GPkit is a Python package for defining and manipulating geometric programming (GP) models.

Our hopes are to bring the mathematics of Geometric Programming into the engineering design process in a disciplined and collaborative way, and to encourage research with and on GPs by providing an easily extensible object-oriented framework.

GPkit abstracts away the backend solver so that users can work directly with engineering equations and optimization concepts. Supported solvers are MOSEK and CVXOPT.

Join our mailing list and/or chatroom for support and examples.
1.1 What is a GP?

A Geometric Program (GP) is a type of non-linear optimization problem whose objective and constraints have a particular form.

The decision variables must be strictly positive (non-zero, non-negative) quantities. This is a good fit for engineering design equations (which are often constructed to have only positive quantities), but any model with variables of unknown sign (such as forces and velocities without a predefined direction) may be difficult to express in a GP. Such models might be better expressed as Signomials.

More precisely, GP objectives and inequalities are formed out of monomials and posynomials. In the context of GP, a monomial is defined as:

\[ f(x) = cx_1^{a_1}x_2^{a_2}...x_n^{a_n} \]

where \( c \) is a positive constant, \( x_{1..n} \) are decision variables, and \( a_{1..n} \) are real exponents. For example, taking \( x, y \) and \( z \) to be positive variables, the expressions

\[ 7x \quad 4xy^2z \quad \frac{2x}{y^2z^{0.3}} \quad \sqrt{2xy} \]

are all monomials. Building on this, a posynomial is defined as a sum of monomials:

\[ g(x) = \sum_{k=1}^{K} c_kx_1^{a_{1,k}}x_2^{a_{2,k}}...x_n^{a_{n,k}} \]

For example, the expressions

\[ x^2 + 2xy + 1 \quad 7xy + 0.4(yz)^{-1/3} \quad 0.56 + \frac{x^{0.7}}{yz} \]

are all posynomials. Alternatively, monomials can be defined as the subset of posynomials having only one term. Using \( f_i \) to represent a monomial and \( g_i \) to represent a posynomial, a GP in standard form is
written as:

\[
\begin{align*}
\text{minimize} & \quad g_0(x) \\
\text{subject to} & \quad f_i(x) = 1, \quad i = 1, \ldots, m \\
& \quad g_i(x) \leq 1, \quad i = 1, \ldots, n
\end{align*}
\]

Boyd et. al. give the following example of a GP in standard form:

\[
\begin{align*}
\text{minimize} & \quad x^{-1}y^{-1/2}z^{-1} + 2.3xz + 4xyz \\
\text{subject to} & \quad (1/3)x^{-2}y^{-2} + (4/3)y^{1/2}z^{-1} \leq 1 \\
& \quad x + 2y + 3z \leq 1 \\
& \quad (1/2)xy = 1
\end{align*}
\]

1.2 Why are GPs special?

Geometric programs have several powerful properties:

1. Unlike most non-linear optimization problems, large GPs can be solved extremely quickly.
2. If there exists an optimal solution to a GP, it is guaranteed to be globally optimal.
3. Modern GP solvers require no initial guesses or tuning of solver parameters.

These properties arise because GPs become convex optimization problems via a logarithmic transformation. In addition to their mathematical benefits, recent research has shown that many practical problems can be formulated as GPs or closely approximated as GPs.

1.3 What are Signomials / Signomial Programs?

When the coefficients in a posynomial are allowed to be negative (but the variables stay strictly positive), that is called a Signomial.

A Signomial Program has signomial constraints. While they cannot be solved as quickly or to global optima, because they build on the structure of a GP they can often be solved more quickly than a generic nonlinear program. More information can be found under Signomial Programming.

1.4 Where can I learn more?

To learn more about GPs, refer to the following resources:

- A tutorial on geometric programming, by S. Boyd, S.J. Kim, L. Vandenberghe, and A. Hassibi.
- Convex optimization, by S. Boyd and L. Vandenberghe.
CHAPTER 2

Installation

1. If you are on Mac or Windows, we recommend installing Anaconda. Alternatively, install pip and create a virtual environment.

2. (optional) Install the MOSEK solver as directed below

3. Run `pip install gpkit` in the appropriate terminal or command prompt.

4. Open a Python prompt and run `import gpkit` to finish installation and run unit tests.

If you encounter any bugs please email gpkit@mit.edu or raise a GitHub issue.

2.1 Installing MOSEK

GPkit interfaces with two off the shelf solvers: cvxopt, and MOSEK. Cvxopt is open source and installed by default; MOSEK requires a commercial licence or (free) academic license.

Mac OS X

- If `which gcc` does not return anything, install the Apple Command Line Tools.
- Download MOSEK 8, then:
  - Move the mosek folder to your home directory
  - Follow these steps for Mac.
  - Request an academic license file and put it in `~/mosek/`

Linux

- Download MOSEK 8, then:
  - Move the mosek folder to your home directory
  - Follow these steps for Linux.
  - Request an academic license file and put it in `~/mosek/`
Windows

- Download MOSEK 8, then:
  - Follow these steps for Windows.
  - Request an academic license file and put it in C:\Users\(your_username)\mosek\n  - Make sure gcc is on your system path.
    * To do this, type gcc into a command prompt.
    * If you get executable not found, then install the 64-bit version (x86_64 installer architecture dropdown option) with GCC version 6.4.0 or older of mingw.
    * In an Anaconda command prompt (or equivalent), run cd C:\Program Files\mingw-w64\x86_64-6.4.0-posix-seh-rt_v5-rev0\ (or whatever corresponds to the correct installation directory; note that if mingw is in Program Files (x86) instead of Program Files you’ve installed the 32-bit version by mistake)
    * Run mingw-64 to add it to your executable path. For step 3 of the install process you’ll need to run pip install gpkit from this prompt.

2.2 Debugging your installation

You may need to rebuild GPkit if any of the following occur:

- You install MOSEK after installing GPkit
- You see Could not load settings file. when importing GPkit, or
- Could not load MOSEK library: ImportError('expopt.so not found.')

To rebuild GPkit run python -c "from gpkit.build import import rebuild; rebuild()".

If that doesn’t solve your issue then try the following:

- pip uninstall gpkit
- pip install --no-cache-dir --no-deps gpkit
- python -c "import gpkit.tests; gpkit.tests.run()"
- If any tests fail, please email gpkit@mit.edu or raise a GitHub issue.

2.3 Bleeding-edge installations

Active developers may wish to install the latest GPkit directly from Github. To do so,

1. pip uninstall gpkit to uninstall your existing GPkit.
2. git clone https://github.com/convexengineering/gpkit.git
3. pip install -e gpkit to install that directory as your environment-wide GPkit.
4. cd ..; python -c "import gpkit.tests; gpkit.tests.run()" to test your installation from a non-local directory.
GPkit is a Python package, so we assume basic familiarity with Python: if you’re new to Python we recommend you take a look at Learn Python. Otherwise, install GPkit and import away:

```python
from gpkit import Variable, VectorVariable, Model
```

### 3.1 Declaring Variables

Instances of the `Variable` class represent scalar variables. They create a `VarKey` to store the variable’s name, units, a description, and value (if the `Variable` is to be held constant), as well as other metadata.

#### 3.1.1 Free Variables

```python
# Declare a variable, x
x = Variable("x")

# Declare a variable, y, with units of meters
y = Variable("y", "m")

# Declare a variable, z, with units of meters, and a description
z = Variable("z", "m", "A variable called z with units of meters")
```

#### 3.1.2 Fixed Variables

To declare a variable with a constant value, use the `Variable` class, as above, but put a number before the units:
# Declare \( \rho \) equal to 1.225 kg/m\(^3\).
# NOTE: in python string literals, backslashes must be doubled
rho = Variable("\rho", 1.225, "kg/m\(^3\)", "Density of air at sea level")

In the example above, the key name "\( \rho \)" is for LaTeX printing (described later). The unit and description arguments are optional.

# Declare pi equal to 3.14
pi = Variable("\pi", 3.14)

## 3.1.3 Vector Variables

Vector variables are represented by the VectorVariable class. The first argument is the length of the vector. All other inputs follow those of the Variable class.

# Declare a 3-element vector variable "x" with units of "m"
x = VectorVariable(3, "x", "m", "Cube corner coordinates")
x_min = VectorVariable(3, "x", [1, 2, 3], "m", "Cube corner minimum")

### 3.2 Creating Monomials and Posynomials

Monomial and posynomial expressions can be created using mathematical operations on variables.

# create a Monomial term \( xy^2/z \)
x = Variable("x")
y = Variable("y")
z = Variable("z")
m = x * y**2 / z

# create a Posynomial expression \( x + xy^2 \)
x = Variable("x")
y = Variable("y")
p = x + x * y**2

### 3.3 Declaring Constraints

Constraint objects represent constraints of the form Monomial \( \geq \) Posynomial or Monomial \( \equiv \) Monomial (which are the forms required for GP-compatibility).

Note that constraints must be formed using \( \leq, \geq, \) or \( \equiv \) operators, not \( < \) or \( > \).

# consider a block with dimensions \( x, y, z \) less than 1
# constrain surface area less than 1.0 m\(^2\)
x = Variable("x", "m")
y = Variable("y", "m")
z = Variable("z", "m")
S = Variable("S", 1.0, "m\(^2\)"

c = (2*x*y + 2*x*z + 2*y*z \leq S)
type(c) # gpkit.nomials.PosynomialInequality
### 3.4 Formulating a Model

The `Model` class represents an optimization problem. To create one, pass an objective and list of Constraints.

By convention, the objective is the function to be minimized. If you wish to maximize a function, take its reciprocal. For example, the code below creates an objective which, when minimized, will maximize \( x \cdot y \cdot z \).

```python
objective = 1/(x*y*z)
constraints = [2*x*y + 2*x*z + 2*y*z <= S, x >= 2*y]
m = Model(objective, constraints)
```

### 3.5 Solving the Model

When solving the model you can change the level of information that gets printed to the screen with the `verbosity` setting. A verbosity of 1 (the default) prints warnings and timing; a verbosity of 2 prints solver output, and a verbosity of 0 prints nothing.

```python
sol = m.solve(verbosity=0)
```

### 3.6 Printing Results

The solution object can represent itself as a table:

```python
print sol.table()
```

```
Cost
----
  15.59 [1/m**3]

Free Variables
--------------
x : 0.5774 [m]
y : 0.2887 [m]
z : 0.3849 [m]

Constants
---------
S : 1 [m**2]

Sensitivities
-------------
S : -1.5
```

We can also print the optimal value and solved variables individually.

```python
print "The optimal value is $s." % sol["cost"]
print "The x dimension is $s." % sol(x)
print "The y dimension is $s." % sol["variables"]["y"]
```
The optimal value is 15.5884619886.
The x dimension is 0.5774 meter.
The y dimension is 0.2887 meter.

3.7 Sensitivities and dual variables

When a GP is solved, the solver returns not just the optimal value for the problem’s variables (known as the “primal solution”) but also the effect that relaxing each constraint would have on the overall objective (the “dual solution”).

From the dual solution GPkit computes the sensitivities for every fixed variable in the problem. This can be quite useful for seeing which constraints are most crucial, and prioritizing remodeling and assumption-checking.

3.7.1 Using variable sensitivities

Fixed variable sensitivities can be accessed from a SolutionArray’s "sensitivities"["constants"] dict, as in this example:

```python
import gpkit
x = gpkit.Variable("x")
x_min = gpkit.Variable("x_{min}”, 2)
sol = gpkit.Model(x, [x_min <= x]).solve()
assert sol["sensitivities"]["constants"][x_min] == 1
```

These sensitivities are actually log derivatives \( \frac{\text{d} \log(y)}{\text{d} \log(x)} \); whereas a regular derivative is a tangent line, these are tangent monomials, so the 1 above indicates that \( x_{\text{min}} \) has a linear relation with the objective. This is confirmed by a further example:

```python
import gpkit
x = gpkit.Variable("x")
x_squared_min = gpkit.Variable("x^{2}_{\text{min}}", 2)
sol = gpkit.Model(x, [x_squared_min <= x**2]).solve()
assert sol["sensitivities"]["constants"][x_squared_min] == 2
```
A number of errors and warnings may be raised when attempting to solve a model. A model may be primal infeasible: there is no possible solution that satisfies all constraints. A model may be dual infeasible: the optimal value of one or more variables is 0 or infinity (negative and positive infinity in logspace).

For a GP model that does not solve, solvers may be able to prove its primal or dual infeasibility, or may return an unknown status.

GPkit contains several tools for diagnosing which constraints and variables might be causing infeasibility. The first thing to do with a model \( m \) that won’t solve is to run \( m.debug() \), which will search for changes that would make the model feasible:

```python
"Debug examples"
from gpkit import Variable, Model, units
x = Variable("x", "ft")
x_min = Variable("x_min", 2, "ft")
x_max = Variable("x_max", 1, "ft")
y = Variable("y", "volts")

m = Model(x/y, [x <= x_max, x >= x_min])
m.debug()

print("# Now let's try a model unsolvable with relaxed constants\n")
Model(x, [x <= units("inch"), x >= units("yard")]).debug()

print("# And one that's only unbounded\n")

# the value of x_min was used up in the previous model!
x_min = Variable("x_min", 2, "ft")
Model(x/y, [x >= x_min]).debug()
```

< DEBUGGING >
> Trying with bounded variables and relaxed constants:

(continues on next page)
Solves with these variables bounded:
  value near upper bound: y
  sensitive to upper bound: y

and these constants relaxed:
  \( x_{\text{min}} \) [ft]: relaxed from 2 to 1

>> Success!

# Now let's try a model unsolvable with relaxed constants

< DEBUGGING >
> Trying with bounded variables and relaxed constants:
>> Failure.
> Trying with relaxed constraints:

Solves with these constraints relaxed:
  1: 3500% relaxed, from \( x \) [ft] >= 1 [yd]
      to 36\( x \) [ft] >= 1 [yd]

>> Success!

