions. We’ve also dropped some features, which are detailed in our deprecation plan, and we’ve begun the deprecation process for some features.

Python compatibility

Django 1.6, like Django 1.5, requires Python 2.6.5 or above. Python 3 is also officially supported. We highly recommend the latest minor release for each supported Python series (2.6.X, 2.7.X, 3.2.X, and 3.3.X).

Django 1.6 will be the final release series to support Python 2.6; beginning with Django 1.7, the minimum supported Python version will be 2.7.

Python 3.4 is not supported, but support will be added in Django 1.7.
What’s new in Django 1.6

Simplified default project and app templates

The default templates used by `startproject` and `startapp` have been simplified and modernized. The `admin` is now enabled by default in new projects; the `sites` framework no longer is. Clickjacking prevention is now on and the database defaults to SQLite.

If the default templates don’t suit your tastes, you can use custom project and app templates.

Improved transaction management

Django’s transaction management was overhauled. Database-level autocommit is now turned on by default. This makes transaction handling more explicit and should improve performance. The existing APIs were deprecated, and new APIs were introduced, as described in the transaction management docs.

Persistent database connections

Django now supports reusing the same database connection for several requests. This avoids the overhead of reestablishing a connection at the beginning of each request. For backwards compatibility, this feature is disabled by default. See Persistent connections for details.

Discovery of tests in any test module

Django 1.6 ships with a new test runner that allows more flexibility in the location of tests. The previous runner (``django.test.simple.DjangoTestSuiteRunner``) found tests only in the `models.py` and `tests.py` modules of a Python package in `INSTALLED_APPS`.

The new runner (``django.test.runner.DiscoverRunner``) uses the test discovery features built into unittest2 (the version of unittest in the Python 2.7+ standard library, and bundled with Django). With test discovery, tests can be located in any module whose name matches the pattern `test*.py`.

In addition, the test labels provided to ``./manage.py test`` to nominate specific tests to run must now be full Python dotted paths (or directory paths), rather than `applabel.TestCase.test_method_name` pseudo-paths. This allows running tests located anywhere in your codebase, rather than only in `INSTALLED_APPS`. For more details, see Testing in Django.

This change is backwards-incompatible; see the backwards-incompatibility notes.
Time zone aware aggregation

The support for time zones introduced in Django 1.4 didn’t work well with `QuerySet.dates()`: aggregation was always performed in UTC. This limitation was lifted in Django 1.6. Use `QuerySet.datetimes()` to perform time zone aware aggregation on a `DateTimeField`.

Support for savepoints in SQLite

Django 1.6 adds support for savepoints in SQLite, with some limitations.

BinaryField model field

A new `django.db.models.BinaryField` model field allows storage of raw binary data in the database.

GeoDjango form widgets

GeoDjango now provides form fields and widgets for its geo-specialized fields. They are OpenLayers-based by default, but they can be customized to use any other JS framework.

check management command added for verifying compatibility

A `check` management command was added, enabling you to verify if your current configuration (currently oriented at settings) is compatible with the current version of Django.

Model.save() algorithm changed

The `Model.save()` method now tries to directly `UPDATE` the database if the instance has a primary key value. Previously `SELECT` was performed to determine if `UPDATE` or `INSERT` were needed. The new algorithm needs only one query for updating an existing row while the old algorithm needed two. See `Model.save()` for more details.

In some rare cases the database doesn’t report that a matching row was found when doing an `UPDATE`. An example is the PostgreSQL ON UPDATE trigger which returns `NULL`. In such cases it is possible to set `django.db.models.Options.select_on_save` flag to force saving to use the old algorithm.
Minor features

- Authentication backends can raise PermissionDenied to immediately fail the authentication chain.
- The HttpOnly flag can be set on the CSRF cookie with CSRF_COOKIE_HTTPONLY.
- The assertQuerysetEqual() now checks for undefined order and raises ValueError if undefined order is spotted. The order is seen as undefined if the given QuerySet isn’t ordered and there is more than one ordered value to compare against.
- Added earliest() for symmetry with latest().
- In addition to year, month and day, the ORM now supports hour, minute and second lookups.
- Django now wraps all PEP 249 exceptions.
- The default widgets for EmailField, URLField, IntegerField, FloatField and DecimalField use the new type attributes available in HTML5 (type='email', type='url', type='number'). Note that due to erratic support of the number input type with localized numbers in current browsers, Django only uses it when numeric fields are not localized.
- The number argument for lazy plural translations can be provided at translation time rather than at definition time.
- For custom management commands: Verification of the presence of valid settings in commands that ask for it by using the BaseCommand.can_import_settings internal option is now performed independently from handling of the locale that should be active during the execution of the command. The latter can now be influenced by the new BaseCommand.leave_locale_alone internal option. See Management commands and locales for more details.
- The success_url of DeletionMixin is now interpolated with its object’s __dict__.
- HttpResponseRedirect and HttpResponsePermanentRedirect now provide an url attribute (equivalent to the URL the response will redirect to).
- The MemcachedCache cache backend now uses the latest pickle protocol available.
- Added SuccessMessageMixin which provides a success_message attribute for FormView based classes.
- Added the django.db.models.ForeignKey.db_constraint and django.db.models.ManyToManyField.db_constraint options.
- The jQuery library embedded in the admin has been upgraded to version 1.9.1.
- Syndication feeds (django.contrib.syndication) can now pass extra context through to feed templates using a new Feed.get_context_data() callback.
- The admin list columns have a column-field_name class in the HTML so the columns header can be styled with CSS, e.g. to set a column width.
- The isolation level can be customized under PostgreSQL.
• The blocktrans template tag now respects TEMPLATE_STRING_IF_INVALID for variables not present in the context, just like other template constructs.

• SimpleLazyObjects will now present more helpful representations in shell debugging situations.

• Generic GeometryField is now editable with the OpenLayers widget in the admin.

• The documentation contains a deployment checklist.

• The diffsettings command gained a --all option.

• django.forms.fields.Field.__init__ now calls super(), allowing field mixins to implement __init__() methods that will reliably be called.

• The validate_max parameter was added to BaseFormSet and formset_factory(), and ModelForm and inline versions of the same. The behavior of validation for formsets with max_num was clarified. The previously undocumented behavior that hardened formsets against memory exhaustion attacks was documented, and the undocumented limit of the higher of 1000 or max_num forms was changed so it is always 1000 more than max_num.

• Added BCryptSHA256PasswordHasher to resolve the password truncation issue with bcrypt.

• Pillow is now the preferred image manipulation library to use with Django. PIL is pending deprecation (support to be removed in Django 1.8). To upgrade, you should first uninstall PIL, then install Pillow.

• ModelForm accepts several new Meta options.
  – Fields included in the localized_fields list will be localized (by setting localize on the form field).
  – The labels, help_texts and error_messages options may be used to customize the default fields, see Overriding the default fields for details.

• The choices argument to model fields now accepts an iterable of iterables instead of requiring an iterable of lists or tuples.

• The reason phrase can be customized in HTTP responses using reason_phrase.

• When giving the URL of the next page for django.contrib.auth.views.logout(), django.contrib.auth.views.password_reset(), django.contrib.auth.views.password_reset_confirm(), and django.contrib.auth.views.password_change(), you can now pass URL names and they will be resolved.

• The new dumpdata --pks option specifies the primary keys of objects to dump. This option can only be used with one model.

• Added QuerySet methods first() and last() which are convenience methods returning the first or last object matching the filters. Returns None if there are no objects matching.

• View and RedirectView now support HTTP PATCH method.

• GenericForeignKey now takes an optional for_concrete_model argument, which when set to False allows the field to reference proxy models. The default is True to retain the old behavior.
• The `LocaleMiddleware` now stores the active language in session if it is not present there. This prevents loss of language settings after session flush, e.g. logout.

• `SuspiciousOperation` has been differentiated into a number of subclasses, and each will log to a matching named logger under the `django.security` logging hierarchy. Along with this change, a `handler400` mechanism and default view are used whenever a `SuspiciousOperation` reaches the WSGI handler to return an `HttpResponseBadRequest`.

• The `DoesNotExist` exception now includes a message indicating the name of the attribute used for the lookup.

• The `get_or_create()` method no longer requires at least one keyword argument.

• The `SimpleTestCase` class includes a new assertion helper for testing formset errors: `assertFormsetError()`.

• The list of related fields added to a `QuerySet` by `select_related()` can be cleared using `select_related(None)`.

• The `get_extra()` and `get_max_num()` methods on `InlineModelAdmin` may be overridden to customize the extra and maximum number of inline forms.

• Formsets now have a `total_error_count()` method.

• `ModelForm` fields can now override error messages defined in model fields by using the `error_messages` argument of a Field’s constructor. To take advantage of this new feature with your custom fields, see the updated recommendation for raising a `ValidationError`.

• `ModelAdmin` now preserves filters on the list view after creating, editing or deleting an object. It’s possible to restore the previous behavior of clearing filters by setting the `preserve_filters` attribute to `False`.

• Added `FormMixin.get_prefix` (which returns `FormMixin.prefix` by default) to allow customizing the `prefix` of the form.

• Raw queries (`Manager.raw()` or `cursor.execute()`) can now use the “pyformat” parameter style, where placeholders in the query are given as ‘%(name)s’ and the parameters are passed as a dictionary rather than a list (except on SQLite). This has long been possible (but not officially supported) on MySQL and PostgreSQL, and is now also available on Oracle.

• The default iteration count for the PBKDF2 password hasher has been increased by 20%. This backwards compatible change will not affect existing passwords or users who have subclassed `django.contrib.auth.hashers.PBKDF2PasswordHasher` to change the default value. Passwords will be upgraded to use the new iteration count as necessary.
Backwards incompatible changes in 1.6

Warning: In addition to the changes outlined in this section, be sure to review the deprecation plan for any features that have been removed. If you haven’t updated your code within the deprecation timeline for a given feature, its removal may appear as a backwards incompatible change.

New transaction management model

Behavior changes

Database-level autocommit is enabled by default in Django 1.6. While this doesn’t change the general spirit of Django’s transaction management, there are a few backwards-incompatibilities.

Savepoints and assertNumQueries

The changes in transaction management may result in additional statements to create, release or rollback savepoints. This is more likely to happen with SQLite, since it didn’t support savepoints until this release.

If tests using assertNumQueries() fail because of a higher number of queries than expected, check that the extra queries are related to savepoints, and adjust the expected number of queries accordingly.

Autocommit option for PostgreSQL

In previous versions, database-level autocommit was only an option for PostgreSQL, and it was disabled by default. This option is now ignored and can be removed.

New test runner

In order to maintain greater consistency with Python’s unittest module, the new test runner (django.test.runner.DiscoverRunner) does not automatically support some types of tests that were supported by the previous runner:

- Tests in models.py and tests/__init__.py files will no longer be found and run. Move them to a file whose name begins with test.

- Doctests will no longer be automatically discovered. To integrate doctests in your test suite, follow the recommendations in the Python documentation.

Django bundles a modified version of the doctest module from the Python standard library (in django.test._doctest) and includes some additional doctest utilities. These utilities are deprecated and will be
removed in Django 1.8; doctest suites should be updated to work with the standard library’s doctest module (or converted to unittest-compatible tests).

If you wish to delay updates to your test suite, you can set your TEST_RUNNER setting to django.test.simple.DjangoTestSuiteRunner to fully restore the old test behavior. DjangoTestSuiteRunner is deprecated but will not be removed from Django until version 1.8.

**Removal of django.contrib.gis.tests.GeoDjangoTestSuiteRunner GeoDjango custom test runner**

This is for developers working on the GeoDjango application itself and related to the item above about changes in the test runners:

The django.contrib.gis.tests.GeoDjangoTestSuiteRunner test runner has been removed and the standalone GeoDjango tests execution setup it implemented isn’t supported anymore. To run the GeoDjango tests simply use the new DiscoverRunner and specify the django.contrib.gis app.

**Custom user models in tests**

The introduction of the new test runner has also slightly changed the way that test models are imported. As a result, any test that overrides AUTH_USER_MODEL to test behavior with one of Django’s test user models (django.contrib.auth.tests.custom_user.CustomUser and django.contrib.auth.tests.custom_user.ExtensionUser) must now explicitly import the User model in your test module:

```
from django.contrib.auth.tests.custom_user import CustomUser

@override_settings(AUTH_USER_MODEL='auth.CustomUser')
class CustomUserFeatureTests(TestCase):
    def test_something(self):
        # Test code here ...
```

This import forces the custom user model to be registered. Without this import, the test will be unable to swap in the custom user model, and you will get an error reporting:

```
ImproperlyConfigured: AUTH_USER_MODEL refers to model 'auth.CustomUser' that has not been installed
```

**Time zone-aware day, month, and week_day lookups**

Django 1.6 introduces time zone support for day, month, and week_day lookups when USE_TZ is True. These lookups were previously performed in UTC regardless of the current time zone.

This requires time zone definitions in the database. If you’re using SQLite, you must install pytz. If you’re using MySQL, you must install pytz and load the time zone tables with mysql_tzinfo_to_sql.
Addition of QuerySet.datetimes()

When the time zone support added in Django 1.4 was active, QuerySet.dates() lookups returned unexpected results, because the aggregation was performed in UTC. To fix this, Django 1.6 introduces a new API, QuerySet.datetimes(). This requires a few changes in your code.

QuerySet.dates() returns date objects

QuerySet.dates() now returns a list of date. It used to return a list of datetime.

QuerySet.dates() returns a list of datetime.

QuerySet.dates() no longer usable on DateTimeField

QuerySet.dates() raises an error if it’s used on DateTimeField when time zone support is active. Use QuerySet.datetimes() instead.

date_hierarchy requires time zone definitions

The date_hierarchy feature of the admin now relies on QuerySet.datetimes() when it’s used on a DateTimeField.

This requires time zone definitions in the database when USE_TZ is True. Learn more.

date_list in generic views requires time zone definitions

For the same reason, accessing date_list in the context of a date-based generic view requires time zone definitions in the database when the view is based on a DateTimeField and USE_TZ is True. Learn more.

New lookups may clash with model fields

Django 1.6 introduces hour, minute, and second lookups on DateTimeField. If you had model fields called hour, minute, or second, the new lookups will clash with you field names. Append an explicit exact lookup if this is an issue.
**BooleanField no longer defaults to False**

When a `BooleanField` doesn’t have an explicit `default`, the implicit default value is `None`. In previous versions of Django, it was `False`, but that didn’t represent accurately the lack of a value.

Code that relies on the default value being `False` may raise an exception when saving new model instances to the database, because `None` isn’t an acceptable value for a `BooleanField`. You should either specify `default=False` in the field definition, or ensure the field is set to `True` or `False` before saving the object.

**Translations and comments in templates**

**Extraction of translations after comments**

Extraction of translatable literals from templates with the `makemessages` command now correctly detects i18n constructs when they are located after a `{# / #}`-type comment on the same line. E.g.:

```
{# A comment #}{% trans "This literal was incorrectly ignored. Not anymore" %}
```

**Location of translator comments**

Comments for translators in templates specified using `{# / #}` need to be at the end of a line. If they are not, the comments are ignored and `makemessages` will generate a warning. For example:

```
{% Translators: This is ignored %}{% trans "Translate me" %}
{{ title }}{% Translators: Extracted and associated with 'Welcome' below %}
<h1>{% trans "Welcome" %}</h1>
```

**Quoting in reverse()**

When reversing URLs, Django didn’t apply `django.utils.http.urlquote` to arguments before interpolating them in URL patterns. This bug is fixed in Django 1.6. If you worked around this bug by applying URL quoting before passing arguments to `reverse()`, this may result in double-quoting. If this happens, simply remove the URL quoting from your code. You will also have to replace special characters in URLs used in `assertRedirects()` with their encoded versions.
Storage of IP addresses in the comments app

The comments app now uses a `GenericIPAddressField` for storing commenters’ IP addresses, to support comments submitted from IPv6 addresses. Until now, it stored them in an `IPAddressField`, which is only meant to support IPv4. When saving a comment made from an IPv6 address, the address would be silently truncated on MySQL databases, and raise an exception on Oracle. You will need to change the column type in your database to benefit from this change.

For MySQL, execute this query on your project’s database:

```sql
ALTER TABLE django_comments MODIFY ip_address VARCHAR(39);
```

For Oracle, execute this query:

```sql
ALTER TABLE DJANGO_COMMENTS MODIFY (ip_address VARCHAR2(39));
```

If you do not apply this change, the behavior is unchanged: on MySQL, IPv6 addresses are silently truncated; on Oracle, an exception is generated. No database change is needed for SQLite or PostgreSQL databases.

Percent literals in `cursor.execute` queries

When you are running raw SQL queries through the `cursor.execute` method, the rule about doubling percent literals (%) inside the query has been unified. Past behavior depended on the database backend. Now, across all backends, you only need to double literal percent characters if you are also providing replacement parameters. For example:

```python
# No parameters, no percent doubling
cursor.execute("SELECT foo FROM bar WHERE baz = '%30%'")

# Parameters passed, non-placeholders have to be doubled
cursor.execute("SELECT foo FROM bar WHERE baz = '%30%%' and id = %s", [self.id])
```

SQLite users need to check and update such queries.

Help text of model form fields for ManyToManyField fields

HTML rendering of model form fields corresponding to `ManyToManyField` model fields used to get the hardcoded sentence:

```
Hold down “Control” , or “Command” on a Mac, to select more than one.
```

(or its translation to the active locale) imposed as the help legend shown along them if neither `model` nor `form help_text` attributes were specified by the user (or this string was appended to any `help_text` that was provided).
Since this happened at the model layer, there was no way to prevent the text from appearing in cases where it wasn’t applicable such as form fields that implement user interactions that don’t involve a keyboard and/or a mouse.

Starting with Django 1.6, as an ad-hoc temporary backward-compatibility provision, the logic to add the “Hold down...” sentence has been moved to the model form field layer and modified to add the text only when the associated widget is `SelectMultiple` or selected subclasses.

The change can affect you in a backward incompatible way if you employ custom model form fields and/or widgets for `ManyToManyField` model fields whose UIs do rely on the automatic provision of the mentioned hard-coded sentence. These form field implementations need to adapt to the new scenario by providing their own handling of the `help_text` attribute.

Applications that use Django model form facilities together with Django built-in form fields and widgets aren’t affected but need to be aware of what’s described in Munging of help text of model form fields for `ManyToManyField` fields below.

**QuerySet iteration**

The `QuerySet` iteration was changed to immediately convert all fetched rows to `Model` objects. In Django 1.5 and earlier the fetched rows were converted to `Model` objects in chunks of 100.

Existing code will work, but the amount of rows converted to objects might change in certain use cases. Such usages include partially looping over a queryset or any usage which ends up doing `__bool__` or `__contains__`.

Notably most database backends did fetch all the rows in one go already in 1.5.

It is still possible to convert the fetched rows to `Model` objects lazily by using the `iterator()` method.

**`BoundField.label_tag now includes the form’s label_suffix**

This is consistent with how methods like `Form.as_p` and `Form.as_ul` render labels.

If you manually render `label_tag` in your templates:

```
{{ form.my_field.label_tag }}: {{ form.my_field }}
```

you’ll want to remove the colon (or whatever other separator you may be using) to avoid duplicating it when upgrading to Django 1.6. The following template in Django 1.6 will render identically to the above template in Django 1.5, except that the colon will appear inside the `<label>` element.

```
{{ form.my_field.label_tag }} {{ form.my_field }}
```

will render something like:
<label for="id_my_field">My Field:</label> <input id="id_my_field" type="text" name="my_field" />

If you want to keep the current behavior of rendering `label_tag` without the `label_suffix`, instantiate the form `label_suffix=''. You can also customize the `label_suffix` on a per-field basis using the new `label_suffix` parameter on `label_tag()`.

**Admin views `_changelist_filters` GET parameter**

To achieve preserving and restoring list view filters, admin views now pass around the `_changelist_filters` GET parameter. It’s important that you account for that change if you have custom admin templates or if your tests rely on the previous URLs. If you want to revert to the original behavior you can set the `preserve_filters` attribute to False.

**django.contrib.auth password reset uses base 64 encoding of User PK**

Past versions of Django used base 36 encoding of the User primary key in the password reset views and URLs (`django.contrib.auth.views.password_reset_confirm()`). Base 36 encoding is sufficient if the user primary key is an integer, however, with the introduction of custom user models in Django 1.5, that assumption may no longer be true.

`django.contrib.auth.views.password_reset_confirm()` has been modified to take a `uidb64` parameter instead of `uidb36`. If you are reversing this view, for example in a custom `password_reset_email.html` template, be sure to update your code.

A temporary shim for `django.contrib.auth.views.password_reset_confirm()` that will allow password reset links generated prior to Django 1.6 to continue to work has been added to provide backwards compatibility; this will be removed in Django 1.7. Thus, as long as your site has been running Django 1.6 for more than `PASSWORD_RESET_TIMEOUT_DAYS`, this change will have no effect. If not (for example, if you upgrade directly from Django 1.5 to Django 1.7), then any password reset links generated before you upgrade to Django 1.7 or later won’t work after the upgrade.

In addition, if you have any custom password reset URLs, you will need to update them by replacing `uidb36` with `uidb64` and the dash that follows that pattern with a slash. Also add `_\-` to the list of characters that may match the `uidb64` pattern.

For example:

```python
url(r'^reset/(?P<uidb36>[0-9A-Za-z]+)-(?P<token>.+)/$','
    'django.contrib.auth.views.password_reset_confirm',
    name='password_reset_confirm'),
```

becomes:
You may also want to add the shim to support the old style reset links. Using the example above, you would modify the existing url by replacing `django.contrib.auth.views.password_reset_confirm` with `django.contrib.auth.views.password_reset_confirm_uidb36` and also remove the `name` argument so it doesn’t conflict with the new url:

```python
url(r'^reset/(?P<uidb36>[0-9A-Za-z-]+)/(?P<token>.+)/$','django.contrib.auth.views.password_reset_confirm_uidb36'),
```

You can remove this URL pattern after your app has been deployed with Django 1.6 for `PASSWORD_RESET_TIMEOUT_DAYS`.

### Default session serialization switched to JSON

Historically, `django.contrib.sessions` used `pickle` to serialize session data before storing it in the backend. If you’re using the signed cookie session backend and `SECRET_KEY` is known by an attacker (there isn’t an inherent vulnerability in Django that would cause it to leak), the attacker could insert a string into their session which, when unpickled, executes arbitrary code on the server. The technique for doing so is simple and easily available on the internet. Although the cookie session storage signs the cookie-stored data to prevent tampering, a `SECRET_KEY` leak immediately escalates to a remote code execution vulnerability.

This attack can be mitigated by serializing session data using JSON rather than `pickle`. To facilitate this, Django 1.5.3 introduced a new setting, `SESSION_SERIALIZER`, to customize the session serialization format. For backwards compatibility, this setting defaulted to using `pickle` in Django 1.5.3, but we’ve changed the default to JSON in 1.6. If you upgrade and switch from pickle to JSON, sessions created before the upgrade will be lost. While JSON serialization does not support all Python objects like `pickle` does, we highly recommend using JSON-serialized sessions. Be aware of the following when checking your code to determine if JSON serialization will work for your application:

- JSON requires string keys, so you will likely run into problems if you are using non-string keys in `request.session`.
- Setting session expiration by passing `datetime` values to `set_expiry()` will not work as `datetime` values are not serializable in JSON. You can use integer values instead.

See the Session serialization documentation for more details.
Object Relational Mapper changes

Django 1.6 contains many changes to the ORM. These changes fall mostly in three categories:

1. Bug fixes (e.g. proper join clauses for generic relations, query combining, join promotion, and join trimming fixes)

2. Preparation for new features. For example the ORM is now internally ready for multicolumn foreign keys.

3. General cleanup.

These changes can result in some compatibility problems. For example, some queries will now generate different table aliases. This can affect `QuerySet.extra()`. In addition some queries will now produce different results. An example is `exclude(condition)` where the condition is a complex one (referencing multijoins inside `Q objects`). In many cases the affected queries didn’t produce correct results in Django 1.5 but do now. Unfortunately there are also cases that produce different results, but neither Django 1.5 nor 1.6 produce correct results.

Finally, there have been many changes to the ORM internal APIs.

Miscellaneous

- The `django.db.models.query.EmptyQuerySet` can’t be instantiated any more - it is only usable as a marker class for checking if `none()` has been called: `isinstance(qs.none(), EmptyQuerySet)`

- If your CSS/JavaScript code used to access HTML input widgets by type, you should review it as `type='text'` widgets might be now output as `type='email'`, `type='url'` or `type='number'` depending on their corresponding field type.

- Form field’s `error_messages` that contain a placeholder should now always use a named placeholder ("Value '%(value)s' is too big" instead of "Value '%%s' is too big"). See the corresponding field documentation for details about the names of the placeholders. The changes in 1.6 particularly affect `DecimalField` and `ModelMultipleChoiceField`.

- Some `error_messages` for `IntegerField`, `EmailField`, `IPAddressField`, `GenericIPAddressField`, and `SlugField` have been suppressed because they duplicated error messages already provided by validators tied to the fields.

- Due to a change in the form validation workflow, `TypedChoiceField coerce` method should always return a value present in the choices field attribute. That limitation should be lift again in Django 1.7.

- There have been changes in the way timeouts are handled in cache backends. Explicitly passing in `timeout=None` no longer results in using the default timeout. It will now set a non-expiring timeout. Passing 0 into the memcache backend no longer uses the default timeout, and now will set-and-expire-immediately the value.
• The `django.contrib.flatpages` app used to set custom HTTP headers for debugging purposes. This functionality was not documented and made caching ineffective so it has been removed, along with its generic implementation, previously available in `django.core.xheaders`.

• The `XViewMiddleware` has been moved from `django.middleware.doc` to `django.contrib.admindocs.middleware` because it is an implementation detail of admindocs, proven not to be reusable in general.

• `GenericIPAddressField` will now only allow `blank` values if `null` values are also allowed. Creating a `GenericIPAddressField` where `blank` is allowed but `null` is not will trigger a model validation error because `blank` values are always stored as `null`. Previously, storing a `blank` value in a field which did not allow `null` would cause a database exception at runtime.

• If a `NoReverseMatch` exception is raised from a method when rendering a template, it is not silenced. For example, `{% obj.view_href %}` will cause template rendering to fail if `view_href()` raises `NoReverseMatch`. There is no change to the `{% url %}` tag, it causes template rendering to fail like always when `NoReverseMatch` is raised.

• `django.test.Client.logout()` now calls `django.contrib.auth.logout()` which will send the `user_logged_out()` signal.

• Authentication views are now reversed by name, not their locations in `django.contrib.auth.views`. If you are using the views without a name, you should update your `urlpatterns` to use `django.conf.urls.url()` with the name parameter. For example:

```
(r'^reset/done/$', 'django.contrib.auth.views.password_reset_complete')
```

becomes:

```
url(r'^reset/done/$', 'django.contrib.auth.views.password_reset_complete', name='password_reset_complete')
```

• `RedirectView` now has a `pattern_name` attribute which allows it to choose the target by reversing the URL.

• In Django 1.4 and 1.5, a blank string was unintentionally not considered to be a valid password. This meant `set_password()` would save a blank password as an unusable password like `set_unusable_password()` does, and thus `check_password()` always returned `False` for blank passwords. This has been corrected in this release: blank passwords are now valid.

• The admin `changelist_view` previously accepted a `pop` GET parameter to signify it was to be displayed in a popup. This parameter has been renamed to `.popup` to be consistent with the rest of the admin views. You should update your custom templates if they use the previous parameter name.

• `validate_email()` now accepts email addresses with `localhost` as the domain.

• The new `makemessages --keep-pot` option prevents deleting the temporary `.pot` file generated before creating the `.po` file.
• The undocumented `django.core.servers.basehttp.WSGIServerException` has been removed. Use `socket.error` provided by the standard library instead. This change was also released in Django 1.5.5.

• The signature of `django.views.generic.base.RedirectView.get_redirect_url()` has changed and now accepts positional arguments as well (`*args`, `**kwargs`). Any unnamed captured group will now be passed to `get_redirect_url()` which may result in a `TypeError` if you don’t update the signature of your custom method.

Features deprecated in 1.6

Transaction management APIs

Transaction management was completely overhauled in Django 1.6, and the current APIs are deprecated:

• `django.middleware.transaction.TransactionMiddleware`
• `django.db.transaction.autocommit`
• `django.db.transaction.commit_on_success`
• `django.db.transaction.commit_manually`
• the `TRANSACTIONS_MANAGED` setting

`django.contrib.comments`

Django’s comment framework has been deprecated and is no longer supported. It will be available in Django 1.6 and 1.7, and removed in Django 1.8. Most users will be better served with a custom solution, or a hosted product like Disqus.

The code formerly known as `django.contrib.comments` is still available in an external repository.

Support for PostgreSQL versions older than 8.4

The end of upstream support periods was reached in December 2011 for PostgreSQL 8.2 and in February 2013 for 8.3. As a consequence, Django 1.6 sets 8.4 as the minimum PostgreSQL version it officially supports.

You’re strongly encouraged to use the most recent version of PostgreSQL available, because of performance improvements and to take advantage of the native streaming replication available in PostgreSQL 9.x.
**Changes to `cycle` and `firstof`**

The template system generally escapes all variables to avoid XSS attacks. However, due to an accident of history, the `cycle` and `firstof` tags render their arguments as-is.

Django 1.6 starts a process to correct this inconsistency. The `future` template library provides alternate implementations of `cycle` and `firstof` that autoescape their inputs. If you’re using these tags, you’re encouraged to include the following line at the top of your templates to enable the new behavior:

```{% load cycle from future %}
```

or:

```{% load firstof from future %}
```

The tags implementing the old behavior have been deprecated, and in Django 1.8, the old behavior will be replaced with the new behavior. To ensure compatibility with future versions of Django, existing templates should be modified to use the `future` versions.

If necessary, you can temporarily disable auto-escaping with `mark_safe()` or `{% autoescape off %}`.

**`CACHE_MIDDLEWARE_ANONYMOUS_ONLY` setting**

`CacheMiddleware` and `UpdateCacheMiddleware` used to provide a way to cache requests only if they weren’t made by a logged-in user. This mechanism was largely ineffective because the middleware correctly takes into account the `Vary: Cookie` HTTP header, and this header is being set on a variety of occasions, such as:

- accessing the session, or
- using CSRF protection, which is turned on by default, or
- using a client-side library which sets cookies, like Google Analytics.

This makes the cache effectively work on a per-session basis regardless of the `CACHE_MIDDLEWARE_ANONYMOUS_ONLY` setting.

**`SEND_BROKEN_LINK_EMAILS` setting**

`CommonMiddleware` used to provide basic reporting of broken links by email when `SEND_BROKEN_LINK_EMAILS` is set to `True`.

Because of intractable ordering problems between `CommonMiddleware` and `LocaleMiddleware`, this feature was split out into a new middleware: `BrokenLinkEmailsMiddleware`.

If you’re relying on this feature, you should add `'django.middleware.common.BrokenLinkEmailsMiddleware'` to your `MIDDLEWARE_CLASSES` setting and remove `SEND_BROKEN_LINK_EMAILS` from your settings.
_has_changed method on widgets

If you defined your own form widgets and defined the _has_changed method on a widget, you should now define this method on the form field itself.

module_name model _meta attribute

Model._meta.module_name was renamed to model_name. Despite being a private API, it will go through a regular deprecation path.

get_(add|change|delete)_permission model _meta methods

Model._meta.get_(add|change|delete)_permission methods were deprecated. Even if they were not part of the public API they'll also go through a regular deprecation path. You can replace them with django.contrib.auth.get_permission_codename('action', Model._meta) where 'action' is 'add', 'change', or 'delete'.

get_query_set and similar methods renamed to get_queryset

Methods that return a QuerySet such as Manager.get_query_set or ModelAdmin.queryset have been renamed to get_queryset.

If you are writing a library that implements, for example, a Manager.get_query_set method, and you need to support old Django versions, you should rename the method and conditionally add an alias with the old name:

```python
class CustomManager(models.Manager):
    def get_queryset(self):
        pass # ...

    if django.VERSION < (1, 6):
        get_query_set = get_queryset

    # For Django >= 1.6, models.Manager provides a get_query_set fallback
    # that emits a warning when used.
```

If you are writing a library that needs to call the get_queryset method and must support old Django versions, you should write:

```python
get_queryset = (some_manager.get_query_set
                if hasattr(some_manager, 'get_query_set')
)```
In the general case of a custom manager that both implements its own `get_queryset` method and calls that method, and needs to work with older Django versions, and libraries that have not been updated yet, it is useful to define a `get_queryset_compat` method as below and use it internally to your manager:

```python
class YourCustomManager(models.Manager):
    def get_queryset(self):
        return YourCustomQuerySet() # for example

    if django.VERSION < (1, 6):
        get_query_set = get_queryset

    def active(self): # for example
        return self.get_queryset_compat().filter(active=True)

    def get_queryset_compat(self):
        get_queryset = (self.get_query_set
                        if hasattr(self, 'get_query_set')
                        else self.get_queryset)
        return get_queryset()
```

This helps to minimize the changes that are needed, but also works correctly in the case of subclasses (such as `RelatedManagers` from Django 1.5) which might override either `get_query_set` or `get_queryset`.

**Shortcut view and URLconf**

The shortcut view was moved from `django.views.defaults` to `django.contrib.contenttypes.views` shortly after the 1.0 release, but the old location was never deprecated. This oversight was corrected in Django 1.6 and you should now use the new location.

The URLconf `django.conf.urls.shortcut` was also deprecated. If you’re including it in an URLconf, simply replace:

```python
(r'\^prefix/\', include('django.conf.urls.shortcut')),  
```

with:

```python
(r'\^prefix/(\?P\<content_type_id>\d+)/?(\?P\<object_id>\.*)/\$', 'django.contrib.contenttypes.views.\_\_shortcut'),
```
ModelForm without fields or exclude

Previously, if you wanted a ModelForm to use all fields on the model, you could simply omit the Meta.fields attribute, and all fields would be used.

This can lead to security problems where fields are added to the model and, unintentionally, automatically become editable by end users. In some cases, particular with boolean fields, it is possible for this problem to be completely invisible. This is a form of Mass assignment vulnerability.

For this reason, this behavior is deprecated, and using the Meta.exclude option is strongly discouraged. Instead, all fields that are intended for inclusion in the form should be listed explicitly in the fields attribute.

If this security concern really does not apply in your case, there is a shortcut to explicitly indicate that all fields should be used - use the special value "__all__" for the fields attribute:

```python
class MyModelForm(ModelForm):
    class Meta:
        fields = "__all__"
        model = MyModel
```

If you have custom ModelForms that only need to be used in the admin, there is another option. The admin has its own methods for defining fields (fieldsets etc.), and so adding a list of fields to the ModelForm is redundant. Instead, simply omit the Meta inner class of the ModelForm, or omit the Meta.model attribute. Since the ModelAdmin subclass knows which model it is for, it can add the necessary attributes to derive a functioning ModelForm. This behavior also works for earlier Django versions.

UpdateView and CreateView without explicit fields

The generic views CreateView and UpdateView, and anything else derived from ModelFormMixin, are vulnerable to the security problem described in the section above, because they can automatically create a ModelForm that uses all fields for a model.

For this reason, if you use these views for editing models, you must also supply the fields attribute (new in Django 1.6), which is a list of model fields and works in the same way as the ModelForm Meta.fields attribute. Alternatively, you can set the form_class attribute to a ModelForm that explicitly defines the fields to be used. Defining an UpdateView or CreateView subclass to be used with a model but without an explicit list of fields is deprecated.
Munging of help text of model form fields for ManyToManyField fields

All special handling of the help_text attribute of ManyToManyField model fields performed by standard model or model form fields as described in Help text of model form fields for ManyToManyField fields above is deprecated and will be removed in Django 1.8.

Help text of these fields will need to be handled either by applications, custom form fields or widgets, just like happens with the rest of the model field types.

9.1.16 1.5 release

Django 1.5.12 release notes

January 2, 2015

Django 1.5.12 fixes a regression in the 1.5.9 security release.

Bugfixes

- Fixed a regression with dynamically generated inlines and allowed field references in the admin (#23754).

Django 1.5.11 release notes

October 22, 2014

Django 1.5.11 fixes a couple regressions in the 1.5.9 security release.

Bugfixes

- Allowed related many-to-many fields to be referenced in the admin (#23604).
- Allowed inline and hidden references to admin fields (#23431).

Django 1.5.10 release notes

September 2, 2014

Django 1.5.10 fixes a regression in the 1.5.9 security release.
Bugfixes

- Allowed inherited and m2m fields to be referenced in the admin (#22486)

Django 1.5.9 release notes

August 20, 2014

Django 1.5.9 fixes several security issues in 1.5.8.

**reverse() could generate URLs pointing to other hosts**

In certain situations, URL reversing could generate scheme-relative URLs (URLs starting with two slashes), which could unexpectedly redirect a user to a different host. An attacker could exploit this, for example, by redirecting users to a phishing site designed to ask for user’s passwords.

To remedy this, URL reversing now ensures that no URL starts with two slashes (//), replacing the second slash with its URL encoded counterpart (%2F). This approach ensures that semantics stay the same, while making the URL relative to the domain and not to the scheme.

**File upload denial-of-service**

Before this release, Django’s file upload handing in its default configuration may degrade to producing a huge number of os.stat() system calls when a duplicate filename is uploaded. Since stat() may invoke IO, this may produce a huge data-dependent slowdown that slowly worsens over time. The net result is that given enough time, a user with the ability to upload files can cause poor performance in the upload handler, eventually causing it to become very slow simply by uploading 0-byte files. At this point, even a slow network connection and few HTTP requests would be all that is necessary to make a site unavailable.

We’ve remedied the issue by changing the algorithm for generating file names if a file with the uploaded name already exists. Storage.get_available_name() now appends an underscore plus a random 7 character alphanumeric string (e.g. "_x3a1gho"), rather than iterating through an underscore followed by a number (e.g. "_1", "_2", etc.).

**RemoteUserMiddleware session hijacking**

When using the RemoteUserMiddleware and the RemoteUserBackend, a change to the REMOTE_USER header between requests without an intervening logout could result in the prior user’s session being co-opted by the subsequent user. The middleware now logs the user out on a failed login attempt.
Data leakage via query string manipulation in contrib.admin

In older versions of Django it was possible to reveal any field’s data by modifying the “popup” and “to_field” parameters of the query string on an admin change form page. For example, requesting a URL like /admin/auth/user/?pop=1&t=password and viewing the page’s HTML allowed viewing the password hash of each user. While the admin requires users to have permissions to view the change form pages in the first place, this could leak data if you rely on users having access to view only certain fields on a model.

To address the issue, an exception will now be raised if a to_field value that isn’t a related field to a model that has been registered with the admin is specified.

Django 1.5.8 release notes

May 14, 2014

Django 1.5.8 fixes two security issues in 1.5.8.

Caches may incorrectly be allowed to store and serve private data

In certain situations, Django may allow caches to store private data related to a particular session and then serve that data to requests with a different session, or no session at all. This can lead to information disclosure and can be a vector for cache poisoning.

When using Django sessions, Django will set a Vary: Cookie header to ensure caches do not serve cached data to requests from other sessions. However, older versions of Internet Explorer (most likely only Internet Explorer 6, and Internet Explorer 7 if run on Windows XP or Windows Server 2003) are unable to handle the Vary header in combination with many content types. Therefore, Django would remove the header if the request was made by Internet Explorer.

To remedy this, the special behavior for these older Internet Explorer versions has been removed, and the Vary header is no longer stripped from the response. In addition, modifications to the Cache-Control header for all Internet Explorer requests with a Content-Disposition header have also been removed as they were found to have similar issues.

Malformed redirect URLs from user input not correctly validated

The validation for redirects did not correctly validate some malformed URLs, which are accepted by some browsers. This allows a user to be redirected to an unsafe URL unexpectedly.

Django relies on user input in some cases (e.g. django.contrib.auth.views.login(), django.contrib.comments, and i18n) to redirect the user to an “on success” URL. The security checks for these redirects (namely django.utils.http.is_safe_url()) did not correctly validate some malformed URLs, such as http:\\\djangoproject.com, which are accepted by some browsers with more liberal URL parsing.
To remedy this, the validation in `is_safe_url()` has been tightened to be able to handle and correctly validate these malformed URLs.

**Django 1.5.7 release notes**

April 28, 2014

Django 1.5.7 fixes a regression in the 1.5.6 security release.

**Bugfixes**

- Restored the ability to `reverse()` views created using `functools.partial()` (#22486).

**Django 1.5.6 release notes**

April 21, 2014

Django 1.5.6 fixes several bugs in 1.5.5, including three security issues.

**Unexpected code execution using `reverse()`**

Django’s URL handling is based on a mapping of regex patterns (representing the URLs) to callable views, and Django’s own processing consists of matching a requested URL against those patterns to determine the appropriate view to invoke.

Django also provides a convenience function – `reverse()` – which performs this process in the opposite direction. The `reverse()` function takes information about a view and returns a URL which would invoke that view. Use of `reverse()` is encouraged for application developers, as the output of `reverse()` is always based on the current URL patterns, meaning developers do not need to change other code when making changes to URLs.

One argument signature for `reverse()` is to pass a dotted Python path to the desired view. In this situation, Django will import the module indicated by that dotted path as part of generating the resulting URL. If such a module has import-time side effects, those side effects will occur.

Thus it is possible for an attacker to cause unexpected code execution, given the following conditions:

1. One or more views are present which construct a URL based on user input (commonly, a “next” parameter in a querystring indicating where to redirect upon successful completion of an action).
2. One or more modules are known to an attacker to exist on the server’s Python import path, which perform code execution with side effects on importing.

To remedy this, `reverse()` will now only accept and import dotted paths based on the view-containing modules listed in the project’s URL pattern configuration, so as to ensure that only modules the developer intended to be imported in this fashion can or will be imported.
Caching of anonymous pages could reveal CSRF token

Django includes both a caching framework and a system for preventing cross-site request forgery (CSRF) attacks. The CSRF-protection system is based on a random nonce sent to the client in a cookie which must be sent by the client on future requests and, in forms, a hidden value which must be submitted back with the form.

The caching framework includes an option to cache responses to anonymous (i.e., unauthenticated) clients. When the first anonymous request to a given page is by a client which did not have a CSRF cookie, the cache framework will also cache the CSRF cookie and serve the same nonce to other anonymous clients who do not have a CSRF cookie. This can allow an attacker to obtain a valid CSRF cookie value and perform attacks which bypass the check for the cookie.

To remedy this, the caching framework will no longer cache such responses. The heuristic for this will be:

1. If the incoming request did not submit any cookies, and
2. If the response did send one or more cookies, and
3. If the Vary: Cookie header is set on the response, then the response will not be cached.

MySQL typecasting

The MySQL database is known to “typecast” on certain queries; for example, when querying a table which contains string values, but using a query which filters based on an integer value, MySQL will first silently coerce the strings to integers and return a result based on that.

If a query is performed without first converting values to the appropriate type, this can produce unexpected results, similar to what would occur if the query itself had been manipulated.

Django’s model field classes are aware of their own types and most such classes perform explicit conversion of query arguments to the correct database-level type before querying. However, three model field classes did not correctly convert their arguments:

- `FilePathField`
- `GenericIPAddressField`
- `IPAddressField`

These three fields have been updated to convert their arguments to the correct types before querying.

Additionally, developers of custom model fields are now warned via documentation to ensure their custom field classes will perform appropriate type conversions, and users of the `raw()` and `extra()` query methods—which allow the developer to supply raw SQL or SQL fragments—will be advised to ensure they perform appropriate manual type conversions prior to executing queries.
Bugfixes

- Fixed `ModelBackend` raising `UnboundLocalError` if `get_user_model()` raised an error (#21439).

Additionally, Django’s vendored version of six, `django.utils.six`, has been upgraded to the latest release (1.6.1).

Django 1.5.5 release notes

October 23, 2013

Django 1.5.5 fixes a couple security-related bugs and several other bugs in the 1.5 series.

Readdressed denial-of-service via password hashers

Django 1.5.4 imposes a 4096-byte limit on passwords in order to mitigate a denial-of-service attack through submission of bogus but extremely large passwords. In Django 1.5.5, we’ve reverted this change and instead improved the speed of our PBKDF2 algorithm by not rehashing the key on every iteration.

Properly rotate CSRF token on login

This behavior introduced as a security hardening measure in Django 1.5.2 did not work properly and is now fixed.

Bugfixes

- Fixed a data corruption bug with `datetime_safe.datetime.combine` (#21256).
- Fixed a Python 3 incompatibility in `django.utils.text.unescape_entities()` (#21185).
- Fixed a couple data corruption issues with `QuerySet` edge cases under Oracle and MySQL (#21203, #21126).
- Fixed crashes when using combinations of `annotate()`, `select_related()`, and `only()` (#16436).

Backwards incompatible changes

- The undocumented `django.core.servers.basehttp.WSGIErrorException` has been removed. Use `socket.error` provided by the standard library instead.
Django 1.5.4 release notes

September 14, 2013

This is Django 1.5.4, the fourth release in the Django 1.5 series. It addresses two security issues and one bug.

Denial-of-service via password hashers

In previous versions of Django, no limit was imposed on the plaintext length of a password. This allowed a denial-of-service attack through submission of bogus but extremely large passwords, tying up server resources performing the (expensive, and increasingly expensive with the length of the password) calculation of the corresponding hash.

As of 1.5.4, Django’s authentication framework imposes a 4096-byte limit on passwords, and will fail authentication with any submitted password of greater length.

Corrected usage of sensitive_post_parameters() in django.contrib.auth’s admin

The decoration of the add_view and user_change_password user admin views with sensitive_post_parameters() did not include method_decorator() (required since the views are methods) resulting in the decorator not being properly applied. This usage has been fixed and sensitive_post_parameters() will now throw an exception if it’s improperly used.

Bugfixes

- Fixed a bug that prevented a QuerySet that uses prefetch_related() from being pickled and unpickled more than once (the second pickling attempt raised an exception) (#21102).

Django 1.5.3 release notes

September 10, 2013

This is Django 1.5.3, the third release in the Django 1.5 series. It addresses one security issue and also contains an opt-in feature to enhance the security of django.contrib.sessions.
Directory traversal vulnerability in ssi template tag

In previous versions of Django it was possible to bypass the ALLOWED_INCLUDE_ROOTS setting used for security with the ssi template tag by specifying a relative path that starts with one of the allowed roots. For example, if ALLOWED_INCLUDE_ROOTS = ("/var/www",) the following would be possible:

```
{% ssi "/var/www/../../etc/passwd" %}
```

In practice this is not a very common problem, as it would require the template author to put the ssi file in a user-controlled variable, but it’s possible in principle.

Mitigating a remote-code execution vulnerability in django.contrib.sessions

django.contrib.sessions currently uses pickle to serialize session data before storing it in the backend. If you’re using the signed cookie session backend and SECRET_KEY is known by an attacker (there isn’t an inherent vulnerability in Django that would cause it to leak), the attacker could insert a string into their session which, when unpickled, executes arbitrary code on the server. The technique for doing so is simple and easily available on the internet. Although the cookie session storage signs the cookie-stored data to prevent tampering, a SECRET_KEY leak immediately escalates to a remote code execution vulnerability.

This attack can be mitigated by serializing session data using JSON rather than pickle. To facilitate this, Django 1.5.3 introduces a new setting, SESSION_SERIALIZER, to customize the session serialization format. For backwards compatibility, this setting defaults to using pickle. While JSON serialization does not support all Python objects like pickle does, we highly recommend switching to JSON-serialized values. Also, as JSON requires string keys, you will likely run into problems if you are using non-string keys in request.session. See the Session serialization documentation for more details.

Django 1.5.2 release notes

August 13, 2013

This is Django 1.5.2, a bugfix and security release for Django 1.5.

Mitigated possible XSS attack via user-supplied redirect URLs

Django relies on user input in some cases (e.g. django.contrib.auth.views.login(), django.contrib.comments, and i18n) to redirect the user to an “on success” URL. The security checks for these redirects (namely django.utils.http.is_safe_url()) didn’t check if the scheme is http(s) and as such allowed javascript:... URLs to be entered. If a developer relied on is_safe_url() to provide safe redirect targets and put such a URL into a link, they could suffer from a XSS attack. This bug doesn’t affect Django currently, since we only put this URL into the Location response header and browsers seem to ignore JavaScript there.
XSS vulnerability in `django.contrib.admin`

If a `URLField` is used in Django 1.5, it displays the current value of the field and a link to the target on the admin change page. The display routine of this widget was flawed and allowed for XSS.

**Bugfixes**

- Fixed a crash with `prefetch_related()` (#19607) as well as some pickle regressions with `prefetch_related` (#20157 and #20257).
- Fixed a regression in `django.contrib.gis` in the Google Map output on Python 3 (#20773).
- Made `DjangoTestSuiteRunner.setup_databases` properly handle aliases for the default database (#19940) and prevented `teardown_databases` from attempting to tear down aliases (#20681).
- Fixed the `django.core.cache.backends.memcached.MemcachedCache` backend’s `get_many()` method on Python 3 (#20722).
- Fixed `django.contrib.humanize` translation syntax errors. Affected languages: Mexican Spanish, Mongolian, Romanian, Turkish (#20695).
- Added support for wheel packages (#19252).
- The CSRF token now rotates when a user logs in.
- Some Python 3 compatibility fixes including #20212 and #20025.
- Fixed some rare cases where `get()` exceptions recursed infinitely (#20278).
- `makemessages` no longer crashes with `UnicodeDecodeError` (#20354).
- Fixed `geojson` detection with Spatialite.
- `assertContains()` once again works with binary content (#20237).
- Fixed `ManyToManyField` if it has a Unicode `name` parameter (#20207).
- Ensured that the WSGI request’s path is correctly based on the `SCRIPT_NAME` environment variable or the `FORCE_SCRIPT_NAME` setting, regardless of whether or not either has a trailing slash (#20169).
- Fixed an obscure bug with the `override_settings()` decorator. If you hit an `AttributeError: 'Settings' object has no attribute '_original_allowed_hosts'` exception, it’s probably fixed (#20636).
Django 1.5.1 release notes

March 28, 2013

This is Django 1.5.1, a bugfix release for Django 1.5. It’s completely backwards compatible with Django 1.5, but includes a handful of fixes.

The biggest fix is for a memory leak introduced in Django 1.5. Under certain circumstances, repeated iteration over querysets could leak memory - sometimes quite a bit of it. If you’d like more information, the details are in our ticket tracker (and in a related issue in Python itself).

If you’ve noticed memory problems under Django 1.5, upgrading to 1.5.1 should fix those issues.

Django 1.5.1 also includes a couple smaller fixes:

- Module-level warnings emitted during tests are no longer silently hidden (#18985).
- Prevented filtering on password hashes in the user admin (#20078).

Django 1.5 release notes

February 26, 2013

Welcome to Django 1.5!

These release notes cover the new features, as well as some backwards incompatible changes you’ll want to be aware of when upgrading from Django 1.4 or older versions. We’ve also dropped some features, which are detailed in our deprecation plan, and we’ve begun the deprecation process for some features.

Overview

The biggest new feature in Django 1.5 is the configurable User model. Before Django 1.5, applications that wanted to use Django’s auth framework (django.contrib.auth) were forced to use Django’s definition of a “user”. In Django 1.5, you can now swap out the User model for one that you write yourself. This could be a simple extension to the existing User model – for example, you could add a Twitter or Facebook ID field – or you could completely replace the User with one totally customized for your site.

Django 1.5 is also the first release with Python 3 support! We’re labeling this support “experimental” because we don’t yet consider it production-ready, but everything’s in place for you to start porting your apps to Python 3. Our next release, Django 1.6, will support Python 3 without reservations.

Other notable new features in Django 1.5 include:

- Support for saving a subset of model’s fields - Model.save() now accepts an update_fields argument, letting you specify which fields are written back to the database when you call save(). This can help in high-concurrency operations, and can improve performance.
- Better support for streaming responses via the new StreamingHttpResponse response class.
• GeoDjango now supports PostGIS 2.0.

• ... and more; see below.

Wherever possible we try to introduce new features in a backwards-compatible manner per our API stability policy. However, as with previous releases, Django 1.5 ships with some minor backwards incompatible changes; people upgrading from previous versions of Django should read that list carefully.

One deprecated feature worth noting is the shift to “new-style” url tag. Prior to Django 1.3, syntax like {% url myview %} was interpreted incorrectly (Django considered "myview" to be a literal name of a view, not a template variable named myview). Django 1.3 and above introduced the {% load url from future %} syntax to bring in the corrected behavior where myview was seen as a variable.

The upshot of this is that if you are not using {% load url from future %} in your templates, you’ll need to change tags like {% url myview %} to {% url "myview" %}. If you were using {% load url from future %} you can simply remove that line under Django 1.5.

Python compatibility

Django 1.5 requires Python 2.6.5 or above, though we highly recommend Python 2.7.3 or above. Support for Python 2.5 and below has been dropped.

This change should affect only a small number of Django users, as most operating-system vendors today are shipping Python 2.6 or newer as their default version. If you’re still using Python 2.5, however, you’ll need to stick to Django 1.4 until you can upgrade your Python version. Per our support policy, Django 1.4 will continue to receive security support until the release of Django 1.6.

Django 1.5 does not run on a Jython final release, because Jython’s latest release doesn’t currently support Python 2.6. However, Jython currently does offer an alpha release featuring 2.7 support, and Django 1.5 supports that alpha release.

Python 3 support

Django 1.5 introduces support for Python 3 - specifically, Python 3.2 and above. This comes in the form of a single codebase; you don’t need to install a different version of Django on Python 3. This means that you can write applications targeted for just Python 2, just Python 3, or single applications that support both platforms.

However, we’re labeling this support “experimental” for now: although it’s received extensive testing via our automated test suite, it’s received very little real-world testing. We’ve done our best to eliminate bugs, but we can’t be sure we covered all possible uses of Django.

Some features of Django aren’t available because they depend on third-party software that hasn’t been ported to Python 3 yet, including:

• the MySQL database backend (depends on MySQLdb)
• **ImageField** (depends on PIL)

• **LiveServerTestCase** (depends on Selenium WebDriver)

Further, Django’s more than a web framework; it’s an ecosystem of pluggable components. At this point, very few third-party applications have been ported to Python 3, so it’s unlikely that a real-world application will have all its dependencies satisfied under Python 3.

Thus, we’re recommending that Django 1.5 not be used in production under Python 3. Instead, use this opportunity to begin porting applications to Python 3. If you’re an author of a pluggable component, we encourage you to start porting now.

We plan to offer first-class, production-ready support for Python 3 in our next release, Django 1.6.

**What’s new in Django 1.5**

**Configurable User model**

In Django 1.5, you can now use your own model as the store for user-related data. If your project needs a username with more than 30 characters, or if you want to store user’s names in a format other than first name/last name, or you want to put custom profile information onto your User object, you can now do so.

If you have a third-party reusable application that references the User model, you may need to make some changes to the way you reference User instances. You should also document any specific features of the User model that your application relies upon.

See the [documentation on custom user models](#) for more details.

**Support for saving a subset of model’s fields**

The method `Model.save()` has a new keyword argument `update_fields`. By using this argument it is possible to save only a select list of model’s fields. This can be useful for performance reasons or when trying to avoid overwriting concurrent changes.

Deferred instances (those loaded by `.only()` or `.defer()`) will automatically save just the loaded fields. If any field is set manually after load, that field will also get updated on save.

See the `Model.save()` documentation for more details.
Caching of related model instances

When traversing relations, the ORM will avoid re-fetching objects that were previously loaded. For example, with the tutorial’s models:

```python
>>> first_poll = Poll.objects.all()[0]
>>> first_choice = first_poll.choice_set.all()[0]
>>> first_choice.poll is first_poll
True
```

In Django 1.5, the third line no longer triggers a new SQL query to fetch `first_choice.poll`; it was set by the second line.

For one-to-one relationships, both sides can be cached. For many-to-one relationships, only the single side of the relationship can be cached. This is particularly helpful in combination with `prefetch_related`.

Explicit support for streaming responses

Before Django 1.5, it was possible to create a streaming response by passing an iterator to `HttpResponse`. But this was unreliable: any middleware that accessed the `content` attribute would consume the iterator prematurely.

You can now explicitly generate a streaming response with the new `StreamingHttpResponse` class. This class exposes a `streaming_content` attribute which is an iterator.

Since `StreamingHttpResponse` does not have a `content` attribute, middleware that needs access to the response content must test for streaming responses and behave accordingly.