# And one that's only unbounded

< DEBUGGING >
> Trying with bounded variables and relaxed constants:

Solves with these variables bounded:
  value near upper bound: y
  sensitive to upper bound: y

>> Success!

Note that certain modeling errors (such as omitting or forgetting a constraint) may be difficult to diagnose from this output.

### 4.1 Potential errors and warnings

- **RuntimeWarning**: final status of solver 'mosek' was 'DUAL_INFEAS_CER', not 'optimal'
  - The solver found a certificate of dual infeasibility: the optimal value of one or more variables is 0 or infinity. See *Dual Infeasibility* below for debugging advice.

- **RuntimeWarning**: final status of solver 'mosek' was 'PRIM_INFEAS_CER', not 'optimal'
  - The solver found a certificate of primal infeasibility: no possible solution satisfies all constraints. See *Primal Infeasibility* below for debugging advice.

- **RuntimeWarning**: final status of solver 'cvxopt' was 'unknown', not 'optimal' or 'Run...
The solver could not solve the model or find a certificate of infeasibility. This may indicate a dual infeasible model, a primal infeasible model, or other numerical issues. Try debugging with the techniques in Dual and Primal Infeasibility below.

- RuntimeWarning: Primal solution violates constraint: 1.0000149786 is greater than 1
  - this warning indicates that the solver-returned solution violates a constraint of the model, likely because the solver’s tolerance for a final solution exceeds GPkit’s tolerance during solution checking. This is sometimes seen in dual infeasible models, see Dual Infeasibility below. If you run into this, please note on this GitHub issue your solver and operating system.

- RuntimeWarning: Dual cost nan does not match primal cost 1.00122315152
  - Similarly to the above, this warning may be seen in dual infeasible models, see Dual Infeasibility below.

### 4.2 Dual Infeasibility

In some cases a model will not solve because the optimal value of one or more variables is 0 or infinity (negative or positive infinity in logspace). Such a problem is dual infeasible because the GP’s dual problem, which determines the optimal values of the sensitivites, does not have any feasible solution. If the solver can prove that the dual is infeasible, it will return a dual infeasibility certificate. Otherwise, it may finish with a solution status of unknown.

gpkit.constraints.bounded.Bounded is a simple tool that can be used to detect unbounded variables and get dual infeasible models to solve by adding extremely large upper bounds and extremely small lower bounds to all variables in a ConstraintSet.

When a model with a Bounded ConstraintSet is solved, it checks whether any variables slid off to the bounds, notes this in the solution dictionary and prints a warning (if verbosity is greater than 0).

For example, Mosek returns DUAL_INFEAS_CER when attempting to solve the following model:

```
"Demonstrate a trivial unbounded variable"
from gpkit import Variable, Model
from gpkit.constraints.bounded import Bounded

x = Variable("x")
constraints = [x >= 1]

m = Model(1/x, constraints)  # MOSEK returns DUAL_INFEAS_CER on .solve()
m = Model(1/x, Bounded(constraints))
# by default, prints bounds warning during solve
sol = m.solve(verbosity=0)
print(sol.summary())
print("sol["boundedness"] is: "; sol["boundedness"])
```

Upon viewing the printed output,

```
Solves with these variables bounded:
  value near upper bound: x
  sensitive to upper bound: x
```

(continues on next page)
Cost
----
1e-30

Free Variables
-------------
x : 1e+30

Tightest Constraints
---------------------
+1 : x <= 1e+30

sol['boundedness'] is: {'value near upper bound': set([x]), 'sensitive to upper bound': set([x])}

The problem, unsurprisingly, is that the cost $1/x$ has no lower bound because $x$ has no upper bound. For details read the Bounded docstring.

4.3 Primal Infeasibility

A model is primal infeasible when there is no possible solution that satisfies all constraints. A simple example is presented below.

"A simple primal infeasible example"
from gpkit import Variable, Model

x = Variable("x")
y = Variable("y")

m = Model(x*y, [
x >= 1,
y >= 2,
x*y >= 0.5,
x*y <= 1.5
])

# m.solve() # raises unknown on cvxopt
# and PRIM_INFEAS_CER on mosek

It is not possible for $x*y$ to be less than 1.5 while $x$ is greater than 1 and $y$ is greater than 2.

A common bug in large models that use substitutions is to substitute overly constraining values in for variables that make the model primal infeasible. An example of this is given below.

"Another simple primal infeasible example"
from gpkit import Variable, Model

# Make the necessary Variables
x = Variable("x")
y = Variable("y", 2)

# make the constraints

(continues on next page)
4.3.1 Relaxation

If you suspect your model is primal infeasible, you can find the nearest primal feasible version of it by relaxing constraints: either relaxing all constraints by the smallest number possible (that is, dividing the less-than side of every constraint by the same number), relaxing each constraint by its own number and minimizing the product of those numbers, or changing each constant by the smallest total percentage possible.

"Relaxation examples"

```python
from gpkit import Variable, Model
x = Variable("x")
x_min = Variable("x_min", 2)
x_max = Variable("x_max", 1)
m = Model(x, [x <= x_max, x >= x_min])
print("Original model")
print(m)
print("")
# m.solve()  # raises a RuntimeWarning!

print("With constraints relaxed equally")
print(""icamente")
from gpkit.constraints.relax import ConstraintsRelaxedEqually
allrelaxed = ConstraintsRelaxedEqually(m)
mrelaxed = Model(allrelaxed.relaxvar, allrelaxed)
print(mrelaxed)
print(mrelaxed.solve(verbosity=0).table())  # solves with an x of 1.414
print(""

print("With constraints relaxed individually")
print(""
from gpkit.constraints.relax import ConstraintsRelaxed
constraintsrelaxed = ConstraintsRelaxed(m)
```
mr2 = Model(constraintsrelaxed.relaxvars.prod() * m.cost**0.01,
            # add a bit of the original cost in
            constraintsrelaxed)
print(mr2)
print(mr2.solve(verbosity=0).table())  # solves with an x of 1.0
print("")

print("With constants relaxed individually")
print("="*40)
from gpkit.constraints.relax import ConstantsRelaxed
constantsrelaxed = ConstantsRelaxed(m)
mr3 = Model(constantsrelaxed.relaxvars.prod() * m.cost**0.01,
            # add a bit of the original cost in
            constantsrelaxed)
print(mr3)
print(mr3.solve(verbosity=0).table())  # brings x_min down to 1.0
print("")

5.1 Sankey Diagrams

5.1.1 Requirements

- jupyter notebook
- ipysankeywidget

5.1.2 Example

Code in this section uses the CE solar model

```python
from solar import *
Vehicle = Aircraft(Npod=1, sp = False)
M = Mission(Vehicle, latitude=[20])
M.cost = M[M.aircraft.Wtotal]
sol = M.solve()

from gpkit.interactive.sankey import Sankey
Sankey(M).diagram(M.aircraft.Wtotal)
```

(objective) adds +1 to the sensitivity of Wtotal_Aircraft
(objective) is Wtotal_Aircraft [lbf]

adds +0.0075 to the overall sensitivity of Wtotal_Aircraft
is Wtotal_Aircraft <= 0.5*CL_Mission/Climb/AircraftDrag/WingAero_(0,)*S_→Aircraft/Wing/Planform.2*V_Mission/Climb_(0, 0)**2*rho_Mission/Climb_(0, 0)

adds +0.0117 to the overall sensitivity of Wtotal_Aircraft
is Wtotal_Aircraft <= 0.5*CL_Mission/Climb/AircraftDrag/WingAero_(1,)*S_→Aircraft/Wing/Planform.2*V_Mission/Climb_(0, 1)**2*rho_Mission/Climb_(0, 1)
5.1.3 Explanation

Sankey diagrams can be used to visualize sensitivity structure in a model. A blue flow from a constraint to its parent indicates that the sensitivity of the chosen variable (or of making the constraint easier, if no variable is given) is negative; that is, the objective of the overall model would improve if that variable’s value were increased in that constraint alone. Red indicates a positive sensitivity: the objective and the constraint ‘want’ that variable’s value decreased. Gray flows indicate a sensitivity whose absolute value is below $1e^{-7}$, i.e. a constraint that is inactive for that variable. Where equal red and blue flows meet, they cancel each other out to gray.

5.1.4 Usage

Variables

In a Sankey diagram of a variable, the variable is on the left with its final sensitivity; to the right of it are all constraints that variable is in.

Free

Free variables have an overall sensitivity of 0, so this visualization shows how the various pressures on that variable in all its constraints cancel each other out; this can get quite complex, as in this diagram of the pressures on wingspan:

```python
Sankey(M).diagram(M.aircraft.b)
```

Fixed

Fixed variables can have a nonzero overall sensitivity. Sankey diagrams can how that sensitivity comes together:

```python
Sankey(M).diagram(M['vgust'])
```

Equivalent Variables

If any variables are equal to the diagram’s variable (modulo some constant factor; e.g. $2x = y$ counts for this, as does $2x <= y$ if the constraint is sensitive), they are found and plotted at the same time, and all shown on the left. The constraints responsible for this are shown next to their labels.

```python
Sankey(M).sorted_by('constraints', 11)
```
Models

When created without a variable, the diagram shows the sensitivity of every named model to becoming locally easier. Because derivatives are additive, these sensitivities are too: a model’s sensitivity is equal to the sum of its constraints’ sensitivities. Gray lines in this diagram indicate models without any tight constraints.

Sankey(M).diagram(left=60, right=90, width=1050)

5.1.5 Syntax

<table>
<thead>
<tr>
<th>Code</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>s = Sankey(M)</td>
<td>Creates Sankey object of a given model</td>
</tr>
<tr>
<td>s.diagram(vars)</td>
<td>Creates the diagram in a way Jupyter knows how to present</td>
</tr>
<tr>
<td>d = s.diagram()</td>
<td><strong>Don’t do this!</strong> Captures output, preventing Jupyter from seeing it.</td>
</tr>
<tr>
<td>s.diagram(width=..)</td>
<td>Sets width in pixels. Same for height.</td>
</tr>
<tr>
<td>s.diagram(left=..)</td>
<td>Sets top margin in pixels. Same for right, top, bottom. Use if the left-hand text is being cut off.</td>
</tr>
<tr>
<td>s. diagram(flowright=True)</td>
<td>Shows the variable / top constraint on the right instead of the left.</td>
</tr>
<tr>
<td>s.sorted_by(&quot;maxflow&quot;, 0)</td>
<td>Creates diagram of the variable with the largest single constraint sensitivity. (change the 0 index to go down the list)</td>
</tr>
<tr>
<td>s.sorted_by(&quot;constraints&quot;, 0)</td>
<td>Creates diagram of the variable that’s in the most constraints. (change the 0 index to go down the list)</td>
</tr>
</tbody>
</table>

5.2 Plotting a 1D Sweep

Methods exist to facilitate creating, solving, and plotting the results of a single-variable sweep (see Sweeps for details). Example usage is as follows:

"Demonstrates manual and auto sweeping and plotting"
import matplotlib as mpl
mpl.use('Agg')
# comment out the lines above to show figures in a window
import numpy as np
from gpkit import Model, Variable, units
from gpkit.constraints.tight import Tight

x = Variable("x", "m", "Swept Variable")
y = Variable("y", "m^2", "Cost")
m = Model(y, [
    y >= (x/2)**-0.5 * units.m**2.5 + 1*units.m**2,
    Tight([y >= (x/2)**2])
])

# arguments are: model, swept: values, posnomial for y-axis

(continues on next page)
Which results in:
5.2. Plotting a 1D Sweep
6.1 Checking for result changes

Tracking the effects of changes to complex models can get out of hand; we recommend saving solutions with `sol.save()`, then checking that new solutions are almost equivalent with `sol1.almost_equal(sol2)` and/or `print sol1.diff(sol2)`, as shown below.

```python
import pickle
...
# build the model
sol = m.solve()
# uncomment the line below to verify a new model
# sol.save("last_verified.sol")
last_verified_sol = pickle.load(open("last_verified.sol"))
if not sol.almost_equal(last_verified_sol, reltol=1e-3):
    print last_verified_sol.diff(sol)

# Note you can replace the last three lines above with
print sol.diff("last_verified.sol")
# if you don't mind doing the diff in that direction.
```

You can also check differences between swept solutions, or between a point solution and a sweep.

6.2 Inheriting from Model

GPkit encourages an object-oriented modeling approach, where the modeler creates objects that inherit from `Model` to break large systems down into subsystems and analysis domains. The benefits of this approach include modularity, reusability, and the ability to more closely follow mental models of system hierarchy. For example: two different models for a simple beam, designed by different modelers, should be able to be used interchangeably inside another subsystem (such as an aircraft wing) without either modeler having to write specifically with that use in mind.
When you create a class that inherits from Model, write a .setup() method to create the model’s variables and return its constraints. GPkit.Model.__init__ will call that method and automatically add your model’s name and unique ID to any created variables.

Variables created in a setup method are added to the model even if they are not present in any constraints. This allows for simplistic ‘template’ models, which assume constant values for parameters and can grow incrementally in complexity as those variables are freed.

At the end of this page a detailed example shows this technique in practice.

### 6.3 Accessing Variables in Models

GPkit provides several ways to access a Variable in a Model (or ConstraintSet):

- using Model.variables_byname(key). This returns all Variables in the Model, as well as in any submodels, that match the key.
- using Model.__getitem__. Model[key] returns the only variable matching the key, even if the match occurs in a submodel. If multiple variables match the key, an error is raised.

These methods are illustrated in the following example.

```python
"Demo of accessing variables in models"
from gpkit import Model, Variable

class Battery(Model):
    """A simple battery
    
    Upper Unbounded
    ---------------
    m
    
    Lower Unbounded
    ---------------
    E
    ""
    def setup(self):
        h = Variable("h", 200, "Wh/kg", "specific energy")
        E = self.E = Variable("E", "MJ", "stored energy")
        m = self.m = Variable("m", "lb", "battery mass")
        return [E <= m*h]

class Motor(Model):
    """Electric motor
    
    Upper Unbounded
    ---------------
    m
    
    Lower Unbounded
    ---------------
    Pmax
    ""
```

(continues on next page)
def setup(self):
    m = self.m = Variable("m", "lb", "motor mass")
    f = Variable("f", 20, "lb/hp", "mass per unit power")
    Pmax = self.Pmax = Variable("P_{\text{max}}", "hp", "max output power")
    return [m >= f * Pmax]

class PowerSystem(Model):
    """A battery powering a motor
    """
    def setup(self):
        battery, motor = Battery(), Motor()
        components = [battery, motor]
        m = self.m = Variable("m", "lb", "mass")
        self.E = battery.E
        self.Pmax = motor.Pmax

        return [components,
                m >= sum(comp.m for comp in components)]

PS = PowerSystem()
print("Getting the only var 'E': $s % PS[E]")
print("The top-level var 'm': $s % PS.m")
print("All the variables 'm': $s % PS.variables_byname("m")")

Getting the only var 'E': PowerSystem.Battery.E [MJ]
The top-level var 'm': PowerSystem.m [lb]
All the variables 'm': [gpkit.Variable(PowerSystem.Battery.m [lb]), gpkit.
                        Variable(PowerSystem.Motor.m [lb]), gpkit.Variable(PowerSystem.m [lb])]

6.4 Vectorization

gpkit.Vectorize creates an environment in which Variables are created with an additional dimension:

"from gpkit/tests/t_vars.py"

def test_shapes(self):
    with gpkit.Vectorize(3):
        with gpkit.Vectorize(5):
            y = gpkit.Variable("y")
            x = gpkit.VectorVariable(2, "x")
            z = gpkit.VectorVariable(7, "z")

            self.assertEqual(y.shape, (5, 3))

    (continues on next page)
This allows models written with scalar constraints to be created with vector constraints:

```python
"""Vectorization demonstration"
from gpkit import Model, Variable, Vectorize
class Test(Model):
    """A simple scalar model
    Upper Unbounded
    """
    x
    
    def setup(self):
        x = self.x = Variable("x")
        return [x >= 1]

print("SCALAR")
m = Test()
m.cost = m["x"]
print(m.solve(verbosity=0).summary())

print("\n")
print("VECTORIZED")
with Vectorize(3):
m = Test()
m.cost = m["x"].prod()
m.append(m["x"][1] >= 2)
print(m.solve(verbosity=0).summary())
```

(continues on next page)
6.5 Multipoint analysis modeling

In many engineering models, there is a physical object that is operated in multiple conditions. Some variables correspond to the design of the object (size, weight, construction) while others are vectorized over the different conditions (speed, temperature, altitude). By combining named models and vectorization we can create intuitive representations of these systems while maintaining modularity and interoperability.

In the example below, the models Aircraft and Wing have a `dynamic()` method which creates instances of AircraftPerformance and WingAero, respectively. The Aircraft and Wing models create variables, such as size and weight without fuel, that represent a physical object. The `dynamic` models create properties that change based on the flight conditions, such as drag and fuel weight.

This means that when an aircraft is being optimized for a mission, you can create the aircraft (AC in this example) and then pass it to a Mission model which can create vectorized aircraft performance models for each flight segment and/or flight condition.

```python
"""Modular aircraft concept"
import pickle
import numpy as np
from gpkit import Model, Vectorize, parse_variables

class AircraftP(Model):
    """Aircraft flight physics: weight <= lift, fuel burn

    Variables
    --------
    Wfuel [lbf] fuel weight
    Wburn [lbf] segment fuel burn

    Upper Unbounded
    ---------------
    Wburn, aircraft.wing.c, aircraft.wing.A

    Lower Unbounded
    ---------------
    Wfuel, aircraft.W, state.mu
    """
    @parse_variables(__doc__, globals())
def setup(self, aircraft, state):
    self.aircraft = aircraft
    self.state = state
    self.wing_aero = aircraft.wing.dynamic(aircraft.wing, state)
```

(continues on next page)
self.perf_models = [self.wing_aero]

W = aircraft.W

6.5. Multipoint analysis modeling
7.1 Derived Variables

7.1.1 Evaluated Fixed Variables

Some fixed variables may be derived from the values of other fixed variables. For example, air density, viscosity, and temperature are functions of altitude. These can be represented by a substitution or value that is a one-argument function accepting `model.substitutions` (for details, see Substitutions below).

```python
# code from t_GPSubs.test_calcconst in tests/t_sub.py
x = Variable("x", "hours")
t_day = Variable("t_{day}", 12, "hours")
t_night = Variable("t_{night}", lambda c: 24 - c[t_day], "hours")
# note that t_night has a function as its value
m = Model(x, [x >= t_day, x >= t_night])
sol = m.solve(verbosity=0)
self.assertAlmostEqual(sol(t_night)/gpkit.ureg.hours, 12)
m.substitutions.update({t_day: ("sweep", [8, 12, 16])})
sol = m.solve(verbosity=0)
sol = m.solve(verbosity=0)
self.assertAlmostEqual(len(sol["cost"]), 3)
npt.assert_allclose(sol(t_day) + sol(t_night), 24)
```

These functions are automatically differentiated with the ad package to provide more accurate sensitivities. In some cases may require using functions from the ad.admath instead of their python or numpy equivalents; the ad documentation contains details on how to do this.

7.1.2 Evaluated Free Variables

Some free variables may be evaluated from the values of other (non-evaluated) free variables after the optimization is performed. For example, if the efficiency $\nu$ of a motor is not a GP-compatible variable, but $(1 - \nu)$ is a valid GP variable, then $\nu$ can be calculated after solving. These evaluated free variables
can be represented by a Variable with evalfn metadata. Note that this variable should not be used in constructing your model!

```python
# code from t_constraints.test_evalfn in tests/t_sub.py
x = Variable("x")
x2 = Variable("x^2", evalfn=lambda v: v[x]**2)
m = Model(x, [x >= 2])
m.unique_varkeys = set([x2.key])
sol = m.solve(verbosity=0)
self.assertAlmostEqual(sol(x2), sol(x)**2)
```

For evaluated variables that can be used during a solution, see externalfn under Sequential Geometric Programs.

## 7.2 Sweeps

Sweeps are useful for analyzing tradeoff surfaces. A sweep “value” is an Iterable of numbers, e.g. [1, 2, 3]. The simplest way to sweep a model is to call `model.sweep({sweepvar: sweepvalues})`, which will return a solution array but not change the model’s substitutions dictionary. If multiple sweepvars are given, the method will run them all as independent one-dimensional sweeps and return a list of one solution per sweep. The method `model.autosweep({sweepvar: (start, end)}, tol=0.01)` behaves very similarly, except that only the bounds of the sweep need be specified and the region in between will be swept to a maximum possible error of tol in the log of the cost. For details see **1D Autosweeps** below.

### 7.2.1 Sweep Substitutions

Alternatively, or to sweep a higher-dimensional grid, Variables can swept with a substitution value takes the form ("sweep", Iterable), such as ("sweep", np.linspace(1e6, 1e7, 100)). During variable declaration, giving an Iterable value for a Variable is assumed to be giving it a sweep value: for example, `x = Variable("x", [1, 2, 3])` will sweep x over three values.

Vector variables may also be substituted for: `{y: ("sweep", np.array([1, 2, 3]))}` will sweep y over three values. These sweeps cannot be specified during Variable creation.

A Model with sweep substitutions will solve for all possible combinations: e.g., if there’s a variable `x` with value ('sweep', [1, 3]) and a variable `y` with value ('sweep', [14, 17]) then the gp will be solved four times, for `(x, y) ∈ { (1,14), (1,17), (3,14), (3,17) }`. The returned solutions will be a one-dimensional array (or 2-D for vector variables), accessed in the usual way.

### 7.2.2 1D Autosweeps

If you’re only sweeping over a single variable, autosweeping lets you specify a tolerance for cost error instead of a number of exact positions to solve at. GPkit will then search the sweep segment for a locally optimal number of sweeps that can guarantee a max absolute error on the log of the cost.

Accessing variable and cost values from an autosweep is slightly different, as can be seen in this example:

```python
"Show autosweep_1d functionality"
import pickle
import numpy as np
import gpkit
from gpkit import units, Variable, Model
```
from gpkit.tools.autosweep import autosweep_1d
from gpkit.small_scripts import mag

A = Variable("A", "m**2")
l = Variable("l", "m")

m1 = Model(A**2, [A >= l**2 + units.m**2])
toll = 1e-3
bst1 = autosweep_1d(m1, toll, l, [1, 10], verbosity=0)
print("Solved after %2i passes, cost logtol +/-%.3g" % (bst1.nsols, bst1.tol))

# autosweep solution accessing
l_vals = np.linspace(1, 10, 10)
soll = bst1.sample_at(l_vals)
print("values of l: %s" % l_vals)
print("values of A: %s" % soll["A"])

cost_estimate = soll["cost"]
cost_lb, cost_ub = soll.cost_lb(), soll.cost_ub()
print("cost lower bound: %s" % cost_lb)
print("cost estimate: %s" % cost_estimate)
print("cost upper bound: %s" % cost_ub)

# you can evaluate arbitrary posynomials
np.testing.assert_allclose(mag(2*soll(A)), mag(soll(2*A)))
assert (soll["cost"] == soll(A**2)).all()

# the cost estimate is the logspace mean of its upper and lower bounds
np.testing.assert_allclose((np.log(mag(cost_lb)) + np.log(mag(cost_ub)))/2, np.log(mag(cost_estimate)))

# save autosweep to a file and retrieve it
bst1.save("autosweep.pkl")
bst1_loaded = pickle.load(open("autosweep.pkl", "rb"))

# this problem is two intersecting lines in logspace
m2 = Model(A**2, [A >= (l/3)**2, A >= (l/3)**0.5 * units.m**1.5])
tol2 = "mosek": 1e-12, "cvxopt": 1e-7,
       "mosek_cli": 1e-6}[gpkit.settings["default_solver"]]

# test Model method
sol2 = m2.autosweep({l: [1, 10]}, tol2, verbosity=0)
bst2 = sol2.bst
print("Solved after %2i passes, cost logtol +/-%.3g" % (bst2.nsols, bst2.tol))
print("Table of solutions used in the autosweep:")
print(bst2.solarray.table())

If you need access to the raw solutions arrays, the smallest simplex tree containing any given point can be gotten with min_bst = bst.min_bst(val), the extents of that tree with bst.bounds and solutions of that tree with bst.sols. More information is in help(bst).

7.3 Tight ConstraintSets

Tight ConstraintSets will warn if any inequalities they contain are not tight (that is, the right side does not equal the left side) after solving. This is useful when you know that a constraint should be tight for a given model, but representing it as an equality would be non-convex.
from gpkit import Variable, Model
from gpkit.constraints.tight import Tight
Tight.reltol = 1e-2  # set the global tolerance of Tight
x = Variable('x')
x_min = Variable('x_{\text{min}}', 2)
m = Model(x, [Tight([x >= 1], reltol=1e-3),  # set the specific tolerance
               x >= x_min])
m.solve(verbosity=0)  # prints warning

7.4 Loose ConstraintSets

Loose ConstraintSets will warn if any GP-compatible constraints they contain are not loose (that is, their sensitivity is above some threshold after solving). This is useful when you want a constraint to be inactive for a given model because it represents an important model assumption (such as a fit only valid over a particular interval).

from gpkit import Variable, Model
from gpkit.constraints.tight import Loose
Tight.reltol = 1e-4  # set the global tolerance of Tight
x = Variable('x')
x_min = Variable('x_{\text{min}}', 1)
m = Model(x, [Loose([x >= 2], senstol=1e-4),  # set the specific tolerance
               x >= x_min])
m.solve(verbosity=0)  # prints warning

7.5 Substitutions

Substitutions are a general-purpose way to change every instance of one variable into either a number or another variable.

7.5.1 Substituting into Posynomials, NomialArrays, and GPs

The examples below all use Posynomials and NomialArrays, but the syntax is identical for GPs (except when it comes to sweep variables).

# adapted from t_sub.py / t_NomialSubs / test_Basic
from gpkit import Variable
x = Variable("x")
p = x**2
assert p.sub(x, 3) == 9
assert p.sub(x.varkeys["x"], 3) == 9
assert p.sub("x", 3) == 9

Here the variable x is being replaced with 3 in three ways: first by substituting for x directly, then by substituting for the VarKey("x"), then by substituting the string “x”. In all cases the substitution is understood as being with the VarKey: when a variable is passed in the VarKey is pulled out of it, and when a string is passed in it is used as an argument to the Posynomial’s varkeys dictionary.
7.5.2 Substituting multiple values

```python
# adapted from t_sub.py / t_NomialSubs / test_Vector
from gpkit import Variable, VectorVariable
x = Variable("x")
y = Variable("y")
z = VectorVariable(2, "z")
p = x*y*z
assert all(p.sub({x: 1, "y": 2}) == 2*z)
assert all(p.sub({x: 1, y: 2, "z": [1, 2]}) == z.sub(z, [2, 4]))
```

To substitute in multiple variables, pass them in as a dictionary where the keys are what will be replaced and values are what it will be replaced with. Note that you can also substitute for VectorVariables by their name or by their NomialArray.