```template
text
%
```

To make it easier to deal with JavaScript templates which collide with Django’s syntax, you can now use the `verbatim` block tag to avoid parsing the tag’s content.

Retrieval of `ContentType` instances associated with proxy models

The methods `ContentTypeManager.get_for_model()` and `ContentTypeManager.get_for_models()` have a new keyword argument –respectively `for_concrete_model` and `for_concrete_models`. By passing `False` using this argument it is now possible to retrieve the `ContentType` associated with proxy models.
New view variable in class-based views context

In all generic class-based views (or any class-based view inheriting from `ContextMixin`), the context dictionary contains a `view` variable that points to the `View` instance.

GeoDjango

- `LineString` and `MultiLineString` GEOS objects now support the `interpolate()` and `project()` methods (so-called linear referencing).
- The `wkb` and `hex` properties of `GEOSGeometry` objects preserve the Z dimension.
- Support for PostGIS 2.0 has been added and support for GDAL < 1.5 has been dropped.

New tutorials

Additions to the docs include a revamped Tutorial 3 and a new tutorial on testing. A new section, “Advanced Tutorials”, offers How to write reusable apps as well as a step-by-step guide for new contributors in Writing your first patch for Django.

Minor features

Django 1.5 also includes several smaller improvements worth noting:

- The template engine now interprets `True`, `False` and `None` as the corresponding Python objects.
- `django.utils.timezone` provides a helper for converting aware datetimes between time zones. See `localtime()`.
- The generic views support OPTIONS requests.
- Management commands do not raise `SystemExit` any more when called by code from `call_command()`. Any exception raised by the command (mostly `CommandError`) is propagated.
  
  Moreover, when you output errors or messages in your custom commands, you should now use `self.stdout.write('message')` and `self.stderr.write('error')` (see the note on management commands output).
- The `dumpdata` management command outputs one row at a time, preventing out-of-memory errors when dumping large datasets.
- In the local flavor for Canada, `pq` was added to the acceptable codes for Quebec. It’s an old abbreviation.
- The `receiver` decorator is now able to connect to more than one signal by supplying a list of signals.
- In the admin, you can now filter users by groups which they are members of.
• `QuerySet.bulk_create()` now has a batch_size argument. By default the batch_size is unlimited except for SQLite where single batch is limited so that 999 parameters per query isn’t exceeded.

• The `LOGIN_URL` and `LOGIN_REDIRECT_URL` settings now also accept view function names and named URL patterns. This allows you to reduce configuration duplication. More information can be found in the `login_required()` documentation.

• Django now provides a mod_wsgi auth handler.

• The `QuerySet.delete()` and `Model.delete()` can now take fast-path in some cases. The fast-path allows for less queries and less objects fetched into memory. See `QuerySet.delete()` for details.

• An instance of `ResolverMatch` is stored on the request as `resolver_match`.

• By default, all logging messages reaching the django logger when `DEBUG` is True are sent to the console (unless you redefine the logger in your `LOGGING` setting).

• When using `RequestContext`, it is now possible to look up permissions by using `{% if 'someapp.someperm' in perms %}` in templates.

• It’s not required any more to have `404.html` and `500.html` templates in the root templates directory. Django will output some basic error messages for both situations when those templates are not found. It’s still recommended as good practice to provide those templates in order to present pretty error pages to the user.

• `django.contrib.auth` provides a new signal that is emitted whenever a user fails to login successfully. See `user_login_failed`

• The new `loaddata --ignorenonexistent` option ignore data for fields that no longer exist.

• `assertXMLEqual()` and `assertXMLNotEqual()` new assertions allow you to test equality for XML content at a semantic level, without caring for syntax differences (spaces, attribute order, etc.).

• RemoteUserMiddleware now forces logout when the REMOTE_USER header disappears during the same browser session.

• The cache-based session backend can store session data in a non-default cache.

• Multi-column indexes can now be created on models. Read the `index_together` documentation for more information.

• During Django’s logging configuration verbose Deprecation warnings are enabled and warnings are captured into the logging system. Logged warnings are routed through the `console` logging handler, which by default requires `DEBUG` to be True for output to be generated. The result is that DeprecationWarnings should be printed to the console in development environments the way they have been in Python versions < 2.7.

• The API for `django.contrib.admin.ModelAdmin.message_user()` method has been modified to accept additional arguments adding capabilities similar to `django.contrib.messages.add_message()`. This is useful for generating error messages from admin actions.
• The admin’s list filters can now be customized per-request thanks to the new `django.contrib.admin.ModelAdmin.get_list_filter()` method.

Backwards incompatible changes in 1.5

Warning: In addition to the changes outlined in this section, be sure to review the deprecation plan for any features that have been removed. If you haven’t updated your code within the deprecation timeline for a given feature, its removal may appear as a backwards incompatible change.

`ALLOWED_HOSTS` required in production

The new `ALLOWED_HOSTS` setting validates the request’s `Host` header and protects against host-poisoning attacks. This setting is now required whenever `DEBUG` is `False`, or else `django.http.HttpRequest.get_host()` will raise `SuspiciousOperation`. For more details see the full documentation for the new setting.

Managers on abstract models

Abstract models are able to define a custom manager, and that manager will be inherited by any concrete models extending the abstract model. However, if you try to use the abstract model to call a method on the manager, an exception will now be raised. Previously, the call would have been permitted, but would have failed as soon as any database operation was attempted (usually with a “table does not exist” error from the database).

If you have functionality on a manager that you have been invoking using the abstract class, you should migrate that logic to a Python `staticmethod` or `classmethod` on the abstract class.

Context in year archive class-based views

For consistency with the other date-based generic views, `YearArchiveView` now passes `year` in the context as a `datetime.date` rather than a string. If you are using `{{ year }}` in your templates, you must replace it with `{{ year|date:"Y" }}`.

`next_year` and `previous_year` were also added in the context. They are calculated according to `allow_empty` and `allow_future`. 
Context in year and month archive class-based views

YearArchiveView and MonthArchiveView were documented to provide a date_list sorted in ascending order in the context, like their function-based predecessors, but it actually was in descending order. In 1.5, the documented order was restored. You may want to add (or remove) the reversed keyword when you’re iterating on date_list in a template:

```latex
{% for date in date_list reversed %}
```

ArchiveIndexView still provides a date_list in descending order.

Context in TemplateView

For consistency with the design of the other generic views, TemplateView no longer passes a params dictionary into the context, instead passing the variables from the URLconf directly into the context.

Non-form data in HTTP requests

request.POST will no longer include data posted via HTTP requests with non form-specific content-types in the header. In prior versions, data posted with content-types other than multipart/form-data or application/x-www-form-urlencoded would still end up represented in the request.POST attribute. Developers wishing to access the raw POST data for these cases, should use the request.body attribute instead.

request_finished signal

Django used to send the request_finished signal as soon as the view function returned a response. This interacted badly with streaming responses that delay content generation.

This signal is now sent after the content is fully consumed by the WSGI gateway. This might be backwards incompatible if you rely on the signal being fired before sending the response content to the client. If you do, you should consider using middleware instead.

Note: Some WSGI servers and middleware do not always call close on the response object after handling a request, most notably uWSGI prior to 1.2.6 and Sentry’s error reporting middleware up to 2.0.7. In those cases the request_finished signal isn’t sent at all. This can result in idle connections to database and memcache servers.
OPTIONS, PUT and DELETE requests in the test client

Unlike GET and POST, these HTTP methods aren’t implemented by web browsers. Rather, they’re used in APIs, which transfer data in various formats such as JSON or XML. Since such requests may contain arbitrary data, Django doesn’t attempt to decode their body.

However, the test client used to build a query string for OPTIONS and DELETE requests like for GET, and a request body for PUT requests like for POST. This encoding was arbitrary and inconsistent with Django’s behavior when it receives the requests, so it was removed in Django 1.5.

If you were using the data parameter in an OPTIONS or a DELETE request, you must convert it to a query string and append it to the path parameter.

If you were using the data parameter in a PUT request without a content_type, you must encode your data before passing it to the test client and set the content_type argument.

System version of simplejson no longer used

As explained below, Django 1.5 deprecates django.utils.simplejson in favor of Python 2.6’s built-in json module. In theory, this change is harmless. Unfortunately, because of incompatibilities between versions of simplejson, it may trigger errors in some circumstances.

JSON-related features in Django 1.4 always used django.utils.simplejson. This module was actually:

- A system version of simplejson, if one was available (i.e. import simplejson works), if it was more recent than Django’s built-in copy or it had the C speedups, or
- The json module from the standard library, if it was available (i.e. Python 2.6 or greater), or
- A built-in copy of version 2.0.7 of simplejson.

In Django 1.5, those features use Python’s json module, which is based on version 2.0.9 of simplejson.

There are no known incompatibilities between Django’s copy of version 2.0.7 and Python’s copy of version 2.0.9. However, there are some incompatibilities between other versions of simplejson:

- While the simplejson API is documented as always returning Unicode strings, the optional C implementation can return a bytestring. This was fixed in Python 2.7.
- simplejson.JSONEncoder gained a namedtuple_as_object keyword argument in version 2.2.

More information on these incompatibilities is available in ticket #18023.

The net result is that, if you have installed simplejson and your code uses Django’s serialization internals directly — for instance django.core.serializers.json.DjangoJSONEncoder, the switch from simplejson to json could break your code. (In general, changes to internals aren’t documented; we’re making an exception here.)

At this point, the maintainers of Django believe that using json from the standard library offers the strongest guarantee of backwards-compatibility. They recommend to use it from now on.
String types of hasher method parameters

If you have written a custom password hasher, your `encode()`, `verify()` or `safe_summary()` methods should accept Unicode parameters (password, salt or encoded). If any of the hashing methods need bytestrings, you can use the `force_bytes()` utility to encode the strings.

Validation of previous_page_number and next_page_number

When using object pagination, the `previous_page_number()` and `next_page_number()` methods of the `Page` object did not check if the returned number was inside the existing page range. It does check it now and raises an `InvalidPage` exception when the number is either too low or too high.

Behavior of autocommit database option on PostgreSQL changed

PostgreSQL’s autocommit option didn’t work as advertised previously. It did work for single transaction block, but after the first block was left the autocommit behavior was never restored. This bug is now fixed in 1.5. While this is only a bug fix, it is worth checking your applications behavior if you are using PostgreSQL together with the autocommit option.

Session not saved on 500 responses

Django’s session middleware will skip saving the session data if the response’s status code is 500.

Email checks on failed admin login

Prior to Django 1.5, if you attempted to log into the admin interface and mistakenly used your email address instead of your username, the admin interface would provide a warning advising that your email address was not your username. In Django 1.5, the introduction of custom user models has required the removal of this warning. This doesn’t change the login behavior of the admin site; it only affects the warning message that is displayed under one particular mode of login failure.

Changes in tests execution

Some changes have been introduced in the execution of tests that might be backward-incompatible for some testing setups:
Database flushing in `django.test.TransactionTestCase`

Previously, the test database was truncated before each test run in a `TransactionTestCase`. In order to be able to run unit tests in any order and to make sure they are always isolated from each other, `TransactionTestCase` will now reset the database after each test run instead.

No more implicit DB sequences reset

`TransactionTestCase` tests used to reset primary key sequences automatically together with the database flushing actions described above. This has been changed so no sequences are implicitly reset. This can cause `TransactionTestCase` tests that depend on hard-coded primary key values to break.

The new `reset_sequences` attribute can be used to force the old behavior for `TransactionTestCase` that might need it.

Ordering of tests

In order to make sure all `TestCase` code starts with a clean database, tests are now executed in the following order:

- First, all unit tests (including `unittest.TestCase`, `SimpleTestCase`, `TestCase` and `TransactionTestCase`) are run with no particular ordering guaranteed nor enforced among them.
- Then any other tests (e.g. doctests) that may alter the database without restoring it to its original state are run.

This should not cause any problems unless you have existing doctests which assume a `TransactionTestCase` executed earlier left some database state behind or unit tests that rely on some form of state being preserved after the execution of other tests. Such tests are already very fragile, and must now be changed to be able to run independently.

`cleaned_data` dictionary kept for invalid forms

The `cleaned_data` dictionary is now always present after form validation. When the form doesn’t validate, it contains only the fields that passed validation. You should test the success of the validation with the `is_valid()` method and not with the presence or absence of the `cleaned_data` attribute on the form.
Behavior of `syncdb` with multiple databases

`syncdb` now queries the database routers to determine if content types (when `contenttypes` is enabled) and permissions (when `auth` is enabled) should be created in the target database. Previously, it created them in the default database, even when another database was specified with the `--database` option.

If you use `syncdb` on multiple databases, you should ensure that your routers allow synchronizing content types and permissions to only one of them. See the docs on the behavior of contrib apps with multiple databases for more information.

XML deserializer will not parse documents with a DTD

In order to prevent exposure to denial-of-service attacks related to external entity references and entity expansion, the XML model deserializer now refuses to parse XML documents containing a DTD (DOCTYPE definition). Since the XML serializer does not output a DTD, this will not impact typical usage, only cases where custom-created XML documents are passed to Django’s model deserializer.

Formsets default `max_num`

A (default) value of `None` for the `max_num` argument to a formset factory no longer defaults to allowing any number of forms in the formset. Instead, in order to prevent memory-exhaustion attacks, it now defaults to a limit of 1000 forms. This limit can be raised by explicitly setting a higher value for `max_num`.

Miscellaneous

- `django.forms.ModelMultipleChoiceField` now returns an empty `QuerySet` as the empty value instead of an empty list.
- `int_to_base36()` properly raises a `TypeError` instead of `ValueError` for non-integer inputs.
- The `slugify` template filter is now available as a standard Python function at `django.utils.text.slugify()`. Similarly, `remove_tags` is available at `django.utils.html.remove_tags()`.
- Uploaded files are no longer created as executable by default. If you need them to be executable change `FILE_UPLOAD_PERMISSIONS` to your needs. The new default value is 0o666 (octal) and the current umask value is first masked out.
- The `F expressions` supported bitwise operators by `&` and `|`. These operators are now available using `.bitand()` and `.bitor()` instead. The removal of `&` and `|` was done to be consistent with `Q()` expressions and `QuerySet` combining where the operators are used as boolean AND and OR operators.
- In a `filter()` call, when `F expressions` contained lookups spanning multi-valued relations, they didn’t always reuse the same relations as other lookups along the same chain. This was changed, and now `F()` expressions will always use the same relations as other lookups within the same `filter()` call.

- The `csrf_token` template tag is no longer enclosed in a div. If you need HTML validation against pre-HTML5 Strict DTDs, you should add a div around it in your pages.

- The template tags library `adminmedia`, which only contained the deprecated template tag `{% admin_media_prefix %}`, was removed. Attempting to load it with `{% load adminmedia %}` will fail. If your templates still contain that line you must remove it.

- Because of an implementation oversight, it was possible to use `django.contrib.redirects` without enabling `django.contrib.sites`. This isn’t allowed any longer. If you’re using `django.contrib.redirects`, make sure `INSTALLED_APPS` contains `django.contrib.sites`.

- `BoundField.label_tag` now escapes its `contents` argument. To avoid the HTML escaping, use `django.utils.safestring.mark_safe()` on the argument before passing it.

- Accessing reverse one-to-one relations fetched via `select_related()` now raises `DoesNotExist` instead of returning `None`.

**Features deprecated in 1.5**

`django.contrib.localflavor`

The `localflavor` contrib app has been split into separate packages. `django.contrib.localflavor` itself will be removed in Django 1.6, after an accelerated deprecation.

The new packages are available on GitHub. The core team cannot efficiently maintain these packages in the long term — it spans just a dozen countries at this time; similar to translations, maintenance will be handed over to interested members of the community.

`django.contrib.markup`

The markup contrib module has been deprecated and will follow an accelerated deprecation schedule. Direct use of Python markup libraries or 3rd party tag libraries is preferred to Django maintaining this functionality in the framework.

**AUTH_PROFILE_MODULE**

With the introduction of custom user models, there is no longer any need for a built-in mechanism to store user profile data.

You can still define user profiles models that have a one-to-one relation with the User model - in fact, for many applications needing to associate data with a User account, this will be an appropriate design pattern to follow. However, the `AUTH_PROFILE_MODULE` setting, and the `django.contrib.auth.models.User.get_profile()` method for accessing the user profile model, should not be used any longer.
**Streaming behavior of HttpResponse**

Django 1.5 deprecates the ability to stream a response by passing an iterator to `HttpResponse`. If you rely on this behavior, switch to `StreamingHttpResponse`. See Explicit support for streaming responses above.

In Django 1.7 and above, the iterator will be consumed immediately by `HttpResponse`.

**django.utils.simplejson**

Since Django 1.5 drops support for Python 2.5, we can now rely on the `json` module being available in Python’s standard library, so we’ve removed our own copy of `simplejson`. You should now import `json` instead of `django.utils.simplejson`.

Unfortunately, this change might have unwanted side-effects, because of incompatibilities between versions of `simplejson`—see the backwards-incompatible changes section. If you rely on features added to `simplejson` after it became Python’s `json`, you should import `simplejson` explicitly.

**django.utils.encoding.StrAndUnicode**

The `django.utils.encoding.StrAndUnicode` mix-in has been deprecated. Define a `__str__` method and apply the `django.utils.encoding.python_2_unicode_compatible` decorator instead.

**django.utils.itercompat.product**

The `django.utils.itercompat.product` function has been deprecated. Use the built-in `itertools.product()` instead.

**cleanup management command**

The `cleanup` management command has been deprecated and replaced by `clearsessions`.

**daily_cleanup.py script**

The undocumented `daily_cleanup.py` script has been deprecated. Use the `clearsessions` management command instead.
depth keyword argument in select_related

The `depth` keyword argument in `select_related()` has been deprecated. You should use field names instead.

9.1.17 1.4 release

Django 1.4.22 release notes

August 18, 2015

Django 1.4.22 fixes a security issue in 1.4.21.

It also fixes support with pip 7+ by disabling wheel support. Older versions of 1.4 would silently build a broken wheel when installed with those versions of pip.

Denial-of-service possibility in logout() view by filling session store

Previously, a session could be created when anonymously accessing the `django.contrib.auth.views.logout()` view (provided it wasn’t decorated with `login_required()` as done in the admin). This could allow an attacker to easily create many new session records by sending repeated requests, potentially filling up the session store or causing other users’ session records to be evicted.

The `SessionMiddleware` has been modified to no longer create empty session records, including when `SESSION_SAVE_EVERY_REQUEST` is active.

Additionally, the `contrib.sessions.backends.base.SessionBase.flush()` and `cache_db.SessionStore.flush()` methods have been modified to avoid creating a new empty session. Maintainers of third-party session backends should check if the same vulnerability is present in their backend and correct it if so.

Django 1.4.21 release notes

July 8, 2015

Django 1.4.21 fixes several security issues in 1.4.20.
Denial-of-service possibility by filling session store

In previous versions of Django, the session backends created a new empty record in the session storage anytime `request.session` was accessed and there was a session key provided in the request cookies that didn’t already have a session record. This could allow an attacker to easily create many new session records simply by sending repeated requests with unknown session keys, potentially filling up the session store or causing other users’ session records to be evicted.

The built-in session backends now create a session record only if the session is actually modified; empty session records are not created. Thus this potential DoS is now only possible if the site chooses to expose a session-modifying view to anonymous users.

As each built-in session backend was fixed separately (rather than a fix in the core sessions framework), maintainers of third-party session backends should check whether the same vulnerability is present in their backend and correct it if so.

Header injection possibility since validators accept newlines in input

Some of Django’s built-in validators (`EmailValidator`, most seriously) didn’t prohibit newline characters (due to the usage of `\$` instead of `\Z` in the regular expressions). If you use values with newlines in HTTP response or email headers, you can suffer from header injection attacks. Django itself isn’t vulnerable because `HttpResponse` and the mail sending utilities in `django.core.mail` prohibit newlines in HTTP and SMTP headers, respectively. While the validators have been fixed in Django, if you’re creating HTTP responses or email messages in other ways, it’s a good idea to ensure that those methods prohibit newlines as well. You might also want to validate that any existing data in your application doesn’t contain unexpected newlines.

`validate_ipv4_address()`, `validate_slug()`, and `URLValidator` and their usage in the corresponding form fields `GenericIPAddressField`, `IPAddressField`, `SlugField`, and `URLField` are also affected.

The undocumented, internally unused `validate_integer()` function is now stricter as it validates using a regular expression instead of simply casting the value using `int()` and checking if an exception was raised.

Django 1.4.20 release notes

March 18, 2015

Django 1.4.20 fixes one security issue in 1.4.19.
Mitigated possible XSS attack via user-supplied redirect URLs

Django relies on user input in some cases (e.g. `django.contrib.auth.views.login()` and `i18n`) to redirect the user to an “on success” URL. The security checks for these redirects (namely `django.utils.http.is_safe_url()`) accepted URLs with leading control characters and so considered URLs like `\x08javascript:...` safe. This issue doesn’t affect Django currently, since we only put this URL into the Location response header and browsers seem to ignore JavaScript there. Browsers we tested also treat URLs prefixed with control characters such as `%08//example.com` as relative paths so redirection to an unsafe target isn’t a problem either.

However, if a developer relies on `is_safe_url()` to provide safe redirect targets and puts such a URL into a link, they could suffer from an XSS attack as some browsers such as Google Chrome ignore control characters at the start of a URL in an anchor `href`.

Django 1.4.19 release notes

January 27, 2015

Django 1.4.19 fixes a regression in the 1.4.18 security release.

Bugfixes

- `GZipMiddleware` now supports streaming responses. As part of the 1.4.18 security release, the `django.views.static.serve()` function was altered to stream the files it serves. Unfortunately, the `GZipMiddleware` consumed the stream prematurely and prevented files from being served properly (#24158).

Django 1.4.18 release notes

January 13, 2015

Django 1.4.18 fixes several security issues in 1.4.17 as well as a regression on Python 2.5 in the 1.4.17 release.

WSGI header spoofing via underscore/dash conflation

When HTTP headers are placed into the WSGI environ, they are normalized by converting to uppercase, converting all dashes to underscores, and prepending HTTP_. For instance, a header `X-Auth-User` would become `HTTP_X_AUTH_USER` in the WSGI environ (and thus also in Django’s `request.META` dictionary).

Unfortunately, this means that the WSGI environ cannot distinguish between headers containing dashes and headers containing underscores: `X-Auth-User` and `X-Auth_User` both become `HTTP_X_AUTH_USER`. This means that if a header is used in a security-sensitive way (for instance, passing authentication information
along from a front-end proxy), even if the proxy carefully strips any incoming value for X-Auth-User, an attacker may be able to provide an X-Auth_User header (with underscore) and bypass this protection.

In order to prevent such attacks, both Nginx and Apache 2.4+ strip all headers containing underscores from incoming requests by default. Django’s built-in development server now does the same. Django’s development server is not recommended for production use, but matching the behavior of common production servers reduces the surface area for behavior changes during deployment.

Mitigated possible XSS attack via user-supplied redirect URLs

Django relies on user input in some cases (e.g. django.contrib.auth.views.login() and i18n) to redirect the user to an “on success” URL. The security checks for these redirects (namely django.utils.http.is_safe_url()) didn’t strip leading whitespace on the tested URL and as such considered URLs like javascript:... safe. If a developer relied on is_safe_url() to provide safe redirect targets and put such a URL into a link, they could suffer from a XSS attack. This bug doesn’t affect Django currently, since we only put this URL into the Location response header and browsers seem to ignore JavaScript there.

Denial-of-service attack against django.views.static.serve

In older versions of Django, the django.views.static.serve() view read the files it served one line at a time. Therefore, a big file with no newlines would result in memory usage equal to the size of that file. An attacker could exploit this and launch a denial-of-service attack by simultaneously requesting many large files. This view now reads the file in chunks to prevent large memory usage.

Note, however, that this view has always carried a warning that it is not hardened for production use and should be used only as a development aid. Now may be a good time to audit your project and serve your files in production using a real front-end web server if you are not doing so.

Bugfixes

• To maintain compatibility with Python 2.5, Django’s vendored version of six, django.utils.six, has been downgraded to 1.8.0 which is the last version to support Python 2.5.

Django 1.4.17 release notes

January 2, 2015

Django 1.4.17 fixes a regression in the 1.4.14 security release.

Additionally, Django’s vendored version of six, django.utils.six, has been upgraded to the latest release (1.9.0).
Bugfixes

- Fixed a regression with dynamically generated inlines and allowed field references in the admin (#23754).

Django 1.4.16 release notes

October 22, 2014

Django 1.4.16 fixes a couple regressions in the 1.4.14 security release and a bug preventing the use of some GEOS versions with GeoDjango.

Bugfixes

- Allowed related many-to-many fields to be referenced in the admin (#23604).
- Allowed inline and hidden references to admin fields (#23431).
- Fixed parsing of the GEOS version string (#20036).

Django 1.4.15 release notes

September 2, 2014

Django 1.4.15 fixes a regression in the 1.4.14 security release.

Bugfixes

- Allowed inherited and m2m fields to be referenced in the admin (#22486)

Django 1.4.14 release notes

August 20, 2014

Django 1.4.14 fixes several security issues in 1.4.13.
reverse() could generate URLs pointing to other hosts

In certain situations, URL reversing could generate scheme-relative URLs (URLs starting with two slashes), which could unexpectedly redirect a user to a different host. An attacker could exploit this, for example, by redirecting users to a phishing site designed to ask for user’s passwords.

To remedy this, URL reversing now ensures that no URL starts with two slashes (/), replacing the second slash with its URL encoded counterpart (%2F). This approach ensures that semantics stay the same, while making the URL relative to the domain and not to the scheme.

File upload denial-of-service

Before this release, Django’s file upload handing in its default configuration may degrade to producing a huge number of os.stat() system calls when a duplicate filename is uploaded. Since stat() may invoke IO, this may produce a huge data-dependent slowdown that slowly worsens over time. The net result is that given enough time, a user with the ability to upload files can cause poor performance in the upload handler, eventually causing it to become very slow simply by uploading 0-byte files. At this point, even a slow network connection and few HTTP requests would be all that is necessary to make a site unavailable.

We’ve remedied the issue by changing the algorithm for generating file names if a file with the uploaded name already exists. Storage.get_available_name() now appends an underscore plus a random 7 character alphanumeric string (e.g. "_x3a1gho"), rather than iterating through an underscore followed by a number (e.g. "_1", "_2", etc.).

RemoteUserMiddleware session hijacking

When using the RemoteUserMiddleware and the RemoteUserBackend, a change to the REMOTE_USER header between requests without an intervening logout could result in the prior user’s session being co-opted by the subsequent user. The middleware now logs the user out on a failed login attempt.

Data leakage via query string manipulation in contrib.admin

In older versions of Django it was possible to reveal any field’s data by modifying the “popup” and “to_field” parameters of the query string on an admin change form page. For example, requesting a URL like /admin/auth/user/?pop=1&t=password and viewing the page’s HTML allowed viewing the password hash of each user. While the admin requires users to have permissions to view the change form pages in the first place, this could leak data if you rely on users having access to view only certain fields on a model.

To address the issue, an exception will now be raised if a to_field value that isn’t a related field to a model that has been registered with the admin is specified.
Django 1.4.13 release notes

May 14, 2014

Django 1.4.13 fixes two security issues in 1.4.12.

Caches may incorrectly be allowed to store and serve private data

In certain situations, Django may allow caches to store private data related to a particular session and then serve that data to requests with a different session, or no session at all. This can lead to information disclosure and can be a vector for cache poisoning.

When using Django sessions, Django will set a `Vary: Cookie` header to ensure caches do not serve cached data to requests from other sessions. However, older versions of Internet Explorer (most likely only Internet Explorer 6, and Internet Explorer 7 if run on Windows XP or Windows Server 2003) are unable to handle the `Vary` header in combination with many content types. Therefore, Django would remove the header if the request was made by Internet Explorer.

To remedy this, the special behavior for these older Internet Explorer versions has been removed, and the `Vary` header is no longer stripped from the response. In addition, modifications to the `Cache-Control` header for all Internet Explorer requests with a `Content-Disposition` header have also been removed as they were found to have similar issues.

Malformed redirect URLs from user input not correctly validated

The validation for redirects did not correctly validate some malformed URLs, which are accepted by some browsers. This allows a user to be redirected to an unsafe URL unexpectedly.

Django relies on user input in some cases (e.g. `django.contrib.auth.views.login()`, `django.contrib.comments`, and `i18n`) to redirect the user to an “on success” URL. The security checks for these redirects (namely `django.utils.http.is_safe_url()`) did not correctly validate some malformed URLs, such as `http:\\\djangoproject.com`, which are accepted by some browsers with more liberal URL parsing.

To remedy this, the validation in `is_safe_url()` has been tightened to be able to handle and correctly validate these malformed URLs.

Django 1.4.12 release notes

April 28, 2014

Django 1.4.12 fixes a regression in the 1.4.11 security release.
Bugfixes

- Restored the ability to `reverse()` views created using `functools.partial()` (#22486).

Django 1.4.11 release notes

April 21, 2014

Django 1.4.11 fixes three security issues in 1.4.10. Additionally, Django’s vendored version of six, `django.utils.six`, has been upgraded to the latest release (1.6.1).

Unexpected code execution using `reverse()`

Django’s URL handling is based on a mapping of regex patterns (representing the URLs) to callable views, and Django’s own processing consists of matching a requested URL against those patterns to determine the appropriate view to invoke.

Django also provides a convenience function – `reverse()` – which performs this process in the opposite direction. The `reverse()` function takes information about a view and returns a URL which would invoke that view. Use of `reverse()` is encouraged for application developers, as the output of `reverse()` is always based on the current URL patterns, meaning developers do not need to change other code when making changes to URLs.

One argument signature for `reverse()` is to pass a dotted Python path to the desired view. In this situation, Django will import the module indicated by that dotted path as part of generating the resulting URL. If such a module has import-time side effects, those side effects will occur.

Thus it is possible for an attacker to cause unexpected code execution, given the following conditions:

1. One or more views are present which construct a URL based on user input (commonly, a “next” parameter in a querystring indicating where to redirect upon successful completion of an action).
2. One or more modules are known to an attacker to exist on the server’s Python import path, which perform code execution with side effects on importing.

To remedy this, `reverse()` will now only accept and import dotted paths based on the view-containing modules listed in the project’s URL pattern configuration, so as to ensure that only modules the developer intended to be imported in this fashion can or will be imported.
Caching of anonymous pages could reveal CSRF token

Django includes both a caching framework and a system for preventing cross-site request forgery (CSRF) attacks. The CSRF-protection system is based on a random nonce sent to the client in a cookie which must be sent by the client on future requests and, in forms, a hidden value which must be submitted back with the form.

The caching framework includes an option to cache responses to anonymous (i.e., unauthenticated) clients. When the first anonymous request to a given page is by a client which did not have a CSRF cookie, the cache framework will also cache the CSRF cookie and serve the same nonce to other anonymous clients who do not have a CSRF cookie. This can allow an attacker to obtain a valid CSRF cookie value and perform attacks which bypass the check for the cookie.

To remedy this, the caching framework will no longer cache such responses. The heuristic for this will be:

1. If the incoming request did not submit any cookies, and
2. If the response did send one or more cookies, and
3. If the Vary: Cookie header is set on the response, then the response will not be cached.

MySQL typecasting

The MySQL database is known to "typecast" on certain queries; for example, when querying a table which contains string values, but using a query which filters based on an integer value, MySQL will first silently coerce the strings to integers and return a result based on that.

If a query is performed without first converting values to the appropriate type, this can produce unexpected results, similar to what would occur if the query itself had been manipulated.

Django’s model field classes are aware of their own types and most such classes perform explicit conversion of query arguments to the correct database-level type before querying. However, three model field classes did not correctly convert their arguments:

- `FilePathField`
- `GenericIPAddressField`
- `IPAddressField`

These three fields have been updated to convert their arguments to the correct types before querying.

Additionally, developers of custom model fields are now warned via documentation to ensure their custom field classes will perform appropriate type conversions, and users of the `raw()` and `extra()` query methods—which allow the developer to supply raw SQL or SQL fragments—will be advised to ensure they perform appropriate manual type conversions prior to executing queries.
Django 1.4.10 release notes

November 6, 2013

Django 1.4.10 fixes a Python-compatibility bug in the 1.4 series.

Python compatibility

Django 1.4.9 inadvertently introduced issues with Python 2.5 compatibility. Django 1.4.10 restores Python 2.5 compatibility. This was issue #21362 in Django’s Trac.

Django 1.4.9 release notes

October 23, 2013

Django 1.4.9 fixes a security-related bug in the 1.4 series and one other data corruption bug.

Readdressed denial-of-service via password hashers

Django 1.4.8 imposes a 4096-byte limit on passwords in order to mitigate a denial-of-service attack through submission of bogus but extremely large passwords. In Django 1.4.9, we’ve reverted this change and instead improved the speed of our PBKDF2 algorithm by not rehashing the key on every iteration.

Bugfixes

- Fixed a data corruption bug with \texttt{datetime\_safe.datetime.combine} (#21256).

Django 1.4.8 release notes

September 14, 2013

Django 1.4.8 fixes two security issues present in previous Django releases in the 1.4 series.

Denial-of-service via password hashers

In previous versions of Django, no limit was imposed on the plaintext length of a password. This allowed a denial-of-service attack through submission of bogus but extremely large passwords, tying up server resources performing the (expensive, and increasingly expensive with the length of the password) calculation of the corresponding hash.

As of 1.4.8, Django’s authentication framework imposes a 4096-byte limit on passwords and will fail authentication with any submitted password of greater length.
Corrected usage of sensitive_post_parameters() in django.contrib.auth’s admin

The decoration of the add_view and user_change_password user admin views with sensitive_post_parameters() did not include method_decorator() (required since the views are methods) resulting in the decorator not being properly applied. This usage has been fixed and sensitive_post_parameters() will now throw an exception if it’s improperly used.

Django 1.4.7 release notes

September 10, 2013

Django 1.4.7 fixes one security issue present in previous Django releases in the 1.4 series.

Directory traversal vulnerability in ssi template tag

In previous versions of Django it was possible to bypass the ALLOWED_INCLUDE_ROOTS setting used for security with the ssi template tag by specifying a relative path that starts with one of the allowed roots. For example, if ALLOWED_INCLUDE_ROOTS = ("/var/www",) the following would be possible:

```snippet
{% ssi "/var/www/../../../etc/passwd" %}
```

In practice this is not a very common problem, as it would require the template author to put the ssi file in a user-controlled variable, but it’s possible in principle.

Django 1.4.6 release notes

August 13, 2013

Django 1.4.6 fixes one security issue present in previous Django releases in the 1.4 series, as well as one other bug.

This is the sixth bugfix/security release in the Django 1.4 series.

Mitigated possible XSS attack via user-supplied redirect URLs

Django relies on user input in some cases (e.g. django.contrib.auth.views.login(), django.contrib.comments, and i18n) to redirect the user to an “on success” URL. The security checks for these redirects (namely django.utils.http.is_safe_url()) didn’t check if the scheme is http(s) and as such allowed javascript:... URLs to be entered. If a developer relied on is_safe_url() to provide safe redirect targets and put such a URL into a link, they could suffer from a XSS attack. This bug doesn’t affect Django currently, since we only put this URL into the Location response header and browsers seem to ignore JavaScript there.
Bugfixes

• Fixed an obscure bug with the `override_settings()` decorator. If you hit an `AttributeError: 'Settings' object has no attribute '_original_allowed_hosts'` exception, it’s probably fixed (#20636).

Django 1.4.5 release notes

February 20, 2013

Django 1.4.5 corrects a packaging problem with yesterday’s 1.4.4 release.

The release contained stray `.pyc` files that caused “bad magic number” errors when running with some versions of Python. This release corrects this, and also fixes a bad documentation link in the project template `settings.py` file generated by `manage.py startproject`.

Django 1.4.4 release notes

February 19, 2013

Django 1.4.4 fixes four security issues present in previous Django releases in the 1.4 series, as well as several other bugs and numerous documentation improvements.

This is the fourth bugfix/security release in the Django 1.4 series.

Host header poisoning

Some parts of Django—indeed, independent of end-user-written applications—make use of full URLs, including domain name, which are generated from the HTTP Host header. Django’s documentation has for some time contained notes advising users on how to configure web servers to ensure that only valid Host headers can reach the Django application. However, it has been reported to us that even with the recommended web server configurations there are still techniques available for tricking many common web servers into supplying the application with an incorrect and possibly malicious Host header.

For this reason, Django 1.4.4 adds a new setting, `ALLOWED_HOSTS`, containing an explicit list of valid host/domain names for this site. A request with a Host header not matching an entry in this list will raise `SuspiciousOperation` if `request.get_host()` is called. For full details see the documentation for the `ALLOWED_HOSTS` setting.

The default value for this setting in Django 1.4.4 is `['*']` (matching any host), for backwards-compatibility, but we strongly encourage all sites to set a more restrictive value.

This host validation is disabled when `DEBUG` is `True` or when running tests.
XML deserialization

The XML parser in the Python standard library is vulnerable to a number of attacks via external entities and entity expansion. Django uses this parser for deserializing XML-formatted database fixtures. This deserializer is not intended for use with untrusted data, but in order to err on the side of safety in Django 1.4.4 the XML deserializer refuses to parse an XML document with a DTD (DOCTYPE definition), which closes off these attack avenues.

These issues in the Python standard library are CVE-2013-1664 and CVE-2013-1665. More information available from the Python security team.

Django’s XML serializer does not create documents with a DTD, so this should not cause any issues with the typical round-trip from dumpdata to loaddata, but if you feed your own XML documents to the loaddata management command, you will need to ensure they do not contain a DTD.

Formset memory exhaustion

Previous versions of Django did not validate or limit the form-count data provided by the client in a formset’s management form, making it possible to exhaust a server’s available memory by forcing it to create very large numbers of forms.

In Django 1.4.4, all formsets have a strictly-enforced maximum number of forms (1000 by default, though it can be set higher via the max_num formset factory argument).

Admin history view information leakage

In previous versions of Django, an admin user without change permission on a model could still view the Unicode representation of instances via their admin history log. Django 1.4.4 now limits the admin history log view for an object to users with change permission for that model.

Other bugfixes and changes

- Prevented transaction state from leaking from one request to the next (#19707).
- Changed an SQL command syntax to be MySQL 4 compatible (#19702).
- Added backwards-compatibility with old unsalted MD5 passwords (#18144).
- Numerous documentation improvements and fixes.
Django 1.4.3 release notes

December 10, 2012

Django 1.4.3 addresses two security issues present in previous Django releases in the 1.4 series.

Please be aware that this security release is slightly different from previous ones. Both issues addressed here have been dealt with in prior security updates to Django. In one case, we have received ongoing reports of problems, and in the other we’ve chosen to take further steps to tighten up Django’s code in response to independent discovery of potential problems from multiple sources.

Host header poisoning

Several earlier Django security releases focused on the issue of poisoning the HTTP Host header, causing Django to generate URLs pointing to arbitrary, potentially-malicious domains.

In response to further input received and reports of continuing issues following the previous release, we’re taking additional steps to tighten Host header validation. Rather than attempt to accommodate all features HTTP supports here, Django’s Host header validation attempts to support a smaller, but far more common, subset:

- Hostnames must consist of characters [A-Za-z0-9] plus hyphen (‘-’) or dot (‘.’).
- IP addresses – both IPv4 and IPv6 – are permitted.
- Port, if specified, is numeric.

Any deviation from this will now be rejected, raising the exception `django.core.exceptions.SuspiciousOperation`.

Redirect poisoning

Also following up on a previous issue: in July of this year, we made changes to Django’s HTTP redirect classes, performing additional validation of the scheme of the URL to redirect to (since, both within Django’s own supplied applications and many third-party applications, accepting a user-supplied redirect target is a common pattern).

Since then, two independent audits of the code turned up further potential problems. So, similar to the Host-header issue, we are taking steps to provide tighter validation in response to reported problems (primarily with third-party applications, but to a certain extent also within Django itself). This comes in two parts:

1. A new utility function, `django.utils.http.is_safe_url`, is added; this function takes a URL and a hostname, and checks that the URL is either relative, or if absolute matches the supplied hostname. This function is intended for use whenever user-supplied redirect targets are accepted, to ensure that such redirects cannot lead to arbitrary third-party sites.
2. All of Django’s own built-in views –primarily in the authentication system –which allow user-supplied redirect targets now use `is_safe_url` to validate the supplied URL.

**Django 1.4.2 release notes**

October 17, 2012

This is the second security release in the Django 1.4 series.

**Host header poisoning**

Some parts of Django –independent of end-user-written applications –make use of full URLs, including domain name, which are generated from the HTTP Host header. Some attacks against this are beyond Django’s ability to control, and require the web server to be properly configured; Django’s documentation has for some time contained notes advising users on such configuration.

Django’s own built-in parsing of the Host header is, however, still vulnerable, as was reported to us recently. The Host header parsing in Django 1.3.3 and Django 1.4.1 –specifically, `django.http.HttpRequest.get_host()` –was incorrectly handling username/password information in the header. Thus, for example, the following Host header would be accepted by Django when running on `validsite.com`:

```
Host: validsite.com:random@evilsite.com
```

Using this, an attacker can cause parts of Django –particularly the password-reset mechanism –to generate and display arbitrary URLs to users.

To remedy this, the parsing in `HttpRequest.get_host()` is being modified; Host headers which contain potentially dangerous content (such as username/password pairs) now raise the exception `django.core.exceptions.SuspiciousOperation`.

Details of this issue were initially posted online as a security advisory.

**Backwards incompatible changes**

- The newly introduced `GenericIPAddressField` constructor arguments have been adapted to match those of all other model fields. The first two keyword arguments are now `verbose_name` and `name`. 
Other bugfixes and changes

- Subclass HTMLParser only for appropriate Python versions (#18239).
- Added batch_size argument to qs.bulk_create() (#17788).
- Fixed a small regression in the admin filters where wrongly formatted dates passed as url parameters caused an unhandled ValidationError (#18530).
- Fixed an endless loop bug when accessing permissions in templates (#18979)
- Fixed some Python 2.5 compatibility issues
- Fixed an issue with quoted filenames in Content-Disposition header (#19006)
- Made the context option in trans and blocktrans tags accept literals wrapped in single quotes (#18881).
- Numerous documentation improvements and fixes.

Django 1.4.1 release notes

July 30, 2012

This is the first security release in the Django 1.4 series, fixing several security issues in Django 1.4. Django 1.4.1 is a recommended upgrade for all users of Django 1.4.

For a full list of issues addressed in this release, see the security advisory.

Django 1.4 release notes

March 23, 2012

Welcome to Django 1.4!

These release notes cover the new features, as well as some backwards incompatible changes you’ll want to be aware of when upgrading from Django 1.3 or older versions. We’ve also dropped some features, which are detailed in our deprecation plan, and we’ve begun the deprecation process for some features.

Overview

The biggest new feature in Django 1.4 is support for time zones when handling date/times. When enabled, this Django will store date/times in UTC, use timezone-aware objects internally, and translate them to users’ local timezones for display.

If you’re upgrading an existing project to Django 1.4, switching to the timezone aware mode may take some care: the new mode disallows some rather sloppy behavior that used to be accepted. We encourage anyone who’s upgrading to check out the timezone migration guide and the timezone FAQ for useful pointers.
Other notable new features in Django 1.4 include:

- A number of ORM improvements, including SELECT FOR UPDATE support, the ability to bulk insert large datasets for improved performance, and QuerySet.prefetch_related, a method to batch-load related objects in areas where select_related() doesn’t work.

- Some nice security additions, including improved password hashing (featuring PBKDF2 and bcrypt support), new tools for cryptographic signing, several CSRF improvements, and simple clickjacking protection.

- An updated default project layout and manage.py that removes the “magic” from prior versions. And for those who don’t like the new layout, you can use custom project and app templates instead!

- Support for in-browser testing frameworks (like Selenium).

- ... and a whole lot more; see below!

Wherever possible we try to introduce new features in a backwards-compatible manner per our API stability policy. However, as with previous releases, Django 1.4 ships with some minor backwards incompatible changes; people upgrading from previous versions of Django should read that list carefully.

**Python compatibility**

Django 1.4 has dropped support for Python 2.4. Python 2.5 is now the minimum required Python version. Django is tested and supported on Python 2.5, 2.6 and 2.7.

This change should affect only a small number of Django users, as most operating-system vendors today are shipping Python 2.5 or newer as their default version. If you’re still using Python 2.4, however, you’ll need to stick to Django 1.3 until you can upgrade. Per our support policy, Django 1.3 will continue to receive security support until the release of Django 1.5.

Django does not support Python 3.x at this time. At some point before the release of Django 1.4, we plan to publish a document outlining our full timeline for deprecating Python 2.x and moving to Python 3.x.

**What’s new in Django 1.4**

**Support for time zones**

In previous versions, Django used “naive” date/times (that is, date/times without an associated time zone), leaving it up to each developer to interpret what a given date/time “really means”. This can cause all sorts of subtle timezone-related bugs.

In Django 1.4, you can now switch Django into a more correct, time-zone aware mode. In this mode, Django stores date and time information in UTC in the database, uses time-zone-aware datetime objects internally and translates them to the end user’s time zone in templates and forms. Reasons for using this feature include:
- Customizing date and time display for users around the world.
- Storing datetimes in UTC for database portability and interoperability. (This argument doesn’t apply to PostgreSQL, because it already stores timestamps with time zone information in Django 1.3.)
- Avoiding data corruption problems around DST transitions.

Time zone support is enabled by default in new projects created with `startproject`. If you want to use this feature in an existing project, read the migration guide. If you encounter problems, there’s a helpful FAQ.

### Support for in-browser testing frameworks

Django 1.4 supports integration with in-browser testing frameworks like Selenium. The new `django.test.LiveServerTestCase` base class lets you test the interactions between your site’s front and back ends more comprehensively. See the documentation for more details and concrete examples.

### Updated default project layout and `manage.py`

Django 1.4 ships with an updated default project layout and `manage.py` file for the `startproject` management command. These fix some issues with the previous `manage.py` handling of Python import paths that caused double imports, trouble moving from development to deployment, and other difficult-to-debug path issues.

The previous `manage.py` called functions that are now deprecated, and thus projects upgrading to Django 1.4 should update their `manage.py`. (The old-style `manage.py` will continue to work as before until Django 1.6. In 1.5 it will raise `DeprecationWarning`).

The new recommended `manage.py` file should look like this:

```python
#!/usr/bin/env python
import os, sys

if __name__ == "__main__":
    os.environ.setdefault("DJANGO_SETTINGS_MODULE", "{{ project_name }}.settings")

    from django.core.management import execute_from_command_line

    execute_from_command_line(sys.argv)
```

{{ project_name }} should be replaced with the Python package name of the actual project.

If settings, URLconf and apps within the project are imported or referenced using the project name prefix (e.g. `myproject.settings`, `ROOT_URLCONF = "myproject.urls"`, etc.), the new `manage.py` will need to be moved one directory up, so it is outside the project package rather than adjacent to `settings.py` and `urls.py`. 
For instance, with the following layout:

```python
manage.py
mysite/
    __init__.py
    settings.py
    urls.py
    myapp/
        __init__.py
        models.py
```

You could import `mysite.settings`, `mysite.urls`, and `mysite.myapp`, but not `settings`, `urls`, or `myapp` as top-level modules.

Anything imported as a top-level module can be placed adjacent to the new `manage.py`. For instance, to decouple `myapp` from the project module and import it as just `myapp`, place it outside the `mysite/` directory:

```python
manage.py
myapp/
    __init__.py
    models.py
mysite/
    __init__.py
    settings.py
    urls.py
```

If the same code is imported inconsistently (some places with the project prefix, some places without it), the imports will need to be cleaned up when switching to the new `manage.py`.

**Custom project and app templates**

The `startapp` and `startproject` management commands now have a `--template` option for specifying a path or URL to a custom app or project template.

For example, Django will use the `/path/to/my_project_template` directory when you run the following command:

```
django-admin.py startproject --template=/path/to/my_project_template myproject
```

You can also now provide a destination directory as the second argument to both `startapp` and `startproject`:

```
django-admin.py startapp myapp /path/to/new/app
django-admin.py startproject myproject /path/to/new/project
```

For more information, see the `startapp` and `startproject` documentation.
Improved WSGI support

The `startproject` management command now adds a `wsgi.py` module to the initial project layout, containing a simple WSGI application that can be used for deploying with WSGI app servers.

The built-in development server now supports using an externally-defined WSGI callable, which makes it possible to run `runserver` with the same WSGI configuration that is used for deployment. The new `WSGI_APPLICATION` setting lets you configure which WSGI callable `runserver` uses.

(The `runfcgi` management command also internally wraps the WSGI callable configured via `WSGI_APPLICATION`.)

SELECT FOR UPDATE support

Django 1.4 includes a `QuerySet.select_for_update()` method, which generates a `SELECT ... FOR UPDATE` SQL query. This will lock rows until the end of the transaction, meaning other transactions cannot modify or delete rows matched by a `FOR UPDATE` query.

For more details, see the documentation for `select_for_update()`.

`Model.objects.bulk_create` in the ORM

This method lets you create multiple objects more efficiently. It can result in significant performance increases if you have many objects.

Django makes use of this internally, meaning some operations (such as database setup for test suites) have seen a performance benefit as a result.

See the `bulk_create()` docs for more information.

`QuerySet.prefetch_related`

Similar to `select_related()` but with a different strategy and broader scope, `prefetch_related()` has been added to `QuerySet`. This method returns a new `QuerySet` that will prefetch each of the specified related lookups in a single batch as soon as the query begins to be evaluated. Unlike `select_related`, it does the joins in Python, not in the database, and supports many-to-many relationships, `GenericForeignKey` and more. This allows you to fix a very common performance problem in which your code ends up doing O(n) database queries (or worse) if objects on your primary `QuerySet` each have many related objects that you also need to fetch.
Improved password hashing

Django’s auth system (django.contrib.auth) stores passwords using a one-way algorithm. Django 1.3 uses the SHA1 algorithm, but increasing processor speeds and theoretical attacks have revealed that SHA1 isn’t as secure as we’d like. Thus, Django 1.4 introduces a new password storage system: by default Django now uses the PBKDF2 algorithm (as recommended by NIST). You can also easily choose a different algorithm (including the popular bcrypt algorithm). For more details, see How Django stores passwords.

HTML5 doctype

We’ve switched the admin and other bundled templates to use the HTML5 doctype. While Django will be careful to maintain compatibility with older browsers, this change means that you can use any HTML5 features you need in admin pages without having to lose HTML validity or override the provided templates to change the doctype.

List filters in admin interface

Prior to Django 1.4, the admin applet you specify change list filters by specifying a field lookup, but it didn’t allow you to create custom filters. This has been rectified with a simple API (previously used internally and known as “FilterSpec”). For more details, see the documentation for list_filter.

Multiple sort in admin interface

The admin change list now supports sorting on multiple columns. It respects all elements of the ordering attribute, and sorting on multiple columns by clicking on headers is designed to mimic the behavior of desktop GUIs. We also added a get_ordering() method for specifying the ordering dynamically (i.e., depending on the request).

New ModelAdmin methods

We added a save_related() method to ModelAdmin to ease customization of how related objects are saved in the admin.

Two other new ModelAdmin methods, get_list_display() and get_list_display_links() enable dynamic customization of fields and links displayed on the admin change list.
Admin inlines respect user permissions

Admin inlines now only allow those actions for which the user has permission. For ManyToMany relationships with an auto-created intermediate model (which does not have its own permissions), the change permission for the related model determines if the user has the permission to add, change or delete relationships.

Tools for cryptographic signing

Django 1.4 adds both a low-level API for signing values and a high-level API for setting and reading signed cookies, one of the most common uses of signing in web applications.

See the cryptographic signing docs for more information.

Cookie-based session backend

Django 1.4 introduces a cookie-based session backend that uses the tools for cryptographic signing to store the session data in the client’s browser.

Warning: Session data is signed and validated by the server, but it’s not encrypted. This means a user can view any data stored in the session but cannot change it. Please read the documentation for further clarification before using this backend.

See the cookie-based session backend docs for more information.

New form wizard

The previous FormWizard from django.contrib.formtools has been replaced with a new implementation based on the class-based views introduced in Django 1.3. It features a pluggable storage API and doesn’t require the wizard to pass around hidden fields for every previous step.

Django 1.4 ships with a session-based storage backend and a cookie-based storage backend. The latter uses the tools for cryptographic signing also introduced in Django 1.4 to store the wizard’s state in the user’s cookies.
reverse_lazy

A lazily evaluated version of `reverse()` was added to allow using URL reversals before the project’s URLconf gets loaded.

**Translating URL patterns**

Django can now look for a language prefix in the URL pattern when using the new `i18n_patterns()` helper function. It’s also now possible to define translatable URL patterns using `django.utils.translation.ugettext_lazy()`. See [Internationalization: in URL patterns](https://docs.djangoproject.com/en/4.2/topics/i18n/#internationalization-in-url-patterns) for more information about the language prefix and how to internationalize URL patterns.

**Contextual translation support for {% trans %} and {% blocktrans %}**

The contextual translation support introduced in Django 1.3 via the `pgettext` function has been extended to the `trans` and `blocktrans` template tags using the new `context` keyword.

**Customizable SingleObjectMixin URLConf kwargs**

Two new attributes, `pk_url_kwarg` and `slug_url_kwarg`, have been added to `SingleObjectMixin` to enable the customization of URLconf keyword arguments used for single object generic views.

**Assignment template tags**

A new `assignment_tag` helper function was added to `template.Library` to ease the creation of template tags that store data in a specified context variable.

***args and **kwargs support for template tag helper functions**

The `simple_tag`, `inclusion_tag` and newly introduced `assignment_tag` template helper functions may now accept any number of positional or keyword arguments. For example:

```python
@register.simple_tag
def my_tag(a, b, *args, **kwargs):
    warning = kwargs['warning']
    profile = kwargs['profile']
    ...
    return ...
```

Then, in the template, any number of arguments may be passed to the template tag. For example:
No wrapping of exceptions in TEMPLATE_DEBUG mode

In previous versions of Django, whenever the TEMPLATE_DEBUG setting was True, any exception raised during template rendering (even exceptions unrelated to template syntax) were wrapped in TemplateSyntaxError and re-raised. This was done in order to provide detailed template source location information in the debug 500 page.

In Django 1.4, exceptions are no longer wrapped. Instead, the original exception is annotated with the source information. This means that catching exceptions from template rendering is now consistent regardless of the value of TEMPLATE_DEBUG, and there’s no need to catch and unwrap TemplateSyntaxError in order to catch other errors.

truncatechars template filter

This new filter truncates a string to be no longer than the specified number of characters. Truncated strings end with a translatable ellipsis sequence ("..."). See the documentation for truncatechars for more details.

static template tag

The staticfiles contrib app has a new static template tag to refer to files saved with the STATICFILES_STORAGE storage backend. It uses the storage backend’s url method and therefore supports advanced features such as serving files from a cloud service.

CachedStaticFilesStorage storage backend

The staticfiles contrib app now has a django.contrib.staticfiles.storage.CachedStaticFilesStorage backend that caches the files it saves (when running the collectstatic management command) by appending the MD5 hash of the file’s content to the filename. For example, the file css/styles.css would also be saved as css/styles.55e7cbb9ba48.css

Simple clickjacking protection

We’ve added a middleware to provide easy protection against clickjacking using the X-Frame-Options header. It’s not enabled by default for backwards compatibility reasons, but you’ll almost certainly want to enable it to help plug that security hole for browsers that support the header.
**CSRF improvements**

We’ve made various improvements to our CSRF features, including the `ensure_csrf_cookie()` decorator, which can help with AJAX-heavy sites; protection for PUT and DELETE requests; and the `CSRF_COOKIE_SECURE` and `CSRF_COOKIE_PATH` settings, which can improve the security and usefulness of CSRF protection. See the CSRF docs for more information.

**Error report filtering**

We added two function decorators, `sensitive_variables()` and `sensitive_post_parameters()`, to allow designating the local variables and POST parameters that may contain sensitive information and should be filtered out of error reports.

All POST parameters are now systematically filtered out of error reports for certain views (`login`, `password_reset_confirm`, `password_change` and `add_view` in `django.contrib.auth.views`, as well as `user_change_password` in the admin app) to prevent the leaking of sensitive information such as user passwords.

You can override or customize the default filtering by writing a custom filter. For more information see the docs on Filtering error reports.

**Extended IPv6 support**

Django 1.4 can now better handle IPv6 addresses with the new `GenericIPAddressField` model field, `GenericIPAddressField` form field and the validators `validate_ipv46_address` and `validate_ipv6_address`.

**HTML comparisons in tests**

The base classes in `django.test` now have some helpers to compare HTML without tripping over irrelevant differences in whitespace, argument quoting/ordering and closing of self-closing tags. You can either compare HTML directly with the new `assertHTMLEqual()` and `assertHTMNOTEqual()` assertions, or use the `html=True` flag with `assertContains()` and `assertNotContains()` to test whether the client’s response contains a given HTML fragment. See the assertions documentation for more.
**Two new date format strings**

Two new *date* formats were added for use in template filters, template tags and *Format localization*:

- `e` - the name of the timezone of the given datetime object
- `o` - the ISO 8601 year number

Please make sure to update your custom format files if they contain either `e` or `o` in a format string. For example a Spanish localization format previously only escaped the `d` format character:

```bash
DATE_FORMAT = r'j \de F \de Y'
```

But now it needs to also escape `e` and `o`:

```bash
DATE_FORMAT = r'j \d\e F \d\e Y'
```

For more information, see the *date* documentation.

**Minor features**

Django 1.4 also includes several smaller improvements worth noting:

- A more usable stacktrace in the technical 500 page. Frames in the stack trace that reference Django’s framework code are dimmed out, while frames in application code are slightly emphasized. This change makes it easier to scan a stacktrace for issues in application code.
- *Tablespace support* in PostgreSQL.
- Customizable names for *simple_tag()*.
- In the documentation, a helpful *security overview* page.
- The `django.contrib.auth.models.check_password` function has been moved to the `django.contrib.auth.hashers` module. Importing it from the old location will still work, but you should update your imports.
- The `collectstatic` management command now has a `--clear` option to delete all files at the destination before copying or linking the static files.
- It’s now possible to load fixtures containing forward references when using MySQL with the InnoDB database engine.
- A new 403 response handler has been added as 'django.views.defaults.permission_denied'. You can set your own handler by setting the value of `django.conf.urls.handler403`. See the documentation about the 403 (HTTP Forbidden) view for more information.
- The `makemessages` command uses a new and more accurate lexer, JsLex, for extracting translatable strings from JavaScript files.
• The `trans` template tag now takes an optional `as` argument to be able to retrieve a translation string without displaying it but setting a template context variable instead.

• The `if` template tag now supports `{% elif %}` clauses.

• If your Django app is behind a proxy, you might find the new `SECURE_PROXY_SSL_HEADER` setting useful. It solves the problem of your proxy “eating” the fact that a request came in via HTTPS. But only use this setting if you know what you’re doing.

• A new, plain-text, version of the HTTP 500 status code internal error page served when `DEBUG` is `True` is now sent to the client when Django detects that the request has originated in JavaScript code. (`is_ajax()` is used for this.)

Like its HTML counterpart, it contains a collection of different pieces of information about the state of the application.

This should make it easier to read when debugging interaction with client-side JavaScript.

• Added the `makemessages --no-location` option.

• Changed the locmem cache backend to use `pickle.HIGHEST_PROTOCOL` for better compatibility with the other cache backends.

• Added support in the ORM for generating `SELECT` queries containing `DISTINCT ON`.

The `distinct() QuerySet` method now accepts an optional list of model field names. If specified, then the `DISTINCT` statement is limited to these fields. This is only supported in PostgreSQL.

For more details, see the documentation for `distinct()`.

• The admin login page will add a password reset link if you include a URL with the name `admin_password_reset` in your `urls.py`, so plugging in the built-in password reset mechanism and making it available is now much easier. For details, see Adding a password reset feature.

• The MySQL database backend can now make use of the savepoint feature implemented by MySQL version 5.0.3 or newer with the InnoDB storage engine.

• It’s now possible to pass initial values to the model forms that are part of both model formsets and inline model formsets as returned from factory functions `modelformset_factory` and `inlineformset_factory` respectively just like with regular formsets. However, initial values only apply to extra forms, i.e. those which are not bound to an existing model instance.

• The sitemaps framework can now handle HTTPS links using the new `Sitemap.protocol` class attribute.

• A new `django.test.SimpleTestCase` subclass of `unittest.TestCase` that’s lighter than `django.test.TestCase` and company. It can be useful in tests that don’t need to hit a database. See Hierarchy of Django unit testing classes.
Backwards incompatible changes in 1.4

SECRET_KEY setting is required

Running Django with an empty or known SECRET_KEY disables many of Django’s security protections and can lead to remote-code-execution vulnerabilities. No Django site should ever be run without a SECRET_KEY.

In Django 1.4, starting Django with an empty SECRET_KEY will raise a DeprecationWarning. In Django 1.5, it will raise an exception and Django will refuse to start. This is slightly accelerated from the usual deprecation path due to the severity of the consequences of running Django with no SECRET_KEY.

django.contrib.admin

The included administration app django.contrib.admin has for a long time shipped with a default set of static files such as JavaScript, images and stylesheets. Django 1.3 added a new contrib app django.contrib.staticfiles to handle such files in a generic way and defined conventions for static files included in apps.

Starting in Django 1.4, the admin’s static files also follow this convention, to make the files easier to deploy. In previous versions of Django, it was also common to define an ADMIN_MEDIA_PREFIX setting to point to the URL where the admin’s static files live on a web server. This setting has now been deprecated and replaced by the more general setting STATIC_URL. Django will now expect to find the admin static files under the URL <STATIC_URL>/admin/.

If you’ve previously used a URL path for ADMIN_MEDIA_PREFIX (e.g. /media/) simply make sure STATIC_URL and STATIC_ROOT are configured and your web server serves those files correctly. The development server continues to serve the admin files just like before. Read the static files howto for more details.

If your ADMIN_MEDIA_PREFIX is set to a specific domain (e.g. http://media.example.com/admin/), make sure to also set your STATIC_URL setting to the correct URL—for example, http://media.example.com/.

Warning: If you’re implicitly relying on the path of the admin static files within Django’s source code, you’ll need to update that path. The files were moved from django/contrib/admin/media/ to django/contrib/admin/static/admin/.

Supported browsers for the admin

Django hasn’t had a clear policy on which browsers are supported by the admin app. Our new policy formalizes existing practices: YUI’s A-grade browsers should provide a fully-functional admin experience, with the notable exception of Internet Explorer 6, which is no longer supported.

Released over 10 years ago, IE6 imposes many limitations on modern web development. The practical implications of this policy are that contributors are free to improve the admin without consideration for these limitations.
This new policy has no impact on sites you develop using Django. It only applies to the Django admin. Feel free to develop apps compatible with any range of browsers.

**Removed admin icons**

As part of an effort to improve the performance and usability of the admin’s change-list sorting interface and horizontal and vertical “filter” widgets, some icon files were removed and grouped into two sprite files.

Specifically: `selector-add.gif`, `selector-addall.gif`, `selector-remove.gif`, `selector-removeall.gif`, `selector_stacked-add.gif` and `selector_stacked-remove.gif` were combined into `selector-icons.gif`; and `arrow-up.gif` and `arrow-down.gif` were combined into `sorting-icons.gif`.

If you used those icons to customize the admin, then you’ll need to replace them with your own icons or get the files from a previous release.

**CSS class names in admin forms**

To avoid conflicts with other common CSS class names (e.g. “button”), we added a prefix ( “field-” ) to all CSS class names automatically generated from the form field names in the main admin forms, stacked inline forms and tabular inline cells. You’ll need to take that prefix into account in your custom style sheets or JavaScript files if you previously used plain field names as selectors for custom styles or JavaScript transformations.

**Compatibility with old signed data**

Django 1.3 changed the cryptographic signing mechanisms used in a number of places in Django. While Django 1.3 kept fallbacks that would accept hashes produced by the previous methods, these fallbacks are removed in Django 1.4.

So, if you upgrade to Django 1.4 directly from 1.2 or earlier, you may lose/invalidate certain pieces of data that have been cryptographically signed using an old method. To avoid this, use Django 1.3 first for a period of time to allow the signed data to expire naturally. The affected parts are detailed below, with 1) the consequences of ignoring this advice and 2) the amount of time you need to run Django 1.3 for the data to expire or become irrelevant.

- **contrib.sessions** data integrity check
  - Consequences: The user will be logged out, and session data will be lost.
  - Time period: Defined by `SESSION_COOKIE_AGE`.

- **contrib.auth** password reset hash
  - Consequences: Password reset links from before the upgrade will not work.
- Time period: Defined by `PASSWORD_RESET_TIMEOUT_DAYS`.

Form-related hashes: these have a much shorter lifetime and are relevant only for the short window where a user might fill in a form generated by the pre-upgrade Django instance and try to submit it to the upgraded Django instance:

- **contrib.comments** form security hash
  - Consequences: The user will see the validation error “Security hash failed.”
  - Time period: The amount of time you expect users to take filling out comment forms.

- **FormWizard** security hash
  - Consequences: The user will see an error about the form having expired and will be sent back to the first page of the wizard, losing the data entered so far.
  - Time period: The amount of time you expect users to take filling out the affected forms.

- **CSRF check**
  - Note: This is actually a Django 1.1 fallback, not Django 1.2, and it applies only if you’re upgrading from 1.1.
  - Consequences: The user will see a 403 error with any CSRF-protected POST form.
  - Time period: The amount of time you expect user to take filling out such forms.

- **contrib.auth** user password hash-upgrade sequence
  - Consequences: Each user’s password will be updated to a stronger password hash when it’s written to the database in 1.4. This means that if you upgrade to 1.4 and then need to downgrade to 1.3, version 1.3 won’t be able to read the updated passwords.
  - Remedy: Set `PASSWORD_HASHERS` to use your original password hashing when you initially upgrade to 1.4. After you confirm your app works well with Django 1.4 and you won’t have to roll back to 1.3, enable the new password hashes.

**django.contrib.flatpages**

Starting in 1.4, the `FlatpageFallbackMiddleware` only adds a trailing slash and redirects if the resulting URL refers to an existing flatpage. For example, requesting `/notaflatpageoravalidurl` in a previous version would redirect to `/notaflatpageoravalidurl/`, which would subsequently raise a 404. Requesting `/notaflatpageoravalidurl/` now will immediately raise a 404.

Also, redirects returned by flatpages are now permanent (with 301 status code), to match the behavior of `CommonMiddleware`. 
Serialization of datetime and time

As a consequence of time-zone support, and according to the ECMA-262 specification, we made changes to the JSON serializer:

- It includes the time zone for aware datetime objects. It raises an exception for aware time objects.
- It includes milliseconds for datetime and time objects. There is still some precision loss, because Python stores microseconds (6 digits) and JSON only supports milliseconds (3 digits). However, it’s better than discarding microseconds entirely.

We changed the XML serializer to use the ISO8601 format for datetimes. The letter T is used to separate the date part from the time part, instead of a space. Time zone information is included in the [+-]HH:MM format. Though the serializers now use these new formats when creating fixtures, they can still load fixtures that use the old format.

supports_timezone changed to False for SQLite

The database feature supports_timezone used to be True for SQLite. Indeed, if you saved an aware datetime object, SQLite stored a string that included an UTC offset. However, this offset was ignored when loading the value back from the database, which could corrupt the data.

In the context of time-zone support, this flag was changed to False, and datetimes are now stored without time-zone information in SQLite. When USE_TZ is False, if you attempt to save an aware datetime object, Django raises an exception.

MySQLdb-specific exceptions

The MySQL backend historically has raised MySQLdb.OperationalError when a query triggered an exception. We’ve fixed this bug, and we now raise django.db.DatabaseError instead. If you were testing for MySQLdb.OperationalError, you’ll need to update your except clauses.

Database connection’s thread-locality

DatabaseWrapper objects (i.e. the connection objects referenced by django.db.connection and django.db.connections["some_alias"]) used to be thread-local. They are now global objects in order to be potentially shared between multiple threads. While the individual connection objects are now global, the django.db.connections dictionary referencing those objects is still thread-local. Therefore if you just use the ORM or DatabaseWrapper.cursor() then the behavior is still the same as before. Note, however, that django.db.connection does not directly reference the default DatabaseWrapper object anymore and is now a proxy to access that object’s attributes. If you need to access the actual DatabaseWrapper object, use django.db.connections[DEFAULT_DB_ALIAS] instead.
As part of this change, all underlying SQLite connections are now enabled for potential thread-sharing (by passing the `check_same_thread=False` attribute to `psycopg2`). `DatabaseWrapper` however preserves the previous behavior by disabling thread-sharing by default, so this does not affect any existing code that purely relies on the ORM or on `DatabaseWrapper.cursor()`.

Finally, while it’s now possible to pass connections between threads, Django doesn’t make any effort to synchronize access to the underlying backend. Concurrency behavior is defined by the underlying backend implementation. Check their documentation for details.

**COMMENTS_BANNED_USERS_GROUP setting**

Django’s comments has historically supported excluding the comments of a special user group, but we’ve never documented the feature properly and didn’t enforce the exclusion in other parts of the app such as the template tags. To fix this problem, we removed the code from the feed class.

If you rely on the feature and want to restore the old behavior, use a custom comment model manager to exclude the user group, like this:

```python
from django.conf import settings
from django.contrib.comments.managers import CommentManager

class BanningCommentManager(CommentManager):
    def get_query_set(self):
        qs = super().get_query_set()
        if hasattr(settings, 'COMMENTS_BANNED_USERS_GROUP', None):
            where = ['user_id NOT IN (SELECT user_id FROM auth_user_groups WHERE group_id = %s)']
            params = [settings.COMMENTS_BANNED_USERS_GROUP]
            qs = qs extra(where=where, params=params)
        return qs
```

Save this model manager in your custom comment app (e.g., in `my_comments_app/managers.py`) and add it your custom comment app model:

```python
from django.db import models
from django.contrib.comments.models import Comment

from my_comments_app.managers import BanningCommentManager

class CommentWithTitle(Comment):
    title = models.CharField(max_length=300)

    objects = BanningCommentManager()
```
**IGNORABLE_404_STARTS and IGNORABLE_404_ENDS settings**

Until Django 1.3, it was possible to exclude some URLs from Django’s 404 error reporting by adding prefixes to `IGNORABLE_404_STARTS` and suffixes to `IGNORABLE_404_ENDS`.

In Django 1.4, these two settings are superseded by `IGNORABLE_404_URLS`, which is a list of compiled regular expressions. Django won’t send an email for 404 errors on URLs that match any of them.

Furthermore, the previous settings had some rather arbitrary default values:

```
IGNORABLE_404_STARTS = ('/cgi-bin/', '/_vti_bin', '/_vti_inf')
IGNORABLE_404_ENDS = ('mail.pl', 'mailform.pl', 'mail.cgi', 'mailform.cgi',
                     'favicon.ico', '.php')
```

It’s not Django’s role to decide if your website has a legacy `/cgi-bin/` section or a `favicon.ico`. As a consequence, the default values of `IGNORABLE_404_URLS`, `IGNORABLE_404_STARTS`, and `IGNORABLE_404_ENDS` are all now empty.

If you have customized `IGNORABLE_404_STARTS` or `IGNORABLE_404_ENDS`, or if you want to keep the old default value, you should add the following lines in your settings file:

```
import re
IGNORABLE_404_URLS = (  
    # for each <prefix> in IGNORABLE_404_STARTS
    re.compile(r'^<prefix>$'),
    # for each <suffix> in IGNORABLE_404_ENDS
    re.compile(r'<suffix>$'),
)
```

Don’t forget to escape characters that have a special meaning in a regular expression, such as periods.

**CSRF protection extended to PUT and DELETE**

Previously, Django’s CSRF protection provided protection only against POST requests. Since use of PUT and DELETE methods in AJAX applications is becoming more common, we now protect all methods not defined as safe by RFC 2616—i.e., we exempt GET, HEAD, OPTIONS and TRACE, and we enforce protection on everything else.

If you’re using PUT or DELETE methods in AJAX applications, please see the instructions about using AJAX and CSRF.
Password reset view now accepts subject_template_name

The password_reset view in django.contrib.auth now accepts a subject_template_name parameter, which is passed to the password save form as a keyword argument. If you are using this view with a custom password reset form, then you will need to ensure your form’s save() method accepts this keyword argument.

django.core.template_loaders

This was an alias to django.template.loader since 2005, and we’ve removed it without emitting a warning due to the length of the deprecation. If your code still referenced this, please use django.template.loader instead.

django.db.models.fields.URLField.verify_exists

This functionality has been removed due to intractable performance and security issues. Any existing usage of verify_exists should be removed.

django.core.files.storage.Storage.open

The open method of the base Storage class used to take an obscure parameter mixin that allowed you to dynamically change the base classes of the returned file object. This has been removed. In the rare case you relied on the mixin parameter, you can easily achieve the same by overriding the open method, like this:

```python
from django.core.files import File
from django.core.files.storage import FileSystemStorage

class Spam(File):
    """
    Spam, spam, spam, spam and spam.
    """
    def ham(self):
        return 'eggs'

class SpamStorage(FileSystemStorage):
    """
    A custom file storage backend.
    """
    def open(self, name, mode='rb'):
        return Spam(open(self.path(name), mode))
```
YAML deserializer now uses `yaml.safe_load`

`yaml.load` is able to construct any Python object, which may trigger arbitrary code execution if you process a YAML document that comes from an untrusted source. This feature isn’t necessary for Django’s YAML deserializer, whose primary use is to load fixtures consisting of simple objects. Even though fixtures are trusted data, the YAML deserializer now uses `yaml.safe_load` for additional security.

**Session cookies now have the `httponly` flag by default**

Session cookies now include the `httponly` attribute by default to help reduce the impact of potential XSS attacks. As a consequence of this change, session cookie data, including `sessionid`, is no longer accessible from JavaScript in many browsers. For strict backwards compatibility, use `SESSION_COOKIE_HTTPONLY = False` in your settings file.

**The `urlize` filter no longer escapes every URL**

When a URL contains a `%xx` sequence, where `xx` are two hexadecimal digits, `urlize` now assumes that the URL is already escaped and doesn’t apply URL escaping again. This is wrong for URLs whose unquoted form contains a `%xx` sequence, but such URLs are very unlikely to happen in the wild, because they would confuse browsers too.

`assertTemplateUsed` and `assertTemplateNotUsed` as context manager

It’s now possible to check whether a template was used within a block of code with `assertTemplateUsed()` and `assertTemplateNotUsed()`. And they can be used as a context manager:

```python
with self.assertTemplateUsed('index.html'):
    render_to_string('index.html')
with self.assertTemplateNotUsed('base.html'):
    render_to_string('index.html')
```

See the assertion documentation for more.

**Database connections after running the test suite**

The default test runner no longer restores the database connections after tests’ execution. This prevents the production database from being exposed to potential threads that would still be running and attempting to create new connections.

If your code relied on connections to the production database being created after tests’ execution, then you can restore the previous behavior by subclassing `DjangoTestRunner` and overriding its `teardown_databases()` method.
Output of `manage.py help`

`manage.py help` now groups available commands by application. If you depended on the output of this command—if you parsed it, for example—then you’ll need to update your code. To get a list of all available management commands in a script, use `manage.py help --commands` instead.

**extends template tag**

Previously, the `extends` tag used a buggy method of parsing arguments, which could lead to it erroneously considering an argument as a string literal when it wasn’t. It now uses `parser.compile_filter`, like other tags.

The internals of the tag aren’t part of the official stable API, but in the interests of full disclosure, the `ExtendsNode.__init__` definition has changed, which may break any custom tags that use this class.

**Loading some incomplete fixtures no longer works**

Prior to 1.4, a default value was inserted for fixture objects that were missing a specific date or datetime value when `auto_now` or `auto_now_add` was set for the field. This was something that should not have worked, and in 1.4 loading such incomplete fixtures will fail. Because fixtures are a raw import, they should explicitly specify all field values, regardless of field options on the model.

**Development Server Multithreading**

The development server is now is multithreaded by default. Use the `runserver --nothreading` option to disable the use of threading in the development server:

```
django-admin.py runserver --nothreading
```

**Attributes disabled in markdown when safe mode set**

Prior to Django 1.4, attributes were included in any markdown output regardless of safe mode setting of the filter. With version > 2.1 of the Python-Markdown library, an `enable_attributes` option was added. When the safe argument is passed to the markdown filter, both the `safe_mode=True` and `enable_attributes=False` options are set. If using a version of the Python-Markdown library less than 2.1, a warning is issued that the output is insecure.
FormMixin get_initial returns an instance-specific dictionary

In Django 1.3, the `get_initial` method of the `django.views.generic.edit.FormMixin` class was returning the class `initial` dictionary. This has been fixed to return a copy of this dictionary, so form instances can modify their initial data without messing with the class variable.

Features deprecated in 1.4

Old styles of calling cache_page decorator

Some legacy ways of calling `cache_page()` have been deprecated. Please see the documentation for the correct way to use this decorator.

Support for PostgreSQL versions older than 8.2

Django 1.3 dropped support for PostgreSQL versions older than 8.0, and we suggested using a more recent version because of performance improvements and, more importantly, the end of upstream support periods for 8.0 and 8.1 was near (November 2010).

Django 1.4 takes that policy further and sets 8.2 as the minimum PostgreSQL version it officially supports.

Request exceptions are now always logged

When we added logging support in Django in 1.3, the admin error email support was moved into the `django.utils.log.AdminEmailHandler`, attached to the 'django.request' logger. In order to maintain the established behavior of error emails, the 'django.request' logger was called only when `DEBUG` was `False`.

To increase the flexibility of error logging for requests, the 'django.request' logger is now called regardless of the value of `DEBUG`, and the default settings file for new projects now includes a separate filter attached to `django.utils.log.AdminEmailHandler` to prevent admin error emails in `DEBUG` mode:

```python
'filters': {
    'require_debug_false': {
        '()': 'django.utils.log.RequireDebugFalse'
    }
},
'handlers': {
    'mail_admins': {
        'level': 'ERROR',
        'filters': ['require_debug_false'],
        'class': 'django.utils.log.AdminEmailHandler'
    }
}
```
If your project was created prior to this change, your `LOGGING` setting will not include this new filter. In order to maintain backwards-compatibility, Django will detect that your `mail_admins` handler configuration includes no `filters` section and will automatically add this filter for you and issue a pending-deprecation warning. This will become a deprecation warning in Django 1.5, and in Django 1.6 the backwards-compatibility shim will be removed entirely.

The existence of any `filters` key under the `mail_admins` handler will disable this backward-compatibility shim and deprecation warning.

`django.conf.urls.defaults`

Until Django 1.3, the `include()`, `patterns()`, and `url()` functions, plus `handler404` and `handler500` were located in a `django.conf.urls.defaults` module.

In Django 1.4, they live in `django.conf.urls`.

`django.contrib.databrowse`

Databrowse has not seen active development for some time, and this does not show any sign of changing. There had been a suggestion for a GSOC project to integrate the functionality of databrowse into the admin, but no progress was made. While Databrowse has been deprecated, an enhancement of `django.contrib.admin` providing a similar feature set is still possible.

The code that powers Databrowse is licensed under the same terms as Django itself, so it’s available to be adopted by an individual or group as a third-party project.

`django.core.management.setup_environ`

This function temporarily modified `sys.path` in order to make the parent “project” directory importable under the old flat `startproject` layout. This function is now deprecated, as its path workarounds are no longer needed with the new `manage.py` and default project layout.

This function was never documented or part of the public API, but it was widely recommended for use in setting up a “Django environment” for a user script. These uses should be replaced by setting the `DJANGO_SETTINGS_MODULE` environment variable or using `django.conf.settings.configure()`.
django.core.management.execute_manager

This function was previously used by manage.py to execute a management command. It is identical to django.core.management.execute_from_command_line, except that it first calls setup_environ, which is now deprecated. As such, execute_manager is also deprecated; execute_from_command_line can be used instead. Neither of these functions is documented as part of the public API, but a deprecation path is needed due to use in existing manage.py files.

is_safe and needs_autoescape attributes of template filters

Two flags, is_safe and needs_autoescape, define how each template filter interacts with Django’s auto-escaping behavior. They used to be attributes of the filter function:

```python
@register.filter
def noop(value):
    return value
noop.is_safe = True
```

However, this technique caused some problems in combination with decorators, especially @stringfilter. Now, the flags are keyword arguments of @register.filter:

```python
@register.filter(is_safe=True)
def noop(value):
    return value
```

See filters and auto-escaping for more information.

Wildcard expansion of application names in INSTALLED_APPS

Until Django 1.3, INSTALLED_APPS accepted wildcards in application names, like django.contrib.*. The expansion was performed by a filesystem-based implementation of from <package> import *. Unfortunately, this can’t be done reliably.

This behavior was never documented. Since it is unpythonic, it was removed in Django 1.4. If you relied on it, you must edit your settings file to list all your applications explicitly.
HttpRequest.raw_post_data renamed to HttpRequest.body

This attribute was confusingly named HttpRequest.raw_post_data, but it actually provided the body of the HTTP request. It’s been renamed to HttpRequest.body, and HttpRequest.raw_post_data has been deprecated.

django.contrib.sitemaps bug fix with potential performance implications

In previous versions, Paginator objects used in sitemap classes were cached, which could result in stale site maps. We’ve removed the caching, so each request to a site map now creates a new Paginator object and calls the items() method of the Sitemap subclass. Depending on what your items() method is doing, this may have a negative performance impact. To mitigate the performance impact, consider using the caching framework within your Sitemap subclass.

Versions of Python-Markdown earlier than 2.1

Versions of Python-Markdown earlier than 2.1 do not support the option to disable attributes. As a security issue, earlier versions of this library will not be supported by the markup contrib app in 1.5 under an accelerated deprecation timeline.

9.1.18 1.3 release

Django 1.3.7 release notes

February 20, 2013

Django 1.3.7 corrects a packaging problem with yesterday’s 1.3.6 release.

The release contained stray .pyc files that caused “bad magic number” errors when running with some versions of Python. This releases corrects this, and also fixes a bad documentation link in the project template settings.py file generated by manage.py startproject.

Django 1.3.6 release notes

February 19, 2013

Django 1.3.6 fixes four security issues present in previous Django releases in the 1.3 series.

This is the sixth bugfix/security release in the Django 1.3 series.
**Host header poisoning**

Some parts of Django –independent of end-user-written applications –make use of full URLs, including domain name, which are generated from the HTTP Host header. Django’s documentation has for some time contained notes advising users on how to configure web servers to ensure that only valid Host headers can reach the Django application. However, it has been reported to us that even with the recommended web server configurations there are still techniques available for tricking many common web servers into supplying the application with an incorrect and possibly malicious Host header.

For this reason, Django 1.3.6 adds a new setting, `ALLOWED_HOSTS`, which should contain an explicit list of valid host/domain names for this site. A request with a Host header not matching an entry in this list will raise `SuspiciousOperation` if `request.get_host()` is called. For full details see the documentation for the `ALLOWED_HOSTS` setting.

The default value for this setting in Django 1.3.6 is `['*']` (matching any host), for backwards-compatibility, but we strongly encourage all sites to set a more restrictive value.

This host validation is disabled when `DEBUG` is `True` or when running tests.

**XML deserialization**

The XML parser in the Python standard library is vulnerable to a number of attacks via external entities and entity expansion. Django uses this parser for deserializing XML-formatted database fixtures. The fixture deserializer is not intended for use with untrusted data, but in order to err on the side of safety in Django 1.3.6 the XML deserializer refuses to parse an XML document with a DTD (DOCTYPE definition), which closes off these attack avenues.

These issues in the Python standard library are CVE-2013-1664 and CVE-2013-1665. More information available from the Python security team.

Django’s XML serializer does not create documents with a DTD, so this should not cause any issues with the typical round-trip from `dumpdata` to `loaddata`, but if you feed your own XML documents to the `loaddata` management command, you will need to ensure they do not contain a DTD.

**Formset memory exhaustion**

Previous versions of Django did not validate or limit the form-count data provided by the client in a formset’s management form, making it possible to exhaust a server’s available memory by forcing it to create very large numbers of forms.

In Django 1.3.6, all formsets have a strictly-enforced maximum number of forms (1000 by default, though it can be set higher via the `max_num` formset factory argument).
Admin history view information leakage

In previous versions of Django, an admin user without change permission on a model could still view the Unicode representation of instances via their admin history log. Django 1.3.6 now limits the admin history log view for an object to users with change permission for that model.

Django 1.3.5 release notes

December 10, 2012

Django 1.3.5 addresses two security issues present in previous Django releases in the 1.3 series.

Please be aware that this security release is slightly different from previous ones. Both issues addressed here have been dealt with in prior security updates to Django. In one case, we have received ongoing reports of problems, and in the other we’ve chosen to take further steps to tighten up Django’s code in response to independent discovery of potential problems from multiple sources.

Host header poisoning

Several earlier Django security releases focused on the issue of poisoning the HTTP Host header, causing Django to generate URLs pointing to arbitrary, potentially-malicious domains.

In response to further input received and reports of continuing issues following the previous release, we’re taking additional steps to tighten Host header validation. Rather than attempt to accommodate all features HTTP supports here, Django’s Host header validation attempts to support a smaller, but far more common, subset:

- Hostnames must consist of characters [A-Za-z0-9-] plus hyphen (‘-’ ) or dot (‘.’ ).
- IP addresses – both IPv4 and IPv6 – are permitted.
- Port, if specified, is numeric.

Any deviation from this will now be rejected, raising the exception django.core.exceptions.SuspiciousOperation.

Redirect poisoning

Also following up on a previous issue: in July of this year, we made changes to Django’s HTTP redirect classes, performing additional validation of the scheme of the URL to redirect to (since, both within Django’s own supplied applications and many third-party applications, accepting a user-supplied redirect target is a common pattern).

Since then, two independent audits of the code turned up further potential problems. So, similar to the Host-header issue, we are taking steps to provide tighter validation in response to reported problems (primarily with third-party applications, but to a certain extent also within Django itself). This comes in two parts:

9.1. Final releases
1. A new utility function, `django.utils.http.is_safe_url`, is added; this function takes a URL and a hostname, and checks that the URL is either relative, or if absolute matches the supplied hostname. This function is intended for use whenever user-supplied redirect targets are accepted, to ensure that such redirects cannot lead to arbitrary third-party sites.

2. All of Django’s own built-in views – primarily in the authentication system – which allow user-supplied redirect targets now use `is_safe_url` to validate the supplied URL.

**Django 1.3.4 release notes**

October 17, 2012

This is the fourth release in the Django 1.3 series.

**Host header poisoning**

Some parts of Django – independent of end-user-written applications – make use of full URLs, including domain name, which are generated from the HTTP Host header. Some attacks against this are beyond Django’s ability to control, and require the web server to be properly configured; Django’s documentation has for some time contained notes advising users on such configuration.

Django’s own built-in parsing of the Host header is, however, still vulnerable, as was reported to us recently. The Host header parsing in Django 1.3.3 and Django 1.4.1 – specifically, `django.http.HttpRequest.get_host()` – was incorrectly handling username/password information in the header. Thus, for example, the following Host header would be accepted by Django when running on `validsite.com`:

```
Host: validsite.com:random@evilsite.com
```

Using this, an attacker can cause parts of Django – particularly the password-reset mechanism – to generate and display arbitrary URLs to users.

To remedy this, the parsing in `HttpRequest.get_host()` is being modified; Host headers which contain potentially dangerous content (such as username/password pairs) now raise the exception `django.core.exceptions.SuspiciousOperation`.

Details of this issue were initially posted online as a security advisory.
Django 1.3.3 release notes

August 1, 2012

Following Monday’s security release of Django 1.3.2, we began receiving reports that one of the fixes applied was breaking Python 2.4 compatibility for Django 1.3. Since Python 2.4 is a supported Python version for that release series, this release fixes compatibility with Python 2.4.

Django 1.3.2 release notes

July 30, 2012

This is the second security release in the Django 1.3 series, fixing several security issues in Django 1.3. Django 1.3.2 is a recommended upgrade for all users of Django 1.3.

For a full list of issues addressed in this release, see the security advisory.

Django 1.3.1 release notes

September 9, 2011

Welcome to Django 1.3.1!

This is the first security release in the Django 1.3 series, fixing several security issues in Django 1.3. Django 1.3.1 is a recommended upgrade for all users of Django 1.3.

For a full list of issues addressed in this release, see the security advisory.

Django 1.3 release notes

March 23, 2011

Welcome to Django 1.3!

Nearly a year in the making, Django 1.3 includes quite a few new features and plenty of bug fixes and improvements to existing features. These release notes cover the new features in 1.3, as well as some backwards-incompatible changes you’ll want to be aware of when upgrading from Django 1.2 or older versions.

Overview

Django 1.3’s focus has mostly been on resolving smaller, long-standing feature requests, but that hasn’t prevented a few fairly significant new features from landing, including:

- A framework for writing class-based views.
- Built-in support for using Python’s logging facilities.
- Contrib support for easy handling of static files.
• Django’s testing framework now supports (and ships with a copy of) the unittest2 library. Wherever possible, new features are introduced in a backwards-compatible manner per our API stability policy policy. As a result of this policy, Django 1.3 begins the deprecation process for some features.

Python compatibility

The release of Django 1.2 was notable for having the first shift in Django’s Python compatibility policy; prior to Django 1.2, Django supported any 2.x version of Python from 2.3 up. As of Django 1.2, the minimum requirement was raised to Python 2.4.

Django 1.3 continues to support Python 2.4, but will be the final Django release series to do so; beginning with Django 1.4, the minimum supported Python version will be 2.5. A document outlining our full timeline for deprecating Python 2.x and moving to Python 3.x will be published shortly after the release of Django 1.3.

What’s new in Django 1.3

Class-based views

Django 1.3 adds a framework that allows you to use a class as a view. This means you can compose a view out of a collection of methods that can be subclassed and overridden to provide common views of data without having to write too much code.

Analogs of all the old function-based generic views have been provided, along with a completely generic view base class that can be used as the basis for reusable applications that can be easily extended.

See the documentation on class-based generic views for more details. There is also a document to help you convert your function-based generic views to class-based views.

Logging

Django 1.3 adds framework-level support for Python’s logging module. This means you can now easily configure and control logging as part of your Django project. A number of logging handlers and logging calls have been added to Django’s own code as well – most notably, the error emails sent on an HTTP 500 server error are now handled as a logging activity. See the documentation on Django’s logging interface for more details.
Extended static files handling

Django 1.3 ships with a new contrib app `django.contrib.staticfiles` - to help developers handle the static media files (images, CSS, JavaScript, etc.) that are needed to render a complete web page.

In previous versions of Django, it was common to place static assets in `MEDIA_ROOT` along with user-uploaded files, and serve them both at `MEDIA_URL`. Part of the purpose of introducing the `staticfiles` app is to make it easier to keep static files separate from user-uploaded files. Static assets should now go in static/ subdirectories of your apps or in other static assets directories listed in `STATICFILES_DIRS`, and will be served at `STATIC_URL`.

See the reference documentation of the app for more details or learn how to manage static files.

unittest2 support

Python 2.7 introduced some major changes to the `unittest` library, adding some extremely useful features. To ensure that every Django project can benefit from these new features, Django ships with a copy of `unittest2`, a copy of the Python 2.7 `unittest` library, backported for Python 2.4 compatibility.

To access this library, Django provides the `django.utils.unittest` module alias. If you are using Python 2.7, or you have installed `unittest2` locally, Django will map the alias to the installed version of the `unittest` library. Otherwise, Django will use its own bundled version of `unittest2`.

To take advantage of this alias, simply use:

```python
from django.utils import unittest
```

wherever you would have historically used:

```python
import unittest
```

If you want to continue to use the base `unittest` library, you can —you just won’t get any of the nice new `unittest2` features.

Transaction context managers

Users of Python 2.5 and above may now use transaction management functions as context managers. For example:

```python
with transaction.autocommit():
    # ...
```
Configurable delete-cascade

`ForeignKey` and `OneToOneField` now accept an `on_delete` argument to customize behavior when the referenced object is deleted. Previously, deletes were always cascaded; available alternatives now include set null, set default, set to any value, protect, or do nothing.

For more information, see the `on_delete` documentation.

Contextual markers and comments for translatable strings

For translation strings with ambiguous meaning, you can now use the `pgettext` function to specify the context of the string.

And if you just want to add some information for translators, you can also add special translator comments in the source.

For more information, see Contextual markers and Comments for translators.

Improvements to built-in template tags

A number of improvements have been made to Django’s built-in template tags:

- The `include` tag now accepts a `with` option, allowing you to specify context variables to the included template
- The `include` tag now accepts an `only` option, allowing you to exclude the current context from the included context
- The `with` tag now allows you to define multiple context variables in a single `with` block.
- The `load` tag now accepts a `from` argument, allowing you to load a single tag or filter from a library.

TemplateResponse

It can sometimes be beneficial to allow decorators or middleware to modify a response after it has been constructed by the view. For example, you may want to change the template that is used, or put additional data into the context.

However, you can’t (easily) modify the content of a basic `HttpResponse` after it has been constructed. To overcome this limitation, Django 1.3 adds a new `TemplateResponse` class. Unlike basic `HttpResponse` objects, `TemplateResponse` objects retain the details of the template and context that was provided by the view to compute the response. The final output of the response is not computed until it is needed, later in the response process.

For more details, see the documentation on the `TemplateResponse` class.
**Caching changes**

Django 1.3 sees the introduction of several improvements to the Django’s caching infrastructure.

Firstly, Django now supports multiple named caches. In the same way that Django 1.2 introduced support for multiple database connections, Django 1.3 allows you to use the new `CACHES` setting to define multiple named cache connections.

Secondly, versioning, site-wide prefixing and transformation have been added to the cache API.

Thirdly, cache key creation has been updated to take the request query string into account on GET requests.

Finally, support for `pylibmc` has been added to the memcached cache backend.

For more details, see the documentation on caching in Django.

**Permissions for inactive users**

If you provide a custom auth backend with `supports_inactive_user` set to True, an inactive User instance will check the backend for permissions. This is useful for further centralizing the permission handling. See the authentication docs for more details.

**GeoDjango**

The GeoDjango test suite is now included when running the Django test suite with `runtests.py` when using spatial database backends.

**MEDIA_URL and STATIC_URL must end in a slash**

Previously, the `MEDIA_URL` setting only required a trailing slash if it contained a suffix beyond the domain name.

A trailing slash is now required for `MEDIA_URL` and the new `STATIC_URL` setting as long as it is not blank. This ensures there is a consistent way to combine paths in templates.

Project settings which provide either of both settings without a trailing slash will now raise a `PendingDeprecationWarning`.

In Django 1.4 this same condition will raise `DeprecationWarning`, and in Django 1.5 will raise an `ImproperlyConfigured` exception.
Everything else

Django 1.1 and 1.2 added lots of big ticket items to Django, like multiple-database support, model validation, and a session-based messages framework. However, this focus on big features came at the cost of lots of smaller features.

To compensate for this, the focus of the Django 1.3 development process has been on adding lots of smaller, long standing feature requests. These include:

- Improved tools for accessing and manipulating the current `Site` object in the `sites` framework.
- A `RequestFactory` for mocking requests in tests.
- A new test assertion `assertNumQueries()`—making it easier to test the database activity associated with a view.
- Support for lookups spanning relations in admin’s `list_filter`.
- Support for `HttpOnly` cookies.
- `mail_admins()` and `mail_managers()` now support easily attaching HTML content to messages.
- `EmailMessage` now supports CC’s.
- Error emails now include more of the detail and formatting of the debug server error page.
- `simple_tag()` now accepts a `takes_context` argument, making it easier to write simple template tags that require access to template context.
- A new `render()` shortcut—an alternative to `django.shortcuts.render_to_response()` providing a `RequestContext` by default.
- Support for combining `F expressions` with `timedelta` values when retrieving or updating database values.

Backwards-incompatible changes in 1.3

CSRF validation now applies to AJAX requests

Prior to Django 1.2.5, Django’s CSRF-prevention system exempted AJAX requests from CSRF verification; due to security issues reported to us, however, all requests are now subjected to CSRF verification. Consult the Django CSRF documentation for details on how to handle CSRF verification in AJAX requests.
Restricted filters in admin interface

Prior to Django 1.2.5, the Django administrative interface allowed filtering on any model field or relation – not just those specified in `list_filter` – via query string manipulation. Due to security issues reported to us, however, query string lookup arguments in the admin must be for fields or relations specified in `list_filter` or `date_hierarchy`.

Deleting a model doesn’t delete associated files

In earlier Django versions, when a model instance containing a `FileField` was deleted, `FileField` took it upon itself to also delete the file from the backend storage. This opened the door to several data-loss scenarios, including rolled-back transactions and fields on different models referencing the same file. In Django 1.3, when a model is deleted the `FileField`’s `delete()` method won’t be called. If you need cleanup of orphaned files, you’ll need to handle it yourself (for instance, with a custom management command that can be run manually or scheduled to run periodically via e.g. cron).

PasswordInput default rendering behavior

The `PasswordInput` form widget, intended for use with form fields which represent passwords, accepts a boolean keyword argument `render_value` indicating whether to send its data back to the browser when displaying a submitted form with errors. Prior to Django 1.3, this argument defaulted to `True`, meaning that the submitted password would be sent back to the browser as part of the form. Developers who wished to add a bit of additional security by excluding that value from the redisplayed form could instantiate a `PasswordInput` passing `render_value=False`.

Due to the sensitive nature of passwords, however, Django 1.3 takes this step automatically; the default value of `render_value` is now `False`, and developers who want the password value returned to the browser on a submission with errors (the previous behavior) must now explicitly indicate this. For example:

```
class LoginForm(forms.Form):
    username = forms.CharField(max_length=100)
    password = forms.CharField(widget=forms.PasswordInput(render_value=True))
```

Clearable default widget for FileField

Django 1.3 now includes a `ClearableFileInput` form widget in addition to `FileInput`. `ClearableFileInput` renders with a checkbox to clear the field’s value (if the field has a value and is not required); `FileInput` provided no means for clearing an existing file from a `FileField`.

`ClearableFileInput` is now the default widget for a `FileField`, so existing forms including `FileField` without assigning a custom widget will need to account for the possible extra checkbox in the rendered form output.
To return to the previous rendering (without the ability to clear the FileField), use the FileInput widget in place of ClearableFileInput. For instance, in a ModelForm for a hypothetical Document model with a FileField named document:

```python
from django import forms
from myapp.models import Document

class DocumentForm(forms.ModelForm):
    class Meta:
        model = Document
        widgets = {'document': forms.FileInput}
```

**New index on database session table**

Prior to Django 1.3, the database table used by the database backend for the sessions app had no index on the **expire_date** column. As a result, date-based queries on the session table — such as the query that is needed to purge old sessions — would be very slow if there were lots of sessions.

If you have an existing project that is using the database session backend, you don’t have to do anything to accommodate this change. However, you may get a significant performance boost if you manually add the new index to the session table. The SQL that will add the index can be found by running the `sqlindexes` admin command:

```
python manage.py sqlindexes sessions
```

**No more naughty words**

Django has historically provided (and enforced) a list of profanities. The comments app has enforced this list of profanities, preventing people from submitting comments that contained one of those profanities.

Unfortunately, the technique used to implement this profanities list was woefully naive, and prone to the Scunthorpe problem. Improving the built-in filter to fix this problem would require significant effort, and since natural language processing isn’t the normal domain of a web framework, we have “fixed” the problem by making the list of prohibited words an empty list.

If you want to restore the old behavior, simply put a PROFANITIES_LIST setting in your settings file that includes the words that you want to prohibit (see the commit that implemented this change if you want to see the list of words that was historically prohibited). However, if avoiding profanities is important to you, you would be well advised to seek out a better, less naive approach to the problem.
Localflavor changes

Django 1.3 introduces the following backwards-incompatible changes to local flavors:

- **Canada (ca)** - The province “Newfoundland and Labrador” has had its province code updated to “NL”, rather than the older “NF”. In addition, the Yukon Territory has had its province code corrected to “YT”, instead of “YK”.

- **Indonesia (id)** - The province “Nanggroe Aceh Darussalam (NAD)” has been removed from the province list in favor of the new official designation “Aceh (ACE)”.

- **United States of America (us)** - The list of “states” used by USStateField has expanded to include Armed Forces postal codes. This is backwards-incompatible if you were relying on USStateField not including them.

FormSet updates

In Django 1.3 FormSet creation behavior is modified slightly. Historically the class didn’t make a distinction between not being passed data and being passed empty dictionary. This was inconsistent with behavior in other parts of the framework. Starting with 1.3 if you pass in empty dictionary the FormSet will raise a ValidationError.

For example with a FormSet:

```python
>>> class ArticleForm(Form):
...     title = CharField()
...     pub_date = DateField()

>>> ArticleFormSet = formset_factory(ArticleForm)
```

default code will raise a ValidationError:

```python
>>> ArticleFormSet({})
Traceback (most recent call last):
...
ValidationError: ['ManagementForm data is missing or has been tampered with']
```

if you need to instantiate an empty FormSet, don’t pass in the data or use None:

```python
>>> formset = ArticleFormSet()
>>> formset = ArticleFormSet(data=None)
```
Callables in templates

Previously, a callable in a template would only be called automatically as part of the variable resolution process if it was retrieved via attribute lookup. This was an inconsistency that could result in confusing and unhelpful behavior:

```
>>> Template("{{ user.get_full_name }}").render(Context({'user': user}))
u'Joe Bloggs'
```

```
>>> Template("{{ full_name }}").render(Context({'full_name': user.get_full_name}))
```

This has been resolved in Django 1.3 - the result in both cases will be `u'Joe Bloggs'`. Although the previous behavior was not useful for a template language designed for web designers, and was never deliberately supported, it is possible that some templates may be broken by this change.

Use of custom SQL to load initial data in tests

Django provides a custom SQL hooks as a way to inject hand-crafted SQL into the database synchronization process. One of the possible uses for this custom SQL is to insert data into your database. If your custom SQL contains `INSERT` statements, those insertions will be performed every time your database is synchronized. This includes the synchronization of any test databases that are created when you run a test suite.

However, in the process of testing the Django 1.3, it was discovered that this feature has never completely worked as advertised. When using database backends that don’t support transactions, or when using a `TransactionTestCase`, data that has been inserted using custom SQL will not be visible during the testing process.

Unfortunately, there was no way to rectify this problem without introducing a backwards incompatibility. Rather than leave SQL-inserted initial data in an uncertain state, Django now enforces the policy that data inserted by custom SQL will not be visible during testing.

This change only affects the testing process. You can still use custom SQL to load data into your production database as part of the `syncdb` process. If you require data to exist during test conditions, you should either insert it using `test fixtures`, or using the `setUp()` method of your test case.

Changed priority of translation loading

Work has been done to simplify, rationalize and properly document the algorithm used by Django at runtime to build translations from the different translations found on disk, namely:

For translatable literals found in Python code and templates (`'django'` gettext domain):

- Priorities of translations included with applications listed in the `INSTALLED_APPS` setting were changed.
  
  To provide a behavior consistent with other parts of Django that also use such setting (templates, etc.)
now, when building the translation that will be made available, the apps listed first have higher precedence than the ones listed later.

- Now it is possible to override the translations shipped with applications by using the `LOCALE_PATHS` setting whose translations have now higher precedence than the translations of `INSTALLED_APPS` applications. The relative priority among the values listed in this setting has also been modified so the paths listed first have higher precedence than the ones listed later.

- The `locale` subdirectory of the directory containing the settings, that usually coincides with and is known as the project directory is being deprecated in this release as a source of translations. (the precedence of these translations is intermediate between applications and `LOCALE_PATHS` translations). See the corresponding deprecated features section of this document.

For translatable literals found in JavaScript code ('djangojs' gettext domain):

- Similarly to the 'django' domain translations: Overriding of translations shipped with applications by using the `LOCALE_PATHS` setting is now possible for this domain too. These translations have higher precedence than the translations of Python packages passed to the `javascript_catalog()` view. Paths listed first have higher precedence than the ones listed later.

- Translations under the `locale` subdirectory of the project directory have never been taken in account for JavaScript translations and remain in the same situation considering the deprecation of such location.

**Transaction management**

When using managed transactions –that is, anything but the default autocommit mode– it is important when a transaction is marked as “dirty”. Dirty transactions are committed by the `commit_on_success` decorator or the `django.middleware.transaction.TransactionMiddleware`, and `commit_manually` forces them to be closed explicitly; clean transactions “get a pass”, which means they are usually rolled back at the end of a request when the connection is closed.

Until Django 1.3, transactions were only marked dirty when Django was aware of a modifying operation performed in them; that is, either some model was saved, some bulk update or delete was performed, or the user explicitly called `transaction.set_dirty()`. In Django 1.3, a transaction is marked dirty when any database operation is performed.

As a result of this change, you no longer need to set a transaction dirty explicitly when you execute raw SQL or use a data-modifying `SELECT`. However, you do need to explicitly close any read-only transactions that are being managed using `commit_manually()`. For example:

```python
@transaction.commit_manually
def my_view(request, name):
    obj = get_object_or_404(MyObject, name__iexact=name)
    return render_to_response('template', {'object': obj})
```
Prior to Django 1.3, this would work without error. However, under Django 1.3, this will raise a
TransactionManagementError because the read operation that retrieves the MyObject instance leaves the
transaction in a dirty state.

**No password reset for inactive users**

Prior to Django 1.3, inactive users were able to request a password reset email and reset their password. In
Django 1.3 inactive users will receive the same message as a nonexistent account.

**Password reset view now accepts from_email**

The django.contrib.auth.views.password_reset() view now accepts a from_email parameter, which is
passed to the password_reset_form’s save() method as a keyword argument. If you are using this view
with a custom password reset form, then you will need to ensure your form’s save() method accepts this
keyword argument.

**Features deprecated in 1.3**

Django 1.3 deprecates some features from earlier releases. These features are still supported, but will be
gradually phased out over the next few release cycles.

Code taking advantage of any of the features below will raise a PendingDeprecationWarning in Django 1.3.
This warning will be silent by default, but may be turned on using Python’s warnings module, or by running
Python with a -Wd or -Wall flag.

In Django 1.4, these warnings will become a DeprecationWarning, which is not silent. In Django 1.5 support
for these features will be removed entirely.

See also:

For more details, see the documentation Django’s release process and our deprecation timeline.

**mod_python support**

The mod_python library has not had a release since 2007 or a commit since 2008. The Apache Foundation
board voted to remove mod_python from the set of active projects in its version control repositories, and
its lead developer has shifted all of his efforts toward the lighter, slimmer, more stable, and more flexible
mod_wsgi backend.

If you are currently using the mod_python request handler, you should redeploy your Django projects using
another request handler. mod_wsgi is the request handler recommended by the Django project, but FastCGI
is also supported. Support for mod_python deployment will be removed in Django 1.5.
**Function-based generic views**

As a result of the introduction of class-based generic views, the function-based generic views provided by Django have been deprecated. The following modules and the views they contain have been deprecated:

- `django.views.generic.create_update`
- `django.views.generic.date_based`
- `django.views.generic.list_detail`
- `django.views.generic.simple`

**Test client response template attribute**

Django’s `test client` returns `Response` objects annotated with extra testing information. In Django versions prior to 1.3, this included a `template` attribute containing information about templates rendered in generating the response: either None, a single `Template` object, or a list of `Template` objects. This inconsistency in return values (sometimes a list, sometimes not) made the attribute difficult to work with.

In Django 1.3 the `template` attribute is deprecated in favor of a new `templates` attribute, which is always a list, even if it has only a single element or no elements.

**DjangoTestRunner**

As a result of the introduction of support for `unittest2`, the features of `django.test.simple.DjangoTestRunner` (including fail-fast and Ctrl-C test termination) have been made redundant. In view of this redundancy, `DjangoTestRunner` has been turned into an empty placeholder class, and will be removed entirely in Django 1.5.

**Changes to url and ssi**

Most template tags will allow you to pass in either constants or variables as arguments—for example:

```latex
{% extends "base.html" %}
```

allows you to specify a base template as a constant, but if you have a context variable `templ` that contains the value `base.html`:

```latex
{% extends templ %}
```

is also legal.
However, due to an accident of history, the `url` and `ssi` are different. These tags use the second, quoteless syntax, but interpret the argument as a constant. This means it isn’t possible to use a context variable as the target of a `url` and `ssi` tag.

Django 1.3 marks the start of the process to correct this historical accident. Django 1.3 adds a new template library —`future`— that provides alternate implementations of the `url` and `ssi` template tags. This `future` library implement behavior that makes the handling of the first argument consistent with the handling of all other variables. So, an existing template that contains:

\{% url sample %\}

should be replaced with:

\{% load url from future %\}
\{% url 'sample' %\}

The tags implementing the old behavior have been deprecated, and in Django 1.5, the old behavior will be replaced with the new behavior. To ensure compatibility with future versions of Django, existing templates should be modified to use the new `future` libraries and syntax.

**Changes to the login methods of the admin**

In previous version the admin app defined login methods in multiple locations and ignored the almost identical implementation in the already used auth app. A side effect of this duplication was the missing adoption of the changes made in r12634 to support a broader set of characters for usernames.

This release refactors the admin’s login mechanism to use a subclass of the `AuthenticationForm` instead of a manual form validation. The previously undocumented method `django.contrib.admin.sites.AdminSite.display_login_form` has been removed in favor of a new `login_form` attribute.

**reset and sqlreset management commands**

Those commands have been deprecated. The `flush` and `sqlflush` commands can be used to delete everything. You can also use `ALTER TABLE` or `DROP TABLE` statements manually.

**GeoDjango**

- The function-based `TEST_RUNNER` previously used to execute the GeoDjango test suite, `django.contrib.gis.tests.run_gis_tests`, was deprecated for the class-based runner, `django.contrib.gis.tests.GeoDjangoTestSuiteRunner`.

- Previously, calling `transform()` would silently do nothing when GDAL wasn’t available. Now, a `GEOSException` is properly raised to indicate possible faulty application code. A warning is now raised if `transform()` is called when the SRID of the geometry is less than 0 or `None`. 
CZBirthNumberField.clean

Previously this field’s `clean()` method accepted a second, gender, argument which allowed stronger validation checks to be made, however since this argument could never actually be passed from the Django form machinery it is now pending deprecation.

CompatCookie

Previously, `django.http` exposed an undocumented `CompatCookie` class, which was a bugfix wrapper around the standard library `SimpleCookie`. As the fixes are moving upstream, this is now deprecated - you should use `from django.http import SimpleCookie` instead.

Loading of project-level translations

This release of Django starts the deprecation process for inclusion of translations located under the so-called project path in the translation building process performed at runtime. The `LOCALE_PATHS` setting can be used for the same task by adding the filesystem path to a `locale` directory containing project-level translations to the value of that setting.

Rationale for this decision:

- The project path has always been a loosely defined concept (actually, the directory used for locating project-level translations is the directory containing the settings module) and there has been a shift in other parts of the framework to stop using it as a reference for location of assets at runtime.

- Detection of the `locale` subdirectory tends to fail when the deployment scenario is more complex than the basic one. e.g. it fails when the settings module is a directory (ticket #10765).

- There are potential strange development- and deployment-time problems like the fact that the `project_dir/locale/` subdir can generate spurious error messages when the project directory is added to the Python path (`manage.py runserver` does this) and then it clashes with the equally named standard library module, this is a typical warning message:

```
/usr/lib/python2.6/gettext.py:49: ImportWarning: Not importing directory '/path/to/project/'
        __locale__: missing __init__.py.
import locale, copy, os, re, struct, sys
```

- This location wasn’t included in the translation building process for JavaScript literals. This deprecation removes such inconsistency.
PermWrapper moved to django.contrib.auth.context_processors

In Django 1.2, we began the process of changing the location of the auth context processor from django.core.context_processors to django.contrib.auth.context_processors. However, the PermWrapper support class was mistakenly omitted from that migration. In Django 1.3, the PermWrapper class has also been moved to django.contrib.auth.context_processors, along with the PermLookupDict support class. The new classes are functionally identical to their old versions; only the module location has changed.

Removal of XMLField

When Django was first released, Django included an XMLField that performed automatic XML validation for any field input. However, this validation function hasn’t been performed since the introduction of newforms, prior to the 1.0 release. As a result, XMLField as currently implemented is functionally indistinguishable from a simple TextField.

For this reason, Django 1.3 has fast-tracked the deprecation of XMLField –instead of a two-release deprecation, XMLField will be removed entirely in Django 1.4.

It’s easy to update your code to accommodate this change –just replace all uses of XMLField with TextField, and remove the schema_path keyword argument (if it is specified).

9.1.19 1.2 release

Django 1.2.7 release notes

September 10, 2011

Welcome to Django 1.2.7!

This is the seventh bugfix/security release in the Django 1.2 series. It replaces Django 1.2.6 due to problems with the 1.2.6 release tarball. Django 1.2.7 is a recommended upgrade for all users of any Django release in the 1.2.X series.

For more information, see the release advisory.

Django 1.2.6 release notes

September 9, 2011

Welcome to Django 1.2.6!

This is the sixth bugfix/security release in the Django 1.2 series, fixing several security issues present in Django 1.2.5. Django 1.2.6 is a recommended upgrade for all users of any Django release in the 1.2.X series.

For a full list of issues addressed in this release, see the security advisory.
**Django 1.2.5 release notes**

Welcome to Django 1.2.5!

This is the fifth "bugfix" release in the Django 1.2 series, improving the stability and performance of the Django 1.2 codebase.

With four exceptions, Django 1.2.5 maintains backwards compatibility with Django 1.2.4. It also contains a number of fixes and other improvements. Django 1.2.5 is a recommended upgrade for any development or deployment currently using or targeting Django 1.2.

For full details on the new features, backwards incompatibilities, and deprecated features in the 1.2 branch, see the Django 1.2 release notes.

**Backwards incompatible changes**

**CSRF exception for AJAX requests**

Django includes a CSRF-protection mechanism, which makes use of a token inserted into outgoing forms. Middleware then checks for the token’s presence on form submission, and validates it.

Prior to Django 1.2.5, our CSRF protection made an exception for AJAX requests, on the following basis:

- Many AJAX toolkits add an X-Requested-With header when using XMLHttpRequest.
- Browsers have strict same-origin policies regarding XMLHttpRequest.
- In the context of a browser, the only way that a custom header of this nature can be added is with XMLHttpRequest.

Therefore, for ease of use, we did not apply CSRF checks to requests that appeared to be AJAX on the basis of the X-Requested-With header. The Ruby on Rails web framework had a similar exemption.

Recently, engineers at Google made members of the Ruby on Rails development team aware of a combination of browser plugins and redirects which can allow an attacker to provide custom HTTP headers on a request to any website. This can allow a forged request to appear to be an AJAX request, thereby defeating CSRF protection which trusts the same-origin nature of AJAX requests.

Michael Koziarski of the Rails team brought this to our attention, and we were able to produce a proof-of-concept demonstrating the same vulnerability in Django’s CSRF handling.

To remedy this, Django will now apply full CSRF validation to all requests, regardless of apparent AJAX origin. This is technically backwards-incompatible, but the security risks have been judged to outweigh the compatibility concerns in this case.

Additionally, Django will now accept the CSRF token in the custom HTTP header X-CSRF_TOKEN, as well as in the form submission itself, for ease of use with popular JavaScript toolkits which allow insertion of custom headers into all AJAX requests.
Please see the CSRF docs for example jQuery code that demonstrates this technique, ensuring that you are looking at the documentation for your version of Django, as the exact code necessary is different for some older versions of Django.

**FileField no longer deletes files**

In earlier Django versions, when a model instance containing a `FileField` was deleted, `FileField` took it upon itself to also delete the file from the backend storage. This opened the door to several potentially serious data-loss scenarios, including rolled-back transactions and fields on different models referencing the same file. In Django 1.2.5, `FileField` will never delete files from the backend storage. If you need cleanup of orphaned files, you’ll need to handle it yourself (for instance, with a custom management command that can be run manually or scheduled to run periodically via e.g. cron).

**Use of custom SQL to load initial data in tests**

Django provides a custom SQL hook as a way to inject hand-crafted SQL into the database synchronization process. One of the possible uses for this custom SQL is to insert data into your database. If your custom SQL contains `INSERT` statements, those insertions will be performed every time your database is synchronized. This includes the synchronization of any test databases that are created when you run a test suite.

However, in the process of testing the Django 1.3, it was discovered that this feature has never completely worked as advertised. When using database backends that don’t support transactions, or when using a TransactionTestCase, data that has been inserted using custom SQL will not be visible during the testing process.

Unfortunately, there was no way to rectify this problem without introducing a backwards incompatibility. Rather than leave SQL-inserted initial data in an uncertain state, Django now enforces the policy that data inserted by custom SQL will not be visible during testing.

This change only affects the testing process. You can still use custom SQL to load data into your production database as part of the `syncdb` process. If you require data to exist during test conditions, you should either insert it using `test fixtures`, or using the `setUp()` method of your test case.

**ModelAdmin.lookup_allowed signature changed**

Django 1.2.4 introduced a method `lookup_allowed` on `ModelAdmin`, to cope with a security issue (changeset [15033]). Although this method was never documented, it seems some people have overridden `lookup_allowed`, especially to cope with regressions introduced by that changeset. While the method is still undocumented and not marked as stable, it may be helpful to know that the signature of this function has changed.
Django 1.2.4 release notes

Welcome to Django 1.2.4!

This is the fourth “bugfix” release in the Django 1.2 series, improving the stability and performance of the Django 1.2 codebase.

With one exception, Django 1.2.4 maintains backwards compatibility with Django 1.2.3. It also contains a number of fixes and other improvements. Django 1.2.4 is a recommended upgrade for any development or deployment currently using or targeting Django 1.2.

For full details on the new features, backwards incompatibilities, and deprecated features in the 1.2 branch, see the Django 1.2 release notes.

Backwards incompatible changes

Restricted filters in admin interface

The Django administrative interface, django.contrib.admin, supports filtering of displayed lists of objects by fields on the corresponding models, including across database-level relationships. This is implemented by passing lookup arguments in the querystring portion of the URL, and options on the ModelAdmin class allow developers to specify particular fields or relationships which will generate automatic links for filtering.

One historically-undocumented and -unofficially-supported feature has been the ability for a user with sufficient knowledge of a model’s structure and the format of these lookup arguments to invent useful new filters on the fly by manipulating the querystring.

However, it has been demonstrated that this can be abused to gain access to information outside of an admin user’s permissions; for example, an attacker with access to the admin and sufficient knowledge of model structure and relations could construct query strings which—with repeated use of regular-expression lookups supported by the Django database API—expose sensitive information such as users’ password hashes.

To remedy this, django.contrib.admin will now validate that querystring lookup arguments either specify only fields on the model being viewed, or cross relations which have been explicitly allowed by the application developer using the preexisting mechanism mentioned above. This is backwards-incompatible for any users relying on the prior ability to insert arbitrary lookups.

One new feature

Ordinarily, a point release would not include new features, but in the case of Django 1.2.4, we have made an exception to this rule.

One of the bugs fixed in Django 1.2.4 involves a set of circumstances whereby a running a test suite on a multiple database configuration could cause the original source database (i.e., the actual production database) to be dropped, causing catastrophic loss of data. In order to provide a fix for this problem, it was necessary
to introduce a new setting `TEST_DEPENDENCIES`—that allows you to define any creation order dependencies in your database configuration.

Most users—even users with multiple-database configurations—need not be concerned about the data loss bug, or the manual configuration of `TEST_DEPENDENCIES`. See the original problem report documentation on controlling the creation order of test databases for details.

**GeoDjango**

The function-based `TEST_RUNNER` previously used to execute the GeoDjango test suite, `django.contrib.gis.tests.run_gis_tests`, was finally deprecated in favor of a class-based test runner, `django.contrib.gis.tests.GeoDjangoTestSuiteRunner`, added in this release.

In addition, the GeoDjango test suite is now included when running the Django test suite with `runtests.py` and using spatial database backends.

**Django 1.2.3 release notes**

Django 1.2.3 fixed a couple of release problems in the 1.2.2 release and was released two days after 1.2.2.

This release corrects the following problems:

- The patch applied for the security issue covered in Django 1.2.2 caused issues with non-ASCII responses using CSRF tokens.
- The patch also caused issues with some forms, most notably the user-editing forms in the Django administrative interface.
- The packaging manifest did not contain the full list of required files.

**Django 1.2.2 release notes**

Welcome to Django 1.2.2!

This is the second “bugfix” release in the Django 1.2 series, improving the stability and performance of the Django 1.2 codebase.

Django 1.2.2 maintains backwards compatibility with Django 1.2.1, but contain a number of fixes and other improvements. Django 1.2.2 is a recommended upgrade for any development or deployment currently using or targeting Django 1.2.

For full details on the new features, backwards incompatibilities, and deprecated features in the 1.2 branch, see the Django 1.2 release notes.
One new feature

Ordinarily, a point release would not include new features, but in the case of Django 1.2.2, we have made an exception to this rule.

In order to test a bug fix that forms part of the 1.2.2 release, it was necessary to add a feature—the `enforce_csrf_checks` flag—to the test client. This flag forces the test client to perform full CSRF checks on forms. The default behavior of the test client hasn’t changed, but if you want to do CSRF checks with the test client, it is now possible to do so.

Django 1.2.1 release notes

Django 1.2.1 was released almost immediately after 1.2.0 to correct two small bugs: one was in the documentation packaging script, the other was a bug that affected datetime form field widgets when localization was enabled.

Django 1.2 release notes

May 17, 2010.

Welcome to Django 1.2!

Nearly a year in the making, Django 1.2 packs an impressive list of new features and lots of bug fixes. These release notes cover the new features, as well as important changes you’ll want to be aware of when upgrading from Django 1.1 or older versions.

Overview

Django 1.2 introduces several large, important new features, including:

- Support for multiple database connections in a single Django instance.
- Model validation inspired by Django’s form validation.
- Vastly improved protection against Cross-Site Request Forgery (CSRF).
- A new user “messages” framework with support for cookie- and session-based message for both anonymous and authenticated users.
- Hooks for object-level permissions, permissions for anonymous users, and more flexible username requirements.
- Customization of email sending via email backends.
- New “smart” if template tag which supports comparison operators.
These are just the highlights; full details and a complete list of features may be found below.

See also:

Django Advent covered the release of Django 1.2 with a series of articles and tutorials that cover some of the new features in depth.

Wherever possible these features have been introduced in a backwards-compatible manner per our API stability policy.

However, a handful of features have changed in ways that, for some users, will be backwards-incompatible.

The big changes are:

- Support for Python 2.3 has been dropped. See the full notes below.
- The new CSRF protection framework is not backwards-compatible with the old system. Users of the old system will not be affected until the old system is removed in Django 1.4.

  However, upgrading to the new CSRF protection framework requires a few important backwards-incompatible changes, detailed in CSRF Protection, below.
- Authors of custom Field subclasses should be aware that a number of methods have had a change in prototype, detailed under get_db_prep_*() methods on Field, below.
- The internals of template tags have changed somewhat; authors of custom template tags that need to store state (e.g. custom control flow tags) should ensure that their code follows the new rules for stateful template tags
- The user_passes_test(), login_required(), and permission_required(), decorators from django.contrib.auth only apply to functions and no longer work on methods. There’s a simple one-line fix detailed below.

Again, these are just the big features that will affect the most users. Users upgrading from previous versions of Django are heavily encouraged to consult the complete list of backwards-incompatible changes and the list of deprecated features.

Python compatibility

While not a new feature, it’s important to note that Django 1.2 introduces the first shift in our Python compatibility policy since Django’s initial public debut. Previous Django releases were tested and supported on 2.x Python versions from 2.3 up; Django 1.2, however, drops official support for Python 2.3. As such, the minimum Python version required for Django is now 2.4, and Django is tested and supported on Python 2.4, 2.5 and 2.6, and will be supported on the as-yet-unreleased Python 2.7.

This change should affect only a small number of Django users, as most operating-system vendors today are shipping Python 2.4 or newer as their default version. If you’re still using Python 2.3, however, you’ll need to stick to Django 1.1 until you can upgrade; per our support policy, Django 1.1 will continue to receive security support until the release of Django 1.3.
A roadmap for Django’s overall 2.x Python support, and eventual transition to Python 3.x, is currently being developed, and will be announced prior to the release of Django 1.3.

**What’s new in Django 1.2**

**Support for multiple databases**

Django 1.2 adds the ability to use more than one database in your Django project. Queries can be issued at a specific database with the `using()` method on `QuerySet` objects. Individual objects can be saved to a specific database by providing a `using` argument when you call `save()`.

**Model validation**

Model instances now have support for validating their own data, and both model and form fields now accept configurable lists of validators specifying reusable, encapsulated validation behavior. Note, however, that validation must still be performed explicitly. Simply invoking a model instance’s `save()` method will not perform any validation of the instance’s data.

**Improved CSRF protection**

Django now has much improved protection against Cross-Site Request Forgery (CSRF) attacks. This type of attack occurs when a malicious website contains a link, a form button or some JavaScript that is intended to perform some action on your website, using the credentials of a logged-in user who visits the malicious site in their browser. A related type of attack, “login CSRF,” where an attacking site tricks a user’s browser into logging into a site with someone else’s credentials, is also covered.

**Messages framework**

Django now includes a robust and configurable messages framework with built-in support for cookie- and session-based messaging, for both anonymous and authenticated clients. The messages framework replaces the deprecated user message API and allows you to temporarily store messages in one request and retrieve them for display in a subsequent request (usually the next one).
Object-level permissions

A foundation for specifying permissions at the per-object level has been added. Although there is no implementation of this in core, a custom authentication backend can provide this implementation and it will be used by `django.contrib.auth.models.User`. See the authentication docs for more information.

Permissions for anonymous users

If you provide a custom auth backend with `supports_anonymous_user` set to `True`, AnonymousUser will check the backend for permissions, just like User already did. This is useful for centralizing permission handling - apps can always delegate the question of whether something is allowed or not to the authorization/authentication backend. See the authentication docs for more details.

Relaxed requirements for usernames

The built-in `User` model’s `username` field now allows a wider range of characters, including @, +, . and - characters.

Email backends

You can now configure the way that Django sends email. Instead of using SMTP to send all email, you can now choose a configurable email backend to send messages. If your hosting provider uses a sandbox or some other non-SMTP technique for sending mail, you can now construct an email backend that will allow Django’s standard mail sending methods to use those facilities.

This also makes it easier to debug mail sending. Django ships with backend implementations that allow you to send email to a file, to the console, or to memory. You can even configure all email to be thrown away.

“Smart” if tag

The `if` tag has been upgraded to be much more powerful. First, we’ve added support for comparison operators. No longer will you have to type:

```ini
{% ifnotequal a b %}
...
{% endifnotequal %}
```

You can now do this:

```ini
{% if a != b %}
...
{% endif %}
```
There’s really no reason to use {% ifequal %} or {% ifnotequal %} anymore, unless you’re the nostalgic type.

The operators supported are ==, !=, <, >, <=, >=, in and not in, all of which work like the Python operators, in addition to and, or and not, which were already supported.

Also, filters may now be used in the if expression. For example:

```html
<div>
  {% if user.email|lower == message.recipient|lower %}
    class="highlight"
  {% endif %}
  {{ message }}
</div>
```

**Template caching**

In previous versions of Django, every time you rendered a template, it would be reloaded from disk. In Django 1.2, you can use a cached template loader to load templates once, then cache the result for every subsequent render. This can lead to a significant performance improvement if your templates are broken into lots of smaller subtemplates (using the {% extends %} or {% include %} tags).

As a side effect, it is now much easier to support non-Django template languages.

**Class-based template loaders**

As part of the changes made to introduce Template caching and following a general trend in Django, the template loaders API has been modified to use template loading mechanisms that are encapsulated in Python classes as opposed to functions, the only method available until Django 1.1.

All the template loaders shipped with Django have been ported to the new API but they still implement the function-based API and the template core machinery still accepts function-based loaders (built-in or third party) so there is no immediate need to modify your TEMPLATE_LOADERS setting in existing projects, things will keep working if you leave it untouched up to and including the Django 1.3 release.

If you have developed your own custom template loaders we suggest to consider porting them to a class-based implementation because the code for backwards compatibility with function-based loaders starts its deprecation process in Django 1.2 and will be removed in Django 1.4. There is a description of the API these loader classes must implement in the template API reference and you can also examine the source code of the loaders shipped with Django.
Natural keys in fixtures

Fixtures can now refer to remote objects using Natural keys. This lookup scheme is an alternative to the normal primary-key based object references in a fixture, improving readability and resolving problems referring to objects whose primary key value may not be predictable or known.

Fast failure for tests

Both the test subcommand of django-admin.py and the runtests.py script used to run Django’s own test suite now support a --failfast option. When specified, this option causes the test runner to exit after encountering a failure instead of continuing with the test run. In addition, the handling of Ctrl-C during a test run has been improved to trigger a graceful exit from the test run that reports details of the tests that were run before the interruption.

BigIntegerField

Models can now use a 64-bit BigIntegerField type.

Improved localization

Django’s internationalization framework has been expanded with locale-aware formatting and form processing. That means, if enabled, dates and numbers on templates will be displayed using the format specified for the current locale. Django will also use localized formats when parsing data in forms. See Format localization for more details.

readonly_fields in ModelAdmin

django.contrib.admin.ModelAdmin.readonly_fields has been added to enable non-editable fields in add/change pages for models and inlines. Field and calculated values can be displayed alongside editable fields.

Customizable syntax highlighting

You can now use a DJANGO_COLORS environment variable to modify or disable the colors used by django-admin.py to provide syntax highlighting.
Syndication feeds as views

Syndication feeds can now be used directly as views in your URLconf. This means that you can maintain complete control over the URL structure of your feeds. Like any other view, feeds views are passed a request object, so you can do anything you would normally do with a view, like user based access control, or making a feed a named URL.

GeoDjango

The most significant new feature for GeoDjango in 1.2 is support for multiple spatial databases. As a result, the following spatial database backends are now included:

- django.contrib.gis.db.backends.postgis
- django.contrib.gis.db.backends.mysql
- django.contrib.gis.db.backends.oracle
- django.contrib.gis.db.backends.spatialite

GeoDjango now supports the rich capabilities added in the PostGIS 1.5 release. New features include support for the geography type and enabling of distance queries with non-point geometries on geographic coordinate systems.

Support for 3D geometry fields was added, and may be enabled by setting the dim keyword to 3 in your GeometryField. The Extent3D aggregate and extent3d() GeoQuerySet method were added as a part of this feature.

The force_rhr(), reverse_geom(), and geohash() GeoQuerySet methods are new.

The GEOS interface was updated to use thread-safe C library functions when available on the platform.

The GDAL interface now allows the user to set a spatial_filter on the features returned when iterating over a Layer.

Finally, GeoDjango’s documentation is now included with Django’s and is no longer hosted separately at geodjango.org.

JavaScript-assisted handling of inline related objects in the admin

If a user has JavaScript enabled in their browser, the interface for inline objects in the admin now allows inline objects to be dynamically added and removed. Users without JavaScript-enabled browsers will see no change in the behavior of inline objects.
New `now` template tag format specifier characters: c and u

The argument to the `now` has gained two new format characters: c to specify that a datetime value should be formatted in ISO 8601 format, and u that allows output of the microseconds part of a datetime or time value.

These are also available in others parts like the `date` and `time` template filters, the `humanize` template tag library and the new `format localization` framework.

Backwards-incompatible changes in 1.2

Wherever possible the new features above have been introduced in a backwards-compatible manner per our API stability policy policy. This means that practically all existing code which worked with Django 1.1 will continue to work with Django 1.2; such code will, however, begin issuing warnings (see below for details).

However, a handful of features have changed in ways that, for some users, will be immediately backwards-incompatible. Those changes are detailed below.

CSRF Protection

We’ve made large changes to the way CSRF protection works, detailed in the CSRF documentation. Here are the major changes you should be aware of:

- `CsrfResponseMiddleware` and `CsrfMiddleware` have been deprecated and will be removed completely in Django 1.4, in favor of a template tag that should be inserted into forms.

- All contrib apps use a `csrf_protect` decorator to protect the view. This requires the use of the `csrf_token` template tag in the template. If you have used custom templates for contrib views, you MUST READ THE UPGRADE INSTRUCTIONS to fix those templates.

Documentation removed

The upgrade notes have been removed in current Django docs. Please refer to the docs for Django 1.3 or older to find these instructions.

- `CsrfViewMiddleware` is included in `MIDDLEWARE_CLASSES` by default. This turns on CSRF protection by default, so views that accept POST requests need to be written to work with the middleware. Instructions on how to do this are found in the CSRF docs.

- All of the CSRF has moved from contrib to core (with backwards compatible imports in the old locations, which are deprecated and will cease to be supported in Django 1.4).
get_db_prep_*( ) methods on Field

Prior to Django 1.2, a custom Field had the option of defining several functions to support conversion of Python values into database-compatible values. A custom field might look something like:

```python
class CustomModelField(models.Field):
    # ...
    def db_type(self):
        # ...
    def get_db_prep_save(self, value):
        # ...
    def get_db_prep_value(self, value):
        # ...
    def get_db_prep_lookup(self, lookup_type, value):
        # ...
```

In 1.2, these three methods have undergone a change in prototype, and two extra methods have been introduced:

```python
class CustomModelField(models.Field):
    # ...
    def db_type(self, connection):
        # ...
    def get_prep_value(self, value):
        # ...
    def get_prep_lookup(self, lookup_type, value):
        # ...
    def get_db_prep_save(self, value, connection):
        # ...
    def get_db_prep_value(self, value, connection, prepared=False):
        # ...
    def get_db_prep_lookup(self, self, lookup_type, value, connection, prepared=False):
        # ...
```

These changes are required to support multiple databases – `db_type` and `get_db_prep_*` can no longer make any assumptions regarding the database for which it is preparing. The `connection` argument now provides
the preparation methods with the specific connection for which the value is being prepared.

The two new methods exist to differentiate general data-preparation requirements from requirements that are database-specific. The prepared argument is used to indicate to the database-preparation methods whether generic value preparation has been performed. If an unprepared (i.e., prepared=False) value is provided to the get_db_prep_*() calls, they should invoke the corresponding get_prep_*() calls to perform generic data preparation.

We’ve provided conversion functions that will transparently convert functions adhering to the old prototype into functions compatible with the new prototype. However, these conversion functions will be removed in Django 1.4, so you should upgrade your Field definitions to use the new prototype as soon as possible.

If your get_db_prep_*() methods made no use of the database connection, you should be able to upgrade by renaming get_db_prep_value() to get_prep_value() and get_db_prep_lookup() to get_prep_lookup(). If you require database specific conversions, then you will need to provide an implementation get_db_prep_* that uses the connection argument to resolve database-specific values.

**Stateful template tags**

Template tags that store rendering state on their Node subclass have always been vulnerable to thread-safety and other issues; as of Django 1.2, however, they may also cause problems when used with the new cached template loader.

All of the built-in Django template tags are safe to use with the cached loader, but if you’re using custom template tags that come from third party packages, or from your own code, you should ensure that the Node implementation for each tag is thread-safe. For more information, see template tag thread safety considerations.

You may also need to update your templates if you were relying on the implementation of Django’s template tags not being thread safe. The cycle tag is the most likely to be affected in this way, especially when used in conjunction with the include tag. Consider the following template fragment:

```{% for object in object_list %}
    {% include "subtemplate.html" %}
{% endfor %}
```

with a subtemplate.html that reads:

```{% cycle 'even' 'odd' %}
```

Using the non-thread-safe, pre-Django 1.2 renderer, this would output:

```
even odd even odd ...
```

Using the thread-safe Django 1.2 renderer, you will instead get:
This is because each rendering of the `include` tag is an independent rendering. When the `cycle` tag was not thread safe, the state of the `cycle` tag would leak between multiple renderings of the same `include`. Now that the `cycle` tag is thread safe, this leakage no longer occurs.

**user_passes_test, login_required and permission_required**

django.contrib.auth.decorators provides the decorators `login_required`, `permission_required` and `user_passes_test`. Previously it was possible to use these decorators both on functions (where the first argument is ‘request’) and on methods (where the first argument is ‘self’, and the second argument is ‘request’). Unfortunately, flaws were discovered in the code supporting this: it only works in limited circumstances, and produces errors that are very difficult to debug when it does not work.

For this reason, the ‘auto adapt’ behavior has been removed, and if you are using these decorators on methods, you will need to manually apply `django.utils.decorators.method_decorator()` to convert the decorator to one that works with methods. For example, you would change code from this:

```python
class MyClass(object):

    @login_required
    def my_view(self, request):
        pass
```

to this:

```python
from django.utils.decorators import method_decorator

class MyClass(object):

    @method_decorator(login_required)
    def my_view(self, request):
        pass
```

or:

```python
from django.utils.decorators import method_decorator

login_required_m = method_decorator(login_required)

class MyClass(object):

    @login_required_m
```

(continues on next page)
def my_view(self, request):
    pass

For those of you who’ve been following the development trunk, this change also applies to other decorators introduced since 1.1, including csrf_protect, cache_control and anything created using decorator_from_middleware.

if tag changes

Due to new features in the if template tag, it no longer accepts ‘and’, ‘or’ and ‘not’ as valid variable names. Previously, these strings could be used as variable names. Now, the keyword status is always enforced, and template code such as {% if not %} or {% if and %} will throw a TemplateSyntaxError. Also, in is a new keyword and so is not a valid variable name in this tag.

LazyObject

LazyObject is an undocumented-but-often-used utility class used for lazily wrapping other objects of unknown type.

In Django 1.1 and earlier, it handled introspection in a non-standard way, depending on wrapped objects implementing a public method named get_all_members(). Since this could easily lead to name clashes, it has been changed to use the standard Python introspection method, involving __members__ and __dir__().

If you used LazyObject in your own code and implemented the get_all_members() method for wrapped objects, you’ll need to make a couple of changes:

First, if your class does not have special requirements for introspection (i.e., you have not implemented __getattr__() or other methods that allow for attributes not discoverable by normal mechanisms), you can simply remove the get_all_members() method. The default implementation on LazyObject will do the right thing.

If you have more complex requirements for introspection, first rename the get_all_members() method to __dir__(). This is the standard introspection method for Python 2.6 and above. If you require support for Python versions earlier than 2.6, add the following code to the class:

```python
__members__ = property(lambda self: self.__dir__())
```
__dict__ on model instances

Historically, the __dict__ attribute of a model instance has only contained attributes corresponding to the fields on a model.

In order to support multiple database configurations, Django 1.2 has added a _state attribute to object instances. This attribute will appear in __dict__ for a model instance. If your code relies on iterating over __dict__ to obtain a list of fields, you must now be prepared to handle or filter out the _state attribute.

Test runner exit status code

The exit status code of the test runners (tests/runtests.py and python manage.py test) no longer represents the number of failed tests, because a failure of 256 or more tests resulted in a wrong exit status code. The exit status code for the test runner is now 0 for success (no failing tests) and 1 for any number of test failures. If needed, the number of test failures can be found at the end of the test runner’s output.

Cookie encoding

To fix bugs with cookies in Internet Explorer, Safari, and possibly other browsers, our encoding of cookie values was changed so that the comma and semicolon are treated as non-safe characters, and are therefore encoded as \054 and \073 respectively. This could produce backwards incompatibilities, especially if you are storing comma or semi-colon in cookies and have JavaScript code that parses and manipulates cookie values client-side.

ModelForm.is_valid() and ModelForm.errors

Much of the validation work for ModelForms has been moved down to the model level. As a result, the first time you call ModelForm.is_valid(), access ModelForm.errors or otherwise trigger form validation, your model will be cleaned in-place. This conversion used to happen when the model was saved. If you need an unmodified instance of your model, you should pass a copy to the ModelForm constructor.

BooleanField on MySQL

In previous versions of Django, a model’s BooleanField under MySQL would return its value as either 1 or 0, instead of True or False; for most people this wasn’t a problem because bool is a subclass of int in Python. In Django 1.2, however, BooleanField on MySQL correctly returns a real bool. The only time this should ever be an issue is if you were expecting the repr of a BooleanField to print 1 or 0.
Changes to the interpretation of max_num in FormSets

As part of enhancements made to the handling of FormSets, the default value and interpretation of the `max_num` parameter to the `django.forms.formsets.formset_factory()` and `django.forms.models.modelformset_factory()` functions has changed slightly. This change also affects the way the `max_num` argument is used for inline admin objects.

Previously, the default value for `max_num` was 0 (zero). FormSets then used the boolean value of `max_num` to determine if a limit was to be imposed on the number of generated forms. The default value of 0 meant that there was no default limit on the number of forms in a FormSet.

Starting with 1.2, the default value for `max_num` has been changed to `None`, and FormSets will differentiate between a value of `None` and a value of 0. A value of `None` indicates that no limit on the number of forms is to be imposed; a value of 0 indicates that a maximum of 0 forms should be imposed. This doesn’t necessarily mean that no forms will be displayed – see the ModelFormSet documentation for more details.

If you were manually specifying a value of 0 for `max_num`, you will need to update your FormSet and/or admin definitions.

See also:

JavaScript-assisted handling of inline related objects in the admin

email_re

An undocumented regular expression for validating email addresses has been moved from `django.form.fields` to `django.core.validators`. You will need to update your imports if you are using it.

Features deprecated in 1.2

Finally, Django 1.2 deprecates some features from earlier releases. These features are still supported, but will be gradually phased out over the next few release cycles.

Code taking advantage of any of the features below will raise a `PendingDeprecationWarning` in Django 1.2. This warning will be silent by default, but may be turned on using Python’s `warnings` module, or by running Python with a `-Wd` or `-Wall` flag.

In Django 1.3, these warnings will become a `DeprecationWarning`, which is not silent. In Django 1.4 support for these features will be removed entirely.

See also:

For more details, see the documentation Django’s release process and our deprecation timeline.
Specifying databases

Prior to Django 1.2, Django used a number of settings to control access to a single database. Django 1.2 introduces support for multiple databases, and as a result the way you define database settings has changed.

Any existing Django settings file will continue to work as expected until Django 1.4. Until then, old-style database settings will be automatically translated to the new-style format.

In the old-style (pre 1.2) format, you had a number of DATABASE_ settings in your settings file. For example:

```python
DATABASE_NAME = 'test_db'
DATABASE_ENGINE = 'postgresql_psycopg2'
DATABASE_USER = 'myusername'
DATABASE_PASSWORD = 's3krit'
```

These settings are now in a dictionary named DATABASES. Each item in the dictionary corresponds to a single database connection, with the name 'default' describing the default database connection. The setting names have also been shortened. The previous sample settings would now look like this:

```python
DATABASES = {
    'default': {
        'NAME': 'test_db',
        'ENGINE': 'django.db.backends.postgresql_psycopg2',
        'USER': 'myusername',
        'PASSWORD': 's3krit',
    }
}
```

This affects the following settings:

<table>
<thead>
<tr>
<th>Old setting</th>
<th>New Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATABASE_ENGINE</td>
<td>ENGINE</td>
</tr>
<tr>
<td>DATABASE_HOST</td>
<td>HOST</td>
</tr>
<tr>
<td>DATABASE_NAME</td>
<td>NAME</td>
</tr>
<tr>
<td>DATABASE_OPTIONS</td>
<td>OPTIONS</td>
</tr>
<tr>
<td>DATABASE_PASSWORD</td>
<td>PASSWORD</td>
</tr>
<tr>
<td>DATABASE_PORT</td>
<td>PORT</td>
</tr>
<tr>
<td>DATABASE_USER</td>
<td>USER</td>
</tr>
<tr>
<td>TEST_DATABASE_CHARSET</td>
<td>TEST_CHARSET</td>
</tr>
<tr>
<td>TEST_DATABASE_COLLATION</td>
<td>TEST_COLLATION</td>
</tr>
<tr>
<td>TEST_DATABASE_NAME</td>
<td>TEST_NAME</td>
</tr>
</tbody>
</table>

These changes are also required if you have manually created a database connection using DatabaseWrapper() from your database backend of choice.
In addition to the change in structure, Django 1.2 removes the special handling for the built-in database backends. All database backends must now be specified by a fully qualified module name (i.e., `django.db.backends.postgresql_psycopg2`, rather than just `postgresql_psycopg2`).

**postgresql database backend**

The `psycopg1` library has not been updated since October 2005. As a result, the `postgresql` database backend, which uses this library, has been deprecated.

If you are currently using the `postgresql` backend, you should migrate to using the `postgresql_psycopg2` backend. To update your code, install the `psycopg2` library and change the `ENGINE` setting to use `django.db.backends.postgresql_psycopg2`.

**CSRF response-rewriting middleware**

`CsrfResponseMiddleware`, the middleware that automatically inserted CSRF tokens into POST forms in outgoing pages, has been deprecated in favor of a template tag method (see above), and will be removed completely in Django 1.4. `CsrfMiddleware`, which includes the functionality of `CsrfResponseMiddleware` and `CsrfViewMiddleware`, has likewise been deprecated.

Also, the CSRF module has moved from contrib to core, and the old imports are deprecated, as described in the upgrading notes.

---

Documentation removed

The upgrade notes have been removed in current Django docs. Please refer to the docs for Django 1.3 or older to find these instructions.

---

**SMTPConnection**

The `SMTPConnection` class has been deprecated in favor of a generic email backend API. Old code that explicitly instantiated an instance of an `SMTPConnection`:

```python
from django.core.mail import SMTPConnection
collection = SMTPConnection()
messages = get_notification_email()
collection.send_messages(messaged)
```

...should now call `get_connection()` to instantiate a generic email connection:
from django.core.mail import get_connection
connection = get_connection()
messages = get_notification_email()
connection.send_messages(messages)

Depending on the value of the `EMAIL_BACKEND` setting, this may not return an SMTP connection. If you explicitly require an SMTP connection with which to send email, you can explicitly request an SMTP connection:

from django.core.mail import get_connection
connection = get_connection('django.core.mail.backends.smtp.EmailBackend')
messages = get_notification_email()
connection.send_messages(messages)

If your call to construct an instance of `SMTPConnection` required additional arguments, those arguments can be passed to the `get_connection()` call:

connection = get_connection('django.core.mail.backends.smtp.EmailBackend', hostname='localhost', ...port=1234)

User Messages API

The API for storing messages in the user `Message` model (via `user.message_set.create`) is now deprecated and will be removed in Django 1.4 according to the standard release process.

To upgrade your code, you need to replace any instances of this:

```
user.message_set.create('a message')
```

...with the following:

```
from django.contrib import messages
messages.add_message(request, messages.INFO, 'a message')
```

Additionally, if you make use of the method, you need to replace the following:

```
for message in user.get_and_delete_messages():
    ...
```

...with:

```
from django.contrib import messages
for message in messages.get_messages(request):
    ...
```
For more information, see the full messages documentation. You should begin to update your code to use the new API immediately.

**Date format helper functions**

django.utils.translation.get_date_formats() and django.utils.translation.get_partial_date_formats() have been deprecated in favor of the appropriate calls to django.utils.formats.get_format(), which is locale-aware when USE_L10N is set to True, and falls back to default settings if set to False.

To get the different date formats, instead of writing this:

```python
from django.utils.translation import get_date_formats
date_format, datetime_format, time_format = get_date_formats()
```

...use:

```python
from django.utils import formats
date_format = formats.get_format('DATE_FORMAT')
datetime_format = formats.get_format('DATETIME_FORMAT')
time_format = formats.get_format('TIME_FORMAT')
```

Or, when directly formatting a date value:

```python
from django.utils import formats
value_formatted = formats.date_format(value, 'DATETIME_FORMAT')
```

The same applies to the globals found in django.forms.fields:

- DEFAULT_DATE_INPUT_FORMATS
- DEFAULT_TIME_INPUT_FORMATS
- DEFAULT_DATETIME_INPUT_FORMATS

Use django.utils.formats.get_format() to get the appropriate formats.

**Function-based test runners**

Django 1.2 changes the test runner tools to use a class-based approach. Old style function-based test runners will still work, but should be updated to use the new class-based runners.
Feed in django.contrib.syndication.feeds

The django.contrib.syndication.feeds.Feed class has been replaced by the django.contrib.syndication.views.Feed class. The old feeds.Feed class is deprecated, and will be removed in Django 1.4.

The new class has an almost identical API, but allows instances to be used as views. For example, consider the use of the old framework in the following URLconf:

```python
from django.conf.urls.defaults import *
from myproject.feeds import LatestEntries, LatestEntriesByCategory

feeds = {
    'latest': LatestEntries,
    'categories': LatestEntriesByCategory,
}

urlpatterns = patterns('',
    # ...
    (r'^feeds/(?:P<url>.*)/$', 'django.contrib.syndication.views.feed',
     {'feed_dict': feeds}),
    # ...
)
```

Using the new Feed class, these feeds can be deployed directly as views:

```python
from django.conf.urls.defaults import *
from myproject.feeds import LatestEntries, LatestEntriesByCategory

urlpatterns = patterns('',
    # ...
    (r'^feeds/latest/$', LatestEntries()),
    (r'^feeds/categories/(?:P<category_id>\d+)/$', LatestEntriesByCategory()),
    # ...
)
```

If you currently use the feed() view, the LatestEntries class would often not need to be modified apart from subclassing the new Feed class. The exception is if Django was automatically working out the name of the template to use to render the feed’s description and title elements (if you were not specifying the title_template and description_template attributes). You should ensure that you always specify title_template and description_template attributes, or provide item_title() and item_description() methods.

However, LatestEntriesByCategory uses the get_object() method with the bits argument to specify a specific category to show. In the new Feed class, get_object() method takes a request and arguments from
the URL, so it would look like this:

```python
from django.contrib.syndication.views import Feed
from django.shortcuts import get_object_or_404
from myproject.models import Category

class LatestEntriesByCategory(Feed):
    def get_object(self, request, category_id):
        return get_object_or_404(Category, id=category_id)

# ...
```

Additionally, the `get_feed()` method on `Feed` classes now take different arguments, which may impact you if you use the `Feed` classes directly. Instead of just taking an optional `url` argument, it now takes two arguments: the object returned by its own `get_object()` method, and the current `request` object.

To take into account `Feed` classes not being initialized for each request, the `__init__()` method now takes no arguments by default. Previously it would have taken the `slug` from the URL and the `request` object.

In accordance with RSS best practices, RSS feeds will now include an `atom:link` element. You may need to update your tests to take this into account.

For more information, see the full syndication framework documentation.

### Technical message IDs

Up to version 1.1 Django used technical message IDs to provide localizers the possibility to translate date and time formats. They were translatable translation strings that could be recognized because they were all upper case (for example `DATETIME_FORMAT`, `DATE_FORMAT`, `TIME_FORMAT`). They have been deprecated in favor of the new Format localization infrastructure that allows localizers to specify that information in a `formats.py` file in the corresponding `django/conf/locale/<locale name>/*` directory.

### GeoDjango

To allow support for multiple databases, the GeoDjango database internals were changed substantially. The largest backwards-incompatible change is that the module `django.contrib.gis.db.backend` was renamed to `django.contrib.gis.db.backends`, where the full-fledged spatial database backends now exist. The following sections provide information on the most-popular APIs that were affected by these changes.
Prior to the creation of the separate spatial backends, the `django.contrib.gis.db.backend.SpatialBackend` object was provided as an abstraction to introspect on the capabilities of the spatial database. All of the attributes and routines provided by `SpatialBackend` are now a part of the `ops` attribute of the database backend.

The old module `django.contrib.gis.db.backend` is still provided for backwards-compatibility access to a `SpatialBackend` object, which is just an alias to the `ops` module of the default spatial database connection.

Users that were relying on undocumented modules and objects within `django.contrib.gis.db.backend`, rather the abstractions provided by `SpatialBackend`, are required to modify their code. For example, the following import which would work in 1.1 and below:

```python
from django.contrib.gis.db.backend.postgis import PostGISAdaptor
```

Would need to be changed:

```python
from django.db import connection
PostGISAdaptor = connection.ops.Adapter
```

**SpatialRefSys and GeometryColumns models**

In previous versions of GeoDjango, `django.contrib.gis.db.models` had `SpatialRefSys` and `GeometryColumns` models for querying the OGC spatial metadata tables `spatial_ref_sys` and `geometry_columns`, respectively.

While these aliases are still provided, they are only for the default database connection and exist only if the default connection is using a supported spatial database backend.

Note: Because the table structure of the OGC spatial metadata tables differs across spatial databases, the `SpatialRefSys` and `GeometryColumns` models can no longer be associated with the `gis` application name. Thus, no models will be returned when using the `get_models` method in the following example:

```python
>>> from django.db.models import get_app, get_models
>>> get_models(get_app('gis'))
[]
```

To get the correct `SpatialRefSys` and `GeometryColumns` for your spatial database use the methods provided by the spatial backend:
Note: When using the models returned from the `spatial_ref_sys()` and `geometry_columns()` method, you’ll still need to use the correct database alias when querying on the non-default connection. In other words, to ensure that the models in the example above use the correct database:

```python
sr_qs = SpatialRefSys.objects.using('my_spatialite').filter(...)
gc_qs = GeometryColumns.objects.using('my_postgis').filter(...)
```

---

### Language code no

The currently used language code for Norwegian Bokmål no is being replaced by the more common language code nb.

---

### Function-based template loaders

Django 1.2 changes the template loading mechanism to use a class-based approach. Old style function-based template loaders will still work, but should be updated to use the new class-based template loaders.

---

### 9.1.20 1.1 release

#### Django 1.1.4 release notes

Welcome to Django 1.1.4!

This is the fourth “bugfix” release in the Django 1.1 series, improving the stability and performance of the Django 1.1 codebase.

With one exception, Django 1.1.4 maintains backwards compatibility with Django 1.1.3. It also contains a number of fixes and other improvements. Django 1.1.4 is a recommended upgrade for any development or deployment currently using or targeting Django 1.1.

For full details on the new features, backwards incompatibilities, and deprecated features in the 1.1 branch, see the [Django 1.1 release notes](https://docs.djangoproject.com/en/1.1/releases/1.1/).
Backwards incompatible changes

CSRF exception for AJAX requests

Django includes a CSRF-protection mechanism, which makes use of a token inserted into outgoing forms. Middleware then checks for the token’s presence on form submission, and validates it.

Prior to Django 1.2.5, our CSRF protection made an exception for AJAX requests, on the following basis:

- Many AJAX toolkits add an X-Requested-With header when using XMLHttpRequest.
- Browsers have strict same-origin policies regarding XMLHttpRequest.
- In the context of a browser, the only way that a custom header of this nature can be added is with XMLHttpRequest.

Therefore, for ease of use, we did not apply CSRF checks to requests that appeared to be AJAX on the basis of the X-Requested-With header. The Ruby on Rails web framework had a similar exemption.

Recently, engineers at Google made members of the Ruby on Rails development team aware of a combination of browser plugins and redirects which can allow an attacker to provide custom HTTP headers on a request to any website. This can allow a forged request to appear to be an AJAX request, thereby defeating CSRF protection which trusts the same-origin nature of AJAX requests.

Michael Koziarski of the Rails team brought this to our attention, and we were able to produce a proof-of-concept demonstrating the same vulnerability in Django’s CSRF handling.

To remedy this, Django will now apply full CSRF validation to all requests, regardless of apparent AJAX origin. This is technically backwards-incompatible, but the security risks have been judged to outweigh the compatibility concerns in this case.

Additionally, Django will now accept the CSRF token in the custom HTTP header X-CSRFToken, as well as in the form submission itself, for ease of use with popular JavaScript toolkits which allow insertion of custom headers into all AJAX requests.

Please see the CSRF docs for example jQuery code that demonstrates this technique, ensuring that you are looking at the documentation for your version of Django, as the exact code necessary is different for some older versions of Django.

Django 1.1.3 release notes

Welcome to Django 1.1.3!

This is the third “bugfix” release in the Django 1.1 series, improving the stability and performance of the Django 1.1 codebase.

With one exception, Django 1.1.3 maintains backwards compatibility with Django 1.1.2. It also contains a number of fixes and other improvements. Django 1.1.2 is a recommended upgrade for any development or deployment currently using or targeting Django 1.1.
For full details on the new features, backwards incompatibilities, and deprecated features in the 1.1 branch, see the Django 1.1 release notes.

**Backwards incompatible changes**

**Restricted filters in admin interface**

The Django administrative interface, `django.contrib.admin`, supports filtering of displayed lists of objects by fields on the corresponding models, including across database-level relationships. This is implemented by passing lookup arguments in the querystring portion of the URL, and options on the ModelAdmin class allow developers to specify particular fields or relationships which will generate automatic links for filtering.

One historically-undocumented and -unofficially-supported feature has been the ability for a user with sufficient knowledge of a model’s structure and the format of these lookup arguments to invent useful new filters on the fly by manipulating the querystring.

However, it has been demonstrated that this can be abused to gain access to information outside of an admin user’s permissions; for example, an attacker with access to the admin and sufficient knowledge of model structure and relations could construct query strings which – with repeated use of regular-expression lookups supported by the Django database API – expose sensitive information such as users’ password hashes.

To remedy this, `django.contrib.admin` will now validate that querystring lookup arguments either specify only fields on the model being viewed, or cross relations which have been explicitly allowed by the application developer using the preexisting mechanism mentioned above. This is backwards-incompatible for any users relying on the prior ability to insert arbitrary lookups.

**Django 1.1.2 release notes**

Welcome to Django 1.1.2!

This is the second “bugfix” release in the Django 1.1 series, improving the stability and performance of the Django 1.1 codebase.

Django 1.1.2 maintains backwards compatibility with Django 1.1.0, but contain a number of fixes and other improvements. Django 1.1.2 is a recommended upgrade for any development or deployment currently using or targeting Django 1.1.

For full details on the new features, backwards incompatibilities, and deprecated features in the 1.1 branch, see the Django 1.1 release notes.
Backwards-incompatible changes in 1.1.2

Test runner exit status code

The exit status code of the test runners (tests/runtests.py and python manage.py test) no longer represents the number of failed tests, since a failure of 256 or more tests resulted in a wrong exit status code. The exit status code for the test runner is now 0 for success (no failing tests) and 1 for any number of test failures. If needed, the number of test failures can be found at the end of the test runner’s output.

Cookie encoding

To fix bugs with cookies in Internet Explorer, Safari, and possibly other browsers, our encoding of cookie values was changed so that the characters comma and semi-colon are treated as non-safe characters, and are therefore encoded as \054 and \073 respectively. This could produce backwards incompatibilities, especially if you are storing comma or semi-colon in cookies and have JavaScript code that parses and manipulates cookie values client-side.

One new feature

Ordinarily, a point release would not include new features, but in the case of Django 1.1.2, we have made an exception to this rule. Django 1.2 (the next major release of Django) will contain a feature that will improve protection against Cross-Site Request Forgery (CSRF) attacks. This feature requires the use of a new csrf_token template tag in all forms that Django renders.

To make it easier to support both 1.1.X and 1.2.X versions of Django with the same templates, we have decided to introduce the csrf_token template tag to the 1.1.X branch. In the 1.1.X branch, csrf_token does nothing - it has no effect on templates or form processing. However, it means that the same template will work with Django 1.2.

Django 1.1 release notes

July 29, 2009

Welcome to Django 1.1!

Django 1.1 includes a number of nifty new features, lots of bug fixes, and an easy upgrade path from Django 1.0.
Backwards-incompatible changes in 1.1

Django has a policy of API stability. This means that, in general, code you develop against Django 1.0 should continue to work against 1.1 unchanged. However, we do sometimes make backwards-incompatible changes if they’re necessary to resolve bugs, and there are a handful of such (minor) changes between Django 1.0 and Django 1.1.

Before upgrading to Django 1.1 you should double-check that the following changes don’t impact you, and upgrade your code if they do.

Changes to constraint names

Django 1.1 modifies the method used to generate database constraint names so that names are consistent regardless of machine word size. This change is backwards incompatible for some users.

If you are using a 32-bit platform, you’re off the hook; you’ll observe no differences as a result of this change.

However, users on 64-bit platforms may experience some problems using the reset management command. Prior to this change, 64-bit platforms would generate a 64-bit, 16 character digest in the constraint name; for example:

```
ALTER TABLE myapp_sometable ADD CONSTRAINT object_id_refs_id_5e8f10c132091d1e FOREIGN KEY ...
```

Following this change, all platforms, regardless of word size, will generate a 32-bit, 8 character digest in the constraint name; for example:

```
ALTER TABLE myapp_sometable ADD CONSTRAINT object_id_refs_id_32091d1e FOREIGN KEY ...
```

As a result of this change, you will not be able to use the reset management command on any table made by a 64-bit machine. This is because the new generated name will not match the historically generated name; as a result, the SQL constructed by the reset command will be invalid.

If you need to reset an application that was created with 64-bit constraints, you will need to manually drop the old constraint prior to invoking reset.

Test cases are now run in a transaction

Django 1.1 runs tests inside a transaction, allowing better test performance (see test performance improvements for details).

This change is slightly backwards incompatible if existing tests need to test transactional behavior, if they rely on invalid assumptions about the test environment, or if they require a specific test case ordering.
For these cases, `TransactionTestCase` can be used instead. This is a just a quick fix to get around test case errors revealed by the new rollback approach; in the long-term tests should be rewritten to correct the test case.

**Removed `SetRemoteAddrFromForwardedFor` middleware**

For convenience, Django 1.0 included an optional middleware class—`django.middleware.http.SetRemoteAddrFromForwardedFor`—which updated the value of `REMOTE_ADDR` based on the HTTP `X-Forwarded-For` header commonly set by some proxy configurations.

It has been demonstrated that this mechanism cannot be made reliable enough for general-purpose use, and that (despite documentation to the contrary) its inclusion in Django may lead application developers to assume that the value of `REMOTE_ADDR` is “safe” or in some way reliable as a source of authentication.

While not directly a security issue, we’ve decided to remove this middleware with the Django 1.1 release. It has been replaced with a class that does nothing other than raise a `DeprecationWarning`.

If you’ve been relying on this middleware, the easiest upgrade path is:

- Examine the code as it existed before it was removed.
- Verify that it works correctly with your upstream proxy, modifying it to support your particular proxy (if necessary).
- Introduce your modified version of `SetRemoteAddrFromForwardedFor` as a piece of middleware in your own project.

**Names of uploaded files are available later**

In Django 1.0, files uploaded and stored in a model’s `FileField` were saved to disk before the model was saved to the database. This meant that the actual file name assigned to the file was available before saving. For example, it was available in a model’s pre-save signal handler.

In Django 1.1 the file is saved as part of saving the model in the database, so the actual file name used on disk cannot be relied on until after the model has been saved.

**Changes to how model formsets are saved**

In Django 1.1, `BaseModelFormSet` now calls `ModelForm.save()`.

This is backwards-incompatible if you were modifying `self.initial` in a model formset’s `__init__`, or if you relied on the internal `_total_form_count` or `_initial_form_count` attributes of `BaseFormSet`. Those attributes are now public methods.
Fixed the join filter’s escaping behavior

The join filter no longer escapes the literal value that is passed in for the connector.

This is backwards incompatible for the special situation of the literal string containing one of the five special HTML characters. Thus, if you were writing {{ foo|join:"&" }}, you now have to write {{ foo|join:"&amp;" }}.

The previous behavior was a bug and contrary to what was documented and expected.

Permanent redirects and the redirect_to() generic view

Django 1.1 adds a permanent argument to the django.views.generic.simple.redirect_to() view. This is technically backwards-incompatible if you were using the redirect_to view with a format-string key called ‘permanent’, which is highly unlikely.

Features deprecated in 1.1

One feature has been marked as deprecated in Django 1.1:

- You should no longer use AdminSite.root() to register that admin views. That is, if your URLconf contains the line:

  ```
  (r'^admin/(.*)', admin.site.root),
  ```

  You should change it to read:

  ```
  (r'^admin/', include(admin.site.urls)),
  ```

  You should begin to remove use of this feature from your code immediately.

AdminSite.root will raise a PendingDeprecationWarning if used in Django 1.1. This warning is hidden by default. In Django 1.2, this warning will be upgraded to a DeprecationWarning, which will be displayed loudly. Django 1.3 will remove AdminSite.root() entirely.

For more details on our deprecation policies and strategy, see Django’s release process.

What’s new in Django 1.1

Quite a bit: since Django 1.0, we’ve made 1,290 code commits, fixed 1,206 bugs, and added roughly 10,000 lines of documentation.

The major new features in Django 1.1 are:
ORM improvements

Two major enhancements have been added to Django’s object-relational mapper (ORM): aggregate support, and query expressions.

**Aggregate support**

It’s now possible to run SQL aggregate queries (i.e. `COUNT()`, `MAX()`, `MIN()`, etc.) from within Django’s ORM. You can choose to either return the results of the aggregate directly, or else annotate the objects in a `QuerySet` with the results of the aggregate query.

This feature is available as new `aggregate()` and `annotate()` methods, and is covered in detail in the ORM aggregation documentation.

**Query expressions**

Queries can now refer to another field on the query and can traverse relationships to refer to fields on related models. This is implemented in the new `F` object; for full details, including examples, consult the `F expressions documentation`.

**Model improvements**

A number of features have been added to Django’s model layer:

**“Unmanaged” models**

You can now control whether or not Django manages the life-cycle of the database tables for a model using the `managed` model option. This defaults to `True`, meaning that Django will create the appropriate database tables in `syncdb` and remove them as part of the `reset` command. That is, Django manages the database table’s lifecycle.

If you set this to `False`, however, no database table creating or deletion will be automatically performed for this model. This is useful if the model represents an existing table or a database view that has been created by some other means.

For more details, see the documentation for the `managed` option.
Proxy models

You can now create proxy models: subclasses of existing models that only add Python-level (rather than database-level) behavior and aren’t represented by a new table. That is, the new model is a proxy for some underlying model, which stores all the real data.

All the details can be found in the proxy models documentation. This feature is similar on the surface to unmanaged models, so the documentation has an explanation of how proxy models differ from unmanaged models.

Deferred fields

In some complex situations, your models might contain fields which could contain a lot of data (for example, large text fields), or require expensive processing to convert them to Python objects. If you know you don’t need those particular fields, you can now tell Django not to retrieve them from the database.

You’ll do this with the new queryset methods `defer()` and `only()`.

Testing improvements

A few notable improvements have been made to the testing framework.

Test performance improvements

Tests written using Django’s testing framework now run dramatically faster (as much as 10 times faster in many cases).

This was accomplished through the introduction of transaction-based tests: when using `django.test.TestCase`, your tests will now be run in a transaction which is rolled back when finished, instead of by flushing and re-populating the database. This results in an immense speedup for most types of unit tests. See the documentation for `TestCase` and `TransactionTestCase` for a full description, and some important notes on database support.

Test client improvements

A couple of small—but highly useful—improvements have been made to the test client:

- The test `Client` now can automatically follow redirects with the `follow` argument to `Client.get()` and `Client.post()`. This makes testing views that issue redirects simpler.

- It’s now easier to get at the template context in the response returned the test client: you’ll simply access the context as `request.context[key]`. The old way, which treats `request.context` as a list of contexts, one for each rendered template in the inheritance chain, is still available if you need it.
New admin features

Django 1.1 adds a couple of nifty new features to Django’s admin interface:

Editable fields on the change list

You can now make fields editable on the admin list views via the new list_editable admin option. These fields will show up as form widgets on the list pages, and can be edited and saved in bulk.

Admin “actions”

You can now define admin actions that can perform some action to a group of models in bulk. Users will be able to select objects on the change list page and then apply these bulk actions to all selected objects.

Django ships with one pre-defined admin action to delete a group of objects in one fell swoop.

Conditional view processing

Django now has much better support for conditional view processing using the standard ETag and Last-Modified HTTP headers. This means you can now easily short-circuit view processing by testing less-expensive conditions. For many views this can lead to a serious improvement in speed and reduction in bandwidth.

URL namespaces

Django 1.1 improves named URL patterns with the introduction of URL “namespaces.”

In short, this feature allows the same group of URLs, from the same application, to be included in a Django URLConf multiple times, with varying (and potentially nested) named prefixes which will be used when performing reverse resolution. In other words, reusable applications like Django’s admin interface may be registered multiple times without URL conflicts.

For full details, see the documentation on defining URL namespaces.

GeoDjango

In Django 1.1, GeoDjango (i.e. django.contrib.gis) has several new features:

- Support for SpatiaLite—a spatial database for SQLite—as a spatial backend.
- Geographic aggregates (Collect, Extent, MakeLine, Union) and F expressions.
- New GeoQuerySet methods: collect, geojson, and snap_to_grid.
A new list interface methods for GEOSGeometry objects.

For more details, see the GeoDjango documentation.

Other improvements

Other new features and changes introduced since Django 1.0 include:

- The CSRF protection middleware has been split into two classes – CsrfViewMiddleware checks incoming requests, and CsrfResponseMiddleware processes outgoing responses. The combined CsrfMiddleware class (which does both) remains for backwards-compatibility, but using the split classes is now recommended in order to allow fine-grained control of when and where the CSRF processing takes place.

- reverse() and code which uses it (e.g., the {% url %} template tag) now works with URLs in Django’s administrative site, provided that the admin URLs are set up via include(admin.site.urls) (sending admin requests to the admin.site.root view still works, but URLs in the admin will not be “reversible” when configured this way).

- The include() function in Django URLconf modules can now accept sequences of URL patterns (generated by patterns()) in addition to module names.

- Instances of Django forms (see the forms overview) now have two additional methods, hidden_fields() and visible_fields(), which return the list of hidden – i.e., <input type="hidden"> – and visible fields on the form, respectively.

- The redirect_to generic view now accepts an additional keyword argument permanent. If permanent is True, the view will emit an HTTP permanent redirect (status code 301). If False, the view will emit an HTTP temporary redirect (status code 302).

- A new database lookup type – week_day – has been added for DateField and DateTimeField. This type of lookup accepts a number between 1 (Sunday) and 7 (Saturday), and returns objects where the field value matches that day of the week. See the full list of lookup types for details.

- The {% for %} tag in Django’s template language now accepts an optional {% empty %} clause, to be displayed when {% for %} is asked to loop over an empty sequence. See the list of built-in template tags for examples of this.

- The dumpdata management command now accepts individual model names as arguments, allowing you to export the data just from particular models.

- There’s a new safeseq template filter which works just like safe for lists, marking each item in the list as safe.

- Cache backends now support incr() and decr() commands to increment and decrement the value of a cache key. On cache backends that support atomic increment/decrement – most notably, the memcached backend – these operations will be atomic, and quite fast.
• Django now can easily delegate authentication to the web server via a new authentication backend that supports the standard `REMOTE_USER` environment variable used for this purpose.

• There’s a new `django.shortcuts.redirect()` function that makes it easier to issue redirects given an object, a view name, or a URL.

• The `postgresql_psycopg2` backend now supports native PostgreSQL autocommit. This is an advanced, PostgreSQL-specific feature, that can make certain read-heavy applications a good deal faster.

What’s next?

We’ll take a short break, and then work on Django 1.2 will begin – no rest for the weary! If you’d like to help, discussion of Django development, including progress toward the 1.2 release, takes place daily on the `django-developers` mailing list and in the `#django-dev` IRC channel on `irc.libera.chat`. Feel free to join the discussions!

Django’s online documentation also includes pointers on how to contribute to Django:

• How to contribute to Django

Contributions on any level – developing code, writing documentation or simply triaging tickets and helping to test proposed bugfixes – are always welcome and appreciated.

And that’s the way it is.

9.1.21 1.0 release

Django 1.0.2 release notes

Welcome to Django 1.0.2!

This is the second “bugfix” release in the Django 1.0 series, improving the stability and performance of the Django 1.0 codebase. As such, Django 1.0.2 contains no new features (and, pursuant to our compatibility policy, maintains backwards compatibility with Django 1.0.0), but does contain a number of fixes and other improvements. Django 1.0.2 is a recommended upgrade for any development or deployment currently using or targeting Django 1.0.

Fixes and improvements in Django 1.0.2

The primary reason behind this release is to remedy an issue in the recently-released Django 1.0.1; the packaging scripts used for Django 1.0.1 omitted some directories from the final release package, including one directory required by `django.contrib.gis` and part of Django’s unit-test suite.

Django 1.0.2 contains updated packaging scripts, and the release package contains the directories omitted from Django 1.0.1. As such, this release contains all of the fixes and improvements from Django 1.0.1; see the Django 1.0.1 release notes for details.
Additionally, in the period since Django 1.0.1 was released:

- Updated Hebrew and Danish translations have been added.
- The default `__repr__` method of Django models has been made more robust in the face of bad Unicode data coming from the `__unicode__` method; rather than raise an exception in such cases, `repr()` will now contain the string “[Bad Unicode data]” in place of the invalid Unicode.
- A bug involving the interaction of Django’s `SafeUnicode` class and the MySQL adapter has been resolved; `SafeUnicode` instances (generated, for example, by template rendering) can now be assigned to model attributes and saved to MySQL without requiring an explicit intermediate cast to `unicode`.
- A bug affecting filtering on a nullable `DateField` in SQLite has been resolved.
- Several updates and improvements have been made to Django’s documentation.

**Django 1.0.1 release notes**

Welcome to Django 1.0.1!

This is the first “bugfix” release in the Django 1.0 series, improving the stability and performance of the Django 1.0 codebase. As such, Django 1.0.1 contains no new features (and, pursuant to our compatibility policy, maintains backwards compatibility with Django 1.0), but does contain a number of fixes and other improvements. Django 1.0.1 is a recommended upgrade for any development or deployment currently using or targeting Django 1.0.

**Fixes and improvements in Django 1.0.1**

Django 1.0.1 contains over two hundred fixes to the original Django 1.0 codebase; full details of every fix are available in the history of the 1.0.X branch, but here are some of the highlights:

- Several fixes in `django.contrib.comments`, pertaining to RSS feeds of comments, default ordering of comments and the XHTML and internationalization of the default templates for comments.
- Multiple fixes for Django’s support of Oracle databases, including pagination support for GIS QuerySets, more efficient slicing of results and improved introspection of existing databases.
- Several fixes for query support in the Django object-relational mapper, including repeated setting and resetting of ordering and fixes for working with `INSERT-only` queries.
- Multiple fixes for inline forms in formsets.
- Multiple fixes for `unique` and `unique_together` model constraints in automatically-generated forms.
- Fixed support for custom callable `upload_to` declarations when handling file uploads through automatically-generated forms.
- Fixed support for sorting an admin change list based on a callable attributes in `list_display`. 
• A fix to the application of autoescaping for literal strings passed to the `join` template filter. Previously, literal strings passed to `join` were automatically escaped, contrary to the documented behavior for autoescaping and literal strings. Literal strings passed to `join` are no longer automatically escaped, meaning you must now manually escape them; this is an incompatibility if you were relying on this bug, but not if you were relying on escaping behaving as documented.

• Improved and expanded translation files for many of the languages Django supports by default.

• And as always, a large number of improvements to Django’s documentation, including both corrections to existing documents and expanded and new documentation.

**Django 1.0 release notes**

Welcome to Django 1.0!

We’ve been looking forward to this moment for over three years, and it’s finally here. Django 1.0 represents the largest milestone in Django’s development to date: a web framework that a group of perfectionists can truly be proud of.

Django 1.0 represents over three years of community development as an Open Source project. Django’s received contributions from hundreds of developers, been translated into fifty languages, and today is used by developers on every continent and in every kind of job.

An interesting historical note: when Django was first released in July 2005, the initial released version of Django came from an internal repository at revision number 8825. Django 1.0 represents revision 8961 of our public repository. It seems fitting that our 1.0 release comes at the moment where community contributions overtake those made privately.

**Stability and forwards-compatibility**

The release of Django 1.0 comes with a promise of API stability and forwards-compatibility. In a nutshell, this means that code you develop against Django 1.0 will continue to work against 1.1 unchanged, and you should need to make only minor changes for any 1.X release.

See the API stability guide for full details.

**Backwards-incompatible changes**

Django 1.0 has a number of backwards-incompatible changes from Django 0.96. If you have apps written against Django 0.96 that you need to port, see our detailed porting guide:
Porting your apps from Django 0.96 to 1.0

Django 1.0 breaks compatibility with 0.96 in some areas.

This guide will help you port 0.96 projects and apps to 1.0. The first part of this document includes the common changes needed to run with 1.0. If after going through the first part your code still breaks, check the section Less-common Changes for a list of a bunch of less-common compatibility issues.

See also:

The 1.0 release notes. That document explains the new features in 1.0 more deeply; the porting guide is more concerned with helping you quickly update your code.

Common changes

This section describes the changes between 0.96 and 1.0 that most users will need to make.

Use Unicode

Change string literals (‘foo’) into Unicode literals (u’foo’). Django now uses Unicode strings throughout. In most places, raw strings will continue to work, but updating to use Unicode literals will prevent some obscure problems.

See Unicode data for full details.

Models

Common changes to your models file:

Rename maxlength to max_length

Rename your maxlength argument to max_length (this was changed to be consistent with form fields):

Replace __str__ with __unicode__

Replace your model’s __str__ function with a __unicode__ method, and make sure you use Unicode (u‘foo’) in that method.
Remove prepopulated_from

Remove the prepopulated_from argument on model fields. It’s no longer valid and has been moved to the ModelAdmin class in admin.py. See the admin, below, for more details about changes to the admin.

Remove core

Remove the core argument from your model fields. It is no longer necessary, since the equivalent functionality (part of inline editing) is handled differently by the admin interface now. You don’t have to worry about inline editing until you get to the admin section, below. For now, remove all references to core.

Replace class Admin: with admin.py

Remove all your inner class Admin declarations from your models. They won’t break anything if you leave them, but they also won’t do anything. To register apps with the admin you’ll move those declarations to an admin.py file; see the admin below for more details.

See also:
A contributor to djangosnippets has written a script that’ll scan your models.py and generate a corresponding admin.py.

Example

Below is an example models.py file with all the changes you’ll need to make:

Old (0.96) models.py:

```python
class Author(models.Model):
    first_name = models.CharField(max_length=30)
    last_name = models.CharField(max_length=30)
    slug = models.CharField(max_length=60, prepopulate_from=('first_name', 'last_name'))

    class Admin:
        list_display = ['first_name', 'last_name']

    def __str__(self):
        return '%s %s' % (self.first_name, self.last_name)
```

New (1.0) models.py:

```python
class Author(models.Model):
    first_name = models.CharField(max_length=30)
```
(continues on next page)
The Admin

One of the biggest changes in 1.0 is the new admin. The Django administrative interface (django.contrib.admin) has been completely refactored; admin definitions are now completely decoupled from model definitions, the framework has been rewritten to use Django’s new form-handling library and redesigned with extensibility and customization in mind.

Practically, this means you’ll need to rewrite all of your class Admin declarations. You’ve already seen in models above how to replace your class Admin with an admin.site.register() call in an admin.py file. Below are some more details on how to rewrite that Admin declaration into the new syntax.

Use new inline syntax

The new edit_inline options have all been moved to admin.py. Here’s an example:

Old (0.96):

```python
class Parent(models.Model):
    ...

class Child(models.Model):
    parent = models.ForeignKey(Parent, edit_inline=models.STACKED, num_in_admin=3)
```

New (1.0):

```python
from django.contrib import admin
from models import Author

class AuthorAdmin(admin.ModelAdmin):
    list_display = ['first_name', 'last_name']
    prepopulated_fields = {
        'slug': ('first_name', 'last_name')
    }

admin.site.register(Author, AuthorAdmin)
```
class ChildInline(admin.StackedInline):
    model = Child
    extra = 3

class ParentAdmin(admin.ModelAdmin):
    model = Parent
    inlines = [ChildInline]

admin.site.register(Parent, ParentAdmin)

See InlineModelAdmin objects for more details.

**Simplify fields, or use fieldsets**

The old `fields` syntax was quite confusing, and has been simplified. The old syntax still works, but you’ll need to use `fieldsets` instead.

Old (0.96):

```python
class ModelOne(models.Model):
    ...

    class Admin:
        fields = (  
            (None, { 'fields': ( 'foo', 'bar' )}),  
        )

class ModelTwo(models.Model):
    ...

    class Admin:
        fields = (  
            ( 'group1', { 'fields': ( 'foo', 'bar' ), 'classes': 'collapse' } ),  
            ( 'group2', { 'fields': ( 'spam', 'eggs' ), 'classes': 'collapse wide' } ),  
        )
```

New (1.0):

```python
class ModelOneAdmin(admin.ModelAdmin):
    fields = ( 'foo', 'bar' )

class ModelTwoAdmin(admin.ModelAdmin):
    fieldsets = (  
        ( 'group1', { 'fields': ( 'foo', 'bar' ), 'classes': 'collapse' } ),  
    )
```

(continues on next page)
See also:

- More detailed information about the changes and the reasons behind them can be found on the NewformsAdminBranch wiki page
- The new admin comes with a ton of new features; you can read about them in the admin documentation.

### URLs

#### Update your root `urls.py`

If you’re using the admin site, you need to update your root `urls.py`.

**Old (0.96) urls.py:**

```python
from django.conf.urls.defaults import *

urlpatterns = patterns('',
    (r'^admin/', include('django.contrib.admin.urls')),

    # ... the rest of your URLs here ...
)
```

**New (1.0) urls.py:**

```python
from django.conf.urls.defaults import *

# The next two lines enable the admin and load each admin.py file:
from django.contrib import admin
admin.autodiscover()

urlpatterns = patterns('',
    (r'^admin/(.*)', admin.site.root),

    # ... the rest of your URLs here ...
)
```
**Views**

**Use django.forms instead of newforms**

Replace `django.newforms` with `django.forms` – Django 1.0 renamed the `newforms` module (introduced in 0.96) to plain old `forms`. The `oldforms` module was also removed.

If you’re already using the `newforms` library, and you used our recommended `import` statement syntax, all you have to do is change your import statements.

Old:

```python
from django import newforms as forms
```

New:

```python
from django import forms
```

If you’re using the old forms system (formerly known as `django.forms` and `django.oldforms`), you’ll have to rewrite your forms. A good place to start is the `forms documentation`.

**Handle uploaded files using the new API**

Replace use of uploaded files – that is, entries in `request.FILES` – as simple dictionaries with the new `UploadedFile`. The old dictionary syntax no longer works.

Thus, in a view like:

```python
def my_view(request):
    f = request.FILES['file_field_name']
...
```

...you’d need to make the following changes:

<table>
<thead>
<tr>
<th>Old (0.96)</th>
<th>New (1.0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>f['content']</td>
<td>f.read()</td>
</tr>
<tr>
<td>f['filename']</td>
<td>f.name</td>
</tr>
<tr>
<td>f['content-type']</td>
<td>f.content_type</td>
</tr>
</tbody>
</table>
Work with file fields using the new API

The internal implementation of `django.db.models.FileField` have changed. A visible result of this is that the way you access special attributes (URL, filename, image size, etc.) of these model fields has changed. You will need to make the following changes, assuming your model’s `FileField` is called `myfile`:

<table>
<thead>
<tr>
<th>Old (0.96)</th>
<th>New (1.0)</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>myfile.get_content_filename()</code></td>
<td><code>myfile.content.path</code></td>
</tr>
<tr>
<td><code>myfile.get_content_url()</code></td>
<td><code>myfile.content.url</code></td>
</tr>
<tr>
<td><code>myfile.get_content_size()</code></td>
<td><code>myfile.content.size</code></td>
</tr>
<tr>
<td><code>myfile.save_content_file()</code></td>
<td><code>myfile.content.save()</code></td>
</tr>
<tr>
<td><code>myfile.get_content_width()</code></td>
<td><code>myfile.content.width</code></td>
</tr>
<tr>
<td><code>myfile.get_content_height()</code></td>
<td><code>myfile.content.height</code></td>
</tr>
</tbody>
</table>

Note that the `width` and `height` attributes only make sense for `ImageField` fields. More details can be found in the model API documentation.

Use Paginator instead of ObjectPaginator

The `ObjectPaginator` in 0.96 has been removed and replaced with an improved version, `django.core.paginator.Paginator`.

Templates

Learn to love autoescaping

By default, the template system now automatically HTML-escapes the output of every variable. To learn more, see Automatic HTML escaping.

To disable auto-escaping for an individual variable, use the `safe` filter:

```
This will be escaped: {{ data }}
This will not be escaped: {{ data|safe }}
```

To disable auto-escaping for an entire template, wrap the template (or just a particular section of the template) in the `autoescape` tag:

```
{% autoescape off %}
    ... unescaped template content here ...
{% endautoescape %}
```
Less-common changes

The following changes are smaller, more localized changes. They should only affect more advanced users, but it’s probably worth reading through the list and checking your code for these things.

Signals

- Add **kwargs to any registered signal handlers.
- Connect, disconnect, and send signals via methods on the Signal object instead of through module methods in django.dispatch.dispatcher.
- Remove any use of the Anonymous and Any sender options; they no longer exist. You can still receive signals sent by any sender by using sender=None
- Make any custom signals you’ve declared into instances of django.dispatch.Signal instead of anonymous objects.

Here’s quick summary of the code changes you’ll need to make:

<table>
<thead>
<tr>
<th>Old (0.96)</th>
<th>New (1.0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>def callback(sender)</td>
<td>def callback(sender, **kwargs)</td>
</tr>
<tr>
<td>sig = object()</td>
<td>sig = django.dispatch.Signal()</td>
</tr>
<tr>
<td>dispatcher.connect(callback, sig)</td>
<td>sig.connect(callback)</td>
</tr>
<tr>
<td>dispatcher.send(sig, sender)</td>
<td>sig.send(sender)</td>
</tr>
<tr>
<td>dispatcher.connect(callback, sig, sender=Any)</td>
<td>sig.connect(callback, sender=None)</td>
</tr>
</tbody>
</table>

Comments

If you were using Django 0.96’s django.contrib.comments app, you’ll need to upgrade to the new comments app introduced in 1.0. See the upgrade guide for details.

Template tags

spaceless tag

The spaceless template tag now removes all spaces between HTML tags, instead of preserving a single space.
Local flavors

U.S. local flavor

django.contrib.localflavor.usa has been renamed to django.contrib.localflavor.us. This change was made to match the naming scheme of other local flavors. To migrate your code, all you need to do is change the imports.

Sessions

Getting a new session key

SessionBase.get_new_session_key() has been renamed to _get_new_session_key(). get_new_session_object() no longer exists.

Fixtures

Loading a row no longer calls save()

Previously, loading a row automatically ran the model’s save() method. This is no longer the case, so any fields (for example: timestamps) that were auto-populated by a save() now need explicit values in any fixture.

Settings

Better exceptions

The old EnvironmentError has split into an ImportError when Django fails to find the settings module and a RuntimeError when you try to reconfigure settings after having already used them.

LOGIN_URL has moved

The LOGIN_URL constant moved from django.contrib.auth into the settings module. Instead of using from django.contrib.auth import LOGIN_URL refer to settings.LOGIN_URL.
**APPEND_SLASH behavior has been updated**

In 0.96, if a URL didn’t end in a slash or have a period in the final component of its path, and `APPEND_SLASH` was True, Django would redirect to the same URL, but with a slash appended to the end. Now, Django checks to see whether the pattern without the trailing slash would be matched by something in your URL patterns. If so, no redirection takes place, because it is assumed you deliberately wanted to catch that pattern.

For most people, this won’t require any changes. Some people, though, have URL patterns that look like this:

```python
r'\some_prefix/(.*)$
```

Previously, those patterns would have been redirected to have a trailing slash. If you always want a slash on such URLs, rewrite the pattern as:

```python
r'\some_prefix/(.+)/$
```

**Smaller model changes**

**Different exception from get()**

Managers now return a `MultipleObjectsReturned` exception instead of `AssertionError`:

Old (0.96):

```python
try:
    Model.objects.get(...)
except AssertionError:
    handle_the_error()
```

New (1.0):

```python
try:
    Model.objects.get(...)
except Model.MultipleObjectsReturned:
    handle_the_error()
```
LazyDate has been fired

The LazyDate helper class no longer exists.

Default field values and query arguments can both be callable objects, so instances of LazyDate can be replaced with a reference to datetime.datetime.now:

Old (0.96):

```python
class Article(models.Model):
    title = models.CharField(max_length=100)
    published = models.DateField(default=LazyDate())
```

New (1.0):

```python
import datetime

class Article(models.Model):
    title = models.CharField(max_length=100)
    published = models.DateField(default=datetime.datetime.now)
```

DecimalField is new, and FloatField is now a proper float

Old (0.96):

```python
class MyModel(models.Model):
    field_name = models.FloatField(max_digits=10, decimal_places=3)
...
```

New (1.0):

```python
class MyModel(models.Model):
    field_name = models.DecimalField(max_digits=10, decimal_places=3)
...
```

If you forget to make this change, you will see errors about FloatField not taking a max_digits attribute in __init__, because the new FloatField takes no precision-related arguments.

If you’re using MySQL or PostgreSQL, no further changes are needed. The database column types for DecimalField are the same as for the old FloatField.

If you’re using SQLite, you need to force the database to view the appropriate columns as decimal types, rather than floats. To do this, you’ll need to reload your data. Do this after you have made the change to using DecimalField in your code and updated the Django code.
Warning: Back up your database first!

For SQLite, this means making a copy of the single file that stores the database (the name of that file is the DATABASE_NAME in your settings.py file).

To upgrade each application to use a `DecimalField`, you can do the following, replacing `<app>` in the code below with each app’s name:

```
$ ./manage.py dumpdata --format=xml <app> > data-dump.xml
$ ./manage.py reset <app>
$ ./manage.py loaddata data-dump.xml
```

Notes:

1. It’s important that you remember to use XML format in the first step of this process. We are exploiting a feature of the XML data dumps that makes porting floats to decimals with SQLite possible.

2. In the second step you will be asked to confirm that you are prepared to lose the data for the application(s) in question. Say yes; we’ll restore this data in the third step.

3. `DecimalField` is not used in any of the apps shipped with Django prior to this change being made, so you do not need to worry about performing this procedure for any of the standard Django models.

If something goes wrong in the above process, just copy your backed up database file over the original file and start again.

**Internationalization**

`django.views.i18n.set_language()` now requires a POST request

Previously, a GET request was used. The old behavior meant that state (the locale used to display the site) could be changed by a GET request, which is against the HTTP specification’s recommendations. Code calling this view must ensure that a POST request is now made, instead of a GET. This means you can no longer use a link to access the view, but must use a form submission of some kind (e.g. a button).

`_()` is no longer in builtins

`_()` (the callable object whose name is a single underscore) is no longer monkeypatched into builtins – that is, it’s no longer available magically in every module.

If you were previously relying on `_()` always being present, you should now explicitly import `ugettext` or `ugettext_lazy`, if appropriate, and alias it to `_` yourself:
HTTP request/response objects

Dictionary access to HttpRequest

HttpRequest objects no longer directly support dictionary-style access; previously, both GET and POST data were directly available on the HttpRequest object (e.g., you could check for a piece of form data by using `if 'some_form_key' in request` or by reading `request['some_form_key']`). This is no longer supported; if you need access to the combined GET and POST data, use `request.REQUEST` instead.

It is strongly suggested, however, that you always explicitly look in the appropriate dictionary for the type of request you expect to receive (`request.GET` or `request.POST`); relying on the combined `request.REQUEST` dictionary can mask the origin of incoming data.

Accessing HTTPResponse headers

django.http.HttpResponse.headers has been renamed to `_headers` and `HttpResponse` now supports containment checking directly. So use `if header in response:` instead of `if header in response.headers:`.

Generic relations

Generic relations have been moved out of core

The generic relation classes – `GenericForeignKey` and `GenericRelation` – have moved into the `django.contrib.contenttypes` module.

Testing

django.test.Client.login() has changed

Old (0.96):

```python
from django.test import Client

c = Client()

c.login('/path/to/login','myuser','mypassword')
```

New (1.0):
# ... same as above, but then:
c.login(username='myuser', password='mypassword')

Management commands

Running management commands from your code

django.core.management has been greatly refactored.

Calls to management services in your code now need to use call_command. For example, if you have some test code that calls flush and load_data:

```python
from django.core import management
management.flush(verbosity=0, interactive=False)
management.load_data(['test_data'], verbosity=0)
```

...you'll need to change this code to read:

```python
from django.core import management
management.call_command('flush', verbosity=0, interactive=False)
management.call_command('loaddata', 'test_data', verbosity=0)
```

Subcommands must now precede options

django-admin.py and manage.py now require subcommands to precede options. So:

```bash
$ django-admin.py --settings=foo.bar runserver
```

...no longer works and should be changed to:

```bash
$ django-admin.py runserver --settings=foo.bar
```

Syndication

Feed.__init__ has changed

The __init__() method of the syndication framework’s Feed class now takes an HttpRequest object as its second parameter, instead of the feed’s URL. This allows the syndication framework to work without requiring the sites framework. This only affects code that subclasses Feed and overrides the __init__() method, and code that calls Feed.__init__() directly.
Data structures

**SortedDictFromList is gone**

django.newforms.forms.SortedDictFromList was removed. django.utils.datastructures.SortedDict can now be instantiated with a sequence of tuples.

To update your code:

1. Use django.utils.datastructures.SortedDict wherever you were using django.newforms.forms.SortedDictFromList.

2. Because django.utils.datastructures.SortedDict.copy doesn’t return a deepcopy as SortedDictFromList.copy() did, you will need to update your code if you were relying on a deepcopy. Do this by using copy.deepcopy directly.

Database backend functions

Database backend functions have been renamed

Almost all of the database backend-level functions have been renamed and/or relocated. None of these were documented, but you’ll need to change your code if you’re using any of these functions, all of which are in django.db:

<table>
<thead>
<tr>
<th>Old (0.96)</th>
<th>New (1.0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>backend.get_autoinc_sql</td>
<td>connection.ops.autoinc_sql</td>
</tr>
<tr>
<td>backend.get_date_extract_sql</td>
<td>connection.ops.date_extract_sql</td>
</tr>
<tr>
<td>backend.get_date_trunc_sql</td>
<td>connection.ops.date_trunc_sql</td>
</tr>
<tr>
<td>backend.get_datetime_cast_sql</td>
<td>connection.ops.datetime_cast_sql</td>
</tr>
<tr>
<td>backend.get_deferrable_sql</td>
<td>connection.ops.deferrable_sql</td>
</tr>
<tr>
<td>backend.get_drop_foreignkey_sql</td>
<td>connection.ops.drop_foreignkey_sql</td>
</tr>
<tr>
<td>backend.get_fulltext_search_sql</td>
<td>connection.ops.fulltext_search_sql</td>
</tr>
<tr>
<td>backend.get_last_insert_id</td>
<td>connection.ops.last_insert_id</td>
</tr>
<tr>
<td>backend.get_limit_offset_sql</td>
<td>connection.ops.limit_offset_sql</td>
</tr>
<tr>
<td>backend.get_max_name_length</td>
<td>connection.ops.max_name_length</td>
</tr>
<tr>
<td>backend.get_pk_default_value</td>
<td>connection.ops.pk_default_value</td>
</tr>
<tr>
<td>backend.get_random_function_sql</td>
<td>connection.ops.random_function_sql</td>
</tr>
<tr>
<td>backend.get_sql_flush</td>
<td>connection.ops.sql_flush</td>
</tr>
<tr>
<td>backend.get_sql_sequence_reset</td>
<td>connection.ops.sequence_reset_sql</td>
</tr>
<tr>
<td>backend.get_start_transaction_sql</td>
<td>connection.ops.start_transaction_sql</td>
</tr>
<tr>
<td>backend.get_tablespace_sql</td>
<td>connection.ops.tablespace_sql</td>
</tr>
</tbody>
</table>

continues on next page
A complete list of backwards-incompatible changes can be found at https://code.djangoproject.com/wiki/BackwardsIncompatibleChanges.

What’s new in Django 1.0

A lot!

Since Django 0.96, we’ve made over 4,000 code commits, fixed more than 2,000 bugs, and edited, added, or removed around 350,000 lines of code. We’ve also added 40,000 lines of new documentation, and greatly improved what was already there.

In fact, new documentation is one of our favorite features of Django 1.0, so we might as well start there. First, there’s a new documentation site:

- https://docs.djangoproject.com/

The documentation has been greatly improved, cleaned up, and generally made awesome. There’s now dedicated search, indexes, and more.

We can’t possibly document everything that’s new in 1.0, but the documentation will be your definitive guide. Anywhere you see something like:

This feature is new in Django 1.0

You’ll know that you’re looking at something new or changed.

The other major highlights of Django 1.0 are:

```
<table>
<thead>
<tr>
<th>Old (0.96)</th>
<th>New (1.0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>backend.quote_name</td>
<td>connection.ops.quote_name</td>
</tr>
<tr>
<td>backend.get_query_set_class</td>
<td>connection.ops.query_set_class</td>
</tr>
<tr>
<td>backend.get_field_cast_sql</td>
<td>connection.ops.field_cast_sql</td>
</tr>
<tr>
<td>backend.get_drop_sequence</td>
<td>connection.ops.drop_sequence_sql</td>
</tr>
<tr>
<td>backend.OPERATOR_MAPPING</td>
<td>connection.operators</td>
</tr>
<tr>
<td>backend.allows_group_by_ordinal</td>
<td>connection.features.allows_group_by_ordinal</td>
</tr>
<tr>
<td>backend.allows_unique_and_pk</td>
<td>connection.features.allows_unique_and_pk</td>
</tr>
<tr>
<td>backend.autoindexes_primary_keys</td>
<td>connection.features.autoindexes_primary_keys</td>
</tr>
<tr>
<td>backend.needs_datetime_string_cast</td>
<td>connection.features.needs_datetime_string_cast</td>
</tr>
<tr>
<td>backend.needs_upper_for_iops</td>
<td>connection.features.needs_upper_for_iops</td>
</tr>
<tr>
<td>backend.supports_constraints</td>
<td>connection.features.supports_constraints</td>
</tr>
<tr>
<td>backend.supports_tablespaces</td>
<td>connection.features.supports_tablespaces</td>
</tr>
<tr>
<td>backend.uses_case_insensitive_names</td>
<td>connection.features.uses_case_insensitive_names</td>
</tr>
<tr>
<td>backend.uses_custom_queryset</td>
<td>connection.features.uses_custom_queryset</td>
</tr>
</tbody>
</table>
```
Refactored admin application

The Django administrative interface (django.contrib.admin) has been completely refactored; admin definitions are now completely decoupled from model definitions (no more class Admin declaration in models!), rewritten to use Django’s new form-handling library (introduced in the 0.96 release as django.newforms, and now available as simply django.forms) and redesigned with extensibility and customization in mind. Full documentation for the admin application is available online in the official Django documentation:

See the admin reference for details

Improved Unicode handling

Django’s internals have been refactored to use Unicode throughout; this drastically simplifies the task of dealing with non-Western-European content and data in Django. Additionally, utility functions have been provided to ease interoperability with third-party libraries and systems which may or may not handle Unicode gracefully. Details are available in Django’s Unicode-handling documentation.

See Unicode data.

An improved ORM

Django’s object-relational mapper –the component which provides the mapping between Django model classes and your database, and which mediates your database queries–has been dramatically improved by a massive refactoring. For most users of Django this is backwards-compatible; the public-facing API for database querying underwent a few minor changes, but most of the updates took place in the ORM’s internals. A guide to the changes, including backwards-incompatible modifications and mentions of new features opened up by this refactoring, is available on the Django wiki.

Automatic escaping of template variables

To provide improved security against cross-site scripting (XSS) vulnerabilities, Django’s template system now automatically escapes the output of variables. This behavior is configurable, and allows both variables and larger template constructs to be marked as safe (requiring no escaping) or unsafe (requiring escaping). A full guide to this feature is in the documentation for the autoescape tag.
**django.contrib.gis (GeoDjango)**

A project over a year in the making, this adds world-class GIS (Geographic Information Systems) support to Django, in the form of a contrib application. Its documentation is currently being maintained externally, and will be merged into the main Django documentation shortly. Huge thanks go to Justin Bronn, Jeremy Dunck, Brett Hoerner and Travis Pinney for their efforts in creating and completing this feature.

See GeoDjango for details.

**Pluggable file storage**

Django’s built-in FileField and ImageField now can take advantage of pluggable file-storage backends, allowing extensive customization of where and how uploaded files get stored by Django. For details, see the files documentation; big thanks go to Marty Alchin for putting in the hard work to get this completed.

**Jython compatibility**

Thanks to a lot of work from Leo Soto during a Google Summer of Code project, Django’s codebase has been refactored to remove incompatibilities with Jython, an implementation of Python written in Java, which runs Python code on the Java Virtual Machine. Django is now compatible with the forthcoming Jython 2.5 release.

**Generic relations in forms and admin**

Classes are now included in django.contrib.contenttypes which can be used to support generic relations in both the admin interface and in end-user forms. See the documentation for generic relations for details.

**INSERT/UPDATE distinction**

Although Django’s default behavior of having a model’s save() method automatically determine whether to perform an INSERT or an UPDATE at the SQL level is suitable for the majority of cases, there are occasional situations where forcing one or the other is useful. As a result, models can now support an additional parameter to save() which can force a specific operation.

See Forcing an INSERT or UPDATE for details.
Split `CacheMiddleware`

Django’s `CacheMiddleware` has been split into three classes: `CacheMiddleware` itself still exists and retains all of its previous functionality, but it is now built from two separate middleware classes which handle the two parts of caching (inserting into and reading from the cache) separately, offering additional flexibility for situations where combining these functions into a single middleware posed problems.

Full details, including updated notes on appropriate use, are in the caching documentation.

Refactored `django.contrib.comments`

As part of a Google Summer of Code project, Thejaswi Puthraya carried out a major rewrite and refactoring of Django’s bundled comment system, greatly increasing its flexibility and customizability.

Removal of deprecated features

A number of features and methods which had previously been marked as deprecated, and which were scheduled for removal prior to the 1.0 release, are no longer present in Django. These include imports of the form library from `django.newforms` (now located simply at `django.forms`), the `form_for_model` and `form_for_instance` helper functions (which have been replaced by `ModelForm`) and a number of deprecated features which were replaced by the dispatcher, file-uploading and file-storage refactoring introduced in the Django 1.0 alpha releases.

Known issues

We’ve done our best to make Django 1.0 as solid as possible, but unfortunately there are a couple of issues that we know about in the release.

Multi-table model inheritance with `to_field`

If you’re using multiple table model inheritance, be aware of this caveat: child models using a custom `parent_link` and `to_field` will cause database integrity errors. A set of models like the following are not valid:

```python
class Parent(models.Model):
    name = models.CharField(max_length=10)
    other_value = models.IntegerField(unique=True)

class Child(Parent):
```

(continues on next page)
father = models.OneToOneField(Parent, primary_key=True, to_field="other_value", parent_link=True)
value = models.IntegerField()

This bug will be fixed in the next release of Django.

Caveats with support of certain databases

Django attempts to support as many features as possible on all database backends. However, not all database backends are alike, and in particular many of the supported database differ greatly from version to version. It’s a good idea to checkout our notes on supported database:

- MySQL notes
- SQLite notes
- Oracle notes

9.1.22 Pre-1.0 releases

Django version 0.96 release notes

Welcome to Django 0.96!

The primary goal for 0.96 is a cleanup and stabilization of the features introduced in 0.95. There have been a few small backwards-incompatible changes since 0.95, but the upgrade process should be fairly simple and should not require major changes to existing applications.

However, we’re also releasing 0.96 now because we have a set of backwards-incompatible changes scheduled for the near future. Once completed, they will involve some code changes for application developers, so we recommend that you stick with Django 0.96 until the next official release; then you’ll be able to upgrade in one step instead of needing to make incremental changes to keep up with the development version of Django.

Backwards-incompatible changes

The following changes may require you to update your code when you switch from 0.95 to 0.96:
MySQLdb version requirement

Due to a bug in older versions of the MySQLdb Python module (which Django uses to connect to MySQL databases), Django’s MySQL backend now requires version 1.2.1p2 or higher of MySQLdb, and will raise exceptions if you attempt to use an older version.

If you’re currently unable to upgrade your copy of MySQLdb to meet this requirement, a separate, backwards-compatible backend, called “mysql_old”, has been added to Django. To use this backend, change the DATABASE_ENGINE setting in your Django settings file from this:

```python
DATABASE_ENGINE = "mysql"
```

to this:

```python
DATABASE_ENGINE = "mysql_old"
```

However, we strongly encourage MySQL users to upgrade to a more recent version of MySQLdb as soon as possible. The “mysql_old” backend is provided only to ease this transition, and is considered deprecated; aside from any necessary security fixes, it will not be actively maintained, and it will be removed in a future release of Django.

Also, note that some features, like the new DATABASE_OPTIONS setting (see the databases documentation for details), are only available on the “mysql” backend, and will not be made available for “mysql_old”.

Database constraint names changed

The format of the constraint names Django generates for foreign key references have changed slightly. These names are generally only used when it is not possible to put the reference directly on the affected column, so they are not always visible.

The effect of this change is that running manage.py reset and similar commands against an existing database may generate SQL with the new form of constraint name, while the database itself contains constraints named in the old form; this will cause the database server to raise an error message about modifying nonexistent constraints.

If you need to work around this, there are two methods available:

1. Redirect the output of manage.py to a file, and edit the generated SQL to use the correct constraint names before executing it.

2. Examine the output of manage.py sqlall to see the new-style constraint names, and use that as a guide to rename existing constraints in your database.
Name changes in manage.py

A few of the options to manage.py have changed with the addition of fixture support:

- There are new dumpdata and loaddata commands which, as you might expect, will dump and load data to/from the database. These commands can operate against any of Django’s supported serialization formats.

- The sqlinitialdata command has been renamed to sqlcustom to emphasize that loaddata should be used for data (and sqlcustom for other custom SQL—views, stored procedures, etc.).

- The vestigial install command has been removed. Use syncdb.

Backslash escaping changed

The Django database API now escapes backslashes given as query parameters. If you have any database API code that matches backslashes, and it was working before (despite the lack of escaping), you’ll have to change your code to “unescape” the slashes one level.

For example, this used to work:

```
# Find text containing a single backslash
MyModel.objects.filter(text__contains='\\')
```

The above is now incorrect, and should be rewritten as:

```
# Find text containing a single backslash
MyModel.objects.filter(text__contains='\')
```

Removed ENABLE_PSYCO setting

The ENABLE_PSYCO setting no longer exists. If your settings file includes ENABLE_PSYCO it will have no effect; to use Psyco, we recommend writing a middleware class to activate it.

What’s new in 0.96?

This revision represents over a thousand source commits and over four hundred bug fixes, so we can’t possibly catalog all the changes. Here, we describe the most notable changes in this release.
New forms library

django.newforms is Django’s new form-handling library. It’s a replacement for django.forms, the old form/manipulator/validation framework. Both APIs are available in 0.96, but over the next two releases we plan to switch completely to the new forms system, and deprecate and remove the old system.

There are three elements to this transition:

- We’ve copied the current django.forms to django.oldforms. This allows you to upgrade your code now rather than waiting for the backwards-incompatible change and rushing to fix your code after the fact. Just change your import statements like this:

```python
from django import forms  # 0.95-style
from django import oldforms as forms  # 0.96-style
```

- The next official release of Django will move the current django.newforms to django.forms. This will be a backwards-incompatible change, and anyone still using the old version of django.forms at that time will need to change their import statements as described above.

- The next release after that will completely remove django.oldforms.

Although the newforms library will continue to evolve, it’s ready for use for most common cases. We recommend that anyone new to form handling skip the old forms system and start with the new.

For more information about django.newforms, read the newforms documentation.

URLconf improvements

You can now use any callable as the callback in URLconfs (previously, only strings that referred to callables were allowed). This allows a much more natural use of URLconfs. For example, this URLconf:

```python
from django.conf.urls.defaults import *

urlpatterns = patterns('',
    ('^myview/$', 'mysite.myapp.views.myview')
)
```

can now be rewritten as:

```python
from django.conf.urls.defaults import *
from mysite.myapp.views import myview

urlpatterns = patterns('',
    ('^myview/$', myview)
)
```
One useful application of this can be seen when using decorators; this change allows you to apply decorators to views in your URLconf. Thus, you can make a generic view require login very easily:

```python
from django.conf.urls.defaults import *
from django.contrib.auth.decorators import login_required
from django.views.generic.list_detail import object_list
from mysite.myapp.models import MyModel