7.5.3 Substituting with nonnumeric values

You can also substitute in sweep variables (see Sweeps), strings, and monomials:

```python
# adapted from t_sub.py / t_NomialSubs
from gpkit import Variable
from gpkit.small_scripts import mag
x = Variable("x", "m")
xvk = x.varkeys.values()[0]
descr_before = x.exp.keys()[0].descr
y = Variable("y", "km")
yvk = y.varkeys.values()[0]
for x_ in ["x", xvk, x]:
    for y_ in ["y", yvk, y]:
        if not isinstance(y_, str) and type(xvk.units) != str:
            expected = 0.001
        else:
            expected = 1.0
        assert abs(expected - mag(x.sub(x_, y_).c)) < 1e-6
if type(xvk.units) != str:  # this means units are enabled
    z = Variable("z", "s")
    # y.sub(y, z) will raise ValueError due to unit mismatch
```

Note that units are preserved, and that the value can be either a string (in which case it just renames the variable), a varkey (in which case it changes its description, including the name) or a Monomial (in which case it substitutes for the variable with a new monomial).

7.5.4 Updating ConstraintSet substitutions

ConstraintSets have a `.substitutions` KeyDict attribute which will be substituted before solving. This KeyDict accepts variable names, VarKeys, and Variable objects as keys, and can be updated (or deleted from) like a regular Python dictionary to change the substitutions that will be used at solve-time. If a ConstraintSet itself contains ConstraintSets, it and all its elements share pointers to the same substitutions dictionary object, so that updating any one of them will update all of them.
7.5.5 Fixed Variables

When a Model is created, any fixed Variables are used to form a dictionary:
```
{var: var.descr['value'] for var in self.varlocs if "value" in var.descr}
```
This dictionary is then substituted into the Model’s cost and constraints before the `substitutions` argument is (and hence values are supplanted by any later substitutions).

```
solution.subinto(p) will substitute the solution(s) for variables into the posynomial p, returning a NominalArray. For a non-swept solution, this is equivalent to p.sub(solution["variables"]).
```
You can also substitute by just calling the solution, i.e. `solution(p)`. This returns a numpy array of just the coefficients (c) of the posynomial after substitution, and will raise a `ValueError` if some of the variables in p were not found in solution.

7.5.6 Freeing Fixed Variables

After creating a Model, it may be useful to “free” a fixed variable and resolve. This can be done using the command `del m.substitutions["x"]`, where `m` is a Model. An example of how to do this is shown below.

```
from gpkit import Variable, Model
x = Variable("x")
y = Variable("y", 3)  # fix value to 3
m = Model(x, [x >= 1 + y, y >= 1])
_ = m.solve()  # optimal cost is 4; y appears in sol["constants"]

del m.substitutions["y"]
_ = m.solve()  # optimal cost is 2; y appears in Free Variables
```

Note that `del m.substitutions["y"]` affects `m` but not `y.key.y.value` will still be 3, and if `y` is used in a new model, it will still carry the value of 3.
Signomial programming finds a local solution to a problem of the form:

\[
\begin{align*}
\text{minimize} & \quad g_0(x) \\
\text{subject to} & \quad f_i(x) = 1, \quad i = 1, \ldots, m \\
& \quad g_i(x) - h_i(x) \leq 1, \quad i = 1, \ldots, n
\end{align*}
\]

where each \( f \) is monomial while each \( g \) and \( h \) is a posynomial.

This requires multiple solutions of geometric programs, and so will take longer to solve than an equivalent geometric programming formulation.

In general, when given the choice of which variables to include in the positive-posynomial / \( g \) side of the constraint, the modeler should:

1. maximize the number of variables in \( g \),
2. prioritize variables that are in the objective,
3. then prioritize variables that are present in other constraints.

The `.localsolve` syntax was chosen to emphasize that signomial programming returns a local optimum. For the same reason, calling `.solve` on an SP will raise an error.

By default, signomial programs are first solved conservatively (by assuming each \( h \) is equal only to its constant portion) and then become less conservative on each iteration.

### 8.1 Example Usage

```python
"""Adapted from t_SP in tests/t_geometric_program.py"
import gpkit

# Decision variables
x = gpkit.Variable('x')
y = gpkit.Variable('y')
```

(continues on next page)
When using the `localsolve` method, the `reltol` argument specifies the relative tolerance of the solver: that is, by what percent does the solution have to improve between iterations? If any iteration improves less than that amount, the solver stops and returns its value.

If you wish to start the local optimization at a particular point $x_k$, however, you may do so by putting that position (a dictionary formatted as you would a substitution) as the `xk` argument.

### 8.2 Sequential Geometric Programs

The method of solving local GP approximations of a non-GP compatible model can be generalized, at the cost of the general smoothness and lack of a need for trust regions that SPs guarantee.

For some applications, it is useful to call external codes which may not be GP compatible. Imagine we wished to solve the following optimization problem:

\[
\begin{align*}
\text{minimize} & \quad y \\
\text{subject to} & \quad y \geq \sin(x) \\
& \quad \frac{\pi}{4} \leq x \leq \frac{\pi}{2}
\end{align*}
\]

This problem is not GP compatible due to the $\sin(x)$ constraint. One approach might be to take the first term of the Taylor expansion of $\sin(x)$ and attempt to solve:

---

```python
import numpy as np
from gpkit import Variable, Model

x = Variable("x")
y = Variable("y")

objective = y

constraints = [y >= x,
               x <= np.pi/2.,
               x >= np.pi/4.,
               ]

m = Model(objective, constraints)
print(m.solve(verbosity=0).summary())
```

---

"Can be found in gpkit/docs/source/examples/sin_approx_example.py"
We can do better, however, by utilizing some built in functionality of GPkit. For simple cases with a single Variable, GPkit looks for \texttt{externalfn} metadata:

```python
"Can be found in gpkit/docs/source/examples/external_sp2.py"
import numpy as np
from gpkit import Variable, Model
x = Variable("x")

def y_ext(self, x0):
    "Returns constraints on y derived from x0"
    if x not in x0:
        return self >= x
    return self >= x/x0[x] * np.sin(x0[x])

y = Variable("y", externalfn=y_ext)
m = Model(y, [np.pi/4 <= x, x <= np.pi/2])
print(m.localsolve(verbosity=0).summary())
```

However, for external functions not intrinsically tied to a single variable it’s best to use the full ConstraintSet API, as follows:

Assume we have some external code which is capable of evaluating our incompatible function:
Now, we can create a ConstraintSet that allows GPkit to treat the incompatible constraint as though it were a signomial programming constraint:

```python
class ExternalConstraint(object):
    "Class for external calling"
    varkeys = {}

    def __init__(self, x, y):
        # We need a GPkit variable defined to return in our constraint. The easiest way to do this is to read in the parameters of interest in the initiation of the class and store them here.
        self.x = x
        self.y = y

    def as_posyslt1(self, _):
        "Ensures this is treated as an SGP constraint"
        raise InvalidGPConstraint("ExternalConstraint cannot solve as a GP.")

    def as_gpconstr(self, x0):
        "Returns locally-approximating GP constraint"

        # Unpacking the GPkit variables
        x = self.x
        y = self.y

        # Creating a default constraint for the first solve
        if not x0:
            return (y >= x)

        # Returns constraint updated with new call to the external code
        else:
            # Unpack Design Variables at the current point
            x_star = x0["x"]

            # Call external code
            res = external_code(x_star)

            # Return linearized constraint
            posynomial_constraint = (y >= res*x/x_star)
            posynomial_constraint.sgp_parent = self
            return posynomial_constraint
```

and replace the incompatible constraint in our GP:
"Can be found in gpkit/docs/source/examples/external_sp.py"

```python
import numpy as np
from gpkit import Variable, Model
from external_constraint import ExternalConstraint

x = Variable("x")
y = Variable("y")

objective = y

constraints = [ExternalConstraint(x, y),
               x <= np.pi/2.,
               x >= np.pi/4.,
               ]

m = Model(objective, constraints)
print(m.localsolve(verbosity=0).summary())
```

which is the expected result. This method has been generalized to larger problems, such as calling XFOIL and AVL.

If you wish to start the local optimization at a particular point $x_0$, however, you may do so by putting that position (a dictionary formatted as you would a substitution) as the $x0$ argument.
9.1 iPython Notebook Examples

More examples, including some with in-depth explanations and interactive visualizations, can be seen on nbviewer.

9.2 A Trivial GP

The most trivial GP we can think of: minimize $x$ subject to the constraint $x \geq 1$.

```python
"Very simple problem: minimize x while keeping x greater than 1."
from gpkit import Variable, Model

# Decision variable
x = Variable("x")

# Constraint
constraints = [x >= 1]

# Objective (to minimize)
optimal = x

# Formulate the Model
m = Model(objective, constraints)

# Solve the Model
sol = m.solve(verbosity=0)

# print selected results
print("Optimal cost: ", sol['cost'])
print("Optimal x val: ", sol['variables'][x])
```

Of course, the optimal value is 1. Output:
9.3 Maximizing the Volume of a Box

This example comes from Section 2.4 of the GP tutorial, by S. Boyd et. al.

"Maximizes box volume given area and aspect ratio constraints."

```python
from gpkit import Variable, Model

# Parameters
alpha = Variable("alpha", 2, ",", "lower limit, wall aspect ratio")
beta = Variable("beta", 10, ",", "upper limit, wall aspect ratio")
gamma = Variable("gamma", 2, ",", "lower limit, floor aspect ratio")
delta = Variable("delta", 10, ",", "upper limit, floor aspect ratio")
A_wall = Variable("A_{wall}\", 200, "m^2", "upper limit, wall area")
A_floor = Variable("A_{floor}\", 50, "m^2", "upper limit, floor area")

# Decision variables
h = Variable("h\", "m", "height")
w = Variable("w\", "m", "width")
d = Variable("d\", "m", "depth")

# Constraints
constraints = [A_wall >= 2*h*w + 2*h*d,
               A_floor >= w*d,
               h/w >= alpha,
               h/w <= beta,
               d/w >= gamma,
               d/w <= delta]

# Objective function
V = h*w*d
objective = 1/V  # To maximize V, we minimize its reciprocal

# Formulate the Model
m = Model(objective, constraints)

# Solve the Model and print the results table
print(m.solve(verbosity=0).table())
```

The output is

```
Cost
-----
0.003674 [1/m**3]

Free Variables

9.4 Water Tank

Say we had a fixed mass of water we wanted to contain within a tank, but also wanted to minimize the cost of the material we had to purchase (i.e. the surface area of the tank):

"Minimizes cylindrical tank surface area for a particular volume."

```python
from gpkit import Variable, VectorVariable, Model

M = Variable("M", 100, "kg", "Mass of Water in the Tank")
rho = Variable("\rho", 1000, "kg/m^3", "Density of Water in the Tank")
A = Variable("A", "m^2", "Surface Area of the Tank")
V = Variable("V", "m^3", "Volume of the Tank")
d = VectorVariable(3, "d", "m", "Dimension Vector")

# because its units are incorrect the line below will print a warning
bad_monomial_equality = (M == V)

              V == d[0]*d[1]*d[2],
              M == V*rho)

m = Model(A, constraints)
sol = m.solve(verbosity=0)
print(sol.summary())
```

The output is

```
Infeasible monomial equality: Cannot convert from 'V [m**3]' to 'M [kg]'

Cost
----
1.293 [m**2]
```

V_{min} : [ +10.0%  +10.0%  +12.0%  +12.0% ] takeoff speed
D : [ +10.3%  -23.5%  +3.0%  -7.0% ] total drag force
W : [ +7.2%  +14.7%  +5.4%  +13.9% ] total aircraft weight
C_f : [ +7.9%  +14.5%  +5.3% ] skin friction coefficient

Solution sensitivity delta
(positive means the argument has a higher sensitivity)
--------------------------

V : [ -0.59  -0.97  -0.25  -0.75 ] cruising speed
V_{min} : [ +0.45  +0.67  +0.05  +0.34 ] takeoff speed
C_{L,max} : [ +0.23  +0.34  +0.02  +0.17 ] max CL with flaps down
\rho : [ -0.05  -0.13  -0.06  -0.19 ] density of air
N_{ult} : [ +0.11  +0.18  +0.04  +0.14 ] ultimate load factor
W_{W_{coeff1}} : [ +0.11  +0.18  +0.04  +0.14 ] Wing Weight to chord ratio
\tau : [ -0.11  -0.18  -0.04  -0.14 ] airfoil thickness
(\frac{S}{S_{wet}}) : [ -0.13  -0.20  -0.02  -0.11 ] wetted area ratio

(continues on next page)
9.6 Simple Beam

In this example we consider a beam subjected to a uniformly distributed transverse force along its length. The beam has fixed geometry so we are not optimizing its shape, rather we are simply solving a discretization of the Euler-Bernoulli beam bending equations using GP.

```python
A simple beam example with fixed geometry. Solves the discretized Euler-Bernoulli beam equations for a constant distributed load

```
def setup(self, N=4):
    # minimize tip displacement (the last w)
    self.cost = self.w_tip = w[-1]
    return {
        "definition of dx": L == (N-1)*dx,
        "boundary_conditions": [
            V[-1] >= V_tip,
            M[-1] >= M_tip,
            th[0] >= th_base,
            w[0] >= w_base
        ],
        # below: trapezoidal integration to form a piecewise-linear
        # approximation of loading, shear, and so on
        # shear and moment increase from tip to base (left > right)
        "shear integration":
            V[:-1] >= V[1:] + 0.5*dx*(q[:-1] + q[1:]),
        "moment integration":
            M[:-1] >= M[1:] + 0.5*dx*(V[:-1] + V[1:]),
        # slope and displacement increase from base to tip (right > left)
        "theta integration":
            th[1:] >= th[:-1] + 0.5*dx*(M[1:] + M[:-1])/EI,
        "displacement integration":
            w[1:] >= w[:-1] + 0.5*dx*(th[1:] + th[:-1])
    }

b = Beam(N=6, substitutions={"L": 6, "EI": 1.1e4, "q": 110*np.ones(6)})
sol = b.solve(verbosity=0)
print(sol.summary(maxcolumns=6))
w_gp = sol("w")  # deflection along beam
L, EI, q = sol("L"), sol("EI"), sol("q")
x = np.linspace(0, mag(L), len(q))*ureg.m  # position along beam
q = q[0]  # assume uniform loading for the check below
w_exact = q/(24.*EI) * x**2 * (x**2 - 4*L*x + 6*L**2)  # analytic soln
assert max(abs(w_gp - w_exact)) <= 1.1*ureg.cm

PLOT = False
if PLOT:
    import matplotlib.pyplot as plt
    x_exact = np.linspace(0, L, 1000)
    w_exact = q/(24.*EI) * x_exact**2 * (x_exact**2 - 4*L*x_exact + 6*L**2)
    plt.plot(x, w_gp, color='red', linestyle='solid', marker='^', markersize=8)
    plt.plot(x_exact, w_exact, color='blue', linestyle='dashed')
    plt.xlabel('x [m]')
    plt.ylabel('Deflection [m]')
    plt.axis('equal')
    plt.legend(['GP solution', 'Analytical solution'])
    plt.show()
Free Variables
-------------
\[
\begin{align*}
x & : 1.2 \\
\rightarrow & \text{Length of an element} \\
M & : [ 1.98e+03 \ 1.27e+03 \ 713 \ 317 \ 79.2 \ 0.0002 ] \ [N \cdot m] \\
\rightarrow & \text{Internal moment} \\
V & : [ 660 \ 528 \ 396 \ 264 \ 132 \ 0.0002 ] \ [N] \\
\rightarrow & \text{Internal shear} \\
\theta & : [ 0.0002 \ 0.177 \ 0.285 \ 0.341 \ 0.363 \ 0.367 ] \\
\rightarrow & \text{Slope} \\
w & : [ 0.0002 \ 0.107 \ 0.384 \ 0.76 \ 1.18 \ 1.62 ] \ [m] \\
\rightarrow & \text{Displacement}
\end{align*}
\]

Most Sensitive
--------------
\[
\begin{align*}
L & : +4 \quad \text{Overall} \\
\rightarrow & \text{beam length} \\
EI & : -1 \quad \text{Bending} \\
q & : [ +0.0072 \ +0.042 \ +0.12 \ +0.23 \ +0.37 \ +0.22 ] \\
\rightarrow & \text{Distributed load}
\end{align*}
\]

Tightest Constraints
---------------------
\[
\begin{align*}
+4 & : L = 5 \times dx \\
+1 & : w[5] >= w[4] + 0.5 \times dx \times (\theta[5] + \theta[4]) \\
+0.74 & : \theta[2] >= \theta[1] + 0.5 \times dx \times (M[2] + M[1])/EI \\
+0.73 & : w[4] >= w[3] + 0.5 \times dx \times (\theta[4] + \theta[3]) \\
+0.64 & : M[1] >= M[2] + 0.5 \times dx \times (V[1] + V[2])
\end{align*}
\]

By plotting the deflection, we can see that the agreement between the analytical solution and the GP solution is good.
For an alphabetical listing of all commands, check out the genindex

10.1 gpkit package

10.1.1 Subpackages

gpkit.constraints package

Submodules

gpkit.constraints.array module

Implements ArrayConstraint

class gpkit.constraints.array.ArrayConstraint (constraints, left, oper, right)
   Bases: gpkit.constraints.single_equation.SingleEquationConstraint,
          gpkit.constraints.set.ConstraintSet

   A ConstraintSet for prettier array-constraint printing.
   ArrayConstraint gets its sub method from ConstrainSet, and so left and right are only used for printing.
   When created by NomialArray left and right are likely to be either NomialArrays or Varkeys of VectorVariables.

gpkit.constraints.bounded module

Implements Bounded
class gpkit.constraints.bounded.Bounded(constraints, verbosity=1, 
                                      eps=1e-30, 
                                      lower=None, upper=None)

Bases: gpkit.constraints.set.ConstraintSet

Bounds contained variables so as to ensure dual feasibility.

constraints [iterable] constraints whose varkeys will be bounded

verbosity [int (default 1)]

how detailed of a warning to print 0: nothing 1: print warnings

eps [float (default 1e-30)] default lower bound is eps, upper bound is 1/eps

lower [float (default None)] lower bound for all varkeys, replaces eps

upper [float (default None)] upper bound for all varkeys, replaces 1/eps

check_boundaries (result)

Creates (and potentially prints) a dictionary of unbounded variables.

logtol_threshold = 3

process_result (result)

Add boundedness to the model’s solution

sens_from_dual (las, nus, result)

Return sensitivities while capturing the relevant lambdas

sens_threshold = 1e-07

gpkit.constraints.bounded.varkey_bounds (varkeys, lower, upper)

Returns constraints list bounding all varkeys.

varkeys [iterable] list of varkeys to create bounds for

lower [float] lower bound for all varkeys

upper [float] upper bound for all varkeys

gpkit.constraints.costed module

Implement CostedConstraintSet

class gpkit.constraints.costed.CostedConstraintSet (cost, constraints, sub-
                                      substitutions=None)

Bases: gpkit.constraints.set.ConstraintSet

A ConstraintSet with a cost

cost : gpkit.Posynomial constraints : Iterable substitutions : dict (None)

constrained_varkeys ()

Return all varkeys in the cost and non-ConstraintSet constraints

reset_varkeys ()

Resets varkeys to what is in the cost and constraints

rootconstr_latex (excluded=())

Latex showing cost, to be used when this is the top constraint

rootconstr_str (excluded=())

String showing cost, to be used when this is the top constraint
**gpkit.constraints.gp module**

Implement the GeometricProgram class

```python
class gpkit.constraints.gp.GeometricProgram(cost, constraints, substitutions, allow_missingbounds=False):

    Standard mathematical representation of a GP.

    solver_out and solver_log are set during a solve result is set at the end of a solve if solution status
    is optimal
    
    >>> gp = gpkit.geometric_program.GeometricProgram(
    # minimize
    x,
    [  # subject to
        1/x  # <= 1, implicitly
    ], {})
    >>> gp.solve()
```

**check_solution** *(cost, primal, nu, la, tol, abstol=1e-20)*

Run a series of checks to mathematically confirm sol solves this GP

- **cost**: float cost returned by solver
- **primal**: list primal solution returned by solver
- **nu**: numpy.ndarray monomial lagrange multiplier
- **la**: numpy.ndarray posynomial lagrange multiplier

RuntimeWarning, if any problems are found

```
gen()  
Generates nomial and solve data (A, p_idxs) from posynomials

generate_result(solver_out, warn_on_check=True, verbosity=0, process_result=True, dual_check=True)  
Generates a full SolutionArray and checks it.
```

**result**

Creates and caches a result from the raw solver_out

```
solve(solver=None, verbosity=1, warn_on_check=False, process_result=True, gen_result=True, **kwargs)  
Solves a GeometricProgram and returns the solution.
```

- **solver** [str or function (optional)] By default uses one of the solvers found during installation.
  If set to “mosek”, “mosek_cli”, or “cvxopt”, uses that solver. If set to a function, passes
  that function cs, A, p_idxs, and k.
- **verbosity** [int (default 1)] If greater than 0, prints solver name and solve time.
  
**kwarg**s: Passed to solver constructor and solver function.

**result**: SolutionArray

- **varkeys**: The NomialData’s varkeys, created when necessary for a substitution.

```
gpkic.constraints.gp.check_mono_eq_bounds(missingbounds, meq_bounds)  
Bounds variables with monomial equalities
```

---

10.1. gpkit package
gpkit.constraints.gp.genA(exps, varlocs, meq_idxs)
Generates A matrix

A [sparse Cootmatrix] Exponents of the various free variables for each monomial: rows
of A are monomials, columns of A are variables.

missingbounds [dict] Keys: variables that lack bounds. Values: which bounds are
missed.

gpkit.constraints.gp.genMonoEqBounds(exps, meq_idxs)
Generate conditional monomial equality bounds

gpkit.constraints.model module

Implements Model

class gpkit.constraints.model.Model(cost=None, constraints=None, *args,
**kwargs)
Bases: gpkit.constraints.costed.CostedConstraintSet
Symbolic representation of an optimization problem.

The Model class is used both directly to create models with constants and sweeps, and indirectly
inherited to create custom model classes.

cost [Posynomial (optional)] Defaults to Monomial(1).

constraints [ConstraintSet or list of constraints (optional)] Defaults to an empty list.

substitutions [dict (optional)] This dictionary will be substituted into the problem before solving,
and also allows the declaration of sweeps and linked sweeps.

program is set during a solve solution is set at the end of a solve

as_gpconstr(x0)
Returns approximating constraint, keeping name and num

autosweep(sweeps, tol=0.01, samplepoints=100, **solveargs)
Autosweeps {var: (start, end)} pairs in sweeps to tol.

Returns swept and sampled solutions. The original simplex tree can be accessed at sol.bst

debug(solver=None, verbosity=1, **solveargs)
Attempts to diagnose infeasible models.

If a model debugs but errors in a process_result call, debug again with process_results=False

gp(constants=None, **kwargs)
Return program version of self

lineage = None

localsolve(solver=None, verbosity=1, skipsweepfailures=False, **kwargs)
Forms a mathematical program and attempts to solve it.

solver [string or function (default None)] If None, uses the default solver found in installation.

verbosity [int (default 1)] If greater than 0 prints runtime messages. Is decremented by one
and then passed to programs.

skipsweepfailures [bool (default False)] If True, when a solve errors during a sweep, skip it.

**kwargs : Passed to solver

sol [SolutionArray] See the SolutionArray documentation for details.
ValueError if the program is invalid. RuntimeWarning if an error occurs in solving or parsing the solution.

**penalty_ccp_solve** *(solver=None, verbosity=1, skipsweepfailures=False, **kwargs)*

Forms a mathematical program and attempts to solve it.

* solver [string or function (default None)] If None, uses the default solver found in installation.
* verbosity [int (default 1)] If greater than 0 prints runtime messages. Is decremented by one and then passed to programs.
* skipsweepfailures [bool (default False)] If True, when a solve errors during a sweep, skip it.
* **kwargs : Passed to solver

**sol** [SolutionArray] See the SolutionArray documentation for details.

ValueError if the program is invalid. RuntimeWarning if an error occurs in solving or parsing the solution.

```
program = None
solution = None
```

**solve** *(solver=None, verbosity=1, skipsweepfailures=False, **kwargs)*

Forms a mathematical program and attempts to solve it.

* solver [string or function (default None)] If None, uses the default solver found in installation.
* verbosity [int (default 1)] If greater than 0 prints runtime messages. Is decremented by one and then passed to programs.
* skipsweepfailures [bool (default False)] If True, when a solve errors during a sweep, skip it.
* **kwargs : Passed to solver

**sol** [SolutionArray] See the SolutionArray documentation for details.

ValueError if the program is invalid. RuntimeWarning if an error occurs in solving or parsing the solution.

```
sp (constants=None, **kwargs)
```

Return program version of self

```
sweep (sweeps, **solveargs)
```

Sweeps \{var: values\} pairs in sweeps. Returns swept solutions.

```
verify_docstring ()
```

Verifies docstring bounds are sufficient but not excessive.

```
gpkit.constraints.model.get_relaxed (relaxvals, mapped_list, min_return=1)
```

Determines which relaxvars are considered ‘relaxed’

```
gpkit.constraints.prog_factories module
```

Scripts for generating, solving and sweeping programs

```
gpkit.constraints.prog_factories.evaluate_linked (constants, linked)
```

Evaluates the values and gradients of linked variables.
gpkit.constraints.prog_factories.run_sweep(genfunction, self, solution, skipsweepfailures, constants, sweep, linked, solver, verbosity, **kwargs)

Runs through a sweep.

**gpkit.constraints.relax module**

Models for assessing primal feasibility

class gpkit.constraints.relax.ConstantsRelaxed(constraints, include_only=None, exclude=None)

Bases: gpkit.constraints.set.ConstraintSet

Relax constants in a constraintset.

constraints [iterable] Constraints which will be relaxed (made easier).

include_only [set (optional)] variable names must be in this set to be relaxed

exclude [set (optional)] variable names in this set will never be relaxed

relaxvars [Variable] The variables controlling the relaxation. A solved value of 1 means no relaxation was necessary or optimal for a particular constant. Higher values indicate the amount by which that constant has been made easier: e.g., a value of 1.5 means it was made 50 percent easier in the final solution than in the original problem. Of course, this can also be determined by looking at the constant’s new value directly.

process_result(result)

class gpkit.constraints.relax.ConstantsRelaxedEqually(constraints)

Bases: gpkit.constraints.set.ConstraintSet

Relax constraints, as in Eqn. 11 of [Boyd2007].

constraints [iterable] Constraints which will be relaxed (made easier).

relaxvar [Variable] The variable controlling the relaxation. A solved value of 1 means no relaxation was necessary or optimal for a particular constraint. Higher values indicate the amount by which that constraint has been made easier: e.g., a value of 1.5 means it was made 50 percent easier in the final solution than in the original problem.

[Boyd2007]: “A tutorial on geometric programming”, Optim Eng 8:67-122

class gpkit.constraints.relax.ConstantsRelaxedEqually(constraints)

Bases: gpkit.constraints.set.ConstraintSet

Relax constraints the same amount, as in Eqn. 10 of [Boyd2007].

constraints [iterable] Constraints which will be relaxed (made easier).

relaxvar [Variable] The variable controlling the relaxation. A solved value of 1 means no relaxation was necessary or optimal for a particular constraint. Higher values indicate the amount by which all constants have been made easier: e.g., a value of 1.5 means all constraints were 50 percent easier in the final solution than in the original problem.

[Boyd2007]: “A tutorial on geometric programming”, Optim Eng 8:67-122
**gpkit.constraints.set module**

Implements ConstraintSet

```python
class gpkit.constraints.set.ConstraintSet(constraints, substitutions=None)
Bases: list, gpkit.repr_conventions.GPkitObject

Recursive container for ConstraintSets and Inequalities

*as_gpconstr* (x0)
  Returns GPConstraint approximating this constraint at x0
  When x0 is none, may return a default guess.