info = {
    "queryset" : MyModel.objects.all(),
}

urlpatterns = patterns('',
    ('^myview/$', login_required(object_list), info)
)
```

Note that both syntaxes (strings and callables) are valid, and will continue to be valid for the foreseeable future.

**The test framework**

Django now includes a test framework so you can start transmuting fear into boredom (with apologies to Kent Beck). You can write tests based on `doctest` or `unittest` and test your views with a simple test client. There is also new support for “fixtures”—initial data, stored in any of the supported serialization formats, that will be loaded into your database at the start of your tests. This makes testing with real data much easier.

See the testing documentation for the full details.

**Improvements to the admin interface**

A small change, but a very nice one: dedicated views for adding and updating users have been added to the admin interface, so you no longer need to worry about working with hashed passwords in the admin.

**Thanks**

Since 0.95, a number of people have stepped forward and taken a major new role in Django’s development. We’d like to thank these people for all their hard work:

- Russell Keith-Magee and Malcolm Tredinnick for their major code contributions. This release wouldn’t have been possible without them.
- Our new release manager, James Bennett, for his work in getting out 0.95.1, 0.96, and (hopefully) future release.
• Our ticket managers Chris Beaven (aka SmileyChris), Simon Greenhill, Michael Radziej, and Gary Wilson. They agreed to take on the monumental task of wrangling our tickets into nicely cataloged submission. Figuring out what to work on is now about a million times easier; thanks again, guys.

• Everyone who submitted a bug report, patch or ticket comment. We can’t possibly thank everyone by name—over 200 developers submitted patches that went into 0.96—but everyone who’s contributed to Django is listed in AUTHORS.

Django version 0.95 release notes

Welcome to the Django 0.95 release.

This represents a significant advance in Django development since the 0.91 release in January 2006. The details of every change in this release would be too extensive to list in full, but a summary is presented below.

Suitability and API stability

This release is intended to provide a stable reference point for developers wanting to work on production-level applications that use Django.

However, it’s not the 1.0 release, and we’ll be introducing further changes before 1.0. For a clear look at which areas of the framework will change (and which ones will not change) before 1.0, see the api-stability.txt file, which lives in the docs/ directory of the distribution.

You may have a need to use some of the features that are marked as “subject to API change” in that document, but that’s OK with us as long as it’s OK with you, and as long as you understand APIs may change in the future.

Fortunately, most of Django’s core APIs won’t be changing before version 1.0. There likely won’t be as big of a change between 0.95 and 1.0 versions as there was between 0.91 and 0.95.

Changes and new features

The major changes in this release (for developers currently using the 0.91 release) are a result of merging the ‘magic-removal’ branch of development. This branch removed a number of constraints in the way Django code had to be written that were a consequence of decisions made in the early days of Django, prior to its open-source release. It’s now possible to write more natural, Pythonic code that works as expected, and there’s less “black magic” happening behind the scenes.

Aside from that, another main theme of this release is a dramatic increase in usability. We’ve made countless improvements in error messages, documentation, etc., to improve developers’ quality of life.

The new features and changes introduced in 0.95 include:
• Django now uses a more consistent and natural filtering interface for retrieving objects from the database.

• User-defined models, functions and constants now appear in the module namespace they were defined in. (Previously everything was magically transferred to the `django.models.*` namespace.)

• Some optional applications, such as the FlatPage, Sites and Redirects apps, have been decoupled and moved into `django.contrib`. If you don’t want to use these applications, you no longer have to install their database tables.

• Django now has support for managing database transactions.

• We’ve added the ability to write custom authentication and authorization backends for authenticating users against alternate systems, such as LDAP.

• We’ve made it easier to add custom table-level functions to models, through a new “Manager” API.

• It’s now possible to use Django without a database. This simply means that the framework no longer requires you to have a working database set up just to serve dynamic pages. In other words, you can just use URLconfs/views on their own. Previously, the framework required that a database be configured, regardless of whether you actually used it.

• It’s now more explicit and natural to override `save()` and `delete()` methods on models, rather than needing to hook into the `pre_save()` and `post_save()` method hooks.

• Individual pieces of the framework now can be configured without requiring the setting of an environment variable. This permits use of, for example, the Django templating system inside other applications.

• More and more parts of the framework have been internationalized, as we’ve expanded internationalization (i18n) support. The Django codebase, including code and templates, has now been translated, at least in part, into 31 languages. From Arabic to Chinese to Hungarian to Welsh, it is now possible to use Django’s admin site in your native language.

The number of changes required to port from 0.91-compatible code to the 0.95 code base are significant in some cases. However, they are, for the most part, reasonably routine and only need to be done once. A list of the necessary changes is described in the Removing The Magic wiki page. There is also an easy checklist for reference when undertaking the porting operation.

**Problem reports and getting help**

Need help resolving a problem with Django? The documentation in the distribution is also available online at the Django website. The FAQ document is especially recommended, as it contains a number of issues that come up time and again.

For more personalized help, the `django-users` mailing list is a very active list, with more than 2,000 subscribers who can help you solve any sort of Django problem. We recommend you search the archives first, though,
because many common questions appear with some regularity, and any particular problem may already have been answered.

Finally, for those who prefer the more immediate feedback offered by IRC, there’s a #django channel on irc.libera.chat that is regularly populated by Django users and developers from around the world. Friendly people are usually available at any hour of the day—to help, or just to chat.

Thanks for using Django!

The Django Team July 2006

### 9.2 Security releases

Whenever a security issue is disclosed via Django’s security policies, appropriate release notes are now added to all affected release series.

Additionally, an archive of disclosed security issues is maintained.

#### 9.2.1 Archive of security issues

Django’s development team is strongly committed to responsible reporting and disclosure of security-related issues, as outlined in Django’s security policies.

As part of that commitment, we maintain the following historical list of issues which have been fixed and disclosed. For each issue, the list below includes the date, a brief description, the CVE identifier if applicable, a list of affected versions, a link to the full disclosure and links to the appropriate patch(es).

Some important caveats apply to this information:

- Lists of affected versions include only those versions of Django which had stable, security-supported releases at the time of disclosure. This means older versions (whose security support had expired) and versions which were in pre-release (alpha/beta/RC) states at the time of disclosure may have been affected, but are not listed.

- The Django project has on occasion issued security advisories, pointing out potential security problems which can arise from improper configuration or from other issues outside of Django itself. Some of these advisories have received CVEs; when that is the case, they are listed here, but as they have no accompanying patches or releases, only the description, disclosure and CVE will be listed.
Issues under Django’s security process

All security issues have been handled under versions of Django’s security process. These are listed below.

July 4, 2022 - CVE-2022-34265

Potential SQL injection via Trunc(kind) and Extract(lookup_name) arguments. Full description

- Django 4.0 (patch)
- Django 3.2 (patch)

April 11, 2022 - CVE-2022-28346

Potential SQL injection in QuerySet.annotate(), aggregate(), and extra(). Full description

- Django 4.0 (patch)
- Django 3.2 (patch)
- Django 2.2 (patch)

April 11, 2022 - CVE-2022-28347

Potential SQL injection via QuerySet.explain(**options) on PostgreSQL. Full description

- Django 4.0 (patch)
- Django 3.2 (patch)
- Django 2.2 (patch)

February 1, 2022 - CVE-2022-22818

Possible XSS via {% debug %} template tag. Full description

Versions affected

- Django 4.0 (patch)
- Django 3.2 (patch)
- Django 2.2 (patch)
February 1, 2022 - CVE-2022-23833

Denial-of-service possibility in file uploads. Full description

Versions affected

- Django 4.0 (patch)
- Django 3.2 (patch)
- Django 2.2 (patch)

January 4, 2022 - CVE-2021-45452

Potential directory-traversal via Storage.save(). Full description

Versions affected

- Django 4.0 (patch)
- Django 3.2 (patch)
- Django 2.2 (patch)

January 4, 2022 - CVE-2021-45116

Potential information disclosure in dictsorc template filter. Full description

Versions affected

- Django 4.0 (patch)
- Django 3.2 (patch)
- Django 2.2 (patch)
January 4, 2022 - CVE-2021-45115

Denial-of-service possibility in `UserAttributeSimilarityValidator`. Full description

**Versions affected**

- Django 4.0 (patch)
- Django 3.2 (patch)
- Django 2.2 (patch)

December 7, 2021 - CVE-2021-44420

Potential bypass of an upstream access control based on URL paths. Full description

**Versions affected**

- Django 3.2 (patch)
- Django 3.1 (patch)
- Django 2.2 (patch)

July 1, 2021 - CVE-2021-35042

Potential SQL injection via unsanitized `QuerySet.order_by()` input. Full description

**Versions affected**

- Django 3.2 (patch)
- Django 3.1 (patch)

June 2, 2021 - CVE-2021-33203

Potential directory traversal via `admindocs`. Full description
Versions affected

- Django 3.2 (patch)
- Django 3.1 (patch)
- Django 2.2 (patch)

June 2, 2021 - CVE-2021-33571

Possible indeterminate SSRF, RFI, and LFI attacks since validators accepted leading zeros in IPv4 addresses. Full description

Versions affected

- Django 3.2 (patch)
- Django 3.1 (patch)
- Django 2.2 (patch)

May 6, 2021 - CVE-2021-32052

Header injection possibility since URLValidator accepted newlines in input on Python 3.9.5+. Full description

Versions affected

- Django 3.2 (patch)
- Django 3.1 (patch)
- Django 2.2 (patch)

May 4, 2021 - CVE-2021-31542

Potential directory-traversal via uploaded files. Full description
April 6, 2021 - CVE-2021-28658

Potential directory-traversal via uploaded files. Full description

February 19, 2021 - CVE-2021-23336

Web cache poisoning via django.utils.http.limited_parse_qsl(). Full description

February 1, 2021 - CVE-2021-3281

Potential directory-traversal via archive.extract(). Full description
Versions affected

- Django 3.1 (patch)
- Django 3.0 (patch)
- Django 2.2 (patch)

September 1, 2020 - CVE-2020-24584

Permission escalation in intermediate-level directories of the file system cache on Python 3.7+. Full description

Versions affected

- Django 3.1 (patch)
- Django 3.0 (patch)
- Django 2.2 (patch)

September 1, 2020 - CVE-2020-24583

Incorrect permissions on intermediate-level directories on Python 3.7+. Full description

Versions affected

- Django 3.1 (patch)
- Django 3.0 (patch)
- Django 2.2 (patch)

June 3, 2020 - CVE-2020-13596

Possible XSS via admin ForeignKeyRawIdWidget. Full description
Versions affected

- Django 3.0 (patch)
- Django 2.2 (patch)

June 3, 2020 - CVE-2020-13254

Potential data leakage via malformed memcached keys. Full description

Versions affected

- Django 3.0 (patch)
- Django 2.2 (patch)

March 4, 2020 - CVE-2020-9402

Potential SQL injection via tolerance parameter in GIS functions and aggregates on Oracle. Full description

Versions affected

- Django 3.0 (patch)
- Django 2.2 (patch)
- Django 1.11 (patch)

February 3, 2020 - CVE-2020-7471

Potential SQL injection via StringAgg(delimiter). Full description

Versions affected

- Django 3.0 (patch)
- Django 2.2 (patch)
- Django 1.11 (patch)
December 18, 2019 - CVE-2019-19844

Potential account hijack via password reset form. Full description

Versions affected

- Django 3.0 (patch)
- Django 2.2 (patch)
- Django 1.11 (patch)

December 2, 2019 - CVE-2019-19118

Privilege escalation in the Django admin. Full description

Versions affected

- Django 3.0 (patch)
- Django 2.2 (patch)
- Django 2.1 (patch)

August 1, 2019 - CVE-2019-14235

Potential memory exhaustion in django.utils.encoding.uri_to_iri(). Full description

Versions affected

- Django 2.2 (patch)
- Django 2.1 (patch)
- Django 1.11 (patch)
August 1, 2019 - CVE-2019-14234

SQL injection possibility in key and index lookups for JSONField/HStoreField. Full description

Versions affected

- Django 2.2 (patch)
- Django 2.1 (patch)
- Django 1.11 (patch)

August 1, 2019 - CVE-2019-14233

Denial-of-service possibility in strip_tags(). Full description

Versions affected

- Django 2.2 (patch)
- Django 2.1 (patch)
- Django 1.11 (patch)

August 1, 2019 - CVE-2019-14232

Denial-of-service possibility in django.utils.text.Truncator. Full description

Versions affected

- Django 2.2 (patch)
- Django 2.1 (patch)
- Django 1.11 (patch)
July 1, 2019 - CVE-2019-12781

Incorrect HTTP detection with reverse-proxy connecting via HTTPS. Full description

Versions affected

- Django 2.2 (patch)
- Django 2.1 (patch)
- Django 1.11 (patch)

June 3, 2019 - CVE-2019-12308

XSS via “Current URL” link generated by AdminURLFieldWidget. Full description

Versions affected

- Django 2.2 (patch)
- Django 2.1 (patch)
- Django 1.11 (patch)

June 3, 2019 - CVE-2019-11358

Prototype pollution in bundled jQuery. Full description

Versions affected

- Django 2.2 (patch)
- Django 2.1 (patch)

February 11, 2019 - CVE-2019-6975

Memory exhaustion in django.utils.numberformat.format(). Full description
Versions affected

- Django 2.1 (patch)
- Django 2.0 (patch and correction)
- Django 1.11 (patch)

January 4, 2019 - CVE-2019-3498

Content spoofing possibility in the default 404 page. Full description

Versions affected

- Django 2.1 (patch)
- Django 2.0 (patch)
- Django 1.11 (patch)

October 1, 2018 - CVE-2018-16984

Password hash disclosure to “view only” admin users. Full description

Versions affected

- Django 2.1 (patch)

August 1, 2018 - CVE-2018-14574

Open redirect possibility in CommonMiddleware. Full description

Versions affected

- Django 2.1 (patch)
- Django 2.0 (patch)
- Django 1.11 (patch)
March 6, 2018 - CVE-2018-7537

Denial-of-service possibility in truncatechars_html and truncatewords_html template filters. Full description

Versions affected

- Django 2.0 (patch)
- Django 1.11 (patch)
- Django 1.8 (patch)

March 6, 2018 - CVE-2018-7536

Denial-of-service possibility in urlize and urlizetrunc template filters. Full description

Versions affected

- Django 2.0 (patch)
- Django 1.11 (patch)
- Django 1.8 (patch)

February 1, 2018 - CVE-2018-6188

Information leakage in AuthenticationForm. Full description

Versions affected

- Django 2.0 (patch)
- Django 1.11 (patch)

September 5, 2017 - CVE-2017-12794

Possible XSS in traceback section of technical 500 debug page. Full description
Versions affected

- Django 1.11 (patch)
- Django 1.10 (patch)

April 4, 2017 - CVE-2017-7234

Open redirect vulnerability in `django.views.static.serve()`. Full description

Versions affected

- Django 1.10 (patch)
- Django 1.9 (patch)
- Django 1.8 (patch)

April 4, 2017 - CVE-2017-7233

Open redirect and possible XSS attack via user-supplied numeric redirect URLs. Full description

Versions affected

- Django 1.10 (patch)
- Django 1.9 (patch)
- Django 1.8 (patch)

November 1, 2016 - CVE-2016-9014

DNS rebinding vulnerability when `DEBUG=True`. Full description

Versions affected

- Django 1.10 (patch)
- Django 1.9 (patch)
- Django 1.8 (patch)
November 1, 2016 - CVE-2016-9013

User with hardcoded password created when running tests on Oracle. **Full description**

**Versions affected**

- Django 1.10 (patch)
- Django 1.9 (patch)
- Django 1.8 (patch)

September 26, 2016 - CVE-2016-7401

CSRF protection bypass on a site with Google Analytics. **Full description**

**Versions affected**

- Django 1.9 (patch)
- Django 1.8 (patch)

July 18, 2016 - CVE-2016-6186

XSS in admin’s add/change related popup. **Full description**

**Versions affected**

- Django 1.9 (patch)
- Django 1.8 (patch)

March 1, 2016 - CVE-2016-2513

User enumeration through timing difference on password hasher work factor upgrade. **Full description**
March 1, 2016 - CVE-2016-2512

Malicious redirect and possible XSS attack via user-supplied redirect URLs containing basic auth. Full description

Versions affected

- Django 1.9 (patch)
- Django 1.8 (patch)

February 1, 2016 - CVE-2016-2048

User with “change” but not “add” permission can create objects for ModelAdmin’s with save_as=True. Full description

Versions affected

- Django 1.9 (patch)

November 24, 2015 - CVE-2015-8213

Settings leak possibility in date template filter. Full description

Versions affected

- Django 1.8 (patch)
- Django 1.7 (patch)
August 18, 2015 - CVE-2015-5963 / CVE-2015-5964

Denial-of-service possibility in `logout()` view by filling session store. Full description

Versions affected

- Django 1.8 (patch)
- Django 1.7 (patch)
- Django 1.4 (patch)

July 8, 2015 - CVE-2015-5145

Denial-of-service possibility in URL validation. Full description

Versions affected

- Django 1.8 (patch)

July 8, 2015 - CVE-2015-5144

Header injection possibility since validators accept newlines in input. Full description

Versions affected

- Django 1.8 (patch)
- Django 1.7 (patch)
- Django 1.4 (patch)

July 8, 2015 - CVE-2015-5143

Denial-of-service possibility by filling session store. Full description
Versions affected

- Django 1.8 (patch)
- Django 1.7 (patch)
- Django 1.4 (patch)

May 20, 2015 - CVE-2015-3982

Fixed session flushing in the cached_db backend. Full description

Versions affected

- Django 1.8 (patch)

March 18, 2015 - CVE-2015-2317

Mitigated possible XSS attack via user-supplied redirect URLs. Full description

Versions affected

- Django 1.4 (patch)
- Django 1.6 (patch)
- Django 1.7 (patch)
- Django 1.8 (patch)

March 18, 2015 - CVE-2015-2316

Denial-of-service possibility with strip_tags(). Full description

Versions affected

- Django 1.6 (patch)
- Django 1.7 (patch)
- Django 1.8 (patch)
March 9, 2015 - CVE-2015-2241

XSS attack via properties in ModelAdmin.readonly_fields. Full description

Versions affected

- Django 1.7 (patch)
- Django 1.8 (patch)

January 13, 2015 - CVE-2015-0222

Database denial-of-service with ModelMultipleChoiceField. Full description

Versions affected

- Django 1.6 (patch)
- Django 1.7 (patch)

January 13, 2015 - CVE-2015-0221

Denial-of-service attack against django.views.static.serve(). Full description

Versions affected

- Django 1.4 (patch)
- Django 1.6 (patch)
- Django 1.7 (patch)

January 13, 2015 - CVE-2015-0220

Mitigated possible XSS attack via user-supplied redirect URLs. Full description
9.2. Security releases

Versions affected

- Django 1.4 (patch)
- Django 1.6 (patch)
- Django 1.7 (patch)

January 13, 2015 - CVE-2015-0219

WSGI header spoofing via underscore/dash conflation. Full description

Versions affected

- Django 1.4 (patch)
- Django 1.6 (patch)
- Django 1.7 (patch)

August 20, 2014 - CVE-2014-0483

Data leakage via querystring manipulation in admin. Full description

Versions affected

- Django 1.4 (patch)
- Django 1.5 (patch)
- Django 1.6 (patch)
- Django 1.7 (patch)

August 20, 2014 - CVE-2014-0482

RemoteUserMiddleware session hijacking. Full description
Versions affected

- Django 1.4 (patch)
- Django 1.5 (patch)
- Django 1.6 (patch)
- Django 1.7 (patch)

August 20, 2014 - CVE-2014-0481

File upload denial of service. Full description

Versions affected

- Django 1.4 (patch)
- Django 1.5 (patch)
- Django 1.6 (patch)
- Django 1.7 (patch)

August 20, 2014 - CVE-2014-0480

reverse() can generate URLs pointing to other hosts. Full description

Versions affected

- Django 1.4 (patch)
- Django 1.5 (patch)
- Django 1.6 (patch)
- Django 1.7 (patch)
May 18, 2014 - CVE-2014-3730

Malformed URLs from user input incorrectly validated. Full description

Versions affected

- Django 1.4 (patch)
- Django 1.5 (patch)
- Django 1.6 (patch)
- Django 1.7 (patch)

May 18, 2014 - CVE-2014-1418

Caches may be allowed to store and serve private data. Full description

Versions affected

- Django 1.4 (patch)
- Django 1.5 (patch)
- Django 1.6 (patch)
- Django 1.7 (patch)

April 21, 2014 - CVE-2014-0474

MySQL typecasting causes unexpected query results. Full description

Versions affected

- Django 1.4 (patch)
- Django 1.5 (patch)
- Django 1.6 (patch)
- Django 1.7 (patch)
April 21, 2014 - CVE-2014-0473

Caching of anonymous pages could reveal CSRF token. Full description

Versions affected

- Django 1.4 (patch)
- Django 1.5 (patch)
- Django 1.6 (patch)
- Django 1.7 (patch)

April 21, 2014 - CVE-2014-0472

Unexpected code execution using reverse(). Full description

Versions affected

- Django 1.4 (patch)
- Django 1.5 (patch)
- Django 1.6 (patch)
- Django 1.7 (patch)

September 14, 2013 - CVE-2013-1443

Denial-of-service via large passwords. Full description

Versions affected

- Django 1.4 (patch and Python compatibility fix)
- Django 1.5 (patch)
September 10, 2013 - CVE-2013-4315

Directory-traversal via `ssi` template tag. Full description

Versions affected

- Django 1.4 (patch)
- Django 1.5 (patch)

August 13, 2013 - CVE-2013-6044

Possible XSS via unvalidated URL redirect schemes. Full description

Versions affected

- Django 1.4 (patch)
- Django 1.5 (patch)

August 13, 2013 - CVE-2013-4249

XSS via admin trusting `URLField` values. Full description

Versions affected

- Django 1.5 (patch)

February 19, 2013 - CVE-2013-0306

Denial-of-service via formset `max_num` bypass. Full description

Versions affected

- Django 1.3 (patch)
- Django 1.4 (patch)
February 19, 2013 - CVE-2013-0305

Information leakage via admin history log. Full description

Versions affected

- Django 1.3 (patch)
- Django 1.4 (patch)

Entity-based attacks against Python XML libraries. Full description

Versions affected

- Django 1.3 (patch)
- Django 1.4 (patch)

February 19, 2013 - No CVE

Additional hardening of Host header handling. Full description

Versions affected

- Django 1.3 (patch)
- Django 1.4 (patch)

December 10, 2012 - No CVE 2

Additional hardening of redirect validation. Full description
Versions affected

- Django 1.3: (patch)
- Django 1.4: (patch)

December 10, 2012 - No CVE 1

Additional hardening of Host header handling. Full description

Versions affected

- Django 1.3 (patch)
- Django 1.4 (patch)

October 17, 2012 - CVE-2012-4520

Host header poisoning. Full description

Versions affected

- Django 1.3 (patch)
- Django 1.4 (patch)

July 30, 2012 - CVE-2012-3444

Denial-of-service via large image files. Full description

Versions affected

- Django 1.3 (patch)
- Django 1.4 (patch)
July 30, 2012 - CVE-2012-3443

Denial-of-service via compressed image files. Full description

Versions affected

- Django 1.3: (patch)
- Django 1.4: (patch)

July 30, 2012 - CVE-2012-3442

XSS via failure to validate redirect scheme. Full description

Versions affected

- Django 1.3: (patch)
- Django 1.4: (patch)

September 9, 2011 - CVE-2011-4140

Potential CSRF via Host header. Full description

Versions affected

This notification was an advisory only, so no patches were issued.

- Django 1.2
- Django 1.3

September 9, 2011 - CVE-2011-4139

Host header cache poisoning. Full description
Versions affected

- Django 1.2 (patch)
- Django 1.3 (patch)

September 9, 2011 - CVE-2011-4138

Information leakage/arbitrary request issuance via `URLField.verify_exists`. Full description

Versions affected

- Django 1.2: (patch)
- Django 1.3: (patch)

September 9, 2011 - CVE-2011-4137

Denial-of-service via `URLField.verify_exists`. Full description

Versions affected

- Django 1.2 (patch)
- Django 1.3 (patch)

September 9, 2011 - CVE-2011-4136

Session manipulation when using memory-cache-backed session. Full description

Versions affected

- Django 1.2 (patch)
- Django 1.3 (patch)
February 8, 2011 - CVE-2011-0698

Directory-traversal on Windows via incorrect path-separator handling. Full description

Versions affected

- Django 1.1 (patch)
- Django 1.2 (patch)

February 8, 2011 - CVE-2011-0697

XSS via unsanitized names of uploaded files. Full description

Versions affected

- Django 1.1 (patch)
- Django 1.2 (patch)

February 8, 2011 - CVE-2011-0696

CSRF via forged HTTP headers. Full description

Versions affected

- Django 1.1 (patch)
- Django 1.2 (patch)

December 22, 2010 - CVE-2010-4535

Denial-of-service in password-reset mechanism. Full description
Versions affected

- Django 1.1 (patch)
- Django 1.2 (patch)

December 22, 2010 - CVE-2010-4534

Information leakage in administrative interface. Full description

Versions affected

- Django 1.1 (patch)
- Django 1.2 (patch)

September 8, 2010 - CVE-2010-3082

XSS via trusting unsafe cookie value. Full description

Versions affected

- Django 1.2 (patch)

October 9, 2009 - CVE-2009-3965

Denial-of-service via pathological regular expression performance. Full description

Versions affected

- Django 1.0 (patch)
- Django 1.1 (patch)
July 28, 2009 - CVE-2009-2659

Directory-traversal in development server media handler. Full description

Versions affected

- Django 0.96 (patch)
- Django 1.0 (patch)

September 2, 2008 - CVE-2008-3909

CSRF via preservation of POST data during admin login. Full description

Versions affected

- Django 0.91 (patch)
- Django 0.95 (patch)
- Django 0.96 (patch)

May 14, 2008 - CVE-2008-2302

XSS via admin login redirect. Full description

Versions affected

- Django 0.91 (patch)
- Django 0.95 (patch)
- Django 0.96 (patch)

October 26, 2007 - CVE-2007-5712

Denial-of-service via arbitrarily-large `Accept-Language` header. Full description
Versions affected

- Django 0.91 (patch)
- Django 0.95 (patch)
- Django 0.96 (patch)

Issues prior to Django’s security process

Some security issues were handled before Django had a formalized security process in use. For these, new releases may not have been issued at the time and CVEs may not have been assigned.

January 21, 2007 - CVE-2007-0405

Apparent “caching” of authenticated user. Full description

Versions affected

- Django 0.95 (patch)

August 16, 2006 - CVE-2007-0404

Filename validation issue in translation framework. Full description

Versions affected

- Django 0.90 (patch)
- Django 0.91 (patch)
- Django 0.95 (patch) (released January 21 2007)
CHAPTER TEN

DJANGO INTERNALS

Documentation for people hacking on Django itself. This is the place to go if you’d like to help improve Django or learn about how Django is managed.

10.1 Contributing to Django

Django is a community that lives on its volunteers. As it keeps growing, we always need more people to help others. You can contribute in many ways, either on the framework itself or in the wider ecosystem.

10.1.1 Work on the Django framework

The work on Django itself falls into three major areas:

Writing code

Fix a bug, or add a new feature. You can make a pull request and see your code in the next version of Django!

Start from the Writing code docs.

Writing documentation

Django’s documentation is one of its key strengths. It’s informative and thorough. You can help to improve the documentation and keep it relevant as the framework evolves.

See Writing documentation for more.

Localizing Django

Django is translated into over 100 languages - There’s even some translation for Klingon?! The i18n team is always looking for translators to help maintain and increase language reach.

See Localizing Django to help translate Django.

If you think working with Django is fun, wait until you start working on it. Really, ANYONE can do something to help make Django better and greater!
This contributing guide contains everything you need to know to help build the Django web framework. Browse the following sections to find out how:

**Advice for new contributors**

New contributor and not sure what to do? Want to help but just don’t know how to get started? This is the section for you.

Get up and running!

If you are new to contributing to Django, the Writing your first patch for Django tutorial will give you an introduction to the tools and the workflow.

This page contains more general advice on ways you can contribute to Django, and how to approach that.

If you are looking for a reference on the details of making code contributions, see the Writing code documentation.

**First steps**

Start with these steps to discover Django’s development process.

- **Triage tickets**

  If an unreviewed ticket reports a bug, try and reproduce it. If you can reproduce it and it seems valid, make a note that you confirmed the bug and accept the ticket. Make sure the ticket is filed under the correct component area. Consider writing a patch that adds a test for the bug’s behavior, even if you don’t fix the bug itself. See more at How can I help with triaging?

- **Look for tickets that are accepted and review patches to build familiarity with the codebase and the process**

  Mark the appropriate flags if a patch needs docs or tests. Look through the changes a patch makes, and keep an eye out for syntax that is incompatible with older but still supported versions of Python. Run the tests and make sure they pass. Where possible and relevant, try them out on a database other than SQLite. Leave comments and feedback!

- **Keep old patches up to date**

  Oftentimes the codebase will change between a patch being submitted and the time it gets reviewed. Make sure it still applies cleanly and functions as expected. Updating a patch is both useful and important! See more on Submitting patches.

- **Write some documentation**
Django’s documentation is great but it can always be improved. Did you find a typo? Do you think that something should be clarified? Go ahead and suggest a documentation patch! See also the guide on Writing documentation.

Note: The reports page contains links to many useful Trac queries, including several that are useful for triaging tickets and reviewing patches as suggested above.

- Sign the Contributor License Agreement

  The code that you write belongs to you or your employer. If your contribution is more than one or two lines of code, you need to sign the CLA. See the Contributor License Agreement FAQ for a more thorough explanation.

Guidelines

As a newcomer on a large project, it’s easy to experience frustration. Here’s some advice to make your work on Django more useful and rewarding.

- Pick a subject area that you care about, that you are familiar with, or that you want to learn about

  You don’t already have to be an expert on the area you want to work on; you become an expert through your ongoing contributions to the code.

- Analyze tickets’ context and history

  Trac isn’t an absolute; the context is just as important as the words. When reading Trac, you need to take into account who says things, and when they were said. Support for an idea two years ago doesn’t necessarily mean that the idea will still have support. You also need to pay attention to who hasn’t spoken—for example, if an experienced contributor hasn’t been recently involved in a discussion, then a ticket may not have the support required to get into Django.

- Start small

  It’s easier to get feedback on a little issue than on a big one. See the easy pickings.

- If you’re going to engage in a big task, make sure that your idea has support first

  This means getting someone else to confirm that a bug is real before you fix the issue, and ensuring that there’s consensus on a proposed feature before you go implementing it.

- Be bold! Leave feedback!

  Sometimes it can be scary to put your opinion out to the world and say “this ticket is correct” or “this patch needs work”, but it’s the only way the project moves forward. The contributions of the broad Django community ultimately have a much greater impact than that of any one person. We can’t do it without you!
• Err on the side of caution when marking things Ready For Check-in

If you’re really not certain if a ticket is ready, don’t mark it as such. Leave a comment instead, letting others know your thoughts. If you’re mostly certain, but not completely certain, you might also try asking on IRC to see if someone else can confirm your suspicions.

• Wait for feedback, and respond to feedback that you receive

Focus on one or two tickets, see them through from start to finish, and repeat. The shotgun approach of taking on lots of tickets and letting some fall by the wayside ends up doing more harm than good.

• Be rigorous

When we say “PEP 8, and must have docs and tests”, we mean it. If a patch doesn’t have docs and tests, there had better be a good reason. Arguments like “I couldn’t find any existing tests of this feature” don’t carry much weight–while it may be true, that means you have the extra-important job of writing the very first tests for that feature, not that you get a pass from writing tests altogether.

• Be patient

It’s not always easy for your ticket or your patch to be reviewed quickly. This isn’t personal. There are a lot of tickets and pull requests to get through.

Keeping your patch up to date is important. Review the ticket on Trac to ensure that the Needs tests, Needs documentation, and Patch needs improvement flags are unchecked once you’ve addressed all review comments.

Remember that Django has an eight-month release cycle, so there’s plenty of time for your patch to be reviewed.

Finally, a well-timed reminder can help. See contributing code FAQ for ideas here.

---

**Reporting bugs and requesting features**

---

**Important:** Please report security issues only to security@djangoproject.com. This is a private list only open to long-time, highly trusted Django developers, and its archives are not public. For further details, please see our security policies.

Otherwise, before reporting a bug or requesting a new feature on the ticket tracker, consider these points:

• Check that someone hasn’t already filed the bug or feature request by searching or running custom queries in the ticket tracker.

• Don’t use the ticket system to ask support questions. Use the django-users list or the #django IRC channel for that.

• Don’t reopen issues that have been marked “wontfix” without finding consensus to do so on django-developers.
• Don’t use the ticket tracker for lengthy discussions, because they’re likely to get lost. If a particular ticket is controversial, please move the discussion to django-developers.

**Reporting bugs**

Well-written bug reports are incredibly helpful. However, there’s a certain amount of overhead involved in working with any bug tracking system so your help in keeping our ticket tracker as useful as possible is appreciated. In particular:

• Do read the FAQ to see if your issue might be a well-known question.

• Do ask on django-users or #django first if you’re not sure if what you’re seeing is a bug.

• Do write complete, reproducible, specific bug reports. You must include a clear, concise description of the problem, and a set of instructions for replicating it. Add as much debug information as you can: code snippets, test cases, exception backtraces, screenshots, etc. A nice small test case is the best way to report a bug, as it gives us a helpful way to confirm the bug quickly.

• Don’t post to django-developers only to announce that you have filed a bug report. All the tickets are mailed to another list, django-updates, which is tracked by developers and interested community members; we see them as they are filed.

To understand the lifecycle of your ticket once you have created it, refer to Triaging tickets.

**Reporting user interface bugs and features**

If your bug or feature request touches on anything visual in nature, there are a few additional guidelines to follow:

• Include screenshots in your ticket which are the visual equivalent of a minimal test case. Show off the issue, not the crazy customizations you’ve made to your browser.

• If the issue is difficult to show off using a still image, consider capturing a brief screencast. If your software permits it, capture only the relevant area of the screen.

• If you’re offering a patch that changes the look or behavior of Django’s UI, you must attach before and after screenshots/screencasts. Tickets lacking these are difficult for triagers to assess quickly.

• Screenshots don’t absolve you of other good reporting practices. Make sure to include URLs, code snippets, and step-by-step instructions on how to reproduce the behavior visible in the screenshots.

• Make sure to set the UI/UX flag on the ticket so interested parties can find your ticket.
**Requesting features**

We’re always trying to make Django better, and your feature requests are a key part of that. Here are some tips on how to make a request most effectively:

- Make sure the feature actually requires changes in Django’s core. If your idea can be developed as an independent application or module — for instance, you want to support another database engine — we’ll probably suggest that you develop it independently. Then, if your project gathers sufficient community support, we may consider it for inclusion in Django.

- First request the feature on the django-developers list, not in the ticket tracker. It’ll get read more closely if it’s on the mailing list. This is even more important for large-scale feature requests. We like to discuss any big changes to Django’s core on the mailing list before actually working on them.

- Describe clearly and concisely what the missing feature is and how you’d like to see it implemented. Include example code (non-functional is OK) if possible.

- Explain why you’d like the feature. Explaining a minimal use case will help others understand where it fits in, and if there are already other ways of achieving the same thing.

If there’s a consensus agreement on the feature, then it’s appropriate to create a ticket. Include a link to the discussion on django-developers in the ticket description.

As with most open-source projects, code talks. If you are willing to write the code for the feature yourself or, even better, if you’ve already written it, it’s much more likely to be accepted. Fork Django on GitHub, create a feature branch, and show us your work!

See also: Documenting new features.

**How we make decisions**

Whenever possible, we strive for a rough consensus. To that end, we’ll often have informal votes on django-developers about a feature. In these votes we follow the voting style invented by Apache and used on Python itself, where votes are given as +1, +0, -0, or -1. Roughly translated, these votes mean:

- +1: “I love the idea and I’m strongly committed to it.”
- +0: “Sounds OK to me.”
- -0: “I’m not thrilled, but I won’t stand in the way.”
- -1: “I strongly disagree and would be very unhappy to see the idea turn into reality.”

Although these votes on django-developers are informal, they’ll be taken very seriously. After a suitable voting period, if an obvious consensus arises we’ll follow the votes.

However, consensus is not always possible. If consensus cannot be reached, or if the discussion toward a consensus fizzles out without a concrete decision, the decision may be deferred to the technical board.
Internally, the technical board will use the same voting mechanism. A proposition will be considered carried if:

- There are at least three “+1” votes from members of the technical board.
- There is no “-1” vote from any member of the technical board.

Votes should be submitted within a week.

Since this process allows any technical board member to veto a proposal, a “-1” vote should be accompanied by an explanation of what it would take to convert that “-1” into at least a “+0”.

Votes on technical matters should be announced and held in public on the django-developers mailing list.

**Triaging tickets**

Django uses Trac for managing the work on the code base. Trac is a community-tended garden of the bugs people have found and the features people would like to see added. As in any garden, sometimes there are weeds to be pulled and sometimes there are flowers and vegetables that need picking. We need your help to sort out one from the other, and in the end, we all benefit together.

Like all gardens, we can aspire to perfection, but in reality there’s no such thing. Even in the most pristine garden there are still snails and insects. In a community garden there are also helpful people who—with the best of intentions—fertilize the weeds and poison the roses. It’s the job of the community as a whole to self-manage, keep the problems to a minimum, and educate those coming into the community so that they can become valuable contributing members.

Similarly, while we aim for Trac to be a perfect representation of the state of Django’s progress, we acknowledge that this will not happen. By distributing the load of Trac maintenance to the community, we accept that there will be mistakes. Trac is “mostly accurate”, and we give allowances for the fact that sometimes it will be wrong. That’s okay. We’re perfectionists with deadlines.

We rely on the community to keep participating, keep tickets as accurate as possible, and raise issues for discussion on our mailing lists when there is confusion or disagreement.

Django is a community project, and every contribution helps. We can’t do this without you!

**Triage workflow**

Unfortunately, not all bug reports and feature requests in the ticket tracker provide all the required details. A number of tickets have patches, but those patches don’t meet all the requirements of a good patch.

One way to help out is to triage tickets that have been created by other users.

Most of the workflow is based around the concept of a ticket’s triage stages. Each stage describes where in its lifetime a given ticket is at any time. Along with a handful of flags, this attribute easily tells us what and who each ticket is waiting on.

Since a picture is worth a thousand words, let’s start there:
The ticket was already reported, was already rejected, isn’t a bug, doesn’t contain enough information, or can’t be reproduced.

The ticket is a bug and should be fixed.

The ticket has a patch which applies cleanly and includes all needed tests and docs. A merger can commit it as is.

We’ve got two roles in this diagram:

- Mergers: people with commit access who are responsible for making the final decision to merge a patch.
- Ticket triagers: anyone in the Django community who chooses to become involved in Django’s development process. Our Trac installation is intentionally left open to the public, and anyone can triage tickets. Django is a community project, and we encourage triage by the community.

By way of example, here we see the lifecycle of an average ticket:

- Alice creates a ticket and sends an incomplete pull request (no tests, incorrect implementation).
- Bob reviews the pull request, marks the ticket as “Accepted”, “needs tests”, and “patch needs improvement”, and leaves a comment telling Alice how the patch could be improved.
- Alice updates the pull request, adding tests (but not changing the implementation). She removes the two flags.
- Charlie reviews the pull request and resets the “patch needs improvement” flag with another comment about improving the implementation.
• Alice updates the pull request, fixing the implementation. She removes the “patch needs improvement” flag.

• Daisy reviews the pull request and marks the ticket as “Ready for checkin”.

• Jacob, a merger, reviews the pull request and merges it.

Some tickets require much less feedback than this, but then again some tickets require much much more.

**Triage stages**

Below we describe in more detail the various stages that a ticket may flow through during its lifetime.

**Unreviewed**

The ticket has not been reviewed by anyone who felt qualified to make a judgment about whether the ticket contained a valid issue, a viable feature, or ought to be closed for any of the various reasons.

**Accepted**

The big gray area! The absolute meaning of “accepted” is that the issue described in the ticket is valid and is in some stage of being worked on. Beyond that there are several considerations:

- **Accepted + No Flags**
  
  The ticket is valid, but no one has submitted a patch for it yet. Often this means you could safely start writing a patch for it. This is generally more true for the case of accepted bugs than accepted features. A ticket for a bug that has been accepted means that the issue has been verified by at least one triager as a legitimate bug - and should probably be fixed if possible. An accepted new feature may only mean that one triager thought the feature would be good to have, but this alone does not represent a consensus view or imply with any certainty that a patch will be accepted for that feature. Seek more feedback before writing an extensive patch if you are in doubt.

- **Accepted + Has Patch**

  The ticket is waiting for people to review the supplied patch. This means downloading the patch and trying it out, verifying that it contains tests and docs, running the test suite with the included patch, and leaving feedback on the ticket.

- **Accepted + Has Patch + Needs . . .**

  This means the ticket has been reviewed, and has been found to need further work. “Needs tests” and “Needs documentation” are self-explanatory. “Patch needs improvement” will generally be accompanied by a comment on the ticket explaining what is needed to improve the code.
Ready For Checkin

The ticket was reviewed by any member of the community other than the person who supplied the patch and found to meet all the requirements for a commit-ready patch. A merger now needs to give the patch a final review prior to being committed.

There are a lot of pull requests. It can take a while for your patch to get reviewed. See the contributing code FAQ for some ideas here.

Someday/Maybe

This stage isn’t shown on the diagram. It’s used sparingly to keep track of high-level ideas or long-term feature requests.

These tickets are uncommon and overall less useful since they don’t describe concrete actionable issues. They are enhancement requests that we might consider adding someday to the framework if an excellent patch is submitted. They are not a high priority.

Other triage attributes

A number of flags, appearing as checkboxes in Trac, can be set on a ticket:

Has patch

This means the ticket has an associated patch. These will be reviewed to see if the patch is “good”.

The following three fields (Needs documentation, Needs tests, Patch needs improvement) apply only if a patch has been supplied.

Needs documentation

This flag is used for tickets with patches that need associated documentation. Complete documentation of features is a prerequisite before we can check them into the codebase.

Needs tests

This flags the patch as needing associated unit tests. Again, this is a required part of a valid patch.
Patch needs improvement

This flag means that although the ticket has a patch, it’s not quite ready for checkin. This could mean the patch no longer applies cleanly, there is a flaw in the implementation, or that the code doesn’t meet our standards.

Easy pickings

Tickets that would require small, easy, patches.

Type

Tickets should be categorized by type between:

- New Feature
  For adding something new.

- Bug
  For when an existing thing is broken or not behaving as expected.

- Cleanup/optimization
  For when nothing is broken but something could be made cleaner, better, faster, stronger.

Component

Tickets should be classified into components indicating which area of the Django codebase they belong to. This makes tickets better organized and easier to find.

Severity

The severity attribute is used to identify blockers, that is, issues that should get fixed before releasing the next version of Django. Typically those issues are bugs causing regressions from earlier versions or potentially causing severe data losses. This attribute is quite rarely used and the vast majority of tickets have a severity of “Normal”.
Version

It is possible to use the version attribute to indicate in which version the reported bug was identified.

UI/UX

This flag is used for tickets that relate to User Interface and User Experiences questions. For example, this flag would be appropriate for user-facing features in forms or the admin interface.

Cc

You may add your username or email address to this field to be notified when new contributions are made to the ticket.

Keywords

With this field you may label a ticket with multiple keywords. This can be useful, for example, to group several tickets on the same theme. Keywords can either be comma or space separated. Keyword search finds the keyword string anywhere in the keywords. For example, clicking on a ticket with the keyword “form” will yield similar tickets tagged with keywords containing strings such as “formset”, “modelformset”, and “ManagementForm”.

Closing Tickets

When a ticket has completed its useful lifecycle, it’s time for it to be closed. Closing a ticket is a big responsibility, though. You have to be sure that the issue is really resolved, and you need to keep in mind that the reporter of the ticket may not be happy to have their ticket closed (unless it’s fixed!). If you’re not certain about closing a ticket, leave a comment with your thoughts instead.

If you do close a ticket, you should always make sure of the following:

- Be certain that the issue is resolved.
- Leave a comment explaining the decision to close the ticket.
- If there is a way they can improve the ticket to reopen it, let them know.
- If the ticket is a duplicate, reference the original ticket. Also cross-reference the closed ticket by leaving a comment in the original one—this allows to access more related information about the reported bug or requested feature.
- Be polite. No one likes having their ticket closed. It can be frustrating or even discouraging. The best way to avoid turning people off from contributing to Django is to be polite and friendly and to offer suggestions for how they could improve this ticket and other tickets in the future.
A ticket can be resolved in a number of ways:

- **fixed**
  Used once a patch has been rolled into Django and the issue is fixed.

- **invalid**
  Used if the ticket is found to be incorrect. This means that the issue in the ticket is actually the result of a user error, or describes a problem with something other than Django, or isn’t a bug report or feature request at all (for example, some new users submit support queries as tickets).

- **wontfix**
  Used when someone decides that the request isn’t appropriate for consideration in Django. Sometimes a ticket is closed as “wontfix” with a request for the reporter to start a discussion on the django-developers mailing list if they feel differently from the rationale provided by the person who closed the ticket. Other times, a mailing list discussion precedes the decision to close a ticket. Always use the mailing list to get a consensus before reopening tickets closed as “wontfix”.

- **duplicate**
  Used when another ticket covers the same issue. By closing duplicate tickets, we keep all the discussion in one place, which helps everyone.

- **worksforme**
  Used when the ticket doesn’t contain enough detail to replicate the original bug.

- **needsinfo**
  Used when the ticket does not contain enough information to replicate the reported issue but is potentially still valid. The ticket should be reopened when more information is supplied.

If you believe that the ticket was closed in error – because you’re still having the issue, or it’s popped up somewhere else, or the triagers have made a mistake – please reopen the ticket and provide further information. Again, please do not reopen tickets that have been marked as “wontfix” and bring the issue to django-developers instead.

**How can I help with triaging?**

The triage process is primarily driven by community members. Really, ANYONE can help.

To get involved, start by creating an account on Trac. If you have an account but have forgotten your password, you can reset it using the password reset page.

Then, you can help out by:

- Closing “Unreviewed” tickets as “invalid”, “worksforme”, or “duplicate”, or “wontfix”.

- Closing “Unreviewed” tickets as “needsinfo” when the description is too sparse to be actionable, or when they’re feature requests requiring a discussion on django-developers.

- Correcting the “Needs tests”, “Needs documentation”, or “Has patch” flags for tickets where they are incorrectly set.
• Setting the “Easy pickings” flag for tickets that are small and relatively straightforward.

• Set the type of tickets that are still uncategorized.

• Checking that old tickets are still valid. If a ticket hasn’t seen any activity in a long time, it’s possible that the problem has been fixed but the ticket hasn’t yet been closed.

• Identifying trends and themes in the tickets. If there are a lot of bug reports about a particular part of Django, it may indicate we should consider refactoring that part of the code. If a trend is emerging, you should raise it for discussion (referencing the relevant tickets) on django-developers.

• Verify if patches submitted by other users are correct. If they are correct and also contain appropriate documentation and tests then move them to the “Ready for Checkin” stage. If they are not correct then leave a comment to explain why and set the corresponding flags ( “Patch needs improvement” , “Needs tests” etc.).

Note: The Reports page contains links to many useful Trac queries, including several that are useful for triaging tickets and reviewing patches as suggested above.

You can also find more Advice for new contributors.

However, we do ask the following of all general community members working in the ticket database:

• Please don’t promote your own tickets to “Ready for checkin”. You may mark other people’s tickets that you’ve reviewed as “Ready for checkin”, but you should get at minimum one other community member to review a patch that you submit.

• Please don’t reverse a decision without posting a message to django-developers to find consensus.

• If you’re unsure if you should be making a change, don’t make the change but instead leave a comment with your concerns on the ticket, or post a message to django-developers. It’s okay to be unsure, but your input is still valuable.

**Bisecting a regression**

A regression is a bug that’s present in some newer version of Django but not in an older one. An extremely helpful piece of information is the commit that introduced the regression. Knowing the commit that caused the change in behavior helps identify if the change was intentional or if it was an inadvertent side-effect. Here’s how you can determine this.

Begin by writing a regression test for Django’s test suite for the issue. For example, we’ll pretend we’re debugging a regression in migrations. After you’ve written the test and confirmed that it fails on the latest main branch, put it in a separate file that you can run standalone. For our example, we’ll pretend we created tests/migrations/test_regression.py, which can be run with:
$ ./runtests.py migrations.test_regression

Next, we mark the current point in history as being “bad” since the test fails:

$ git bisect bad
You need to start by "git bisect start"
Do you want me to do it for you [Y/n]? y

Now, we need to find a point in git history before the regression was introduced (i.e. a point where the test passes). Use something like `git checkout HEAD~100` to check out an earlier revision (100 commits earlier, in this case). Check if the test fails. If so, mark that point as “bad” (`git bisect bad`), then check out an earlier revision and recheck. Once you find a revision where your test passes, mark it as “good”:

$ git bisect good
Bisecting: X revisions left to test after this (roughly Y steps)
...

Now we’re ready for the fun part: using `git bisect run` to automate the rest of the process:

$ git bisect run tests/runtests.py migrations.test_regression

You should see `git bisect` use a binary search to automatically checkout revisions between the good and bad commits until it finds the first “bad” commit where the test fails.

Now, report your results on the Trac ticket, and please include the regression test as an attachment. When someone writes a fix for the bug, they’ll already have your test as a starting point.

Writing code

So you’d like to write some code to improve Django? Awesome! There are several ways you can help Django’s development:

- Report bugs in our ticket tracker.
- Join the django-developers mailing list and share your ideas for how to improve Django. We’re always open to suggestions. You can also interact on the Django forum and the #django-dev IRC channel.
- Submit patches for new and/or fixed behavior. If you’re looking for a way to get started contributing to Django read the Writing your first patch for Django tutorial and have a look at the easy pickings tickets. The Patch review checklist will also be helpful.
- Improve the documentation or write unit tests.
- Triage tickets and review patches created by other users.
- Read the Advice for new contributors to help you get orientated in the development process.
Browse the following sections to find out how to give your code patches the best chances to be included in Django core:

**Coding style**

Please follow these coding standards when writing code for inclusion in Django.

**Pre-commit checks**

`pre-commit` is a framework for managing pre-commit hooks. These hooks help to identify simple issues before committing code for review. By checking for these issues before code review it allows the reviewer to focus on the change itself, and it can also help to reduce the number of CI runs.

To use the tool, first install `pre-commit` and then the git hooks:

```
$ python -m pip install pre-commit
$ pre-commit install
```

On the first commit `pre-commit` will install the hooks, these are installed in their own environments and will take a short while to install on the first run. Subsequent checks will be significantly faster. If an error is found an appropriate error message will be displayed. If the error was with `black` or `isort` then the tool will go ahead and fix them for you. Review the changes and re-stage for commit if you are happy with them.

**Python style**

- All files should be formatted using the `black` auto-formatter. This will be run by `pre-commit` if that is configured.

- The project repository includes an `.editorconfig` file. We recommend using a text editor with EditorConfig support to avoid indentation and whitespace issues. The Python files use 4 spaces for indentation and the HTML files use 2 spaces.

- Unless otherwise specified, follow PEP 8.

  Use `flake8` to check for problems in this area. Note that our `setup.cfg` file contains some excluded files (deprecated modules we don’t care about cleaning up and some third-party code that Django vendors) as well as some excluded errors that we don’t consider as gross violations. Remember that PEP 8 is only a guide, so respect the style of the surrounding code as a primary goal.

  An exception to PEP 8 is our rules on line lengths. Don’t limit lines of code to 79 characters if it means the code looks significantly uglier or is harder to read. We allow up to 88 characters as this is the line length used by `black`. This check is included when you run `flake8`. Documentation, comments, and docstrings should be wrapped at 79 characters, even though PEP 8 suggests 72.
• String variable interpolation may use `%`-formatting, f-strings, or `str.format()` as appropriate, with the goal of maximizing code readability.

Final judgments of readability are left to the Merger’s discretion. As a guide, f-strings should use only plain variable and property access, with prior local variable assignment for more complex cases:

```python
# Allowed
f'hello {user}'
f'hello {user.name} '
f'hello {self.user.name} '

# Disallowed
f'hello {get_user}()'
f'you are {user.age * 365.25} days old'

# Allowed with local variable assignment
user = get_user()
f'hello {user}'
user_days_old = user.age * 365.25
f'you are {user_days_old} days old'
```

f-strings should not be used for any string that may require translation, including error and logging messages. In general `format()` is more verbose, so the other formatting methods are preferred.

Don’t waste time doing unrelated refactoring of existing code to adjust the formatting method.

• Avoid use of “we” in comments, e.g. “Loop over” rather than “We loop over”.

• Use underscores, not camelCase, for variable, function and method names (i.e. `poll.get_unique_voters()`, not `poll.getUniqueVoters()`).

• Use `InitialCaps` for class names (or for factory functions that return classes).

• In docstrings, follow the style of existing docstrings and PEP 257.

• In tests, use `assertRaisesMessage()` and `assertWarnsMessage()` instead of `assertRaises()` and `assertWarns()` so you can check the exception or warning message. Use `assertRaisesRegex()` and `assertWarnsRegex()` only if you need regular expression matching.

  Use `assertIs(..., True/False)` for testing boolean values, rather than `assertTrue()` and `assertFalse()`, so you can check the actual boolean value, not the truthiness of the expression.

• In test docstrings, state the expected behavior that each test demonstrates. Don’t include preambles such as “Tests that” or “Ensures that”.

  Reserve ticket references for obscure issues where the ticket has additional details that can’t be easily described in docstrings or comments. Include the ticket number at the end of a sentence like this:
```python
def test_foo():
    """
    A test docstring looks like this (#123456).
    """
    ...
```

**Imports**

- Use `isort` to automate import sorting using the guidelines below.

  **Quick start:**

  ```
  $ python -m pip install "isort >= 5.1.0"
  $ isort .
  ```

  This runs `isort` recursively from your current directory, modifying any files that don’t conform to the guidelines. If you need to have imports out of order (to avoid a circular import, for example) use a comment like this:

  ```
  import module  # isort:skip
  ```

- Put imports in these groups: future, standard library, third-party libraries, other Django components, local Django component, try/excepts. Sort lines in each group alphabetically by the full module name. Place all `import module` statements before `from module import objects` in each section. Use absolute imports for other Django components and relative imports for local components.

- On each line, alphabetize the items with the uppercase items grouped before the lowercase items.

- Break long lines using parentheses and indent continuation lines by 4 spaces. Include a trailing comma after the last import and put the closing parenthesis on its own line.

  Use a single blank line between the last import and any module level code, and use two blank lines above the first function or class.

  For example (comments are for explanatory purposes only):

  ```
  Listing 1: django/contrib/admin/example.py
  
  # future
  from __future__ import unicode_literals

  # standard library
  import json
  from itertools import chain
  ```
# third-party
import bcrypt

# Django
from django.http import Http404
from django.http.response import (Http404, HttpResponse, HttpResponseNotAllowed, StreamingHttpResponse, cookie,
)

# local Django
from .models import LogEntry

# try/except
try:
    import yaml
except ImportError:
    yaml = None

CONSTANT = 'foo'

class Example:
    # ...

• Use convenience imports whenever available. For example, do this:

    from django.views import View

instead of:

    from django.views.generic.base import View

Template style

• In Django template code, put one (and only one) space between the curly brackets and the tag contents.

    Do this:

        {{ foo }}

    Don’t do this:
View style

- In Django views, the first parameter in a view function should be called `request`.

  Do this:

  ```python
def my_view(request, foo):
    # ...
  ```

  Don’t do this:

  ```python
def my_view(req, foo):
    # ...
  ```

Model style

- Field names should be all lowercase, using underscores instead of camelCase.

  Do this:

  ```python
class Person(models.Model):
    first_name = models.CharField(max_length=20)
    last_name = models.CharField(max_length=40)
  ```

  Don’t do this:

  ```python
class Person(models.Model):
    FirstName = models.CharField(max_length=20)
    Last_Name = models.CharField(max_length=40)
  ```

- The `class Meta` should appear after the fields are defined, with a single blank line separating the fields and the class definition.

  Do this:

  ```python
class Person(models.Model):
    first_name = models.CharField(max_length=20)
    last_name = models.CharField(max_length=40)

    class Meta:
      verbose_name_plural = 'people'
  ```

  Don’t do this:
class Person(models.Model):
    first_name = models.CharField(max_length=20)
    last_name = models.CharField(max_length=40)
    class Meta:
        verbose_name_plural = 'people'

Don’t do this, either:

class Person(models.Model):
    class Meta:
        verbose_name_plural = 'people'
    first_name = models.CharField(max_length=20)
    last_name = models.CharField(max_length=40)

• The order of model inner classes and standard methods should be as follows (noting that these are not all required):
  – All database fields
  – Custom manager attributes
  – class Meta
  – def __str__()
  – def save()
  – def get_absolute_url()
  – Any custom methods

• If choices is defined for a given model field, define each choice as a list of tuples, with an all-uppercase name as a class attribute on the model. Example:

class MyModel(models.Model):
    DIRECTION_UP = 'U'
    DIRECTION_DOWN = 'D'
    DIRECTION_CHOICES = [
        (DIRECTION_UP, 'Up'),
        (DIRECTION_DOWN, 'Down'),
    ]
Use of `django.conf.settings`

Modules should not in general use settings stored in `django.conf.settings` at the top level (i.e. evaluated when the module is imported). The explanation for this is as follows:

Manual configuration of settings (i.e. not relying on the `DJANGO_SETTINGS_MODULE` environment variable) is allowed and possible as follows:

```python
from django.conf import settings
settings.configure({}, SOME_SETTING='foo')
```

However, if any setting is accessed before the `settings.configure` line, this will not work. (Internally, `settings` is a LazyObject which configures itself automatically when the settings are accessed if it has not already been configured).

So, if there is a module containing some code as follows:

```python
from django.conf import settings
from django.urls import get_callable

default_foo_view = get_callable(settings.FOO_VIEW)
```

...then importing this module will cause the settings object to be configured. That means that the ability for third parties to import the module at the top level is incompatible with the ability to configure the settings object manually, or makes it very difficult in some circumstances.

Instead of the above code, a level of laziness or indirection must be used, such as `django.utils.functional.LazyObject`, `django.utils.functional.lazy()` or `lambda`.

**Miscellaneous**

- Mark all strings for internationalization; see the i18n documentation for details.
- Remove `import` statements that are no longer used when you change code. flake8 will identify these imports for you. If an unused import needs to remain for backwards-compatibility, mark the end of with `# NOQA` to silence the flake8 warning.
- Systematically remove all trailing whitespaces from your code as those add unnecessary bytes, add visual clutter to the patches and can also occasionally cause unnecessary merge conflicts. Some IDE’s can be configured to automatically remove them and most VCS tools can be set to highlight them in diff outputs.
- Please don’t put your name in the code you contribute. Our policy is to keep contributors’ names in the AUTHORS file distributed with Django –not scattered throughout the codebase itself. Feel free to include a change to the AUTHORS file in your patch if you make more than a single trivial change.
**JavaScript style**

For details about the JavaScript code style used by Django, see JavaScript.

**Unit tests**

Django comes with a test suite of its own, in the tests directory of the code base. It’s our policy to make sure all tests pass at all times.

We appreciate any and all contributions to the test suite!

The Django tests all use the testing infrastructure that ships with Django for testing applications. See Writing and running tests for an explanation of how to write new tests.

**Running the unit tests**

**Quickstart**

First, fork Django on GitHub.

Second, create and activate a virtual environment. If you’re not familiar with how to do that, read our contributing tutorial.

Next, clone your fork, install some requirements, and run the tests:

```
$ git clone https://github.com/YourGitHubName/django.git django-repo
$ cd django-repo/tests
$ python -m pip install -e ..
$ python -m pip install -r requirements/py3.txt
$ ./runtests.py
```

Installing the requirements will likely require some operating system packages that your computer doesn’t have installed. You can usually figure out which package to install by doing a web search for the last line or so of the error message. Try adding your operating system to the search query if needed.

If you have trouble installing the requirements, you can skip that step. See Running all the tests for details on installing the optional test dependencies. If you don’t have an optional dependency installed, the tests that require it will be skipped.

Running the tests requires a Django settings module that defines the databases to use. To help you get started, Django provides and uses a sample settings module that uses the SQLite database. See Using another settings module to learn how to use a different settings module to run the tests with a different database.

Having problems? See Troubleshooting for some common issues.
Running tests using tox

Tox is a tool for running tests in different virtual environments. Django includes a basic tox.ini that automates some checks that our build server performs on pull requests. To run the unit tests and other checks (such as import sorting, the documentation spelling checker, and code formatting), install and run the tox command from any place in the Django source tree:

```
$ python -m pip install tox
$ tox
```

By default, tox runs the test suite with the bundled test settings file for SQLite, black, flake8, isort, and the documentation spelling checker. In addition to the system dependencies noted elsewhere in this documentation, the command python3 must be on your path and linked to the appropriate version of Python. A list of default environments can be seen as follows:

```
$ tox -l
py3
black
flake8>=3.7.0
docs
isort>=5.1.0
```

Testing other Python versions and database backends

In addition to the default environments, tox supports running unit tests for other versions of Python and other database backends. Since Django’s test suite doesn’t bundle a settings file for database backends other than SQLite, however, you must create and provide your own test settings. For example, to run the tests on Python 3.9 using PostgreSQL:

```
$ tox -e py39-postgres -- --settings=my_postgres_settings
```

This command sets up a Python 3.9 virtual environment, installs Django’s test suite dependencies (including those for PostgreSQL), and calls runtests.py with the supplied arguments (in this case, --settings=my_postgres_settings).

The remainder of this documentation shows commands for running tests without tox, however, any option passed to runtests.py can also be passed to tox by prefixing the argument list with --, as above.

Tox also respects the DJANGO_SETTINGS_MODULE environment variable, if set. For example, the following is equivalent to the command above:

```
$ DJANGO_SETTINGS_MODULE=my_postgres_settings tox -e py39-postgres
```

Windows users should use:
...

```bash
set DJANGO_SETTINGS_MODULE=my_postgres_settings
...

\$ tox -e py39-postgres
```

**Running the JavaScript tests**

Django includes a set of JavaScript unit tests for functions in certain contrib apps. The JavaScript tests aren’t run by default using tox because they require Node.js to be installed and aren’t necessary for the majority of patches. To run the JavaScript tests using tox:

```bash
$ tox -e javascript
```

This command runs `npm install` to ensure test requirements are up to date and then runs `npm test`.

**Running tests using django-docker-box**

`django-docker-box` allows you to run the Django’s test suite across all supported databases and python versions. See the `django-docker-box` project page for installation and usage instructions.

**Using another settings module**

The included settings module (`tests/test_sqlite.py`) allows you to run the test suite using SQLite. If you want to run the tests using a different database, you’ll need to define your own settings file. Some tests, such as those for `contrib.postgres`, are specific to a particular database backend and will be skipped if run with a different backend. Some tests are skipped or expected failures on a particular database backend (see `DatabaseFeatures.django_test_skips` and `DatabaseFeatures.django_test_expected_failures` on each backend).

To run the tests with different settings, ensure that the module is on your `PYTHONPATH` and pass the module with `--settings`.

The `DATABASES` setting in any test settings module needs to define two databases:

- A default database. This database should use the backend that you want to use for primary testing.
- A database with the alias `other`. The `other` database is used to test that queries can be directed to different databases. This database should use the same backend as the default, and it must have a different name.

If you’re using a backend that isn’t SQLite, you will need to provide other details for each database:

- The `USER` option needs to specify an existing user account for the database. That user needs permission to execute `CREATE DATABASE` so that the test database can be created.
- The `PASSWORD` option needs to provide the password for the `USER` that has been specified.
Test databases get their names by prepending `test_` to the value of the `NAME` settings for the databases defined in `DATABASES`. These test databases are deleted when the tests are finished.

You will also need to ensure that your database uses UTF-8 as the default character set. If your database server doesn’t use UTF-8 as a default charset, you will need to include a value for `CHARSET` in the test settings dictionary for the applicable database.

**Running only some of the tests**

Django’s entire test suite takes a while to run, and running every single test could be redundant if, say, you just added a test to Django that you want to run quickly without running everything else. You can run a subset of the unit tests by appending the names of the test modules to `runtests.py` on the command line.

For example, if you’d like to run tests only for generic relations and internationalization, type:

```
$ ./runtests.py --settings=path.to.settings generic_relations i18n
```

How do you find out the names of individual tests? Look in `tests/` — each directory name there is the name of a test.

If you want to run only a particular class of tests, you can specify a list of paths to individual test classes. For example, to run the `TranslationTests` of the `i18n` module, type:

```
$ ./runtests.py --settings=path.to.settings i18n.tests.TranslationTests
```

Going beyond that, you can specify an individual test method like this:

```
$ ./runtests.py --settings=path.to.settings i18n.tests.TranslationTests.test_lazy_objects
```

You can run tests starting at a specified top-level module with `--start-at` option. For example:

```
$ ./runtests.py --start-at=wsgi
```

You can also run tests starting after a specified top-level module with `--start-after` option. For example:

```
$ ./runtests.py --start-after=wsgi
```

Note that the `--reverse` option doesn’t impact on `--start-at` or `--start-after` options. Moreover these options cannot be used with test labels.
Running the Selenium tests

Some tests require Selenium and a web browser. To run these tests, you must install the selenium package and run the tests with the `--selenium=<BROWSERS>` option. For example, if you have Firefox and Google Chrome installed:

```
$ ./runtests.py --selenium=firefox,chrome
```

See the `selenium.webdriver` package for the list of available browsers.

Specifying `--selenium` automatically sets `--tags=selenium` to run only the tests that require selenium. Some browsers (e.g. Chrome or Firefox) support headless testing, which can be faster and more stable. Add the `--headless` option to enable this mode.

Running all the tests

If you want to run the full suite of tests, you’ll need to install a number of dependencies:

- aiosmtpd
- argon2-cffi 19.1.0+
- asgiref 3.5.2+ (required)
- bcrypt
- colorama
- docutils
- geoip2
- jinja2 2.7+
- numpy
- Pillow 6.2.0+
- PyYAML
- pytz (required)
- pywatchman
- redis
- setuptools
- memcached, plus a supported Python binding
- gettext (gettext on Windows)
- selenium
• sqlparse 0.2.2+ (required)
• tblib 1.5.0+

You can find these dependencies in pip requirements files inside the tests/requirements directory of the Django source tree and install them like so:

```bash
$ python -m pip install -r tests/requirements/py3.txt
```

If you encounter an error during the installation, your system might be missing a dependency for one or more of the Python packages. Consult the failing package’s documentation or search the web with the error message that you encounter.

You can also install the database adapter(s) of your choice using oracle.txt, mysql.txt, or postgres.txt.

If you want to test the memcached or Redis cache backends, you’ll also need to define a CACHES setting that points at your memcached or Redis instance respectively.

To run the GeoDjango tests, you will need to set up a spatial database and install the Geospatial libraries.

Each of these dependencies is optional. If you’re missing any of them, the associated tests will be skipped.

To run some of the autoreload tests, you’ll need to install the Watchman service.

### Code coverage

Contributors are encouraged to run coverage on the test suite to identify areas that need additional tests. The coverage tool installation and use is described in testing code coverage.

Coverage should be run in a single process to obtain accurate statistics. To run coverage on the Django test suite using the standard test settings:

```bash
$ coverage run ./runtests.py --settings=test_sqlite --parallel=1
```

After running coverage, generate the html report by running:

```bash
$ coverage html
```

When running coverage for the Django tests, the included .coveragerc settings file defines coverage_html as the output directory for the report and also excludes several directories not relevant to the results (test code or external code included in Django).
Contrib apps

Tests for contrib apps can be found in the tests/ directory, typically under `<app_name>_tests`. For example, tests for contrib.auth are located in tests/auth_tests.

Troubleshooting

Test suite hangs or shows failures on main branch

Ensure you have the latest point release of a supported Python version, since there are often bugs in earlier versions that may cause the test suite to fail or hang.

On macOS (High Sierra and newer versions), you might see this message logged, after which the tests hang:

```
objc[42074]: +[__NSPlaceholderDate initialize] may have been in progress in another thread when fork() was called.
```

To avoid this set an `OBJC_DISABLE_INITIALIZE_FORK_SAFETY` environment variable, for example:

```
$ OBJC_DISABLE_INITIALIZE_FORK_SAFETY=YES ./runtests.py
```

Or add `export OBJC_DISABLE_INITIALIZE_FORK_SAFETY=YES` to your shell’s startup file (e.g. `~/.profile`).

Many test failures with UnicodeEncodeError

If the `locales` package is not installed, some tests will fail with a `UnicodeEncodeError`.

You can resolve this on Debian-based systems, for example, by running:

```
$ apt-get install locales
$ dpkg-reconfigure locales
```

You can resolve this for macOS systems by configuring your shell’s locale:

```
$ export LANG="en_US.UTF-8"
$ export LC_ALL="en_US.UTF-8"
```

Run the `locale` command to confirm the change. Optionally, add those export commands to your shell’s startup file (e.g. `~/.bashrc` for Bash) to avoid having to retype them.
Tests that only fail in combination

In case a test passes when run in isolation but fails within the whole suite, we have some tools to help analyze the problem.

The `--bisect` option of `runtests.py` will run the failing test while halving the test set it is run together with on each iteration, often making it possible to identify a small number of tests that may be related to the failure.

For example, suppose that the failing test that works on its own is `ModelTest.test_eq`, then using:

```
$ ./runtests.py --bisect basic.tests.ModelTest.test_eq
```

will try to determine a test that interferes with the given one. First, the test is run with the first half of the test suite. If a failure occurs, the first half of the test suite is split in two groups and each group is then run with the specified test. If there is no failure with the first half of the test suite, the second half of the test suite is run with the specified test and split appropriately as described earlier. The process repeats until the set of failing tests is minimized.

The `--pair` option runs the given test alongside every other test from the suite, letting you check if another test has side-effects that cause the failure. So:

```
$ ./runtests.py --pair basic.tests.ModelTest.test_eq
```

will pair `test_eq` with every test label.

With both `--bisect` and `--pair`, if you already suspect which cases might be responsible for the failure, you may limit tests to be cross-analyzed by specifying further test labels after the first one:

```
$ ./runtests.py --pair basic.tests.ModelTest.test_eq queries transactions
```

You can also try running any set of tests in a random or reverse order using the `--shuffle` and `--reverse` options. This can help verify that executing tests in a different order does not cause any trouble:

```
$ ./runtests.py basic --shuffle
$ ./runtests.py basic --reverse
```

Seeing the SQL queries run during a test

If you wish to examine the SQL being run in failing tests, you can turn on SQL logging using the `--debug-sql` option. If you combine this with `--verbosity=2`, all SQL queries will be output:

```
$ ./runtests.py basic --debug-sql
```
Seeing the full traceback of a test failure

By default, tests are run in parallel with one process per core. When the tests are run in parallel, however, you’ll only see a truncated traceback for any test failures. You can adjust this behavior with the `--parallel` option:

```
$ ./runtests.py basic --parallel=1
```

You can also use the `DJANGO_TEST_PROCESSES` environment variable for this purpose.

Tips for writing tests

Isolating model registration

To avoid polluting the global `apps` registry and prevent unnecessary table creation, models defined in a test method should be bound to a temporary `Apps` instance. To do this, use the `isolate_apps()` decorator:

```python
from django.db import models
from django.test import SimpleTestCase
from django.test.utils import isolate_apps

class TestModelDefinition(SimpleTestCase):
    @isolate_apps('app_label')
    def test_model_definition(self):
        class TestModel(models.Model):
            pass
        ...
```

Setting `app_label`

Models defined in a test method with no explicit `app_label` are automatically assigned the label of the app in which their test class is located.

In order to make sure the models defined within the context of `isolate_apps()` instances are correctly installed, you should pass the set of targeted `app_label` as arguments:

```
Listing 2: tests/app_label/tests.py
```

```python
from django.db import models
from django.test import SimpleTestCase
from django.test.utils import isolate_apps

class TestModelDefinition(SimpleTestCase):
    ...
```

(continues on next page)
@isolate_apps('app_label', 'other_app_label')
def test_model_definition(self):
    # This model automatically receives app_label='app_label'
    class TestModel(models.Model):
        pass

    class OtherAppModel(models.Model):
        class Meta:
            app_label = 'other_app_label'
...

Submitting patches

We’re always grateful for patches to Django’s code. Indeed, bug reports with associated patches will get fixed far more quickly than those without patches.

Typo fixes and trivial documentation changes

If you are fixing a really trivial issue, for example changing a word in the documentation, the preferred way to provide the patch is using GitHub pull requests without a Trac ticket.

See the Working with Git and GitHub for more details on how to use pull requests.

“Claiming” tickets

In an open-source project with hundreds of contributors around the world, it’s important to manage communication efficiently so that work doesn’t get duplicated and contributors can be as effective as possible.

Hence, our policy is for contributors to “claim” tickets in order to let other developers know that a particular bug or feature is being worked on.

If you have identified a contribution you want to make and you’re capable of fixing it (as measured by your coding ability, knowledge of Django internals and time availability), claim it by following these steps:

- Login using your GitHub account or create an account in our ticket system. If you have an account but have forgotten your password, you can reset it using the password reset page.
- If a ticket for this issue doesn’t exist yet, create one in our ticket tracker.
- If a ticket for this issue already exists, make sure nobody else has claimed it. To do this, look at the “Owned by” section of the ticket. If it’s assigned to “nobody,” then it’s available to be claimed. Otherwise, somebody else may be working on this ticket. Either find another bug/feature to work on, or
contact the developer working on the ticket to offer your help. If a ticket has been assigned for weeks or months without any activity, it’s probably safe to reassign it to yourself.

- Log into your account, if you haven’t already, by clicking “GitHub Login” or “DjangoProject Login” in the upper left of the ticket page.

- Claim the ticket by clicking the “assign to myself” radio button under “Action” near the bottom of the page, then click “Submit changes.”

Note: The Django software foundation requests that anyone contributing more than a trivial patch to Django sign and submit a Contributor License Agreement, this ensures that the Django Software Foundation has clear license to all contributions allowing for a clear license for all users.

Ticket claimers’ responsibility

Once you’ve claimed a ticket, you have a responsibility to work on that ticket in a reasonably timely fashion. If you don’t have time to work on it, either unclaim it or don’t claim it in the first place!

If there’s no sign of progress on a particular claimed ticket for a week or two, another developer may ask you to relinquish the ticket claim so that it’s no longer monopolized and somebody else can claim it.

If you’ve claimed a ticket and it’s taking a long time (days or weeks) to code, keep everybody updated by posting comments on the ticket. If you don’t provide regular updates, and you don’t respond to a request for a progress report, your claim on the ticket may be revoked.

As always, more communication is better than less communication!

Which tickets should be claimed?

Going through the steps of claiming tickets is overkill in some cases.

In the case of small changes, such as typos in the documentation or small bugs that will only take a few minutes to fix, you don’t need to jump through the hoops of claiming tickets. Submit your patch directly and you’re done!

It is always acceptable, regardless whether someone has claimed it or not, to submit patches to a ticket if you happen to have a patch ready.
Patch style

Make sure that any contribution you do fulfills at least the following requirements:

- The code required to fix a problem or add a feature is an essential part of a patch, but it is not the only part. A good patch should also include a regression test to validate the behavior that has been fixed and to prevent the problem from arising again. Also, if some tickets are relevant to the code that you’ve written, mention the ticket numbers in some comments in the test so that one can easily trace back the relevant discussions after your patch gets committed, and the tickets get closed.

- If the code associated with a patch adds a new feature, or modifies behavior of an existing feature, the patch should also contain documentation.

When you think your work is ready to be reviewed, send a GitHub pull request. Please review the patch yourself using our patch review checklist first.

If you can’t send a pull request for some reason, you can also use patches in Trac. When using this style, follow these guidelines.

- Submit patches in the format returned by the `git diff` command.

- Attach patches to a ticket in the ticket tracker, using the “attach file” button. Please don’t put the patch in the ticket description or comment unless it’s a single line patch.

- Name the patch file with a `.diff` extension; this will let the ticket tracker apply correct syntax highlighting, which is quite helpful.

Regardless of the way you submit your work, follow these steps.

- Make sure your code fulfills the requirements in our patch review checklist.

- Check the “Has patch” box on the ticket and make sure the “Needs documentation”, “Needs tests”, and “Patch needs improvement” boxes aren’t checked. This makes the ticket appear in the “Patches needing review” queue on the Development dashboard.

Non-trivial patches

A “non-trivial” patch is one that is more than a small bug fix. It’s a patch that introduces Django functionality and makes some sort of design decision.

If you provide a non-trivial patch, include evidence that alternatives have been discussed on django-developers.

If you’re not sure whether your patch should be considered non-trivial, ask on the ticket for opinions.
Deprecating a feature

There are a couple of reasons that code in Django might be deprecated:

- If a feature has been improved or modified in a backwards-incompatible way, the old feature or behavior will be deprecated.

- Sometimes Django will include a backport of a Python library that’s not included in a version of Python that Django currently supports. When Django no longer needs to support the older version of Python that doesn’t include the library, the library will be deprecated in Django.

As the deprecation policy describes, the first release of Django that deprecates a feature (A.B) should raise a RemovedInDjangoXXWarning (where XX is the Django version where the feature will be removed) when the deprecated feature is invoked. Assuming we have good test coverage, these warnings are converted to errors when running the test suite with warnings enabled: python -Wa runtests.py. Thus, when adding a RemovedInDjangoXXWarning you need to eliminate or silence any warnings generated when running the tests.

The first step is to remove any use of the deprecated behavior by Django itself. Next you can silence warnings in tests that actually test the deprecated behavior by using the ignore_warnings decorator, either at the test or class level:

1) In a particular test:

```python
from django.test import ignore_warnings
from django.utils.deprecation import RemovedInDjangoXXWarning

@ignore_warnings(category=RemovedInDjangoXXWarning)
def test_foo(self):
    ...
```

2) For an entire test case:

```python
from django.test import ignore_warnings
from django.utils.deprecation import RemovedInDjangoXXWarning

@ignore_warnings(category=RemovedInDjangoXXWarning)
class MyDeprecatedTests(unittest.TestCase):
    ...
```

You can also add a test for the deprecation warning:

```python
from django.utils.deprecation import RemovedInDjangoXXWarning

def test_foo_deprecation_warning(self):
    msg = 'Expected deprecation message'
```
Finally, there are a couple of updates to Django’s documentation to make:

1) If the existing feature is documented, mark it deprecated in documentation using the .. deprecated:: A.B annotation. Include a short description and a note about the upgrade path if applicable.

2) Add a description of the deprecated behavior, and the upgrade path if applicable, to the current release notes (docs/releases/A.B.txt) under the “Features deprecated in A.B” heading.

3) Add an entry in the deprecation timeline (docs/internals/deprecation.txt) under the appropriate version describing what code will be removed.

Once you have completed these steps, you are finished with the deprecation. In each feature release, all RemovedInDjangoXXWarnings matching the new version are removed.

JavaScript patches

For information on JavaScript patches, see the JavaScript patches documentation.

Patch review checklist

Use this checklist to review a pull request. If you are reviewing a pull request that is not your own and it passes all the criteria below, please set the “Triage Stage” on the corresponding Trac ticket to “Ready for checkin”. If you’ve left comments for improvement on the pull request, please tick the appropriate flags on the Trac ticket based on the results of your review: “Patch needs improvement”, “Needs documentation”, and/or “Needs tests”. As time and interest permits, mergers do final reviews of “Ready for checkin” tickets and will either commit the patch or bump it back to “Accepted” if further work needs to be done. If you’re looking to become a merger, doing thorough reviews of patches is a great way to earn trust.

Looking for a patch to review? Check out the “Patches needing review” section of the Django Development Dashboard. Looking to get your patch reviewed? Ensure the Trac flags on the ticket are set so that the ticket appears in that queue.

Documentation

- Does the documentation build without any errors (make html, or make.bat html on Windows, from the docs directory)?
- Does the documentation follow the writing style guidelines in Writing documentation?
- Are there any spelling errors?
Bugs

- Is there a proper regression test (the test should fail before the fix is applied)?

- If it’s a bug that qualifies for a backport to the stable version of Django, is there a release note in `docs/releases/A.B.C.txt`? Bug fixes that will be applied only to the main branch don’t need a release note.

New Features

- Are there tests to “exercise” all of the new code?

- Is there a release note in `docs/releases/A.B.txt`?

- Is there documentation for the feature and is it annotated appropriately with `. versionadded:: A.B` or `. versionchanged:: A.B`?

Deprecating a feature

See the Deprecating a feature guide.

All code changes

- Does the coding style conform to our guidelines? Are there any `black`, `flake8`, or `isort` errors? You can install the `pre-commit` hooks to automatically catch these errors.

- If the change is backwards incompatible in any way, is there a note in the release notes (`docs/releases/A.B.txt`)?

- Is Django’s test suite passing?

All tickets

- Is the pull request a single squashed commit with a message that follows our commit message format?

- Are you the patch author and a new contributor? Please add yourself to the `AUTHORS` file and submit a Contributor License Agreement.
Working with Git and GitHub

This section explains how the community can contribute code to Django via pull requests. If you’re interested in how mergers handle them, see Committing code.

Below, we are going to show how to create a GitHub pull request containing the changes for Trac ticket #xxxxx. By creating a fully-ready pull request, you will make the reviewer’s job easier, meaning that your work is more likely to be merged into Django.

You could also upload a traditional patch to Trac, but it’s less practical for reviews.

Installing Git

Django uses Git for its source control. You can download Git, but it’s often easier to install with your operating system’s package manager.

Django’s Git repository is hosted on GitHub, and it is recommended that you also work using GitHub.

After installing Git, the first thing you should do is set up your name and email:

```bash
$ git config --global user.name "Your Real Name"
$ git config --global user.email "you@email.com"
```

Note that user.name should be your real name, not your GitHub nick. GitHub should know the email you use in the user.email field, as this will be used to associate your commits with your GitHub account.

Setting up local repository

When you have created your GitHub account, with the nick “GitHub_nick”, and forked Django’s repository, create a local copy of your fork:

```bash
git clone https://github.com/GitHub_nick/django.git
```

This will create a new directory “django”, containing a clone of your GitHub repository. The rest of the git commands on this page need to be run within the cloned directory, so switch to it now:

```bash
 cd django
```

Your GitHub repository will be called “origin” in Git.

You should also set up django/django as an “upstream” remote (that is, tell git that the reference Django repository was the source of your fork of it):

```bash
 git remote add upstream https://github.com/django/django.git
 git fetch upstream
```
You can add other remotes similarly, for example:

```bash
git remote add akaariai https://github.com/akaariai/django.git
```

### Working on a ticket

When working on a ticket, create a new branch for the work, and base that work on `upstream/main`:

```bash
git checkout -b ticket_xxxxx upstream/main
```

The `-b` flag creates a new branch for you locally. Don’t hesitate to create new branches even for the smallest things - that’s what they are there for.

If instead you were working for a fix on the 1.4 branch, you would do:

```bash
git checkout -b ticket_xxxxx_1_4 upstream/stable/1.4.x
```

Assume the work is carried on the `ticket_xxxxx` branch. Make some changes and commit them:

```bash
git commit
```

When writing the commit message, follow the [commit message guidelines](https://www.djangoproject.com) to ease the work of the merger. If you’re uncomfortable with English, try at least to describe precisely what the commit does.

If you need to do additional work on your branch, commit as often as necessary:

```bash
git commit -m 'Added two more tests for edge cases'
```

### Publishing work

You can publish your work on GitHub by running:

```bash
git push origin ticket_xxxxx
```

When you go to your GitHub page, you will notice a new branch has been created.

If you are working on a Trac ticket, you should mention in the ticket that your work is available from branch `ticket_xxxxx` of your GitHub repo. Include a link to your branch.

Note that the above branch is called a “topic branch” in Git parlance. You are free to rewrite the history of this branch, by using `git rebase` for example. Other people shouldn’t base their work on such a branch, because their clone would become corrupt when you edit commits.

There are also “public branches”. These are branches other people are supposed to fork, so the history of these branches should never change. Good examples of public branches are the `main` and `stable/A.B.x` branches in the `django/django` repository.
When you think your work is ready to be pulled into Django, you should create a pull request at GitHub. A good pull request means:

- commits with one logical change in each, following the coding style,
- well-formed messages for each commit: a summary line and then paragraphs wrapped at 72 characters thereafter –see the committing guidelines for more details,
- documentation and tests, if needed –actually tests are always needed, except for documentation changes.

The test suite must pass and the documentation must build without warnings.

Once you have created your pull request, you should add a comment in the related Trac ticket explaining what you’ve done. In particular, you should note the environment in which you ran the tests, for instance: “all tests pass under SQLite and MySQL”.

Pull requests at GitHub have only two states: open and closed. The merger who will deal with your pull request has only two options: merge it or close it. For this reason, it isn’t useful to make a pull request until the code is ready for merging –or sufficiently close that a merger will finish it themselves.

**Rebasing branches**

In the example above, you created two commits, the “Fixed ticket_xxxxx” commit and “Added two more tests” commit.

We do not want to have the entire history of your working process in your repository. Your commit “Added two more tests” would be unhelpful noise. Instead, we would rather only have one commit containing all your work.

To rework the history of your branch you can squash the commits into one by using interactive rebase:

```
git rebase -i HEAD~2
```

The HEAD~2 above is shorthand for two latest commits. The above command will open an editor showing the two commits, prefixed with the word “pick”.

Change “pick” on the second line to “squash” instead. This will keep the first commit, and squash the second commit into the first one. Save and quit the editor. A second editor window should open, so you can reword the commit message for the commit now that it includes both your steps.

You can also use the “edit” option in rebase. This way you can change a single commit, for example to fix a typo in a docstring:

```
git rebase -i HEAD~3
```

(continues on next page)
git commit --amend
# Reword the commit message if needed

git rebase --continue
# The second and third commits should be applied.

If your topic branch is already published at GitHub, for example if you’re making minor changes to take into account a review, you will need to force-push the changes:

git push -f origin ticket_xxxxx

Note that this will rewrite history of ticket_xxxxx - if you check the commit hashes before and after the operation at GitHub you will notice that the commit hashes do not match anymore. This is acceptable, as the branch is a topic branch, and nobody should be basing their work on it.

**After upstream has changed**

When upstream (django/django) has changed, you should rebase your work. To do this, use:

```
git fetch upstream

git rebase
```

The work is automatically rebased using the branch you forked on, in the example case using `upstream/main`.

The rebase command removes all your local commits temporarily, applies the upstream commits, and then applies your local commits again on the work.

If there are merge conflicts, you will need to resolve them and then use `git rebase --continue`. At any point you can use `git rebase --abort` to return to the original state.

Note that you want to rebase on upstream, not merge the upstream.

The reason for this is that by rebasing, your commits will always be on top of the upstream’s work, not mixed in with the changes in the upstream. This way your branch will contain only commits related to its topic, which makes squashing easier.

**After review**

It is unusual to get any non-trivial amount of code into core without changes requested by reviewers. In this case, it is often a good idea to add the changes as one incremental commit to your work. This allows the reviewer to easily check what changes you have done.

In this case, do the changes required by the reviewer. Commit as often as necessary. Before publishing the changes, rebase your work. If you added two commits, you would run:
git rebase -i HEAD~2

Squash the second commit into the first. Write a commit message along the lines of:

```
Made changes asked in review by <reviewer>
- Fixed whitespace errors in foobar
- Reworded the docstring of bar()
```

Finally, push your work back to your GitHub repository. Since you didn’t touch the public commits during the rebase, you should not need to force-push:

```
git push origin ticket_xxxxx
```

Your pull request should now contain the new commit too.

Note that the merger is likely to squash the review commit into the previous commit when committing the code.

**Working on a patch**

One of the ways that developers can contribute to Django is by reviewing patches. Those patches will typically exist as pull requests on GitHub and can be easily integrated into your local repository:

```
git checkout -b pull_xxxxx upstream/main
curl https://github.com/django/django/pull/xxxxx.patch | git am
```

This will create a new branch and then apply the changes from the pull request to it. At this point you can run the tests or do anything else you need to do to investigate the quality of the patch.

For more detail on working with pull requests see the guidelines for mergers.

**Summary**

- Work on GitHub if you can.
- Announce your work on the Trac ticket by linking to your GitHub branch.
- When you have something ready, make a pull request.
- Make your pull requests as good as you can.
- When doing fixes to your work, use `git rebase -i` to squash the commits.
- When upstream has changed, do `git fetch upstream; git rebase`.
JavaScript

While most of Django core is Python, the admin and gis contrib apps contain JavaScript code.

Please follow these coding standards when writing JavaScript code for inclusion in Django.

Code style

- Please conform to the indentation style dictated in the .editorconfig file. We recommend using a text editor with EditorConfig support to avoid indentation and whitespace issues. Most of the JavaScript files use 4 spaces for indentation, but there are some exceptions.

- When naming variables, use camelCase instead of underscore_case. Different JavaScript files sometimes use a different code style. Please try to conform to the code style of each file.

- Use the ESLint code linter to check your code for bugs and style errors. ESLint will be run when you run the JavaScript tests. We also recommended installing a ESLint plugin in your text editor.

- Where possible, write code that will work even if the page structure is later changed with JavaScript. For instance, when binding a click handler, use $(‘body’).on(‘click’, selector, func) instead of $(selector).click(func). This makes it easier for projects to extend Django’s default behavior with JavaScript.

JavaScript patches

Django’s admin system leverages the jQuery framework to increase the capabilities of the admin interface. In conjunction, there is an emphasis on admin JavaScript performance and minimizing overall admin media file size.

JavaScript tests

Django’s JavaScript tests can be run in a browser or from the command line. The tests are located in a top level js_tests directory.

Writing tests

Django’s JavaScript tests use QUnit. Here is an example test module:

```javascript
QUnit.module('magicTricks', {
    beforeEach: function() {
        const $ = django.jQuery;
        $('.qunit-fixture').append('<button class="button"></button>');</
    }
});

(continues on next page)
QUnit.test('removeOnClick removes button on click', function(assert) {
    const $ = django.jQuery;
    removeOnClick('.button');
    assert.equal($('.button').length, 1);
    $('.button').click();
    assert.equal($('.button').length, 0);
});

QUnit.test('copyOnClick adds button on click', function(assert) {
    const $ = django.jQuery;
    copyOnClick('.button');
    assert.equal($('.button').length, 1);
    $('.button').click();
    assert.equal($('.button').length, 2);
});

Please consult the QUnit documentation for information on the types of assertions supported by QUnit.

Running tests

The JavaScript tests may be run from a web browser or from the command line.

Testing from a web browser

To run the tests from a web browser, open up js_tests/tests.html in your browser.

To measure code coverage when running the tests, you need to view that file over HTTP. To view code coverage:

- Execute python -m http.server from the root directory (not from inside js_tests).

Testing from the command line

To run the tests from the command line, you need to have Node.js installed.

After installing Node.js, install the JavaScript test dependencies by running the following from the root of your Django checkout:

$ npm install
Then run the tests with:

$ npm test

**Writing documentation**

We place high importance on the consistency and readability of documentation. After all, Django was created in a journalism environment! So we treat our documentation like we treat our code: we aim to improve it as often as possible.

Documentation changes generally come in two forms:

- **General improvements**: typo corrections, error fixes and better explanations through clearer writing and more examples.
- **New features**: documentation of features that have been added to the framework since the last release.

This section explains how writers can craft their documentation changes in the most useful and least error-prone ways.

**Getting the raw documentation**

Though Django’s documentation is intended to be read as HTML at https://docs.djangoproject.com/, we edit it as a collection of text files for maximum flexibility. These files live in the top-level `docs/` directory of a Django release.

If you’d like to start contributing to our docs, get the development version of Django from the source code repository (see Installing the development version). The development version has the latest-and-greatest documentation, just as it has the latest-and-greatest code. We also backport documentation fixes and improvements, at the discretion of the merger, to the last release branch. That’s because it’s highly advantageous to have the docs for the last release be up-to-date and correct (see Differences between versions).

**Getting started with Sphinx**

Django’s documentation uses the Sphinx documentation system, which in turn is based on docutils. The basic idea is that lightly-formatted plain-text documentation is transformed into HTML, PDF, and any other output format.

To build the documentation locally, install Sphinx:

$ python -m pip install Sphinx

Then from the `docs` directory, build the HTML:
To get started contributing, you’ll want to read the reStructuredText reference.

Your locally-built documentation will be themed differently than the documentation at docs.djangoproject.com. This is OK! If your changes look good on your local machine, they’ll look good on the website.

How the documentation is organized

The documentation is organized into several categories:

- **Tutorials** take the reader by the hand through a series of steps to create something.

  The important thing in a tutorial is to help the reader achieve something useful, preferably as early as possible, in order to give them confidence.

  Explain the nature of the problem we’re solving, so that the reader understands what we’re trying to achieve. Don’t feel that you need to begin with explanations of how things work - what matters is what the reader does, not what you explain. It can be helpful to refer back to what you’ve done and explain afterward.

- **Topic guides** aim to explain a concept or subject at a fairly high level.

  Link to reference material rather than repeat it. Use examples and don’t be reluctant to explain things that seem very basic to you - it might be the explanation someone else needs.

  Providing background context helps a newcomer connect the topic to things that they already know.

- **Reference guides** contain technical references for APIs. They describe the functioning of Django’s internal machinery and instruct in its use.

  Keep reference material tightly focused on the subject. Assume that the reader already understands the basic concepts involved but needs to know or be reminded of how Django does it.

  Reference guides aren’t the place for general explanation. If you find yourself explaining basic concepts, you may want to move that material to a topic guide.

- **How-to guides** are recipes that take the reader through steps in key subjects.

  What matters most in a how-to guide is what a user wants to achieve. A how-to should always be result-oriented rather than focused on internal details of how Django implements whatever is being discussed.

  These guides are more advanced than tutorials and assume some knowledge about how Django works. Assume that the reader has followed the tutorials and don’t hesitate to refer the reader back to the appropriate tutorial rather than repeat the same material.
Writing style

When using pronouns in reference to a hypothetical person, such as “a user with a session cookie”, gender-neutral pronouns (they/their/them) should be used. Instead of:

- he or she... use they.
- him or her... use them.
- his or her... use their.
- his or hers... use theirs.
- himself or herself... use themselves.

Try to avoid using words that minimize the difficulty involved in a task or operation, such as “easily”, “simply”, “just”, “merely”, “straightforward”, and so on. People’s experience may not match your expectations, and they may become frustrated when they do not find a step as “straightforward” or “simple” as it is implied to be.

Commonly used terms

Here are some style guidelines on commonly used terms throughout the documentation:

- Django – when referring to the framework, capitalize Django. It is lowercase only in Python code and in the djangoproject.com logo.
- email – no hyphen.
- HTTP – the expected pronunciation is “Aitch Tee Tee Pee” and therefore should be preceded by “an” and not “a”.
- MySQL, PostgreSQL, SQLite
- SQL – when referring to SQL, the expected pronunciation should be “Ess Queue Ell” and not “sequel”. Thus in a phrase like “Returns an SQL expression”, “SQL” should be preceded by “an” and not “a”.
- Python – when referring to the language, capitalize Python.
- realize, customize, initialize, etc. – use the American “ize” suffix, not “ise.”
- subclass – it’s a single word without a hyphen, both as a verb ( “subclass that model” ) and as a noun ( “create a subclass” ).
- the web, web framework – it’s not capitalized.
- website – use one word, without capitalization.
Django-specific terminology

- model – it’s not capitalized.
- template – it’s not capitalized.
- URLconf – use three capitalized letters, with no space before “conf.”
- view – it’s not capitalized.

Guidelines for reStructuredText files

These guidelines regulate the format of our reST (reStructuredText) documentation:

- In section titles, capitalize only initial words and proper nouns.
- Wrap the documentation at 80 characters wide, unless a code example is significantly less readable when split over two lines, or for another good reason.
- The main thing to keep in mind as you write and edit docs is that the more semantic markup you can add the better. So:

```
Add `django.contrib.auth` to your `INSTALLED_APPS`...
```

Isn’t nearly as helpful as:

```
Add :mod:`django.contrib.auth` to your :setting:`INSTALLED_APPS`...
```

This is because Sphinx will generate proper links for the latter, which greatly helps readers.

You can prefix the target with a - (that’s a tilde) to get only the “last bit” of that path. So :

```
:mod:`~django.contrib.auth` will display a link with the title “auth”.
```

- Use intersphinx to reference Python’s and Sphinx’ documentation.
- Add .. code-block:: <lang> to literal blocks so that they get highlighted. Prefer relying on automatic highlighting using :: (two colons). This has the benefit that if the code contains some invalid syntax, it won’t be highlighted. Adding .. code-block:: python, for example, will force highlighting despite invalid syntax.
- To improve readability, use .. admonition:: Descriptive title rather than .. note::. Use these boxes sparingly.
- Use these heading styles:

```
===
One
===
```
• Use :rfc: to reference RFC and try to link to the relevant section if possible. For example, use rfc:`2324#section-2.3.2` or rfc:`Custom link text <2324#section-2.3.2>`.

• Use :pep: to reference a Python Enhancement Proposal (PEP) and try to link to the relevant section if possible. For example, use pep:`20#easter-egg` or pep:`Easter Egg <20#easter-egg>`.

• Use :mimetype: to refer to a MIME Type unless the value is quoted for a code example.

• Use :envvar: to refer to an environment variable. You may also need to define a reference to the documentation for that environment variable using .. envvar::.

**Django-specific markup**

Besides Sphinx’s built-in markup, Django’s docs define some extra description units:

• Settings:

```settings:: INSTALLED_APPS```

To link to a setting, use `setting: `INSTALLED_APPS``.

• Template tags:

```templatetag:: regroup```

To link, use `ttag:` `regroup`

• Template filters:

```templatefilter:: linebreaksbr```

To link, use `tfILTER:` `linebreaksbr`

• Field lookups (i.e. `Foo.objects.filter(bar__exact=whatever)`):
To link, use `lookup:`exact`.

- **django-admin commands:**
  
  To link, use `djadmin:`migrate`

- **django-admin command-line options:**

  To link, use `option:`command_name --traceback` (or omit `command_name` for the options shared by all commands like `--verbosity`).

- Links to Trac tickets (typically reserved for patch release notes):

  :ticket:`12345`

Django’s documentation uses a custom `console` directive for documenting command-line examples involving `django-admin`, `manage.py`, `python`, etc.). In the HTML documentation, it renders a two-tab UI, with one tab showing a Unix-style command prompt and a second tab showing a Windows prompt.

For example, you can replace this fragment:

```
use this command:

.. code-block:: console

    $ python manage.py shell
```

with this one:

```
use this command:

.. console::

    $ python manage.py shell
```

Notice two things:

- You usually will replace occurrences of the `.. code-block:: console` directive.
- You don’t need to change the actual content of the code example. You still write it assuming a Unix-y environment (i.e. a `'$'` prompt symbol, `'/'` as filesystem path components separator, etc.)

The example above will render a code example block with two tabs. The first one will show:
$ python manage.py shell

(No changes from what .. code-block:: console would have rendered).

The second one will show:

```bash
...\> py manage.py shell
```

**Documenting new features**

Our policy for new features is:

All documentation of new features should be written in a way that clearly designates the features that are only available in the Django development version. Assume documentation readers are using the latest release, not the development version.

Our preferred way for marking new features is by prefacing the features’ documentation with: “.. versionadded:: X.Y”, followed by a mandatory blank line and an optional description (indented).

General improvements or other changes to the APIs that should be emphasized should use the “.. versionchanged:: X.Y” directive (with the same format as the versionadded mentioned above.

These versionadded and versionchanged blocks should be “self-contained.” In other words, since we only keep these annotations around for two releases, it’s nice to be able to remove the annotation and its contents without having to reflow, reindent, or edit the surrounding text. For example, instead of putting the entire description of a new or changed feature in a block, do something like this:

```python
.. class:: Author(first_name, last_name, middle_name=None)

    A person who writes books.

    ``first_name`` is ...

    ...

    ``middle_name`` is ...

.. versionchanged:: A.B

    The ``middle_name`` argument was added.
```

Put the changed annotation notes at the bottom of a section, not the top.

Also, avoid referring to a specific version of Django outside a versionadded or versionchanged block. Even inside a block, it’s often redundant to do so as these annotations render as “New in Django A.B:” and “Changed in Django A.B”, respectively.
If a function, attribute, etc. is added, it’s also okay to use a `versionadded` annotation like this:

```
.. attribute:: Author.middle_name

.. versionadded:: A.B

An author’s middle name.
```

We can remove the `.. versionadded:: A.B` annotation without any indentation changes when the time comes.

**Minimizing images**

Optimize image compression where possible. For PNG files, use OptiPNG and AdvanceCOMP’s `advpng`:

```
$ cd docs
$ optipng -o7 -z1-9 -i0 -strip all `find . -type f -not -path "./_build/*" -name ".*.png"`
$ advpng -z4 `find . -type f -not -path "./_build/*" -name ".*.png"`
```

This is based on OptiPNG version 0.7.5. Older versions may complain about the `-strip all` option being lossy.

**An example**

For a quick example of how it all fits together, consider this hypothetical example:

- First, the `ref/settings.txt` document could have an overall layout like this:

```
========
Settings
========
...

.. _available-settings:

Available settings
==================
...

.. _deprecated-settings:

Deprecated settings
```

(continues on next page)
• Next, the topics/settings.txt document could contain something like this:

```plaintext
You can access a :ref:`listing of all available settings <available-settings>`. For a list of deprecated settings see :ref:`deprecated-settings`.

You can find both in the :doc:`settings reference document <ref/settings>`.
```

We use the Sphinx doc cross-reference element when we want to link to another document as a whole and the ref element when we want to link to an arbitrary location in a document.

• Next, notice how the settings are annotated:

```plaintext
.. setting:: ADMINS

ADMINS
=======

Default: `[]` (Empty list)

A list of all the people who get code error notifications. When ``DEBUG=False`` and a view raises an exception, Django will email these people with the full exception information. Each member of the list should be a tuple of (Full name, email address). Example::

    [('John', 'john@example.com'), ('Mary', 'mary@example.com')]

Note that Django will email *all* of these people whenever an error happens. See :doc:`/howto/error-reporting` for more information.
```

This marks up the following header as the “canonical” target for the setting ADMINS. This means any time I talk about ADMINS, I can reference it using :setting:`ADMINS`.

That’s basically how everything fits together.
**Spelling check**

Before you commit your docs, it’s a good idea to run the spelling checker. You’ll need to install `sphinxcontrib-spelling` first. Then from the `docs` directory, run `make spelling`. Wrong words (if any) along with the file and line number where they occur will be saved to `_build/spelling/output.txt`.

If you encounter false-positives (error output that actually is correct), do one of the following:

- Surround inline code or brand/technology names with grave accents (``).
- Find synonyms that the spell checker recognizes.
- If, and only if, you are sure the word you are using is correct - add it to `docs/spelling_wordlist` (please keep the list in alphabetical order).

**Link check**

Links in documentation can become broken or changed such that they are no longer the canonical link. Sphinx provides a builder that can check whether the links in the documentation are working. From the `docs` directory, run `make linkcheck`. Output is printed to the terminal, but can also be found in `_build/linkcheck/output.txt` and `_build/linkcheck/output.json`.

Entries that have a status of “working” are fine, those that are “unchecked” or “ignored” have been skipped because they either cannot be checked or have matched ignore rules in the configuration.

Entries that have a status of “broken” need to be fixed. Those that have a status of “redirected” may need to be updated to point to the canonical location, e.g. the scheme has changed `http:// → https://`. In certain cases, we do not want to update a “redirected” link, e.g. a rewrite to always point to the latest or stable version of the documentation, e.g. `/en/stable/ → /en/3.2/`.

**Translating documentation**

See Localizing the Django documentation if you’d like to help translate the documentation into another language.

**django-admin man page**

Sphinx can generate a manual page for the `django-admin` command. This is configured in `docs/conf.py`. Unlike other documentation output, this man page should be included in the Django repository and the releases as `docs/man/django-admin.1`. There isn’t a need to update this file when updating the documentation, as it’s updated once as part of the release process.

To generate an updated version of the man page, run `make man` in the `docs` directory. The new man page will be written in `docs/_build/man/django-admin.1`. 
Localizing Django

Various parts of Django, such as the admin site and validation error messages, are internationalized. This means they display differently depending on each user’s language or country. For this, Django uses the same internationalization and localization infrastructure available to Django applications, described in the i18n documentation.

Translations

Translations are contributed by Django users worldwide. The translation work is coordinated at Transifex. If you find an incorrect translation or want to discuss specific translations, go to the Django project page. If you would like to help out with translating or adding a language that isn’t yet translated, here’s what to do:

- Introduce yourself on the Django internationalization forum.
- Make sure you read the notes about Specialties of Django translation.
- Sign up at Transifex and visit the Django project page.
- On the Django project page, choose the language you want to work on, or—in case the language doesn’t exist yet—request a new language team by clicking on the “Request language” link and selecting the appropriate language.
- Then, click the “Join this Team” button to become a member of this team. Every team has at least one coordinator who is responsible to review your membership request. You can also contact the team coordinator to clarify procedural problems and handle the actual translation process.
- Once you are a member of a team choose the translation resource you want to update on the team page. For example, the “core” resource refers to the translation catalog that contains all non-contrib translations. Each of the contrib apps also has a resource (prefixed with “contrib”).

Note: For more information about how to use Transifex, read the Transifex User Guide.

Translations from Transifex are only integrated into the Django repository at the time of a new feature release. We try to update them a second time during one of the following patch releases, but that depends on the translation manager’s availability. So don’t miss the string freeze period (between the release candidate and the feature release) to take the opportunity to complete and fix the translations for your language!
Formats

You can also review `conf/locale/<locale>/formats.py`. This file describes the date, time and numbers formatting particularities of your locale. See Format localization for details.

The format files aren’t managed by the use of Transifex. To change them, you must create a patch against the Django source tree, as for any code change:

- Create a diff against the current Git main branch.
- Open a ticket in Django’s ticket system, set its Component field to Translations, and attach the patch to it.

Documentation

There is also an opportunity to translate the documentation, though this is a huge undertaking to complete entirely (you have been warned!). We use the same Transifex tool. The translations will appear at https://docs.djangoproject.com/<language_code>/ when at least the docs/intro/* files are fully translated in your language.

Once translations are published, updated versions from Transifex will be irregularly ported to the django/django-docs-translations repository and to the documentation website. Only translations for the latest stable Django release are updated.

Committing code

This section is addressed to the mergers and to anyone interested in knowing how code gets committed into Django. If you’re a community member who wants to contribute code to Django, look at Working with Git and GitHub instead.

Handling pull requests

Since Django is hosted on GitHub, patches are provided in the form of pull requests.

When committing a pull request, make sure each individual commit matches the commit guidelines described below. Contributors are expected to provide the best pull requests possible. In practice mergers - who will likely be more familiar with the commit guidelines - may decide to bring a commit up to standard themselves.

You may want to have Jenkins or GitHub actions test the pull request with one of the pull request builders that doesn’t run automatically, such as Oracle or Selenium. See the CI wiki page for instructions.

If you find yourself checking out pull requests locally more often, this git alias will be helpful:

```
[alias]
    pr = !sh -c "git fetch upstream pull/${1}/head:pr/${1} && git checkout pr/${1}"
```
Add it to your ~/.gitconfig, and set upstream to be django/django. Then you can run `git pr ####` to checkout the corresponding pull request.

At this point, you can work on the code. Use `git rebase -i` and `git commit --amend` to make sure the commits have the expected level of quality. Once you’re ready:

```bash
$ # Pull in the latest changes from main.
$ git checkout main
$ git pull upstream main
$ # Rebase the pull request on main.
$ git checkout pr/####
$ git rebase main
$ git checkout main
$ # Merge the work as "fast-forward" to main to avoid a merge commit.
$ # (in practice, you can omit "--ff-only" since you just rebased)
$ git merge --ff-only pr/XXX
$ # If you’re not sure if you did things correctly, check that only the
$ # changes you expect will be pushed to upstream.
$ git push --dry-run upstream main
$ # Push!
$ git push upstream main
$ # Delete the pull request branch.
$ git branch -d pr/xxxx
```

Force push to the branch after rebasing on main but before merging and pushing to upstream. This allows the commit hashes on main and the branch to match which automatically closes the pull request.

If a pull request doesn’t need to be merged as multiple commits, you can use GitHub’s “Squash and merge” button on the website. Edit the commit message as needed to conform to the guidelines and remove the pull request number that’s automatically appended to the message’s first line.

When rewriting the commit history of a pull request, the goal is to make Django’s commit history as usable as possible:

- If a patch contains back-and-forth commits, then rewrite those into one. For example, if a commit adds some code and a second commit fixes stylistic issues introduced in the first commit, those commits should be squashed before merging.

- Separate changes to different commits by logical grouping: if you do a stylistic cleanup at the same time as you do other changes to a file, separating the changes into two different commits will make reviewing history easier.

- Beware of merges of upstream branches in the pull requests.

- Tests should pass and docs should build after each commit. Neither the tests nor the docs should emit warnings.

- Trivial and small patches usually are best done in one commit. Medium to large work may be split into
multiple commits if it makes sense.

Practicality beats purity, so it is up to each merger to decide how much history mangling to do for a pull request. The main points are engaging the community, getting work done, and having a usable commit history.

**Committing guidelines**

In addition, please follow the following guidelines when committing code to Django’s Git repository:

- Never change the published history of `django/django` branches by force pushing. If you absolutely must (for security reasons for example), first discuss the situation with the team.

- For any medium-to-big changes, where “medium-to-big” is according to your judgment, please bring things up on the `django-developers` mailing list before making the change.

  If you bring something up on `django-developers` and nobody responds, please don’t take that to mean your idea is great and should be implemented immediately because nobody contested it. Everyone doesn’t always have a lot of time to read mailing list discussions immediately, so you may have to wait a couple of days before getting a response.

- Write detailed commit messages in the past tense, not present tense.
  - Good: “Fixed Unicode bug in RSS API.”
  - Bad: “Fixes Unicode bug in RSS API.”
  - Bad: “Fixing Unicode bug in RSS API.”

  The commit message should be in lines of 72 chars maximum. There should be a subject line, separated by a blank line and then paragraphs of 72 char lines. The limits are soft. For the subject line, shorter is better. In the body of the commit message more detail is better than less:

  ```
  Fixed #18307 -- Added git workflow guidelines.
  Refactored the Django’s documentation to remove mentions of SVN specific tasks. Added guidelines of how to use Git, GitHub, and how to use pull request together with Trac instead.
  ```

  Credit the contributors in the commit message: “Thanks A for the report and B for review.” Use git’s `Co-Authored-By` as appropriate.

- For commits to a branch, prefix the commit message with the branch name. For example: “[1.4.x] Fixed #xxxxxx –Added support for mind reading.”

- Limit commits to the most granular change that makes sense. This means, use frequent small commits rather than infrequent large commits. For example, if implementing feature X requires a small change to library Y, first commit the change to library Y, then commit feature X in a separate commit. This goes a long way in helping everyone follow your changes.
• Separate bug fixes from feature changes. Bug fixes may need to be backported to the stable branch, according to Supported versions.

• If your commit closes a ticket in the Django ticket tracker, begin your commit message with the text “Fixed #xxxxx”, where “xxxxx” is the number of the ticket your commit fixes. Example: “Fixed #123 – Added whizbang feature.”. We’ve rigged Trac so that any commit message in that format will automatically close the referenced ticket and post a comment to it with the full commit message.

  For the curious, we’re using a Trac plugin for this.

Note: Note that the Trac integration doesn’t know anything about pull requests. So if you try to close a pull request with the phrase “closes #400” in your commit message, GitHub will close the pull request, but the Trac plugin will not close the same numbered ticket in Trac.

• If your commit references a ticket in the Django ticket tracker but does not close the ticket, include the phrase “Refs #xxxxx”, where “xxxxx” is the number of the ticket your commit references. This will automatically post a comment to the appropriate ticket.

• Write commit messages for backports using this pattern:

  ![Commit Message Pattern](image)

  For example:

  ![Example Commit Message](image)

  There’s a script on the wiki to automate this.

  If the commit fixes a regression, include this in the commit message:

  ![Regression Message](image)

  (use the commit hash where the regression was introduced).
Reverting commits

Nobody’s perfect; mistakes will be committed.

But try very hard to ensure that mistakes don’t happen. Just because we have a reversion policy doesn’t relax your responsibility to aim for the highest quality possible. Really: double-check your work, or have it checked by another merger before you commit it in the first place!

When a mistaken commit is discovered, please follow these guidelines:

• If possible, have the original author revert their own commit.
• Don’t revert another author’s changes without permission from the original author.
• Use git revert – this will make a reverse commit, but the original commit will still be part of the commit history.
• If the original author can’t be reached (within a reasonable amount of time – a day or so) and the problem is severe – crashing bug, major test failures, etc. – then ask for objections on the django-developers mailing list then revert if there are none.
• If the problem is small (a feature commit after feature freeze, say), wait it out.
• If there’s a disagreement between the merger and the reverter-to-be then try to work it out on the django-developers mailing list. If an agreement can’t be reached then it should be put to a vote.
• If the commit introduced a confirmed, disclosed security vulnerability then the commit may be reverted immediately without permission from anyone.
• The release branch maintainer may back out commits to the release branch without permission if the commit breaks the release branch.
• If you mistakenly push a topic branch to django/django, delete it. For instance, if you did: git push upstream feature_antigravity, do a reverse push: git push upstream :feature_antigravity.

10.1.2 Join the Django community

We’re passionate about helping Django users make the jump to contributing members of the community. There are several other ways you can help the Django community and others to maintain a great ecosystem to work in:

• Join the Django forum. This forum is a place for discussing the Django framework and applications and projects that use it. This is also a good place to ask and answer any questions related to installing, using, or contributing to Django.
• Join the django-users mailing list and answer questions. This mailing list has a huge audience, and we really want to maintain a friendly and helpful atmosphere. If you’re new to the Django community, you should read the posting guidelines.
• Join the #django IRC channel on Libera.Chat and answer questions. By explaining Django to other users, you’re going to learn a lot about the framework yourself.

• Blog about Django. We syndicate all the Django blogs we know about on the community page; if you’d like to see your blog on that page you can register it here.

• Contribute to open-source Django projects, write some documentation, or release your own code as an open-source pluggable application. The ecosystem of pluggable applications is a big strength of Django, help us build it!

We’re looking forward to working with you. Welcome aboard! 🛥️

10.2 Mailing lists

Important: Please report security issues only to security@djangoproject.com. This is a private list only open to long-time, highly trusted Django developers, and its archives are not public. For further details, please see our security policies.

Django has several official mailing lists on Google Groups that are open to anyone.

10.2.1 django-users

This is the right place if you are looking to ask any question regarding the installation, usage, or debugging of Django.

Note: If it’s the first time you send an email to this list, your email must be accepted first so don’t worry if your message does not appear instantly.

• django-users mailing archive
• django-users subscription email address
• django-users posting email
10.2.2 django-developers

The discussion about the development of Django itself takes place here.

Before asking a question about how to contribute, read Contributing to Django. Many frequently asked questions are answered there.

Note: Please make use of django-users mailing list if you want to ask for tech support, doing so in this list is inappropriate.

- django-developers mailing archive
- django-developers subscription email address
- django-developers posting email

10.2.3 django-announce

A (very) low-traffic list for announcing upcoming security releases, new releases of Django, and security advisories.

- django-announce mailing archive
- django-announce subscription email address
- django-announce posting email

10.2.4 django-updates

All the ticket updates are mailed automatically to this list, which is tracked by developers and interested community members.

- django-updates mailing archive
- django-updates subscription email address
- django-updates posting email
10.3 Organization of the Django Project

10.3.1 Principles

The Django Project is managed by a team of volunteers pursuing three goals:

- Driving the development of the Django web framework,
- Fostering the ecosystem of Django-related software,
- Leading the Django community in accordance with the values described in the Django Code of Conduct.

The Django Project isn’t a legal entity. The Django Software Foundation, a non-profit organization, handles financial and legal matters related to the Django Project. Other than that, the Django Software Foundation lets the Django Project manage the development of the Django framework, its ecosystem and its community.

10.3.2 Mergers

Role

Mergers are a small set of people who merge pull requests to the Django Git repository.

Prerogatives

Mergers hold the following prerogatives:

- Merging any pull request which constitutes a minor change (small enough not to require the use of the DEP process). A Merger must not merge a change primarily authored by that Merger, unless the pull request has been approved by:
  - another Merger,
  - a technical board member,
  - a member of the triage & review team, or
  - a member of the security team.

- Initiating discussion of a minor change in the appropriate venue, and request that other Mergers refrain from merging it while discussion proceeds.

- Requesting a vote of the technical board regarding any minor change if, in the Merger’s opinion, discussion has failed to reach a consensus.

- Requesting a vote of the technical board when a major change (significant enough to require the use of the DEP process) reaches one of its implementation milestones and is intended to merge.
Membership

The technical board selects Mergers as necessary to maintain their number at a minimum of three, in order to spread the workload and avoid over-burdening or burning out any individual Merger. There is no upper limit to the number of Mergers.

It’s not a requirement that a Merger is also a Django Fellow, but the Django Software Foundation has the power to use funding of Fellow positions as a way to make the role of Merger sustainable.

The following restrictions apply to the role of Merger:

• A person must not simultaneously serve as a member of the technical board. If a Merger is elected to the technical board, they shall cease to be a Merger immediately upon taking up membership in the technical board.

• A person may serve in the roles of Releaser and Merger simultaneously.

The selection process, when a vacancy occurs or when the technical board deems it necessary to select additional persons for such a role, occur as follows:

• Any member in good standing of an appropriate discussion venue, or the Django Software Foundation board acting with the input of the DSF’s Fellowship committee, may suggest a person for consideration.

• The technical board considers the suggestions put forth, and then any member of the technical board formally nominates a candidate for the role.

• The technical board votes on nominees.

Mergers may resign their role at any time, but should endeavor to provide some advance notice in order to allow the selection of a replacement. Termination of the contract of a Django Fellow by the Django Software Foundation temporarily suspends that person’s Merger role until such time as the technical board can vote on their nomination.

Otherwise, a Merger may be removed by:

• Becoming disqualified due to election to the technical board.

• Becoming disqualified due to actions taken by the Code of Conduct committee of the Django Software Foundation.

• A vote of the technical board.
10.3.3 Releasers

Role

Releasers are a small set of people who have the authority to upload packaged releases of Django to the Python Package Index, and to the djangoproject.com website.

Prerogatives

Releasers build Django releases and upload them to the Python Package Index, and to the djangoproject.com website.

Membership

The technical board selects Releasers as necessary to maintain their number at a minimum of three, in order to spread the workload and avoid over-burdening or burning out any individual Releaser. There is no upper limit to the number of Releasers.

It’s not a requirement that a Releaser is also a Django Fellow, but the Django Software Foundation has the power to use funding of Fellow positions as a way to make the role of Releaser sustainable.

A person may serve in the roles of Releaser and Merger simultaneously.

The selection process, when a vacancy occurs or when the technical board deems it necessary to select additional persons for such a role, occur as follows:

- Any member in good standing of an appropriate discussion venue, or the Django Software Foundation board acting with the input of the DSF’s Fellowship committee, may suggest a person for consideration.
- The technical board considers the suggestions put forth, and then any member of the technical board formally nominates a candidate for the role.
- The technical board votes on nominees.

Releasers may resign their role at any time, but should endeavor to provide some advance notice in order to allow the selection of a replacement. Termination of the contract of a Django Fellow by the Django Software Foundation temporarily suspends that person’s Releaser role until such time as the technical board can vote on their nomination.

Otherwise, a Releaser may be removed by:

- Becoming disqualified due to actions taken by the Code of Conduct committee of the Django Software Foundation.
- A vote of the technical board.
10.3.4 Technical board

Role

The technical board is a group of experienced contributors who:

• provide oversight of Django’s development and release process,
• assist in setting the direction of feature development and releases,
• take part in filling certain roles, and
• have a tie-breaking vote when other decision-making processes fail.

Their main concern is to maintain the quality and stability of the Django Web Framework.

Prerogatives

The technical board holds the following prerogatives:

• Making a binding decision regarding any question of a technical change to Django.
• Vetoing the merging of any particular piece of code into Django or ordering the reversion of any particular merge or commit.
• Announcing calls for proposals and ideas for the future technical direction of Django.
• Setting and adjusting the schedule of releases of Django.
• Selecting and removing mergers and releasers.
• Participating in the removal of members of the technical board, when deemed appropriate.
• Calling elections of the technical board outside of those which are automatically triggered, at times when the technical board deems an election is appropriate.
• Participating in modifying Django’s governance (see Changing the organization).
• Declining to vote on a matter the technical board feels is unripe for a binding decision, or which the technical board feels is outside the scope of its powers.
• Taking charge of the governance of other technical teams within the Django open-source project, and governing those teams accordingly.
Membership

The **technical board** is an elected group of five experienced contributors who demonstrate:

- A history of technical contributions to Django or the Django ecosystem. This history must begin at least 18 months prior to the individual’s candidacy for the technical board.

- A history of participation in Django’s development outside of contributions merged to the Django Git repository. This may include, but is not restricted to:
  - Participation in discussions on the django-developers mailing list or the Django forum.
  - Reviewing and offering feedback on pull requests in the Django source-code repository.
  - Assisting in triage and management of the Django bug tracker.

- A history of recent engagement with the direction and development of Django. Such engagement must have occurred within a period of no more than two years prior to the individual’s candidacy for the technical board.

A new board is elected after each release cycle of Django. The election process works as follows:

1. The technical board direct one of its members to notify the Secretary of the Django Software Foundation, in writing, of the triggering of the election, and the condition which triggered it. The Secretary post to the appropriate venue – the django-developers mailing list and the Django forum - to announce the election and its timeline.

2. As soon as the election is announced, the DSF Board begin a period of voter registration. All individual members of the DSF are automatically registered and need not explicitly register. All other persons who believe themselves eligible to vote, but who have not yet registered to vote, may make an application to the DSF Board for voting privileges. The voter registration form and roll of voters is maintained by the DSF Board. The DSF Board may challenge and reject the registration of voters it believes are registering in bad faith or who it believes have falsified their qualifications or are otherwise unqualified.

3. Registration of voters close one week after the announcement of the election. At that point, registration of candidates begin. Any qualified person may register as a candidate. The candidate registration form and roster of candidates are maintained by the DSF Board, and candidates must provide evidence of their qualifications as part of registration. The DSF Board may challenge and reject the registration of candidates it believes do not meet the qualifications of members of the Technical Board, or who it believes are registering in bad faith.

4. Registration of candidates close one week after it has opened. One week after registration of candidates closes, the Secretary of the DSF publish the roster of candidates to the django-developers mailing list and the Django forum, and the election begin. The DSF Board provide a voting form accessible to registered voters, and is the custodian of the votes.

5. Voting is by secret ballot containing the roster of candidates, and any relevant materials regarding the candidates, in a randomized order. Each voter may vote for up to five candidates on the ballot.
6. The election conclude one week after it begins. The DSF Board then tally the votes and produce a summary, including the total number of votes cast and the number received by each candidate. This summary is ratified by a majority vote of the DSF Board, then posted by the Secretary of the DSF to the django-developers mailing list and the Django Forum. The five candidates with the highest vote totals are immediately become the new technical board.

A member of the technical board may be removed by:

- Becoming disqualified due to actions taken by the Code of Conduct committee of the Django Software Foundation.
- Determining that they did not possess the qualifications of a member of the technical board. This determination must be made jointly by the other members of the technical board, and the DSF Board. A valid determination of ineligibility requires that all other members of the technical board and all members of the DSF Board vote who can vote on the issue (the affected person, if a DSF Board member, must not vote) vote “yes” on a motion that the person in question is ineligible.

10.3.5 Changing the organization

Changes to this document require the use of the DEP process, with modifications described in DEP 0010.

10.4 Django’s security policies

Django’s development team is strongly committed to responsible reporting and disclosure of security-related issues. As such, we’ve adopted and follow a set of policies which conform to that ideal and are geared toward allowing us to deliver timely security updates to the official distribution of Django, as well as to third-party distributions.

10.4.1 Reporting security issues

Short version: please report security issues by emailing security@djangoproject.com.

Most normal bugs in Django are reported to our public Trac instance, but due to the sensitive nature of security issues, we ask that they not be publicly reported in this fashion.

Instead, if you believe you’ve found something in Django which has security implications, please send a description of the issue via email to security@djangoproject.com. Mail sent to that address reaches the security team.

Once you’ve submitted an issue via email, you should receive an acknowledgment from a member of the security team within 48 hours, and depending on the action to be taken, you may receive further followup emails.
Sending encrypted reports

If you want to send an encrypted email (optional), the public key ID for security@djangoproject.com is 0xfcb84b8d1d17f80b, and this public key is available from most commonly-used keyservers.

10.4.2 Supported versions

At any given time, the Django team provides official security support for several versions of Django:

- The main development branch, hosted on GitHub, which will become the next major release of Django, receives security support. Security issues that only affect the main development branch and not any stable released versions are fixed in public without going through the disclosure process.

- The two most recent Django release series receive security support. For example, during the development cycle leading to the release of Django 1.5, support will be provided for Django 1.4 and Django 1.3. Upon the release of Django 1.5, Django 1.3’s security support will end.

- Long-term support releases will receive security updates for a specified period.

When new releases are issued for security reasons, the accompanying notice will include a list of affected versions. This list is comprised solely of supported versions of Django: older versions may also be affected, but we do not investigate to determine that, and will not issue patches or new releases for those versions.

10.4.3 How Django discloses security issues

Our process for taking a security issue from private discussion to public disclosure involves multiple steps.

Approximately one week before public disclosure, we send two notifications:

First, we notify django-announce of the date and approximate time of the upcoming security release, as well as the severity of the issues. This is to aid organizations that need to ensure they have staff available to handle triaging our announcement and upgrade Django as needed. Severity levels are:

High:

- Remote code execution
- SQL injection

Moderate:

- Cross site scripting (XSS)
- Cross site request forgery (CSRF)
- Denial-of-service attacks
- Broken authentication

10.4. Django’s security policies
Low:

- Sensitive data exposure
- Broken session management
- Unvalidated redirects/forwards
- Issues requiring an uncommon configuration option

Second, we notify a list of people and organizations, primarily composed of operating-system vendors and other distributors of Django. This email is signed with the PGP key of someone from Django’s release team and consists of:

- A full description of the issue and the affected versions of Django.
- The steps we will be taking to remedy the issue.
- The patch(es), if any, that will be applied to Django.
- The date on which the Django team will apply these patches, issue new releases and publicly disclose the issue.

On the day of disclosure, we will take the following steps:

1. Apply the relevant patch(es) to Django’s codebase.
2. Issue the relevant release(s), by placing new packages on the Python Package Index and on the Django website, and tagging the new release(s) in Django’s git repository.
3. Post a public entry on the official Django development blog, describing the issue and its resolution in detail, pointing to the relevant patches and new releases, and crediting the reporter of the issue (if the reporter wishes to be publicly identified).
4. Post a notice to the django-announce and oss-security@lists.openwall.com mailing lists that links to the blog post.

If a reported issue is believed to be particularly time-sensitive – due to a known exploit in the wild, for example – the time between advance notification and public disclosure may be shortened considerably.

Additionally, if we have reason to believe that an issue reported to us affects other frameworks or tools in the Python/web ecosystem, we may privately contact and discuss those issues with the appropriate maintainers, and coordinate our own disclosure and resolution with theirs.

The Django team also maintains an archive of security issues disclosed in Django.
10.4.4 Who receives advance notification

The full list of people and organizations who receive advance notification of security issues is not and will not be made public.

We also aim to keep this list as small as effectively possible, in order to better manage the flow of confidential information prior to disclosure. As such, our notification list is not simply a list of users of Django, and being a user of Django is not sufficient reason to be placed on the notification list.

In broad terms, recipients of security notifications fall into three groups:

1. Operating-system vendors and other distributors of Django who provide a suitably-generic (i.e., not an individual’s personal email address) contact address for reporting issues with their Django package, or for general security reporting. In either case, such addresses must not forward to public mailing lists or bug trackers. Addresses which forward to the private email of an individual maintainer or security-response contact are acceptable, although private security trackers or security-response groups are strongly preferred.

2. On a case-by-case basis, individual package maintainers who have demonstrated a commitment to responding to and responsibly acting on these notifications.

3. On a case-by-case basis, other entities who, in the judgment of the Django development team, need to be made aware of a pending security issue. Typically, membership in this group will consist of some of the largest and/or most likely to be severely impacted known users or distributors of Django, and will require a demonstrated ability to responsibly receive, keep confidential and act on these notifications.

Security audit and scanning entities

As a policy, we do not add these types of entities to the notification list.

10.4.5 Requesting notifications

If you believe that you, or an organization you are authorized to represent, fall into one of the groups listed above, you can ask to be added to Django’s notification list by emailing security@djangoproject.com. Please use the subject line “Security notification request”.

Your request must include the following information:

- Your full, real name and the name of the organization you represent, if applicable, as well as your role within that organization.
- A detailed explanation of how you or your organization fit at least one set of criteria listed above.
- A detailed explanation of why you are requesting security notifications. Again, please keep in mind that this is not simply a list for users of Django, and the overwhelming majority of users should subscribe to...
**django-announce** to receive advanced notice of when a security release will happen, without the details of the issues, rather than request detailed notifications.

- The email address you would like to have added to our notification list.
- An explanation of who will be receiving/reviewing mail sent to that address, as well as information regarding any automated actions that will be taken (i.e., filing of a confidential issue in a bug tracker).
- For individuals, the ID of a public key associated with your address which can be used to verify email received from you and encrypt email sent to you, as needed.

Once submitted, your request will be considered by the Django development team; you will receive a reply notifying you of the result of your request within 30 days.

Please also bear in mind that for any individual or organization, receiving security notifications is a privilege granted at the sole discretion of the Django development team, and that this privilege can be revoked at any time, with or without explanation.

---

Provide all required information

A failure to provide the required information in your initial contact will count against you when making the decision on whether or not to approve your request.

---

### 10.5 Django’s release process

#### 10.5.1 Official releases

Since version 1.0, Django’s release numbering works as follows:

- Versions are numbered in the form A.B or A.B.C.
- A.B is the feature release version number. Each version will be mostly backwards compatible with the previous release. Exceptions to this rule will be listed in the release notes.
- C is the patch release version number, which is incremented for bugfix and security releases. These releases will be 100% backwards-compatible with the previous patch release. The only exception is when a security or data loss issue can’t be fixed without breaking backwards-compatibility. If this happens, the release notes will provide detailed upgrade instructions.
- Before a new feature release, we’ll make alpha, beta, and release candidate releases. These are of the form A.B alpha/beta/rc N, which means the Nth alpha/beta/release candidate of version A.B.

In git, each Django release will have a tag indicating its version number, signed with the Django release key. Additionally, each release series has its own branch, called `stable/A.B.x`, and bugfix/security releases will be issued from those branches.
For more information about how the Django project issues new releases for security purposes, please see our security policies.

Feature release

Feature releases (A.B, A.B+1, etc.) will happen roughly every eight months – see release process for details. These releases will contain new features, improvements to existing features, and such.

Patch release

Patch releases (A.B.C, A.B.C+1, etc.) will be issued as needed, to fix bugs and/or security issues.

These releases will be 100% compatible with the associated feature release, unless this is impossible for security reasons or to prevent data loss. So the answer to “should I upgrade to the latest patch release?” will always be “yes.”

Long-term support release

Certain feature releases will be designated as long-term support (LTS) releases. These releases will get security and data loss fixes applied for a guaranteed period of time, typically three years.

See the download page for the releases that have been designated for long-term support.

10.5.2 Release cadence

Starting with Django 2.0, version numbers will use a loose form of semantic versioning such that each version following an LTS will bump to the next “dot zero” version. For example: 2.0, 2.1, 2.2 (LTS), 3.0, 3.1, 3.2 (LTS), etc.

SemVer makes it easier to see at a glance how compatible releases are with each other. It also helps to anticipate when compatibility shims will be removed. It’s not a pure form of SemVer as each feature release will continue to have a few documented backwards incompatibilities where a deprecation path isn’t possible or not worth the cost. Also, deprecations started in an LTS release (X.2) will be dropped in a non-dot-zero release (Y.1) to accommodate our policy of keeping deprecation shims for at least two feature releases. Read on to the next section for an example.

10.5.3 Deprecation policy

A feature release may deprecate certain features from previous releases. If a feature is deprecated in feature release A.x, it will continue to work in all A.x versions (for all versions of x) but raise warnings. Deprecated features will be removed in the B.0 release, or B.1 for features deprecated in the last A.x feature release to ensure deprecations are done over at least 2 feature releases.

So, for example, if we decided to start the deprecation of a function in Django 4.2:

• Django 4.2 will contain a backwards-compatible replica of the function which will raise a RemovedInDjango51Warning.

• Django 5.0 (the version that follows 4.2) will still contain the backwards-compatible replica.
• Django 5.1 will remove the feature outright.

The warnings are silent by default. You can turn on display of these warnings with the `python -Wd` option.

A more generic example:

• X.0
• X.1
• X.2 LTS
• Y.0: Drop deprecation shims added in X.0 and X.1.
• Y.1: Drop deprecation shims added in X.2.
• Y.2 LTS: No deprecation shims dropped (while Y.0 is no longer supported, third-party apps need to maintain compatibility back to X.2 LTS to ease LTS to LTS upgrades).
• Z.0: Drop deprecation shims added in Y.0 and Y.1.

See also the Deprecating a feature guide.

### 10.5.4 Supported versions

At any moment in time, Django’s developer team will support a set of releases to varying levels. See the supported versions section of the download page for the current state of support for each version.

• The current development branch `main` will get new features and bug fixes requiring non-trivial refactoring.

• Patches applied to the main branch must also be applied to the last feature release branch, to be released in the next patch release of that feature series, when they fix critical problems:
  
  – Security issues.
  – Data loss bugs.
  – Crashing bugs.
  – Major functionality bugs in new features of the latest stable release.
  – Regressions from older versions of Django introduced in the current release series.

The rule of thumb is that fixes will be backported to the last feature release for bugs that would have prevented a release in the first place (release blockers).

• Security fixes and data loss bugs will be applied to the current main branch, the last two feature release branches, and any other supported long-term support release branches.

• Documentation fixes generally will be more freely backported to the last release branch. That’s because it’s highly advantageous to have the docs for the last release be up-to-date and correct, and the risk of introducing regressions is much less of a concern.
As a concrete example, consider a moment in time halfway between the release of Django 5.1 and 5.2. At this point in time:

- Features will be added to the development main branch, to be released as Django 5.2.
- Critical bug fixes will be applied to the `stable/5.1.x` branch, and released as 5.1.1, 5.1.2, etc.
- Security fixes and bug fixes for data loss issues will be applied to `main` and to the `stable/5.1.x`, `stable/5.0.x`, and `stable/4.2.x` (LTS) branches. They will trigger the release of 5.1.1, 5.0.5, 4.2.8, etc.
- Documentation fixes will be applied to `main`, and, if easily backported, to the latest stable branch, 5.1.x.

### 10.5.5 Release process

Django uses a time-based release schedule, with feature releases every eight months or so.

After each feature release, the release manager will announce a timeline for the next feature release.

#### Release cycle

Each release cycle consists of three parts:

**Phase one: feature proposal**

The first phase of the release process will include figuring out what major features to include in the next version. This should include a good deal of preliminary work on those features – working code trumps grand design.

Major features for an upcoming release will be added to the wiki roadmap page, e.g. https://code.djangoproject.com/wiki/Version1.11Roadmap.

**Phase two: development**

The second part of the release schedule is the “heads-down” working period. Using the roadmap produced at the end of phase one, we’ll all work very hard to get everything on it done.

At the end of phase two, any unfinished features will be postponed until the next release.

Phase two will culminate with an alpha release. At this point, the `stable/A.B.x` branch will be forked from `main`.
Phase three: bugfixes

The last part of a release cycle is spent fixing bugs – no new features will be accepted during this time. We’ll try to release a beta release one month after the alpha and a release candidate one month after the beta.

The release candidate marks the string freeze, and it happens at least two weeks before the final release. After this point, new translatable strings must not be added.

During this phase, mergers will be more and more conservative with backports, to avoid introducing regressions. After the release candidate, only release blockers and documentation fixes should be backported.

In parallel to this phase, main can receive new features, to be released in the A.B+1 cycle.

Bug-fix releases

After a feature release (e.g. A.B), the previous release will go into bugfix mode.

The branch for the previous feature release (e.g. stable/A.B-1.x) will include bugfixes. Critical bugs fixed on main must also be fixed on the bugfix branch; this means that commits need to cleanly separate bug fixes from feature additions. The developer who commits a fix to main will be responsible for also applying the fix to the current bugfix branch.

10.6 Django Deprecation Timeline

This document outlines when various pieces of Django will be removed or altered in a backward incompatible way, following their deprecation, as per the deprecation policy. More details about each item can often be found in the release notes of two versions prior.

10.6.1 5.1

See the Django 4.2 release notes for more details on these changes.

- The BaseUserManager.make_random_password() method will be removed.

10.6.2 5.0

See the Django 4.0 release notes for more details on these changes.

- The SERIALIZE test setting will be removed.
- The undocumented django.utils.baseconv module will be removed.
- The undocumented django.utils.datetime_safe module will be removed.
- The default value of the USE_TZ setting will change from False to True.
• The default sitemap protocol for sitemaps built outside the context of a request will change from 'http' to 'https'.

• The `extra_tests` argument for `DiscoverRunner.build_suite()` and `DiscoverRunner.run_tests()` will be removed.

• The `django.contrib.postgres.aggregates.ArrayAgg`, `JSONBAgg`, and `StringAgg` aggregates will return `None` when there are no rows instead of `[]`, `[]`, and `'` respectively.

• The `USE_L10N` setting will be removed.

• The `USE_DEPRECATED_PYTZ` transitional setting will be removed.

• Support for `pytz` timezones will be removed.

• The `is_dst` argument will be removed from:
  - `QuerySet.datetimes()`
  - `django.utils.timezone.make_aware()`
  - `django.db.models.functions.Trunc()`
  - `django.db.models.functions.TruncSecond()`
  - `django.db.models.functions.TruncMinute()`
  - `django.db.models.functions.TruncHour()`
  - `django.db.models.functions.TruncDay()`
  - `django.db.models.functions.TruncWeek()`
  - `django.db.models.functions.TruncMonth()`
  - `django.db.models.functions.TruncQuarter()`
  - `django.db.models.functions.TruncYear()`

• The `django.contrib.gis.admin.GeoModelAdmin` and `OSMGeoAdmin` classes will be removed.

• The undocumented `BaseForm._html_output()` method will be removed.

• The ability to return a `str`, rather than a `SafeString`, when rendering an `ErrorDict` and `ErrorList` will be removed.

See the **Django 4.1 release notes** for more details on these changes.

• The `SitemapIndexItem.__str__()` method will be removed.

• The `CSRFCOOKIE_MASKED` transitional setting will be removed.

• The `name` argument of `django.utils.functional.cached_property()` will be removed.

• The `opclasses` argument of `django.contrib.postgres.constraints.ExclusionConstraint` will be removed.
- The undocumented ability to pass errors=None to SimpleTestCase.assertFormError() and assertFormsetError() will be removed.

- django.contrib.sessions.serializers.PickleSerializer will be removed.

- The usage of QuerySet.iterator() on a queryset that prefetches related objects without providing the chunk_size argument will no longer be allowed.

- Passing unsaved model instances to related filters will no longer be allowed.

- created=True will be required in the signature of RemoteUserBackend.configure_user() subclasses.

- Support for logging out via GET requests in the django.contrib.auth.views.LogoutView and django.contrib.auth.views.logout_then_login() will be removed.

- The django.utils.timezone.utc alias to datetime.timezone.utc will be removed.

- Passing a response object and a form/formset name to SimpleTestCase.assertFormError() and assertFormsetError() will no longer be allowed.

- The django.contrib.gis.admin.OpenLayersWidget will be removed.

- The django.contrib.auth.hashers.CryptPasswordHasher will be removed.

- The "django/forms/default.html" and "django/forms/formsets/default.html" templates will be removed.

- The ability to pass nulls_first=False or nulls_last=False to Expression.asc() and Expression.desc() methods, and the OrderBy expression will be removed.

10.6.3 4.1

See the Django 3.2 release notes for more details on these changes.

- Support for assigning objects which don’t support creating deep copies with copy.deepcopy() to class attributes in TestCase.setUpTestData() will be removed.

- BaseCommand.requires_system_checks won’t support boolean values.

- The whitelist argument and domain_whitelist attribute of django.core.validators.EmailValidator will be removed.

- The default_app_config module variable will be removed.

- TransactionTestCase.assertQuerysetEqual() will no longer automatically call repr() on a queryset when compared to string values.

- django.core.cache.backends.memcached.MemcachedCache will be removed.

- Support for the pre-Django 3.2 format of messages used by django.contrib.messages.storage.cookie.CookieStorage will be removed.
10.6.4 4.0

See the Django 3.0 release notes for more details on these changes.

- `django.utils.http.urlquote()`, `urlquote_plus()`, `urlunquote()`, and `urlunquote_plus()` will be removed.
- `django.utils.encoding.force_text()` and `smart_text()` will be removed.
- `django.utils.translation.ugettext()`, `ugettext_lazy()`, `ugettext_noop()`, `ungettext()`, and `ungettext_lazy()` will be removed.
- `django.views.i18n.set_language()` will no longer set the user language in `request.session` (key `django.utils.translation.LANGUAGE_SESSION_KEY`).
- `alias=None` will be required in the signature of `django.db.models.Expression.get_group_by_cols()` subclasses.
- `django.utils.text.unescape_entities()` will be removed.
- `django.utils.http.is_safe_url()` will be removed.

See the Django 3.1 release notes for more details on these changes.

- The `PASSWORD_RESET_TIMEOUT_DAYS` setting will be removed.
- The undocumented usage of the `isnull` lookup with non-boolean values as the right-hand side will no longer be allowed.
- The `django.db.models.query_utils.InvalidQuery` exception class will be removed.
- The `django-admin.py` entry point will be removed.
- The `HttpRequest.is_ajax()` method will be removed.
- Support for the pre-Django 3.1 encoding format of cookies values used by `django.contrib.messages.storage.cookie.CookieStorage` will be removed.
- Support for the pre-Django 3.1 password reset tokens in the admin site (that use the SHA-1 hashing algorithm) will be removed.
- Support for the pre-Django 3.1 encoding format of sessions will be removed.
- Support for the pre-Django 3.1 encoding format of sessions will be removed.
- Support for the pre-Django 3.1 `django.core.signing.Signer` signatures (encoded with the SHA-1 algorithm) will be removed.
- Support for the pre-Django 3.1 `django.core.signing.dumps()` signatures (encoded with the SHA-1 algorithm) in `django.core.signing.loads()` will be removed.
- Support for the pre-Django 3.1 user sessions (that use the SHA-1 algorithm) will be removed.
- The `get_response` argument for `django.utils.deprecation.MiddlewareMixin.__init__()` will be required and won’t accept `None`. 
- The `providing_args` argument for `django.dispatch.Signal` will be removed.
- The `length` argument for `django.utils.crypto.get_random_string()` will be required.
- The list message for `ModelMultipleChoiceField` will be removed.
- Support for passing raw column aliases to `QuerySet.order_by()` will be removed.
- The model `NullBooleanField` will be removed. A stub field will remain for compatibility with historical migrations.
- `django.conf.urls.url()` will be removed.
- The model `django.contrib.postgres.fields.JSONField` will be removed. A stub field will remain for compatibility with historical migrations.
- `django.contrib.postgres.forms.JSONField`, `django.contrib.postgres.fields.jsonb.KeyTransform`, and `django.contrib.postgres.fields.jsonb.KeyTextTransform` will be removed.
- The `{% ifequal %}` and `{% ifnotequal %}` template tags will be removed.
- The `DEFAULT_HASHING_ALGORITHM` transitional setting will be removed.

**10.6.5 3.1**

See the [Django 2.2 release notes](https://docs.djangoproject.com/en/2.2/releases/2.2/) for more details on these changes.

- `django.utils.timezone.FixedOffset` will be removed.
- `django.core.paginator.QuerySetPaginator` will be removed.
- A model’s `Meta.ordering` will no longer affect `GROUP BY` queries.
- `django.contrib.postgres.fields.FloatRangeField` and `django.contrib.postgres.forms.FloatRangeField` will be removed.
- The `FILE_CHARSET` setting will be removed.
- `django.contrib.staticfiles.storage.CachedStaticFilesStorage` will be removed.
- `RemoteUserBackend.configure_user()` will require `request` as the first positional argument.
- Support for `SimpleTestCase.allow_database_queries` and `TransactionTestCase.multi_db` will be removed.
**10.6.6 3.0**

See the [Django 2.0 release notes](https://docs.djangoproject.com/en/3.0/releases/2.0/) for more details on these changes.

- The `django.db.backends.postgresql_psycopg2` module will be removed.
- `django.shortcuts.render_to_response()` will be removed.
- The `DEFAULT_CONTENT_TYPE` setting will be removed.
- `HttpRequest.xreadlines()` will be removed.
- Support for the `context` argument of `Field.from_db_value()` and `Expression.convert_value()` will be removed.
- The `field_name` keyword argument of `QuerySet.earliest()` and `latest()` will be removed.

See the [Django 2.1 release notes](https://docs.djangoproject.com/en/2.1/releases/2.1/) for more details on these changes.

- `django.contrib.gis.db.models.functions.ForceRHR` will be removed.
- `django.utils.http.cookie_date()` will be removed.
- The `staticfiles` and `admin_static` template tag libraries will be removed.
- `django.contrib.staticfiles.templatetags.static()` will be removed.
- The shim to allow `InlineModelAdmin.has_add_permission()` to be defined without an `obj` argument will be removed.

**10.6.7 2.1**

See the [Django 1.11 release notes](https://docs.djangoproject.com/en/1.11/releases/1.11/) for more details on these changes.

- `contrib.auth.views.login()`, `logout()`, `password_change()`, `password_change_done()`, `password_reset()`, `password_reset_done()`, `password_reset_confirm()`, and `password_reset_complete()` will be removed.
- The `extra_context` parameter of `contrib.auth.views.logout_then_login()` will be removed.
- `django.test.runner.setup_databases()` will be removed.
- `django.utils.translation.string_concat()` will be removed.
- `django.core.cache.backends.memcached.PyLibMCCache` will no longer support passing pylibmc behavior settings as top-level attributes of `OPTIONS`.
- The `host` parameter of `django.utils.http.is_safe_url()` will be removed.
- Silencing of exceptions raised while rendering the `{% include %}` template tag will be removed.
- `DatabaseIntrospection.get_indexes()` will be removed.
• The `authenticate()` method of authentication backends will require `request` as the first positional argument.
• The `django.db.models.permalink()` decorator will be removed.
• The `USE_ETAGS` setting will be removed. `CommonMiddleware` and `django.utils.cache.patch_response_headers()` will no longer set ETags.
• The `Model._meta.has_auto_field` attribute will be removed.
• `url()`’s support for inline flags in regular expression groups ((?i), (?L), (?m), (?s), and (?u)) will be removed.
• Support for `Widget.render()` methods without the `renderer` argument will be removed.

10.6.8 2.0

See the Django 1.9 release notes for more details on these changes.

• The `weak` argument to `django.dispatch.signals.Signal.disconnect()` will be removed.
• `django.db.backends.base.BaseDatabaseOperations.check_aggregate_support()` will be removed.
• The `django.forms.extras` package will be removed.
• The `assignment_tag` helper will be removed.
• The `host` argument to `assertsRedirects` will be removed. The compatibility layer which allows absolute URLs to be considered equal to relative ones when the path is identical will also be removed.
• `Field.rel` will be removed.
• `Field.remote_field.to` attribute will be removed.
• The `on_delete` argument for `ForeignKey` and `OneToOneField` will be required.
• `django.db.models.fields.add_lazy_relation()` will be removed.
• When time zone support is enabled, database backends that don’t support time zones won’t convert aware datetimes to naive values in UTC anymore when such values are passed as parameters to SQL queries executed outside of the ORM, e.g. with `cursor.execute()`.
• The `django.contrib.auth.tests.utils.skipIfCustomUser()` decorator will be removed.
• The `GeoManager` and `GeoQuerySet` classes will be removed.
• The `django.contrib.gis.geoip` module will be removed.
• The `supports_recursion` check for template loaders will be removed from:
  - `django.template.engine.Engine.find_template()`
  - `django.template.loader_tags.ExtendsNode.find_template()`
- `django.template.loaders.base.Loader.supports_recursion()`
- `django.template.loaders.cached.Loader.supports_recursion()`

- The `load_template()` and `load_template_sources()` template loader methods will be removed.
- The `template_dirs` argument for template loaders will be removed:
  - `django.template.loaders.base.Loader.get_template()`
  - `django.template.loaders.cached.Loader.cache_key()`
  - `django.template.loaders.cached.Loader.get_template()`
  - `django.template.loaders.cached.Loader.get_template_sources()`
  - `django.template.loaders.filesystem.Loader.get_template_sources()`

- The `django.template.loaders.base.Loader.__call__() ` method will be removed.
- Support for custom error views with a single positional parameter will be dropped.
- The `mime_type` attribute of `django.utils.feedgenerator.Atom1Feed` and `django.utils.feedgenerator.RssFeed` will be removed in favor of `content_type`.
- The `app_name` argument to `django.conf.urls.include()` will be removed.
- Support for passing a 3-tuple as the first argument to `include()` will be removed.
- Support for setting a URL instance namespace without an application namespace will be removed.
- `Field._get_val_from_obj()` will be removed in favor of `Field.value_from_object()`.
- `django.template.loaders.eggs.Loader` will be removed.
- The `current_app` parameter to the `contrib.auth` views will be removed.
- The `callable_obj` keyword argument to `SimpleTestCase.assertRaisesMessage()` will be removed.
- Support for the `allow_tags` attribute on `ModelAdmin` methods will be removed.
- The `enclosure` keyword argument to `SyndicationFeed.add_item()` will be removed.
- The `django.template.loader.LoaderOrigin` and `django.template.base.StringOrigin` aliases for `django.template.base.Origin` will be removed.

See the [Django 1.10 release notes](https://docs.djangoproject.com/en/1.10/releases/1.10/) for more details on these changes.

- The `makemigrations --exit` option will be removed.
- Support for direct assignment to a reverse foreign key or many-to-many relation will be removed.
- The `get_srid()` and `set_srid()` methods of `django.contrib.gis.geos.GEOSGeometry` will be removed.
- The `get_x()`, `set_x()`, `get_y()`, `set_y()`, `get_z()`, and `set_z()` methods of `django.contrib.gis.geos.Point` will be removed.
- The `get_coords()` and `set_coords()` methods of `django.contrib.gis.geos.Point` will be removed.
- The `cascaded_union` property of `django.contrib.gis.geos.MultiPolygon` will be removed.
- `django.utils.functional.allow_lazy()` will be removed.
- The `shell --plain` option will be removed.
- The `django.core.urlresolvers` module will be removed.
- The model `CommaSeparatedIntegerField` will be removed. A stub field will remain for compatibility with historical migrations.
- Support for the template `Context.has_key()` method will be removed.
- Support for the `django.core.files.storage.Storage.accessed_time()`, `created_time()`, and `modified_time()` methods will be removed.
- Support for query lookups using the model name when `Meta.default_related_name` is set will be removed.
- The `_search` query lookup and the `DatabaseOperations.fulltext_search_sql()` method will be removed.
- The shim for supporting custom related manager classes without a `_apply_rel_filters()` method will be removed.
- Using `User.is_authenticated()` and `User.is_anonymous()` as methods will no longer be supported.
- The private attribute `virtual_fields` of `Model._meta` will be removed.
- The private keyword arguments `virtual_only` in `Field.contribute_to_class()` and `virtual` in `Model._meta.add_field()` will be removed.
- The `javascript_catalog()` and `json_catalog()` views will be removed.
- The `django.contrib.gis.utils.precision_wkt()` function will be removed.
- In multi-table inheritance, implicit promotion of a `OneToOneField` to a `parent_link` will be removed.
- Support for `Widget._format_value()` will be removed.
- `FileField` methods `get_directory_name()` and `get_filename()` will be removed.
- The `mark_for_escaping()` function and the classes it uses: `EscapeData`, `EscapeBytes`, `EscapeText`, `EscapeString`, and `EscapeUnicode` will be removed.
- The `escape` filter will change to use `django.utils.html.conditional_escape()`.
- `Manager.use_for_related_fields` will be removed.
- Model `Manager` inheritance will follow MRO inheritance rules and the `Meta.manager_inheritance_from_future` to opt-in to this behavior will be removed.
- Support for old-style middleware using `settings.MIDDLEWARE_CLASSES` will be removed.
10.6.9 1.10

See the Django 1.8 release notes for more details on these changes.

- Support for calling a SQLCompiler directly as an alias for calling its quote_name_unless_alias method will be removed.

- cycle and firstof template tags will be removed from the future template tag library (used during the 1.6/1.7 deprecation period).

- django.conf.urls.patterns() will be removed.

- Support for the prefix argument to django.conf.urls.i18n.i18n_patterns() will be removed.

- SimpleTestCase.urls will be removed.

- Using an incorrect count of unpacked values in the for template tag will raise an exception rather than fail silently.

- The ability to reverse URLs using a dotted Python path will be removed.

- The ability to use a dotted Python path for the LOGIN_URL and LOGIN_REDIRECT_URL settings will be removed.

- Support for optparse will be dropped for custom management commands (replaced by argparse).

- The class django.core.management.NoArgsCommand will be removed. Use BaseCommand instead, which takes no arguments by default.

- django.core.context_processors module will be removed.

- django.db.models.sql.aggregates module will be removed.

- django.contrib.gis.db.models.sql.aggregates module will be removed.

- The following methods and properties of django.db.sql.query.Query will be removed:
  - Properties: aggregates and aggregate_select
  - Methods: add_aggregate, set_aggregate_mask, and append_aggregate_mask.

- django.template.resolve_variable will be removed.

- The following private APIs will be removed from django.db.models.options.Options (Model._meta):
  - get_field_by_name()
  - get_all_field_names()
  - get_fields_with_model()
  - get_concrete_fields_with_model()
  - get_m2m_with_model()
- `get_all_related_objects()`
- `get_all_related_objects_with_model()`
- `get_all_related_many_to_many_objects()`
- `get_all_related_m2m_objects_with_model()`

• The `error_message` argument of `django.forms.RegexField` will be removed.
• The unordered list filter will no longer support old style lists.
• Support for string view arguments to `url()` will be removed.
• The backward compatible shim to rename `django.forms.Form._has_changed()` to `has_changed()` will be removed.
• The `removetags` template filter will be removed.
• The `remove_tags()` and `strip_entities()` functions in `django.utils.html` will be removed.
• The `is_admin_site` argument to `django.contrib.auth.views.password_reset()` will be removed.
• `django.db.models.field.subclassing.SubfieldBase` will be removed.
• `django.utils.checksums` will be removed; its functionality is included in `django-localflavor` 1.1+.
• The original `content_type_id` attribute on `django.contrib.admin.helpers.InlineAdminForm` will be removed.
• The backwards compatibility shim to allow `FormMixin.get_form()` to be defined with no default value for its `form_class` argument will be removed.
• The following settings will be removed:
  - ALLOWED_INCLUDE_ROOTS
  - TEMPLATE_CONTEXT_PROCESSORS
  - TEMPLATE_DEBUG
  - TEMPLATE_DIRS
  - TEMPLATE_LOADERS
  - TEMPLATE_STRING_IF_INVALID
• The backwards compatibility alias `django.template.loader.BaseLoader` will be removed.
• Django template objects returned by `get_template()` and `select_template()` won’t accept a `Context` in their `render()` method anymore.
• Template response APIs will enforce the use of `dict` and backend-dependent template objects instead of `Context` and `Template` respectively.
• The `current_app` parameter for the following function and classes will be removed:
  - `django.shortcuts.render()`
- django.template.Context()
- django.template.RequestContext()
- django.template.response.TemplateResponse()

• The dictionary and context_instance parameters for the following functions will be removed:
  - django.shortcuts.render()
  - django.shortcuts.render_to_response()
  - django.template.loader.render_to_string()

• The dirs parameter for the following functions will be removed:
  - django.template.loader.get_template()
  - django.template.loader.select_template()
  - django.shortcuts.render()
  - django.shortcuts.render_to_response()

• Session verification will be enabled regardless of whether or not 'django.contrib.auth.middleware.SessionAuthenticationMiddleware' is in MIDDLEWARE_CLASSES.

• Private attribute django.db.models.Field.related will be removed.

• The --list option of the migrate management command will be removed.

• The ssi template tag will be removed.

• Support for the = comparison operator in the if template tag will be removed.

• The backwards compatibility shims to allow Storage.get_available_name() and Storage.save() to be defined without a max_length argument will be removed.

• Support for the legacy %(<foo>)s syntax in ModelFormMixin.success_url will be removed.

• GeoQuerySet aggregate methods collect(), extent(), extent3d(), make_line(), and unionagg() will be removed.

• Ability to specify ContentType.name when creating a content type instance will be removed.

• Support for the old signature of allow_migrate will be removed. It changed from allow_migrate(self, db, model) to allow_migrate(self, db, app_label, model_name=None, **hints).

• Support for the syntax of {% cycle %} that uses comma-separated arguments will be removed.

• The warning that Signer issues when given an invalid separator will become an exception.
10.6.10 1.9

See the Django 1.7 release notes for more details on these changes.

- `django.utils.dictconfig` will be removed.
- `django.utils.importlib` will be removed.
- `django.utils.tzinfo` will be removed.
- `django.utils.unittest` will be removed.
- The `syncdb` command will be removed.
- `django.db.models.signals.pre_syncdb` and `django.db.models.signals.post_syncdb` will be removed.
- `allow_syncdb` on database routers will no longer automatically become `allow_migrate`.
- Automatic syncing of apps without migrations will be removed. Migrations will become compulsory for all apps unless you pass the `--run-syncdb` option to `migrate`.
- The SQL management commands for apps without migrations, `sql`, `sqlall`, `sqlclear`, `sqldropindexes`, and `sqlindexes`, will be removed.
- Support for automatic loading of `initial_data` fixtures and initial SQL data will be removed.
- All models will need to be defined inside an installed application or declare an explicit `app_label`. Furthermore, it won’t be possible to import them before their application is loaded. In particular, it won’t be possible to import models inside the root package of their application.
- The model and form `IPAddressField` will be removed. A stub field will remain for compatibility with historical migrations.
- `AppCommand.handle_app()` will no longer be supported.
- `RequestSite` and `get_current_site()` will no longer be importable from `django.contrib.sites.models`.
- FastCGI support via the `runfcgi` management command will be removed. Please deploy your project using WSGI.
- `django.utils.datastructures.SortedDict` will be removed. Use `collections.OrderedDict` from the Python standard library instead.
- `ModelAdmin.declared_fieldsets` will be removed.
- Instances of `util.py` in the Django codebase have been renamed to `utils.py` in an effort to unify all util and utils references. The modules that provided backwards compatibility will be removed:
  - `django.contrib.admin.util`
  - `django.contrib.gis.db.backends.util`
- `django.db.backends.util`
- `django.forms.util`

- `ModelAdmin.get_formsets` will be removed.
- The backward compatibility shim introduced to rename the `BaseMemcachedCache._get_memcache_timeout()` method to `get_backend_timeout()` will be removed.
- The `--natural` and `-n` options for `dumpdata` will be removed.
- The `use_natural_keys` argument for `serializers.serialize()` will be removed.
- Private API `django.forms.forms.get_declared_fields()` will be removed.
- The ability to use a `SplitDateTimeWidget` with `DateTimeField` will be removed.
- The `WSGIRequest.REQUEST` property will be removed.
- The class `django.utils.datastructures.MergeDict` will be removed.
- The `zh-cn` and `zh-tw` language codes will be removed and have been replaced by the `zh-hans` and `zh-hant` language code respectively.
- The internal `django.utils.functional.memoize` will be removed.
- `django.core.cache.get_cache` will be removed. Add suitable entries to `CACHES` and use `django.core.cache.caches` instead.
- `django.db.models.loading` will be removed.
- Passing callable arguments to querysets will no longer be possible.
- `BaseCommand.requires_model_validation` will be removed in favor of `requires_system_checks`. Admin validators will be replaced by admin checks.
- The `ModelAdmin.validator_class` and `default_validator_class` attributes will be removed.
- `ModelAdmin.validate()` will be removed.
- `django.db.backends.DatabaseValidation.validate_field` will be removed in favor of the `check_field` method.
- The `validate` management command will be removed.
- `django.utils.module_loading.import_by_path` will be removed in favor of `django.utils.module_loading.import_string`.
- `ssi` and `url` template tags will be removed from the `future` template tag library (used during the 1.3/1.4 deprecation period).
- `django.utils.text/javascript_quote` will be removed.
- Database test settings as independent entries in the database settings, prefixed by `TEST_`, will no longer be supported.
- The `cache_choices` option to `ModelChoiceField` and `ModelMultipleChoiceField` will be removed.
- The default value of the `RedirectView.permanent` attribute will change from `True` to `False`.
- `django.contrib.sitemaps.FlatPageSitemap` will be removed in favor of `django.contrib.flatpages.sitemaps.FlatPageSitemap`.
- Private API `django.test.utils.TestTemplateLoader` will be removed.
- The `django.contrib.contenttypes.generic` module will be removed.
- Private APIs `django.db.models.sql.where.WhereNode.make_atom()` and `django.db.models.sql.where.Constraint` will be removed.

### 10.6.11 1.8

See the [Django 1.6 release notes](https://docs.djangoproject.com/en/1.6/releases/1.6/) for more details on these changes.

- `django.contrib.comments` will be removed.
- The following transaction management APIs will be removed:
  - `TransactionMiddleware`,
  - the decorators and context managers `autocommit`, `commit_on_success`, and `commit_manually`, defined in `django.db.transaction`,
  - the functions `commit_unless_managed` and `rollback_unless_managed`, also defined in `django.db.transaction`,
  - the `TRANSACTIONS_MANAGED` setting.
- The `cycle` and `firstof` template tags will auto-escape their arguments. In 1.6 and 1.7, this behavior is provided by the version of these tags in the `future` template tag library.
- The `SEND_BROKEN_LINK_EMAILS` setting will be removed. Add the `django.middleware.common.BrokenLinkEmailsMiddleware` middleware to your `MIDDLEWARE_CLASSES` setting instead.
- `django.middleware.doc.XViewMiddleware` will be removed. Use `django.contrib.admindocs.middleware.XViewMiddleware` instead.
- `Model._meta.module_name` was renamed to `model_name`.
- Remove the backward compatible shims introduced to rename `get_query_set` and similar queryset methods. This affects the following classes: `BaseModelAdmin`, `ChangeList`, `BaseCommentNode`, `GenericType`, `Manager`, `SingleRelatedObjectDescriptor` and `ReverseSingleRelatedObjectDescriptor`.
- Remove the backward compatible shims introduced to rename the attributes `ChangeList.root_query_set` and `ChangeList.query_set`. 
• `django.views.defaults.shortcut` will be removed, as part of the goal of removing all `django.contrib` references from the core Django codebase. Instead use `django.contrib.contenttypes.views.shortcut`. `django.conf.urls.shortcut` will also be removed.

• Support for the Python Imaging Library (PIL) module will be removed, as it no longer appears to be actively maintained & does not work on Python 3.

• The following private APIs will be removed:
  – `django.db.backend`
  – `django.db.close_connection()`
  – `django.db.backends.creation.BaseDatabaseCreation.set_autocommit()`
  – `django.db.transaction.is_managed()`
  – `django.db.transaction.managed()`

• `django.forms.widgets.RadioInput` will be removed in favor of `django.forms.widgets.RadioChoiceInput`.

• The module `django.test.simple` and the class `django.test.simple.DjangoTestSuiteRunner` will be removed. Instead use `django.test.runner.DiscoverRunner`.

• The module `django.test._doctest` will be removed. Instead use the doctest module from the Python standard library.

• The `CACHE_MIDDLEWARE_ANONYMOUS_ONLY` setting will be removed.

• Usage of the hard-coded Hold down “Control”, or “Command” on a Mac, to select more than one. string to override or append to user-provided `help_text` in forms for ManyToMany model fields will not be performed by Django anymore either at the model or forms layer.

• The `Model._meta.get_(add|change|delete)_permission` methods will be removed.

• The session key `django_language` will no longer be read for backwards compatibility.

• Geographic Sitemaps will be removed (`django.contrib.gis.sitemaps.views.index` and `django.contrib.gis.sitemaps.views.sitemap`).

• `django.utils.html.fix_ampersands`, the `fix_ampersands` template filter and `django.utils.html.clean_html` will be removed following an accelerated deprecation.
**10.6.12 1.7**

See the Django 1.5 release notes for more details on these changes.

- The module `django.utils.simplejson` will be removed. The standard library provides `json` which should be used instead.

- The function `django.utils.itercompat.product` will be removed. The Python builtin version should be used instead.

- Auto-correction of INSTALLED_APPS and TEMPLATE_DIRS settings when they are specified as a plain string instead of a tuple will be removed and raise an exception.

- The `mimetype` argument to the `__init__` methods of `HttpResponse`, `SimpleTemplateResponse`, and `TemplateResponse`, will be removed. `content_type` should be used instead. This also applies to the `render_to_response()` shortcut and the sitemap views, `index()` and `sitemap()`.

- When `HttpResponse` is instantiated with an iterator, or when `content` is set to an iterator, that iterator will be immediately consumed.

- The `AUTH_PROFILE_MODULE` setting, and the `get_profile()` method on the User model, will be removed.

- The `cleanup` management command will be removed. It’s replaced by `clearsessions`.

- The `daily_cleanup.py` script will be removed.

- The `depth` keyword argument will be removed from `select_related()`.

- The undocumented `get_warnings_state() / restore_warnings_state()` functions from `django.test.utils` and the `save_warnings_state() / restore_warnings_state()` `django.test.*TestCase` methods are deprecated. Use the `warnings.catch_warnings` context manager available starting with Python 2.6 instead.

- The undocumented `check_for_test_cookie` method in `AuthenticationForm` will be removed following an accelerated deprecation. Users subclassing this form should remove calls to this method, and instead ensure that their auth related views are CSRF protected, which ensures that cookies are enabled.

- The version of `django.contrib.auth.views.password_reset_confirm()` that supports base36 encoded user IDs (`django.contrib.auth.views.password_reset_confirm_uidb36`) will be removed. If your site has been running Django 1.6 for more than `PASSWORD_RESET_TIMEOUT_DAYS`, this change will have no effect. If not, then any password reset links generated before you upgrade to Django 1.7 won’t work after the upgrade.

- The `django.utils.encoding.StrAndUnicode` mix-in will be removed.
10.6.13 1.6

See the Django 1.4 release notes for more details on these changes.

- `django.contrib.databrowse` will be removed.
- `django.contrib.localflavor` will be removed following an accelerated deprecation.
- `django.contrib.markup` will be removed following an accelerated deprecation.
- The compatibility modules `django.utils.copycompat` and `django.utils.hashcompat` as well as the functions `django.utils.itercompat.all` and `django.utils.itercompat.any` will be removed. The Python built-in versions should be used instead.
- The `csrf_response_exempt` and `csrf_view_exempt` decorators will be removed. Since 1.4 `csrf_response_exempt` has been a no-op (it returns the same function), and `csrf_view_exempt` has been a synonym for `django.views.decorators.csrf.csrf_exempt`, which should be used to replace it.
- The `django.core.cache.backends.memcached.CacheClass` backend was split into two in Django 1.3 in order to introduce support for PyLibMC. The historical `CacheClass` will be removed in favor of `django.core.cache.backends.memcached.MemcachedCache`.
- The UK-prefixed objects of `django.contrib.localflavor.uk` will only be accessible through their GB-prefixed names (GB is the correct ISO 3166 code for United Kingdom).
- The `IGNORABLE_404_STARTS` and `IGNORABLE_404_ENDS` settings have been superseded by `IGNORABLE_404_URLS` in the 1.4 release. They will be removed.
- The form wizard has been refactored to use class-based views with pluggable backends in 1.4. The previous implementation will be removed.
- Legacy ways of calling `cache_page()` will be removed.
- The backward-compatibility shim to automatically add a debug-false filter to the `mail_admins` logging handler will be removed. The `LOGGING` setting should include this filter explicitly if it is desired.
- The builtin truncation functions `django.utils.text.truncate_words()` and `django.utils.text.truncate_html_words()` will be removed in favor of the `django.utils.text.Truncator` class.
- The `django.contrib.gis.geoip.GeoIP` class was moved to `django.contrib.gis.geoip` in 1.4—the shortcut in `django.contrib.gis.utils` will be removed.
- `django.conf.urls.defaults` will be removed. The functions `include()`, `patterns()`, and `url()` plus `handler404` and `handler500` are now available through `django.conf.urls`.
- The functions `setup_environ()` and `execute_manager()` will be removed from `django.core.management`. This also means that the old (pre-1.4) style of `manage.py` file will no longer work.
- Setting the `is_safe` and `needs_autoescape` flags as attributes of template filter functions will no longer be supported.
• The attribute HttpRequest.raw_post_data was renamed to HttpRequest.body in 1.4. The backward compatibility will be removed –HttpRequest.raw_post_data will no longer work.

• The value for the post_url_continue parameter in ModelAdmin.response_add() will have to be either None (to redirect to the newly created object’s edit page) or a pre-formatted url. String formats, such as the previous default ‘../%s/’, will not be accepted any more.

**10.6.14 1.5**

See the Django 1.3 release notes for more details on these changes.

• Starting Django without a SECRET_KEY will result in an exception rather than a DeprecationWarning. (This is accelerated from the usual deprecation path; see the Django 1.4 release notes.)

• The mod_python request handler will be removed. The mod_wsgi handler should be used instead.

• The template attribute on django.test.client.Response objects returned by the test client will be removed. The templates attribute should be used instead.

• The django.test.simple.DjangoTestRunner will be removed. Instead use unittest-native class. The features of the django.test.simple.DjangoTestRunner (including fail-fast and Ctrl-C test termination) can be provided by unittest.TextTestRunner.

• The undocumented function django.contrib.formtools.utils.security_hash will be removed, instead use django.contrib.formtools.utils.form_hmac

• The function-based generic view modules will be removed in favor of their class-based equivalents, outlined here.

• The django.core.servers.basehttp.AdminMediaHandler will be removed. In its place use django.contrib.staticfiles.handlers.StaticFilesHandler.

• The template tags library adminmedia and the template tag {{ admin_media_prefix }} will be removed in favor of the generic static files handling. (This is faster than the usual deprecation path; see the Django 1.4 release notes.)

• The url and ssi template tags will be modified so that the first argument to each tag is a template variable, not an implied string. In 1.4, this behavior is provided by a version of the tag in the future template tag library.

• The reset and sqlreset management commands will be removed.

• Authentication backends will need to support an inactive user being passed to all methods dealing with permissions. The supports_inactive_user attribute will no longer be checked and can be removed from custom backends.

• transform() will raise a GEOSException when called on a geometry with no SRID value.

• **django.core.context_processors.PermWrapper** and **django.core.context_processors.PermLookupDict** will be removed in favor of the corresponding **django.contrib.auth.context_processors.PermWrapper** and **django.contrib.auth.context_processors.PermLookupDict**, respectively.

• The **MEDIA_URL** or **STATIC_URL** settings will be required to end with a trailing slash to ensure there is a consistent way to combine paths in templates.

• **django.db.models.fields.URLField.verify_exists** will be removed. The feature was deprecated in 1.3.1 due to intractable security and performance issues and will follow a slightly accelerated deprecation timeframe.

• Translations located under the so-called project path will be ignored during the translation building process performed at runtime. The **LOCALE_PATHS** setting can be used for the same task by including the filesystem path to a locale directory containing non-app-specific translations in its value.

• The Markup contrib app will no longer support versions of Python-Markdown library earlier than 2.1. An accelerated timeline was used as this was a security related deprecation.

• The **CACHE_BACKEND** setting will be removed. The cache backend(s) should be specified in the **CACHES** setting.

### 10.6.15 1.4

See the [Django 1.2 release notes](https://docs.djangoproject.com/en/1.2/releases/1.2/) for more details on these changes.

• **CsrfResponseMiddleware** and **CsrfMiddleware** will be removed. Use the `{% csrf_token %}` template tag inside forms to enable CSRF protection. **CsrfViewMiddleware** remains and is enabled by default.

• The old imports for CSRF functionality (**django.contrib.csrf.***), which moved to core in 1.2, will be removed.

• The **django.contrib.gis.db.backend** module will be removed in favor of the specific backends.

• **SMTPConnection** will be removed in favor of a generic email backend API.

• The many to many SQL generation functions on the database backends will be removed.

• The ability to use the **DATABASE_*** family of top-level settings to define database connections will be removed.

• The ability to use shorthand notation to specify a database backend (i.e., **sqlite3** instead of **django.db.backends.sqlite3**) will be removed.

• The **get_db_prep_save**, **get_db_prep_value** and **get_db_prep_lookup** methods will have to support multiple databases.

• The **Message** model (in **django.contrib.auth**), its related manager in the **User** model (**user.message_set**), and the associated methods (**user.message_set.create()** and **user.get_and_delete_messages()**), will be removed. The **messages framework** should be used instead.
The related `messages` variable returned by the auth context processor will also be removed. Note that this means that the admin application will depend on the messages context processor.

- Authentication backends will need to support the `obj` parameter for permission checking. The `supports_object_permissions` attribute will no longer be checked and can be removed from custom backends.

- Authentication backends will need to support the `AnonymousUser` class being passed to all methods dealing with permissions. The `supports_anonymous_user` variable will no longer be checked and can be removed from custom backends.

- The ability to specify a callable template loader rather than a `Loader` class will be removed, as will the `load_template_source` functions that are included with the built-in template loaders for backwards compatibility.

- `django.utils.translation.get_date_formats()` and `django.utils.translation.get_partial_date_formats()`. These functions will be removed; use the locale-aware `django.utils.formats.get_format()` to get the appropriate formats.

- In `django.forms.fields`, the constants: `DEFAULT_DATE_INPUT_FORMATS`, `DEFAULT_TIME_INPUT_FORMATS` and `DEFAULT_DATETIME_INPUT_FORMATS` will be removed. Use `django.utils.formats.get_format()` to get the appropriate formats.

- The ability to use a function-based test runner will be removed, along with the `django.test.simple.run_tests()` test runner.

- The `views.feed()` view and `feeds.Feed` class in `django.contrib.syndication` will be removed. The class-based view `views.Feed` should be used instead.

- `django.core.context_processors.auth`. This release will remove the old method in favor of the new method in `django.contrib.auth.context_processors.auth`.

- The `postgresql` database backend will be removed, use the `postgresql_psycopg2` backend instead.

- The `no` language code will be removed and has been replaced by the `nb` language code.

- Authentication backends will need to define the boolean attribute `supports_inactive_user` until version 1.5 when it will be assumed that all backends will handle inactive users.

- `django.db.models.fields.XMLField` will be removed. This was deprecated as part of the 1.3 release. An accelerated deprecation schedule has been used because the field hasn’t performed any role beyond that of a simple `TextField` since the removal of `oldforms`. All uses of `XMLField` can be replaced with `TextField`.

- The undocumented `mixin` parameter to the `open()` method of `django.core.files.storage.Storage` (and subclasses) will be removed.
10.6.16 1.3

See the Django 1.1 release notes for more details on these changes.

- **AdminSite.root()**. This method of hooking up the admin URLs will be removed in favor of including `admin.site.urls`.

- Authentication backends need to define the boolean attributes `supports_object_permissions` and `supports_anonymous_user` until version 1.4, at which point it will be assumed that all backends will support these options.

10.7 The Django source code repository

When deploying a Django application into a real production environment, you will almost always want to use an official packaged release of Django.

However, if you’d like to try out in-development code from an upcoming release or contribute to the development of Django, you’ll need to obtain a clone of Django’s source code repository.

This document covers the way the code repository is laid out and how to work with and find things in it.

10.7.1 High-level overview

The Django source code repository uses Git to track changes to the code over time, so you’ll need a copy of the Git client (a program called git) on your computer, and you’ll want to familiarize yourself with the basics of how Git works.

Git’s website offers downloads for various operating systems. The site also contains vast amounts of documentation.

The Django Git repository is located online at `github.com/django/django`. It contains the full source code for all Django releases, which you can browse online.

The Git repository includes several branches:

- **main** contains the main in-development code which will become the next packaged release of Django. This is where most development activity is focused.

- **stable/A.B.x** are the branches where release preparation work happens. They are also used for bugfix and security releases which occur as necessary after the initial release of a feature version.

The Git repository also contains tags. These are the exact revisions from which packaged Django releases were produced, since version 1.0.

A number of tags also exist under the `archive/` prefix for archived work.

The source code for the DjangoProject.com website can be found at `github.com/django/djangoproject.com`.
10.7.2 The main branch

If you’d like to try out the in-development code for the next release of Django, or if you’d like to contribute to Django by fixing bugs or developing new features, you’ll want to get the code from the main branch.

Note: Prior to March 2021, the main branch was called master.

Note that this will get all of Django: in addition to the top-level django module containing Python code, you’ll also get a copy of Django’s documentation, test suite, packaging scripts and other miscellaneous bits. Django’s code will be present in your clone as a directory named django.

To try out the in-development code with your own applications, place the directory containing your clone on your Python import path. Then import statements which look for Django will find the django module within your clone.

If you’re going to be working on Django’s code (say, to fix a bug or develop a new feature), you can probably stop reading here and move over to the documentation for contributing to Django, which covers things like the preferred coding style and how to generate and submit a patch.

10.7.3 Stable branches

Django uses branches to prepare for releases of Django. Each major release series has its own stable branch. These branches can be found in the repository as stable/A.B.x branches and will be created right after the first alpha is tagged.

For example, immediately after Django 1.5 alpha 1 was tagged, the branch stable/1.5.x was created and all further work on preparing the code for the final 1.5 release was done there.

These branches also provide bugfix and security support as described in Supported versions.

For example, after the release of Django 1.5, the branch stable/1.5.x receives only fixes for security and critical stability bugs, which are eventually released as Django 1.5.1 and so on, stable/1.4.x receives only security and data loss fixes, and stable/1.3.x no longer receives any updates.

Historical information

This policy for handling stable/A.B.x branches was adopted starting with the Django 1.5 release cycle.

Previously, these branches weren’t created until right after the releases and the stabilization work occurred on the main repository branch. Thus, no new feature development work for the next release of Django could be committed until the final release happened.

For example, shortly after the release of Django 1.3 the branch stable/1.3.x was created. Official support for that release has expired, and so it no longer receives direct maintenance from the Django project. How-
ever, that and all other similarly named branches continue to exist, and interested community members have occasionally used them to provide unofficial support for old Django releases.

## 10.7.4 Tags

Each Django release is tagged and signed by the releaser.

The tags can be found on GitHub’s [tags](https://github.com/django/django/tags) page.

### Archived feature-development work

Historical information

Since Django moved to Git in 2012, anyone can clone the repository and create their own branches, alleviating the need for official branches in the source code repository.

The following section is mostly useful if you’re exploring the repository’s history, for example if you’re trying to understand how some features were designed.

Feature-development branches tend by their nature to be temporary. Some produce successful features which are merged back into Django’s main branch to become part of an official release, but others do not; in either case, there comes a time when the branch is no longer being actively worked on by any developer.

At this point the branch is considered closed.

Django used to be maintained with the Subversion revision control system, that has no standard way of indicating this. As a workaround, branches of Django which are closed and no longer maintained were moved into [attic](https://github.com/django/django/commits/attic).

A number of tags exist under the `archive/` prefix to maintain a reference to this and other work of historical interest.

The following tags under the `archive/attic/` prefix reference the tip of branches whose code eventually became part of Django itself:

- **boulder-oracle-sprint**: Added support for Oracle databases to Django’s object-relational mapper. This has been part of Django since the 1.0 release.
- **gis**: Added support for geographic/spatial queries to Django’s object-relational mapper. This has been part of Django since the 1.0 release, as the bundled application `django.contrib.gis`.
- **i18n**: Added [internationalization support](https://docs.djangoproject.com/en/3.2/topics/i18n/) to Django. This has been part of Django since the 0.90 release.
- **magic-removal**: A major refactoring of both the internals and public APIs of Django’s object-relational mapper. This has been part of Django since the 0.95 release.
• multi-auth: A refactoring of Django’s bundled authentication framework which added support for authentication backends. This has been part of Django since the 0.95 release.

• new-admin: A refactoring of Django’s bundled administrative application. This became part of Django as of the 0.91 release, but was superseded by another refactoring (see next listing) prior to the Django 1.0 release.

• newforms-admin: The second refactoring of Django’s bundled administrative application. This became part of Django as of the 1.0 release, and is the basis of the current incarnation of django.contrib.admin.

• queryset-refactor: A refactoring of the internals of Django’s object-relational mapper. This became part of Django as of the 1.0 release.

• unicode: A refactoring of Django’s internals to consistently use Unicode-based strings in most places within Django and Django applications. This became part of Django as of the 1.0 release.

Additionally, the following tags under the archive/attic/ prefix reference the tips of branches that were closed, but whose code was never merged into Django, and the features they aimed to implement were never finished:

• full-history
• generic-auth
• multiple-db-support
• per-object-permissions
• schema-evolution
• schema-evolution-ng
• search-api
• sqlalchemy

Finally, under the archive/ prefix, the repository contains soc20XX/<project> tags referencing the tip of branches that were used by students who worked on Django during the 2009 and 2010 Google Summer of Code programs.

10.8 How is Django Formed?

This document explains how to release Django.

Please, keep these instructions up-to-date if you make changes! The point here is to be descriptive, not prescriptive, so feel free to streamline or otherwise make changes, but update this document accordingly!
10.8.1 Overview

There are three types of releases that you might need to make:

- Security releases: disclosing and fixing a vulnerability. This’ll generally involve two or three simultaneous releases – e.g. 1.5.x, 1.6.x, and, depending on timing, perhaps a 1.7 alpha/beta/rc.

- Regular version releases: either a final release (e.g. 1.5) or a bugfix update (e.g. 1.5.1).

- Pre-releases: e.g. 1.6 alpha, beta, or rc.

The short version of the steps involved is:

1. If this is a security release, pre-notify the security distribution list one week before the actual release.
2. Proofread the release notes, looking for organization and writing errors. Draft a blog post and email announcement.
3. Update version numbers and create the release package(s).
4. Upload the package(s) to the djangoproject.com server.
5. Upload the new version(s) to PyPI.
7. Post the blog entry and send out the email announcements.

There are a lot of details, so please read on.

10.8.2 Prerequisites

You’ll need a few things before getting started:

- A GPG key. If the key you want to use is not your default signing key, you’ll need to add -u you@example.com to every GPG signing command below, where you@example.com is the email address associated with the key you want to use.

- An install of some required Python packages:

  $ python -m pip install wheel twine

- Access to Django’s record on PyPI. Create a file with your credentials:
Listing 3: ~/.pypirc

[pypi]
username:YourUsername
password:YourPassword

- Access to the djangoproject.com server to upload files.
- Access to the admin on djangoproject.com as a “Site maintainer”.
- Access to post to django-announce.
- If this is a security release, access to the pre-notification distribution list.

If this is your first release, you’ll need to coordinate with another releaser to get all these things lined up.

10.8.3 Pre-release tasks

A few items need to be taken care of before even beginning the release process. This stuff starts about a week before the release; most of it can be done any time leading up to the actual release:

1. If this is a security release, send out pre-notification one week before the release. The template for that email and a list of the recipients are in the private django-security GitHub wiki. BCC the pre-notification recipients. Sign the email with the key you’ll use for the release and include CVE IDs (requested with Vendor: djangoproject, Product: django) and patches for each issue being fixed. Also, notify django-announce of the upcoming security release.

2. As the release approaches, watch Trac to make sure no release blockers are left for the upcoming release.

3. Check with the other mergers to make sure they don’t have any uncommitted changes for the release.

4. Proofread the release notes, including looking at the online version to catch any broken links or reST errors, and make sure the release notes contain the correct date.

5. Double-check that the release notes mention deprecation timelines for any APIs noted as deprecated, and that they mention any changes in Python version support.

6. Double-check that the release notes index has a link to the notes for the new release; this will be in docs/releases/index.txt.

7. If this is a feature release, ensure translations from Transifex have been integrated. This is typically done by a separate translation’s manager rather than the releaser, but here are the steps. Provided you have an account on Transifex:

   $ python scripts/manage_translations.py fetch

   and then commit the changed/added files (both .po and .mo). Sometimes there are validation errors which need to be debugged, so avoid doing this task immediately before a release is needed.
8. Update the django-admin manual page:

```
$ cd docs
$ make man
$ man _build/man/django-admin.1  # do a quick sanity check
$ cp _build/man/django-admin.1 man/django-admin.1
```

and then commit the changed man page.

9. If this is the alpha release of a new series, create a new stable branch from main. For example, when releasing Django 3.1:

```
$ git checkout -b stable/3.1.x origin/main
$ git push origin -u stable/3.1.x:stable/3.1.x
```

At the same time, update the django_next_version variable in docs/conf.py on the stable release branch to point to the new development version. For example, when creating stable/4.2.x, set django_next_version to '5.0' on the new branch.

10. If this is the “dot zero” release of a new series, create a new branch from the current stable branch in the django-docs-translations repository. For example, when releasing Django 2.2:

```
$ git checkout -b stable/2.2.x origin/stable/2.1.x
$ git push origin stable/2.2.x:stable/2.2.x
```

### 10.8.4 Preparing for release

Write the announcement blog post for the release. You can enter it into the admin at any time and mark it as inactive. Here are a few examples: example security release announcement, example regular release announcement, example pre-release announcement.

### 10.8.5 Actually rolling the release

OK, this is the fun part, where we actually push out a release!

1. Check Jenkins is green for the version(s) you’re putting out. You probably shouldn’t issue a release until it’s green.

2. A release always begins from a release branch, so you should make sure you’re on a stable branch and up-to-date. For example:

```
$ git checkout stable/1.5.x
$ git pull
```
3. If this is a security release, merge the appropriate patches from `django-security`. Rebase these patches as necessary to make each one a plain commit on the release branch rather than a merge commit. To ensure this, merge them with the `--ff-only` flag; for example:

```bash
$ git checkout stable/1.5.x
$ git merge --ff-only security/1.5.x
```

(This assumes `security/1.5.x` is a branch in the `django-security` repo containing the necessary security patches for the next release in the 1.5 series.)

If `git` refuses to merge with `--ff-only`, switch to the security-patch branch and rebase it on the branch you are about to merge it into (`git checkout security/1.5.x; git rebase stable/1.5.x`) and then switch back and do the merge. Make sure the commit message for each security fix explains that the commit is a security fix and that an announcement will follow (example `security` commit).

4. For a feature release, remove the `UNDER DEVELOPMENT` header at the top of the release notes and add the release date on the next line. For a patch release, replace `*Under Development*` with the release date. Make this change on all branches where the release notes for a particular version are located.

5. Update the version number in `django/__init__.py` for the release. Please see notes on setting the `VERSION` tuple below for details on `VERSION`.

6. If this is a pre-release package, update the “Development Status” trove classifier in `setup.cfg` to reflect this. Otherwise, make sure the classifier is set to `Development Status :: 5 - Production/Stable`.

7. Tag the release using `git tag`. For example:

```bash
$ git tag --sign --message="Tag 1.5.1" 1.5.1
```

You can check your work by running `git tag --verify <tag>`.

8. Push your work, including the tag: `git push --tags`.

9. Make sure you have an absolutely clean tree by running `git clean -dfx`.

10. Run `make -f extras/Makefile` to generate the release packages. This will create the release packages in a `dist/` directory.

11. Generate the hashes of the release packages:

```bash
$ cd dist
$ md5sum *
$ sha1sum *
$ sha256sum *
```

12. Create a “checkmarks” file, `Django-<VERSION>.checksum.txt` containing the hashes and release information. Start with this template and insert the correct version, date, GPG key ID (from `gpg --list-keys --keyid-format LONG`), release manager’s GitHub username, release URL, and check-sums:
This file contains MD5, SHA1, and SHA256 checksums for the source-code tarball and wheel files of Django <<VERSION>>, released <<DATE>>.

To use this file, you will need a working install of PGP or other compatible public-key encryption software. You will also need to have the Django release manager's public key in your keyring. This key has the ID `XXXXXXXXXXXXXXXX` and can be imported from the MIT keyserver, for example, if using the open-source GNU Privacy Guard implementation of PGP:

```bash
  gpg --keyserver pgp.mit.edu --recv-key XXXXXXXXXXXXXXXX
```
or via the GitHub API:

```bash
  curl https://github.com/<<RELEASE MANAGER GITHUB USERNAME>>.gpg | gpg --import -
```

Once the key is imported, verify this file:

```bash
  gpg --verify <<THIS FILENAME>>
```

Once you have verified this file, you can use normal MD5, SHA1, or SHA256 checksumming applications to generate the checksums of the Django package and compare them to the checksums listed below.

Release packages:

`------------------`

https://www.djangoproject.com/m/releases/<<RELEASE TAR.GZ FILENAME>>
https://www.djangoproject.com/m/releases/<<RELEASE WHL FILENAME>>

MD5 checksums:

`--------------`

<<MD5SUM>>  <<RELEASE TAR.GZ FILENAME>>
<<MD5SUM>>  <<RELEASE WHL FILENAME>>

SHA1 checksums:

`-------------`

<<SHA1SUM>>  <<RELEASE TAR.GZ FILENAME>>
<<SHA1SUM>>  <<RELEASE WHL FILENAME>>

SHA256 checksums:

`--------------`

(continues on next page)

If you’re issuing multiple releases, repeat these steps for each release.

### 10.8.6 Making the release(s) available to the public

Now you’re ready to actually put the release out there. To do this:

1. Upload the release package(s) to the djangoproject server, replacing A.B. with the appropriate version number, e.g. 1.5 for a 1.5.x release:

   ```bash
   $ scp Django-* djangoproject.com:/home/www/www/media/releases/A.B
   ```

   If this is the alpha release of a new series, you will need to create the directory A.B.

2. Upload the checksum file(s):

   ```bash
   ```

3. Test that the release packages install correctly using `pip`. Here’s one method:

   ```bash
   $ RELEASE_VERSION='1.7.2'
   $ MAJOR_VERSION=`echo $RELEASE_VERSION | cut -c 1-3`
   $ python -m venv django-pip
   $ . django-pip/bin/activate
   $ python -m pip install https://www.djangoproject.com/m/releases/$MAJOR_VERSION/Django-...$RELEASE_VERSION.tar.gz
   $ deactivate
   $ python -m venv django-pip-wheel
   $ . django-pip-wheel/bin/activate
   $ python -m pip install https://www.djangoproject.com/m/releases/$MAJOR_VERSION/Django-...$RELEASE_VERSION-py3-none-any.whl
   $ deactivate
   ```

   This just tests that the tarballs are available (i.e. redirects are up) and that they install correctly, but it’ll catch silly mistakes.
4. Ask a few people on IRC to verify the checksums by visiting the checksums file (e.g. https://media.djangoproject.com/pgp/Django-1.5b1.checksum.txt) and following the instructions in it. For bonus points, they can also unpack the downloaded release tarball and verify that its contents appear to be correct (proper version numbers, no stray .pyc or other undesirable files).

5. Upload the release packages to PyPI (for pre-releases, only upload the wheel file):

   ```bash
   $ twine upload -s dist/*
   ```

6. Go to the Add release page in the admin, enter the new release number exactly as it appears in the name of the tarball (Django-<version>.tar.gz). So for example enter “1.5.1” or “1.4c2”, etc. If the release is part of an LTS branch, mark it so.

   If this is the alpha release of a new series, also create a Release object for the final release, ensuring that the Release date field is blank, thus marking it as unreleased. For example, when creating the Release object for 3.1alpha1, also create 3.1 with the Release date field blank.

7. Make the blog post announcing the release live.

8. For a new version release (e.g. 1.5, 1.6), update the default stable version of the docs by flipping the `is_default` flag to True on the appropriate DocumentRelease object in the docs.djangoproject.com database (this will automatically flip it to False for all others); you can do this using the site’s admin.

   Create new DocumentRelease objects for each language that has an entry for the previous release. Update djangoproject.com’s robots.docs.txt file by copying entries from manage_translations.py robots_txt from the current stable branch in the django-docs-translations repository. For example, when releasing Django 2.2:

   ```bash
   $ git checkout stable/2.2.x
   $ git pull
   $ python manage_translations.py robots_txt
   ```

9. Post the release announcement to the django-announce, django-developers, and django-users mailing lists. This should include a link to the announcement blog post.

10. If this is a security release, send a separate email to oss-security@lists.openwall.com. Provide a descriptive subject, for example, “Django” plus the issue title from the release notes (including CVE ID). The message body should include the vulnerability details, for example, the announcement blog post text. Include a link to the announcement blog post.

11. Add a link to the blog post in the topic of the #django IRC channel: /msg chanserv TOPIC #django new topic goes here.
10.8.7 Post-release

You’re almost done! All that’s left to do now is:

1. Update the VERSION tuple in `django/__init__.py` again, incrementing to whatever the next expected release will be. For example, after releasing 1.5.1, update `VERSION` to `VERSION = (1, 5, 2, 'alpha', 0)`.

2. Add the release in Trac’s versions list if necessary (and make it the default by changing the `default_version` setting in the code.djangoproject.com’s trac.ini, if it’s a final release). The new X.Y version should be added after the alpha release and the default version should be updated after “dot zero” release.

3. If this was a security release, update Archive of security issues with details of the issues addressed.

10.8.8 New stable branch tasks

There are several items to do in the time following the creation of a new stable branch (often following an alpha release). Some of these tasks don’t need to be done by the releaser.

1. Create a new `DocumentRelease` object in the docs.djangoproject.com database for the new version’s docs, and update the docs/fixtures/doc_releases.json JSON fixture, so people without access to the production DB can still run an up-to-date copy of the docs site.

2. Create a stub release note for the new feature version. Use the stub from the previous feature release version or copy the contents from the previous feature version and delete most of the contents leaving only the headings.

3. Increase the default PBKDF2 iterations in `django.contrib.auth.hashers.PBKDF2PasswordHasher` by about 20% (pick a round number). Run the tests, and update the 3 failing hasher tests with the new values. Make sure this gets noted in the release notes (see the 1.8 release notes for an example).

4. Remove features that have reached the end of their deprecation cycle. Each removal should be done in a separate commit for clarity. In the commit message, add a “refs #XXXX” to the original ticket where the deprecation began if possible.

5. Remove .. versionadded::, .. versionadded::, and .. deprecated:: annotations in the documentation from two releases ago. For example, in Django 1.9, notes for 1.7 will be removed.

6. Add the new branch to Read the Docs. Since the automatically generated version names (“stable-A.B.x”) differ from the version names used in Read the Docs (“A.B.x”), create a ticket requesting the new version.

7. Request the new classifier on PyPI. For example `Framework :: Django :: 3.1`. 
10.8.9 Notes on setting the VERSION tuple

Django’s version reporting is controlled by the VERSION tuple in django/__init__.py. This is a five-element tuple, whose elements are:

1. Major version.
4. Status – can be one of “alpha”, “beta”, “rc” or “final”.
5. Series number, for alpha/beta/RC packages which run in sequence (allowing, for example, “beta 1”, “beta 2”, etc.).

For a final release, the status is always “final” and the series number is always 0. A series number of 0 with an “alpha” status will be reported as “pre-alpha”.

Some examples:

- (1, 2, 1, 'final', 0) → “1.2.1”
- (1, 3, 0, 'alpha', 0) → “1.3 pre-alpha”
- (1, 3, 0, 'beta', 2) → “1.3 beta 2”