*as_posyslt1* (substitutions=None)
  Returns list of posynomials which must be kept <= 1

*as_view* ()
  Return a ConstraintSetView of this ConstraintSet.

*constrained_varkeys* ()
  Return all varkeys in non-ConstraintSet constraints

*flat* (constraintsets=False)
  Yields contained constraints, optionally including constraintsets.

*idxlookup* = None

*latex* (excluded=(u'units',))
  LaTeX representation of a ConstraintSet.

*lines_without* (excluded)
  Lines representation of a ConstraintSet.

*name_collision_varkeys* ()
  Returns the set of contained varkeys whose names are not unique

*process_result* (result)
  Does arbitrary computation / manipulation of a program’s result
  There’s no guarantee what order different constraints will process results in, so any changes
  made to the program’s result should be careful not to step on other constraint’s toes.
  • check that an inequality was tight
  • add values computed from solved variables

*reset_varkeys* ()
  Goes through constraints and collects their varkeys.

*sens_from_dual* (las, nus, result)
  Computes constraint and variable sensitivities from dual solution
  las [list] Sensitivity of each posynomial returned by self.as_posyslt1
  nus: list of lists Each posynomial’s monomial sensitivities

  constraint_sens [dict] The interesting and computable sensitivities of this constraint
  var_senss [dict] The variable sensitivities of this constraint

*str_without* (excluded=(u'unnecessary lineage', u'units'))
  String representation of a ConstraintSet.

*unique_varkeys* = frozenset([])
```

10.1. gpkit package
variables_byname(key)
    Get all variables with a given name

varkeys = None

class gpkit.constraints.set.ConstraintSetView(constraintset, index=())
    Bases: object
    Class to access particular views on a set’s variables

gpkit.constraints.set.add_meq_bounds(bounded, meq_bounded)
    Iterates through meq_bounds until convergence

gpkit.constraints.set.raise_badelement(cns, i, constraint)
    Identify the bad element and raise a ValueError

gpkit.constraints.set.raise_elementhasnumpybools(constraint)
    Identify the bad subconstraint array and raise a ValueError

gpkit.constraints.sgp module

Implement the SequentialGeometricProgram class

class gpkit.constraints.sgp.SequentialGeometricProgram(cost, constraints, substitutions)
    Bases: gpkit.constraints.costed.CostedConstraintSet
    Prepares a collection of signomials for a SP solve.

cost [Posynomial] Objective to minimize when solving

constraints [list of Constraint or SignomialConstraint objects] Constraints to maintain when solving (implicitly Signomials <= 1)

verbosity [int (optional)] Currently has no effect: SequentialGeometricPrograms don’t know anything new after being created, unlike GeometricPrograms.

gps is set during a solve result is set at the end of a solve

>>> gp = gpkit.geometric_program.SequentialGeometricProgram(
    # minimize
    x,
    [  # subject to
        1/x - y/x, # <= 1, implicitly
        y/10 # <= 1
    ]
)

>>> gp.solve()

gp (x0=None, mutategp=False)
    The GP approximation of this SP at x0.

init_gp(substitutions, x0=None)
    Generates a simplified GP representation for later modification

localsolve(solver=None, verbosity=1, x0=None, reltol=0.0001, iteration_limit=50, mutategp=True, **kwargs)
    Locally solves a SequentialGeometricProgram and returns the solution.

solver [str or function (optional)] By default uses one of the solvers found during installation.
If set to “mosek”, “mosek_cli”, or “cvxopt”, uses that solver. If set to a function, passes that function cs, A, p_idxs, and k.
verbosity [int (optional)] If greater than 0, prints solve time and number of iterations. Each
GP is created and solved with verbosity one less than this, so if greater than 1, prints
solver name and time for each GP.

x0 [dict (optional)] Initial location to approximate signomials about.

reltol [float] Iteration ends when this is greater than the distance between two consecutive
solve’s objective values.

iteration_limit [int] Maximum GP iterations allowed.

mutategp: boolean Prescribes whether to mutate the previously generated GP or to create a
new GP with every solve.

*args, **kwargs : Passed to solver function.

result [dict] A dictionary containing the translated solver result.

penalty_ccp (exp=10.0)
Returns the penalty convex-concave form of this SP.

penalty_ccp_solve (solver=None, verbosity=1, x0=None, reltol=0.0001, iteration_limit=50, mutategp=True, exp=10.0, **kwargs)
Implements the penalty convex-concave algorithm [Lipp.Boyd 2016] instead of vanilla SP
heuristic.

Same arguments as localsolve, but also exp : float (optional)
Sets penalty for violated signomial constraints

results
Creates and caches results from the raw solver_outs

gpkit.constraints.sigeq module

Implements SignomialEquality

class gpkit.constraints.sigeq.SignomialEquality (left, right)
Bases: gpkit.constraints.set.ConstraintSet

A constraint of the general form posynomial == posynomial

gpkit.constraints.single_equation module

Implements SingleEquationConstraint

class gpkit.constraints.single_equation.SingleEquationConstraint (left, oper, right)
Bases: gpkit.repr_conventions.GPkitObject

Constraint expressible in a single equation.

func_opers = {u'<=': <built-in function le>, u'=': <built-in function eq>, u'>':
latex (excluded=u'units')
Latex representation without attributes in excluded list
latex_opers = {u'<=': u'\leq', u'=': u'=', u'>': u'\geq'}
**str_without** *(excluded=u'units')*

String representation without attributes in excluded list

---

**gpkit.constraints.tight module**

Implements Tight

**class gpkit.constraints.tight.Tight** *(constraints, reltol=None, raiseerror=False, **kwargs)*

Bases: gpkit.constraints.set.ConstraintSet

ConstraintSet whose inequalities must result in an equality.

**process_result** *(result)*

Checks that all constraints are satisfied with equality

```
reltol = 0.001
```

---

**Module contents**

Contains ConstraintSet and related classes and objects

---

**gpkit.interactive package**

**Submodules**

**gpkit.interactive.chartjs module**

**gpkit.interactive.plot_sweep module**

Implements plot_sweep1d function

**gpkit.interactive.plot_sweep.assign_axes** *(var, posys, axes)*

Assigns axes to posys, creating and formatting if necessary

**gpkit.interactive.plot_sweep.format_and_label_axes** *(var, posys, axes, ylabel=True)*

Formats and labels axes

**gpkit.interactive.plot_sweep.plot_1dsweepgrid** *(model, sweeps, posys, orisol=None, tol=0.01, **solveargs)*

Creates and plots a sweep from an existing model

Example usage: f, _ = plot_sweep_1d(m, {'x': np.linspace(1, 2, 5)}, 'y') f.savefig('mysweep.png')

---

**gpkit.interactive.plotting module**

Plotting methods

**gpkit.interactive.plotting.compare** *(models, sweeps, posys, tol=0.001)*

Compares the values of posys over a sweep of several models.

If posys is of the same length as models, this will plot different variables from different models.
Currently only supports a single sweepvar.
Example Usage: `compare([aec, fbc], {"R": (160, 300)},
    ["cost", ("W_{rm batt}", "W_{rm fuel}")], tol=0.001)

`gpkit.interactive.plotting.plot_convergence(model)`
Plots the convergence of a signomial programming model

`model`: Model  Signomial programming model that has already been solved

`matplotlib.pyplot Figure`  Plot of cost as functions of SP iteration #
\texttt{\texttt{str\_without}} \texttt{(excluded=())}

Returns string without certain fields (such as ‘lineage’).

\texttt{\texttt{sub}} \texttt{(subs, require\_positive=True)}

Substitutes into the array

\texttt{\texttt{sum}} \texttt{(*args, **kwargs)}

Returns a sum. O(N) if no arguments are given.

\texttt{units}

units must have same dimensions across the entire nominal array

\texttt{\texttt{vectorize}} \texttt{(function, *args, **kwargs)}

Apply a function to each terminal constraint, returning the array

\texttt{gpkit.nomials.array.array\_constraint} \texttt{(symbol, func)}

Return function which creates constraints of the given operator.

\texttt{\texttt{gpkit.nomials.core}} \texttt{\texttt{module}}

The shared non-mathematical backbone of all Nomials

\texttt{\texttt{class}} \texttt{gpkit.nomials.core.Nomial} \texttt{(hmap)}

Bases: \texttt{gpkit.nomials.data.NomialData}

Shared non-mathematical properties of all nominals

\texttt{\texttt{latex}} \texttt{(excluded=())}

Latex representation, parsing \texttt{excluded} just as \texttt{str\_without} does

\texttt{\texttt{prod}()}\n
Return self for compatibility with NomialArray

\texttt{\texttt{str\_without}} \texttt{(excluded=())}

String representation, excluding fields (‘units’, varkey attributes)

\texttt{\texttt{sub} = None}

\texttt{\texttt{sum}()}\n
Return self for compatibility with NomialArray

\texttt{\texttt{value}}\n
Self, with values substituted for variables that have values

float, if no symbolic variables remain after substitution (Monomial, Posynomial, or Nomial), otherwise.

\texttt{\texttt{gpkit.nomials.data}} \texttt{\texttt{module}}

Machinery for \texttt{exps}, \texttt{cs}, \texttt{varlocs} data – common to nomials and programs

\texttt{\texttt{class}} \texttt{gpkit.nomials.data.NomialData} \texttt{(hmap)}

Bases: \texttt{gpkit.repr_conventions.GPkitObject}

Object for holding \texttt{cs}, \texttt{exps}, and other basic ‘nomial’ properties.

\texttt{\texttt{cs}}: array (coefficient of each monomial term) \texttt{exps}: tuple of \{\texttt{VarKey}: float\} (exponents of each monomial term) \texttt{varlocs}: \{\texttt{VarKey}: list\} (terms each variable appears in) \texttt{units}: pint.UnitsContainer
cs
  Create cs or return cached cs

exps
  Create exps or return cached exps

to (units)
  Create new Signomial converted to new units

varkeys
  The NomialData’s varkeys, created when necessary for a substitution.

varkeyvalues()
  Returns the NomialData’s keys’ values

varlocs
  Create varlocs or return cached varlocs

gpkit.nomials.map module

Implements the NomialMap class

class gpkit.nomials.map.NomialMap
  Bases: gpkit.small_classes.HashVector
  Class for efficient algebraic representation of a nominal

  A NomialMap is a mapping between hashvectors representing exponents and their coefficients in a
  posynomial.

  For example, {{x : 1}: 2.0, {y: 1}: 3.0} represents 2*x + 3*y, where x and y are VarKey objects.

copy()
  Return a copy of this

cormap = None

diff(varkey)
  Differentiates a NomialMap with respect to a varkey

expmap = None

mmap (orig)
  Maps substituted monomials back to the original nominal

  self.expmap is the map from pre- to post-substitution exponents, and takes the form
  {original_exp: new_exp}

  self.cormap is the map from pre-substitution exponents to coefficients.

  m_from_ms is of the form {new_exp: [old_exps, ]}

  pmap is of the form [{orig_idx1: fraction1, orig_idx2: fraction2}, ] where at the index
  corresponding to each new_exp is a dictionary mapping the indices corresponding to
  the old exps to their fraction of the post-substitution coefficient

sub(substitutions, varkeys, parsedsubs=False)
  Applies substitutions to a NomialMap

  substitutions [(dict-like)] list of substitutions to perform

  varkeys [(set-like)] varkeys that are present in self (required argument so as to require effi-
  cient code)
parsedsubs [bool] flag if the substitutions have already been parsed to contain only keys in varkeys

to (to_units)
Returns a new NomialMap of the given units

units = None

units_of_product (thing, thing2=None)
Sets units to those of thing*thing2. Ugly optimized code.

gpkit.nomials.map.subinplace (cp, exp, o_exp, vk, cval, squished)
Modifies cp by substituing cval/expval for vk in exp

**gpkit.nomials.math module**

Signomial, Posynomial, Monomial, Constraint, & MonoEQConstraint classes

class gpkit.nomials.math.Monomial (hmap=None, cs=1, require_positive=True)
Bases: gpkit.nomials.math.Posynomial

A Posynomial with only one term

c
Creates c or returns a cached c

exp
Creates exp or returns a cached exp

mono_approximation (x0)

class gpkit.nomials.math.MonomialEquality (left, right)
Bases: gpkit.nomials.math.PosynomialInequality

A Constraint of the form Monomial == Monomial.

as_posyslt1 (substitutions=None)
Tags posynomials for dual feasibility checking

oper = u'='

sens_from_dual (la, nu, result)
Returns the variable/constraint sensitivities from lambda/nu

class gpkit.nomials.math.Posynomial (hmap=None, cs=1, require_positive=True)
Bases: gpkit.nomials.math.Signomial

A Signomial with strictly positive cs

mono_lower_bound (x0)
Monomial lower bound at a point x0

x0 (dict): point to make lower bound exact

Monomial

class gpkit.nomials.math.PosynomialInequality (left, oper, right)
Bases: gpkit.nomials.math.ScalarSingleEquationConstraint

A constraint of the general form monomial >= posynomial Stored in the posylt1_rep attribute as a single Posynomial (self <= 1) Usually initialized via operator overloading, e.g. cc = (y**2 >= 1 + x)
as_gpconstr (x0)
The GP version of a Posynomial constraint is itself

as_posyslt1 (substitutions=None)
Returns the posys <= 1 representation of this constraint.

feastol = 0.001

relax_sensitivity = None

sens_from_dual (la, nu, result)
Returns the variable/constraint sensitivities from lambda/nu

sgp_parent = None

class gpkit.nomials.math.ScalarSingleEquationConstraint (left, oper, right)
Bases: gpkit.constraints.single_equation.SingleEquationConstraint
A SingleEquationConstraint with scalar left and right sides.
	nomials = []

relaxed (relaxvar)
Returns the relaxation of the constraint in a list.

class gpkit.nomials.math.Signomial (hmap=None, cs=1, require_positive=True)
Bases: gpkit.nomials.core.Nomial
A representation of a Signomial.

exps: tuple of dicts Exponent dicts for each monomial term

cs: tuple Coefficient values for each monomial term

require_positive: bool If True and Signomials not enabled, c <= 0 will raise ValueError

Signomial Posynomial (if the input has only positive cs) Monomial (if the input has one term and only positive cs)

chop ()
Returns a list of monomials in the signomial.

diff (var)
Derivative of this with respect to a Variable

var [Variable key] Variable to take derivative with respect to

Signomial (or Posynomial or Monomial)

mono_approximation (x0)
Monomial approximation about a point x0

x0 (dict): point to monomialize about
Monomial (unless self(x0) < 0, in which case a Signomial is returned)

posy_negy ()
Get the positive and negative parts, both as Posynomials

Posynomial, Posynomial: p_pos and p_neg in (self = p_pos - p_neg) decomposition,

sub (substitutions, require_positive=True)
Returns a nominal with substituted values.

3 == (x**2 + y).sub({'x': 1, y: 2}) 3 == (x).gp.sub(x, 3)
substitutions [dict or key] Either a dictionary whose keys are strings, Variables, or VarKeys, and whose values are numbers, or a string, Variable or Varkey.

val [number (optional)] If the substitutions entry is a single key, val holds the value

require_positive [boolean (optional, default is True)] Controls whether the returned value can be a Signomial.

Returns substituted nominal.

class gpkit.nomials.math.SignomialInequality(left, oper, right)
Bases: gpkit.nomials.math.ScalarSingleEquationConstraint

A constraint of the general form posynomial >= posynomial

Stored internally (exps, cs) as a single Signomial (0 >= self)

as_approxsgt(x0)
Returns monomial-greater-than sides, to be called after as_approxlt1

as_approxslt() Returns posynomial-less-than sides of a signomial constraint

as_gpconstr(x0)
Returns GP approximation of an SP constraint at x0

as_posyslt1(substitutions=None)
Returns the posys <= 1 representation of this constraint.

sens_from_dual(la, nu, result)
We want to do the following chain: \( \frac{d \log(\text{Obj})}{d \log(\text{monomial}[i])} = \frac{\text{nu}[i]}{\text{dlog(\text{monomial})/d(monomial)}} = 1/(\text{monomial value}) \times \frac{\text{d(monomial)/d(var)}}{\text{d(var)/dlog(var)}} = \frac{\text{d(coeff)/d(var)*1/negy}}{\text{d(1/negy)/d(var)*coeff - d(coeff)/d(var)*1/negy*coeff*1/negy**2}} \)

class gpkit.nomials.math.SingleSignomialEquality(left, right)
Bases: gpkit.nomials.math.SignomialInequality

A constraint of the general form posynomial == posynomial

as_approxsgt(x0)
Returns monomial-greater-than sides, to be called after as_approxlt1

as_approxslt() Returns posynomial-less-than sides of a signomial constraint

as_gpconstr(x0)
Returns GP approximation of an SP constraint at x0

as_posyslt1(substitutions=None)
Returns the posys <= 1 representation of this constraint.

gpkit.nomials.substitution module

Scripts to parse and collate substitutions

gpkit.nomials.substitution.append_sub(sub, keys, constants, sweep, linkedsweep)
Appends sub to constants, sweep, or linkedsweep.
gpkit.nomials.substitution.parse_subs(varkeys, substitutions, clean=False)

Separates subs into the constants, sweeps, linkedsweeps actually present.

**gpkit.nomials.variables module**

Implement Variable and ArrayVariable classes

class gpkit.nomials.variables.ArrayVariable
    Bases: gpkit.nomials.array.NomialArray
    A described vector of singlet Monomials.
    shape [int or tuple] length or shape of resulting array
    *args :
        may contain “name” (Strings)
        “value” (Iterable) “units” (Strings)
        and/or “label” (Strings)
    **descr :** VarKey description
    NomialArray of Monomials, each containing a VarKey with name ‘$name_[i]’, where $name is the vector’s name and i is the VarKey’s index.

class gpkit.nomials.variables.Variable(*args, **descr)
    Bases: gpkit.nomials.math.Monomial
    A described singlet Monomial.
    *args [list]
        may contain “name” (Strings)
        “value” (Numbers + Quantity) or (Iterable) for a sweep “units” (Strings)
        and/or “label” (Strings)
    **descr :** [dict] VarKey description
    Monomials containing a VarKey with the name ‘$name’, where $name is the vector’s name and i is the VarKey’s index.
    sub (*args, **kwargs)
        Same as nomial substitution, but also allows single-argument calls
        x = Variable('x') assert x.sub(3) == Variable('x', value=3)
    to (units)
        Create new Signomial converted to new units

class gpkit.nomials.variables.VectorizableVariable(*args, **descr)
    Bases: gpkit.nomials.variables.Variable, gpkit.nomials.variables.ArrayVariable
    A Variable outside a vectorized environment, an ArrayVariable within.

gpkit.nomials.variables.addmodelstodescr(descr, addtonamedvars=None)
    Add models to descr, optionally adding the second argument to NAMEDVARS

gpkit.nomials.variables.veclinkedfn(linkedfn, i)
    Generate an indexed linking function.
Module contents

Contains nomials, inequalities, and arrays

gpkit.tools package

Submodules

gpkit.tools.autosweep module

Tools for optimal fits to GP sweeps

class gpkit.tools.autosweep.BinarySweepTree(bounds, sols, sweptvar, cost_posy)

Bases: object

Spans a line segment. May contain two subtrees that divide the segment.

bounds [two-element list] The left and right boundaries of the segment
sols [two-element list] The left and right solutions of the segment
costs [array] The left and right logcosts of the segment
splits [None or two-element list] If not None, contains the left and right subtrees
splitval [None or float] The worst-error point, where the split will be if tolerance is too low
splitlb [None or float] The cost lower bound at splitval
splitub [None or float] The cost upper bound at splitval

add_split (splitval, splitsol)
Creates subtrees from bounds[0] to splitval and splitval to bounds[1]

add_splitcost (splitval, splitlb, splitub)
Adds a splitval, lower bound, and upper bound

cost_at (_, value, bound=None)
Logspace interpolates between split and costs. Guaranteed bounded.

min_bst (value)
Returns smallest bst around value.

posy_at (posy, value)
Logspace interpolates between sols to get posynomial values.

No guarantees, just like a regular sweep.

sample_at (values)
Creates a SolutionOracle at a given range of values

save (filename='autosweep.p')
Pickles the autosweep and saves it to a file.

The saved autosweep is identical except for two things:

- the cost is made unitless
- each solution’s ‘program’ attribute is removed

Solution can then be loaded with e.g.:
```python
>>> import cPickle as pickle
>>> pickle.load(open("autosweep.p"))
```

**solarray**

Returns a solution array of all the solutions in an autosweep

**sollist**

Returns a list of all the solutions in an autosweep

```python
class gpkit.tools.autosweep.SolutionOracle(bst, sampled_at)
```
Bases: object

Acts like a SolutionArray for autosweeps

```python
cost_lb()
```

Gets cost lower bounds from the BST and units them

```python
cost_ub()
```

Gets cost upper bounds from the BST and units them

```python
plot(posys=None, axes=None)
```

Plots the sweep for each posy

```python
gpkit.tools.autosweep.autosweep_1d(model, logtol, sweepvar, bounds, **solvekwargs)
```

Autosweep a model over one sweepvar

```python
gpkit.tools.autosweep.get_tol(costs, bounds, sols, variable)
```

Gets the intersection point and corresponding bounds from two solutions.

```python
gpkit.tools.autosweep.recurse_splits(model, bst, variable, logtol, solvekwargs, sols)
```

Recursively splits a BST until logtol is reached

**gpkit.tools.docstring module**

Docstring-parsing methods

```python
gpkit.tools.docstring.check_and_parse_flag(string, flag, declaration_func=None)
```
Checks for instances of flag in string and parses them.

```python
gpkit.tools.docstring.constant_declare(string, flag, idx2, countstr)
```

Turns Variable declarations into Constant ones

```python
gpkit.tools.docstring.expected_unbounded(instance, doc)
```

Gets expected-unbounded variables from a string

```python
class gpkit.tools.docstring.parse_variables(string, scopevars=None)
```
Bases: object

decorator for adding local Variables from a string.

Generally called as `@parse_variables(__doc__, globals())`.

```python
gpkit.tools.docstring.parse_varstring(string)
```
Parses a string to determine what variables to create from it

```python
gpkit.tools.docstring.variable_declaration(nameval, units, label, line, errorcatch=True)
```

Turns parsed output into a Variable declaration
gpkit Documentation, Release 0.9.1

**gpkit.tools.docstring.vv_declare**(string, flag, idx2, countstr)

Turns Variable declarations into VectorVariable ones

**gpkit.tools.fmincon module**

**gpkit.tools.spdata module**

**gpkit.tools.tools module**

Non-application-specific convenience methods for GPkit

**gpkit.tools.tools.te_exp_minus1**(posy, nterm)

Taylor expansion of $e^{\text{posy}} - 1$

- **posy** [gpkit.Posynomial] Variable or expression to exponentiate
- **nterm** [int] Number of non-constant terms in resulting Taylor expansion

**gpkit.Posynomial**  Taylor expansion of $e^{\text{posy}} - 1$, carried to nterm terms

**gpkit.tools.tools.te_secant**(var, nterm)

Taylor expansion of secant(var).

- **var** [gpkit.monomial] Variable or expression argument
- **nterm** [int] Number of non-constant terms in resulting Taylor expansion

**gpkit.Posynomial**  Taylor expansion of secant(x), carried to nterm terms

**gpkit.tools.tools.te_tangent**(var, nterm)

Taylor expansion of tangent(var).

- **var** [gpkit.monomial] Variable or expression argument
- **nterm** [int] Number of non-constant terms in resulting Taylor expansion

**gpkit.Posynomial**  Taylor expansion of tangent(x), carried to nterm terms

**Module contents**

Contains miscellaneous tools including fmincon comparison tool

**10.1.2 Submodules**

**10.1.3 gpkit.build module**

Finds solvers, sets gpkit settings, and builds gpkit

**class** gpkit.build.CVXopt

Bases: gpkit.build.SolverBackend

CVXopt finder.

**look**()

Attempts to import cvxopt.
name = u'cvxopt'

class gpkit.build.Mosek
    Bases: gpkit.build.SolverBackend
    MOSEK finder and builder.
    bin_dir = None
    build()
        Builds a dynamic library to GPKITBUILD or $HOME/.gpkit
    expopt_files = None
    flags = None
    lib_name = None
    lib_path = None
    look()
        Looks in default install locations for latest mosek version.
    name = u'mosek'
    patches = {u'dgopt.c': {u'printf("Number of Hessian non-zeros: %d\n",nlh[0]->numhesnz);': ...
    version = None

class gpkit.build.MosekCLI
    Bases: gpkit.build.SolverBackend
    MOSEK command line interface finder.
    look()
        Attempts to run mskexpopt.
    name = u'mosek_cli'

class gpkit.build.SolverBackend
    Bases: object
    Inheritable class for finding solvers. Logs.
    build = None
    installed = False
    look = None
    name = None

gpkit.build.build()
    Builds GPkit

gpkit.build.call(cmd)
    Calls subprocess. Logs.

gpkit.build.diff(filename, diff_dict)
    Applies a simple diff to a file. Logs.

gpkit.build.isfile(path)
    Returns true if there's a file at path. Logs.

gpkit.build.log(*args)
    Print a line and append it to the log string.
gpkit.build.pathjoin(*args)
    Join paths, collating multiple arguments.

gpkit.build.replacedir(path)
    Replaces directory at $path. Logs.

10.1.4 gpkit.exceptions module

GPkit-specific Exception classes

exception gpkit.exceptions.InvalidGPConstraint
    Bases: exceptions.Exception
    Raised when a non-GP-compatible constraint is used in a GP

exception gpkit.exceptions.InvalidPosynomial
    Bases: exceptions.Exception
    Raised when a Posynomial would be created with a negative coefficient

10.1.5 gpkit.globals module

global mutable variables

class gpkit.globals.NamedVariables(name)
    Bases: object
    Creates an environment in which all variables have a model name and num appended to their varkeys.
    lineage = ()
    modelnums = {}
    namedvars = {}
    classmethod reset_modelnumbers()
        Clear all model number counters

class gpkit.globals.SignomialsEnabled
    Bases: object
    Class to put up and tear down signomial support in an instance of GPkit.

>>> import gpkit
>>> x = gpkit.Variable("x")
>>> y = gpkit.Variable("y", 0.1)
>>> with SignomialsEnabled():
>>>     constraints = [x >= 1-y]
>>>     gpkit.Model(x, constraints).localsolve()

class gpkit.globals.SignomialsEnabledMeta
    Bases: type
    Metaclass to implement falsiness for SignomialsEnabled

class gpkit.globals.Vectorize(dimension_length)
    Bases: object
    Creates an environment in which all variables are extended in an additional dimension.
10.1.6 gpkit.keydict module

Implements KeyDict and KeySet classes

class gpkit.keydict.KeyDict(*args, **kwargs)
    Bases: dict
    KeyDicts do two things over a dict: map keys and collapse arrays.
    >>>>> kd = gpkit.keydict.KeyDict()
    If .keymapping is True, a KeyDict keeps an internal list of VarKeys as canonical keys, and their values can be accessed with any object whose key attribute matches one of those VarKeys, or with strings matching any of the multiple possible string interpretations of each key:

    For example, after creating the KeyDict kd and setting kd[x] = v (where x is a Variable or VarKey), v can be accessed with by the following keys:
    • x
    • x.key
    • x.name (a string)
    • “x_modelname” (x’s name including modelname)

    Note that if a item is set using a key that does not have a .key attribute, that key can be set and accessed normally.

    If .collapse_arrays is True then VarKeys which have a shape parameter (indicating they are part of an array) are stored as numpy arrays, and automatically de-indexed when a matching VarKey with a particular idx parameter is used as a key.

    See also: gpkit/tests/t_keydict.py.

collapse_arrays = True
get(k, d) → D[k] if k in D, else d. d defaults to None.
keymap = []
keymapping = True
parse_and_index(key)
    Returns key if key had one, and veckey/idx for indexed veckeys.
update(*args, **kwargs)
    Iterates through the dictionary created by args and kwargs
update_keymap()
    Updates the keymap with the keys in _unmapped_keys

class gpkit.keydict.KeySet(*args, **kwargs)
    Bases: gpkit.keydict.KeyDict
    KeyDicts that don’t collapse arrays or store values.

    add(item)
        Adds an item to the keyset
collapse_arrays = False

update(*args, **kwargs)
    Iterates through the dictionary created by args and kwargs

gpkit.keydict.clean_value(key, value)
    Gets the value of variable-less monomials, so that x.sub({x: gpkit.units.m}) and x.sub({x: gpkit.ureg.m}) are equivalent.

    Also converts any quantities to the key’s units, because quantities can’t/shouldn’t be stored as elements of numpy arrays.

10.1.7 gpkit.repr_conventions module

Repository for representation standards

class gpkit.repr_conventions.GPkitObject
    Bases: object

    This class combines various printing methods for easier adoption.

    ast = None
    cached_strs = None

    latex_unitstr()
        Returns latex unitstr

    lineagestr(modelnums=True)
        Returns properly formatted lineage string

    parse_ast(excluded=u'units')
        Turns the AST of this object’s construction into a faithful string

    unitstr(into=u'%s', options=u':~', dimless=u")
        Returns the string corresponding to an object’s units.

gpkit.repr_conventions.lineagestr(lineage, modelnums=True)
    Returns properly formatted lineage string

gpkit.repr_conventions.parenthesize(string, addi=True, mult=True)
    Parenthesizes a string if it needs it and isn’t already.

gpkit.repr_conventions.strify(val, excluded)
    Turns a value into as pretty a string as possible.

gpkit.repr_conventions.unitstr(units, into=u'%s', options=u':~', dimless=u")
    Returns the string corresponding to an object’s units.

10.1.8 gpkit.small_classes module

Miscellaneous small classes

class gpkit.small_classes.CootMatrix(row, col, data)
    Bases: object

    A very simple sparse matrix representation.

    dot(arg)
        Returns dot product with arg.
toco()  
Converts to another type of matrix.

tocsc()  
Converts to another type of matrix.

tocsr()  
Converts to a Scipy sparse csr_matrix

todense()  
Converts to another type of matrix.

todia()  
Converts to another type of matrix.

todok()  
Converts to another type of matrix.

class gpkit.small_classes.Count  
Bases: object
Like python 2's itertools.count, for Python 3 compatibility.

next()  
Increment self.count and return it

class gpkit.small_classes.DictOfLists  
Bases: dict
A hierarchy of dictionaries, with lists at the bottom.

append(sol)  
Appends a dict (of dicts) of lists to all held lists.

atindex(i)  
Indexes into each list independently.

to_arrays()  
Converts all lists into array.

class gpkit.small_classes.FixedScalar  
Bases: object
Instances of this class are scalar Nomials with no variables

class gpkit.small_classes.FixedScalarMeta  
Bases: type
Metaclass to implement instance checking for fixed scalars

class gpkit.small_classes.HashVector  
Bases: dict
A simple, sparse, string-indexed vector. Inherits from dict.
The HashVector class supports element-wise arithmetic: any undeclared variables are assumed to have a value of zero.

arg : iterable

>>> x = gpkit.nomials.Monomial('x')
>>> exp = gpkit.small_classes.HashVector({x: 2})

copy()  
Return a copy of this
hashvalue = None

class gpkit.small_classes.SolverLog(verbosity=0, output=None, **kwargs)
    Bases: list
    Adds a write method to list so it’s file-like and can replace stdout.
    write (writ)
        Append and potentially write the new line.

gpkit.small_classes.matrix_converter(name)
    Generates conversion function.

10.1.9 gpkit.small_scripts module

Assorted helper methods

class gpkit.small_scripts.SweepValue(value)
    Bases: object
    Object to represent a swept substitution.

appendsolwarning(msg, data, result, category='uncategorized')
    Append a particular category of warnings to a solution.

gpkit.small_scripts.get_sweepval(sub)
    Returns a given substitution’s indicated sweep, or None.

gpkit.small_scripts.is_sweepvar(sub)
    Determines if a given substitution indicates a sweep.

gpkit.small_scripts.latex_num(c)
    Returns latex string of numbers, potentially using exponential notation.

gpkit.small_scripts.mag(c)
    Return magnitude of a Number or Quantity

gpkit.small_scripts.maybe_flatten(value)
    Extract values from 0-d numpy arrays, if necessary

gpkit.small_scripts.nomial_latex_helper(c, pos_vars, neg_vars)
    Combines (varlatex, exponent) tuples, separated by positive vs negative exponent, into a single latex string

gpkit.small_scripts.splitsweep(sub)
    Splits a substitution into (is_sweepvar, sweepval)

gpkit.small_scripts.try_str_without(item, excluded, latex=False)
    Try to call item.str_without(excluded); fall back to str(item)

10.1.10 gpkit.solution_array module

Defines SolutionArray class

class gpkit.solution_array.SolutionArray
    Bases: gpkit.small_classes.DictOfLists
    A dictionary (of dictionaries) of lists, with convenience methods.
    cost : array variables: dict of arrays sensitivities: dict containing:
monomials : array posynomials : array variables: dict of arrays

localmodels [NomialArray] Local power-law fits (small sensitivities are cut off)

```python
>>> import gpkit
>>> import numpy as np

x = gpkit.Variable("x")

x_min = gpkit.Variable("x_{\text{min}}", 2)

sol = gpkit.Model(x, [x >= x_min]).solve(verbosity=0)

>>> # VALUES
>>> values = [sol(x), sol.subinto(x), sol["variables"]['x']]
>>> assert all(np.array(values) == 2)

>>> # SENSITIVITIES
>>> senss = [sol.sens(x_min), sol.sens(x_min)]
>>> senss.append(sol["sensitivities"]['variables']['x_{\text{min}}'])
>>> assert all(np.array(senss) == 1)
```

almost_equal (sol, reltol=0.001, sens_abstol=0.01)
Checks for almost-equality between two solutions
diff (sol, showvars=None, min_percent=1.0, show_sensitivities=True, min_senss_delta=0.1, sortbymodel=True)
Outputs differences between this solution and another

- sol [solution or string] Strings are treated as paths to valid pickled solutions
- min_percent [float] The smallest percentage difference in the result to consider
- show_sensitivities [boolean] if True, also computer sensitivity deltas
- min_senss_delta [float] The smallest absolute difference in sensitivities to consider

str
model = None

name_collision_varkeys ()
Returns the set of contained varkeys whose names are not unique

pickle_prep ()
After calling this, the SolutionArray is ready to pickle

plot (posys=None, axes=None)
Plots a sweep for each posy

program = None

save (filename=\'solution.pkl\')
Pickles the solution and saves it to a file.

The saved solution is identical except for two things:
- the cost is made unitless
- the solution’s ‘program’ attribute is removed
- the solution’s ‘model’ attribute is removed
- the data field is removed from the solution’s warnings (the “message” field is preserved)
Solution can then be loaded with e.g.: >>> import pickle >>> pickle.load(open("solution.pkl"))

`savecsv`(`showvars=None, filename=u’solution.csv’, valcols=5, **kwargs)`
Saves primal solution as a CSV sorted by modelname, like the tables.

`savemat`(`filename=u’solution.mat’, showvars=None, excluded=(u’unnecessary lineage’, u’vec’)`)  
Saves primal solution as matlab file

`savetxt`(`filename=u’solution.txt’, printmodel=True, **kwargs`)  
Saves solution table as a text file

`subinto`(`posy`)  
Returns NomialArray of each solution substituted into posy.

`summary`(`showvars=(), ntopsenss=5, **kwargs`)  
Print summary table, showing top sensitivities and no constants

`table`(`showvars=(), tables=(u’cost’, u’warnings’, u’sweepvariables’, u’freevariables’, u’constants’, u’variables’, u’tightest constraints’), **kwargs`)  
A table representation of this SolutionArray

`tables: Iterable`  
Which to print of (“cost”, “sweepvariables”, “freevariables”, “constants”, “sensitivities”)  
fixedcols: If true, print vectors in fixed-width format latex: int  
If > 0, return latex format (options 1-3); otherwise plain text

`included_models: Iterable of strings`  
If specified, the models (by name) to include

`excluded_models: Iterable of strings`  
If specified, model names to exclude

`str`  

```python

```python

table_titles = {u'constants': u'Constants', u'freevariables': u'Free Variables',
```

`todataframe`(`showvars=None, excluded=(u’unnecessary lineage’, u’vec’)`)  
Returns primal solution as pandas dataframe

`varnames`(`showvars, exclude`)  
Returns list of variables, optionally with minimal unique names

`gpkit.solution_array.constraint_table`(`data, sortbymodel=True, showmodels=True, **_)`  
Creates lines for tables where the right side is a constraint.

`gpkit.solution_array.insenss_table`(`data, _, maxval=0.1, **kwargs`)  
Returns insensitivity table lines

`gpkit.solution_array.loose_table`(`self, _, min_senss=1e-05, **kwargs`)  
Returns constraint tightness lines

`gpkit.solution_array.reldiff`(`val1, val2`)  
Relative difference between val1 and val2 (positive if val2 is larger)

`gpkit.solution_array.senss_table`(`data, showvars=(), title=u'Sensitivities', **kwargs`)  
Returns sensitivity table lines
**gpkit.solver_array.tight_table**

```python
self, ntightconstrs=5, tight_senss=0.01, **kwargs)
```

Return constraint tightness lines

**gpkit.solver_array.topsenss_filter**

```python
data, showvars, nvars=5)
```

Filters sensitivities down to top N vars

**gpkit.solver_array.topsenss_table**

```python
data, showvars, nvars=5, **kwargs)
```

Returns top sensitivity table lines

**gpkit.solver_array.var_table**

```python
data, title, printunits=True, latex=False, rawlines=True, varfmt=u'%s : ', valfmt=u'%-.4g ', vecfmt=u'%-8.3g', minval=0, sortbyvals=False, hidebelowminval=False, included_models=None, excluded_models=None, sortbymodel=True, maxcolumns=5, **_)```

Pretty string representation of a dict of VarKeys, iterable values are handled specially (partial printing)

- `data` [dict whose keys are VarKey’s] data to represent in table
- `title` : string
- `printunits` : bool
- `latex` : int
  - If > 0, return latex format (options 1-3); otherwise plain text
- `varfmt` [string] format for variable names
- `valfmt` [string] format for scalar values
- `vecfmt` [string] format for vector values
- `minval` [float] skip values with all(abs(value)) < minval
- `sortbyvals` [boolean] If true, rows are sorted by their average value instead of by name.
- `included_models` [Iterable of strings] If specified, the models (by name) to include
- `excluded_models` [Iterable of strings] If specified, model names to exclude

**gpkit.solver_array.warnings_table**

```python
self, **kwargs)
```

Makes a table for all warnings in the solution.

### 10.1.11 gpkit.varkey module

Defines the VarKey class

**class gpkit.varkey.VarKey**

```python
name=None, **kwargs)
```

Bases: `gpkit.repr_conventions.GPkitObject`

An object to correspond to each ‘variable name’.

- `name` [str, VarKey, or Monomial] Name of this Variable, or object to derive this Variable from.
- **kwargs : Any additional attributes, which become the descr attribute (a dict).

VarKey with the given name and descr.

- `latex (excluded=())`
  - Returns latex representation.

- `models` Returns a tuple of just the names of models in self.lineage

### 10.1. gpkit package

89
\texttt{str\_without}(\textit{excluded} = ())

    Returns string without certain fields (such as 'lineage').

\texttt{subscripts} = (u'\texttt{lineage}', u'\texttt{idx}')

\texttt{classmethod unique\_id()}

    Increment self.count and return it

\texttt{vars\_of\_a\_name} = ()

\section*{10.1.12 Module contents}

GP and SP modeling package
CHAPTER 11

Citing GPkit

If you use GPkit, please cite it with the following bibtex:

```bibtex
@Misc{gpkit,
  author={Edward Burnell and Warren Hoburg},
  title={GPkit software for geometric programming},
  howpublished={\url{https://github.com/convexengineering/gpkit}},
  year={2014},
  note={Version 0.9.1}
}
```
We thank the following contributors for helping to improve GPkit:

- Marshall Galbraith for setting up continuous integration.
- Stephen Boyd for inspiration and suggestions.
- Kirsten Bray for designing the GPkit logo.
Release notes are available on Github
