| 7.3 Instantiating simulation models | 68 |
| 7.4 Connecting entities | 68 |
| 7.5 Running the simulation | 69 |
| 7.6 How to achieve bi-directional data-flows | 70 |
| 7.7 How to filter entity sets | 70 |
| 7.8 How to create user-defined connection rules | 71 |
| 7.9 How to retrieve static data from entities | 72 |
Contents:
This guide assumes that you are somewhat proficient with Python and know what `pip` and `virtualenv` is. Else, you should follow the detailed instructions.

Mosaik runs on Linux, OS X and Windows. It requires Python 3.3 or higher. To install everything, you need the package manager `Pip` which is bundled with Python 3.4 and above.

We also strongly recommend you to install everything into a `virtualenv`.

You can then install mosaik with pip:

```
$ pip install mosaik
```

This provides you with the mosaik framework. There is also a simple demo scenario which may help you to get started. Please refer to our detailed instructions for installation.
CHAPTER 2

Installation

This guide contains detailed installation instructions for Linux, OS X and Windows. It covers the installation of the mosaik framework followed by the instructions to install the demo.

2.1 Linux

This guide is based on (K)ubuntu 14.04 Trusty Tahr, 64bit.

Mosaik and the demo scenario require Python >= 3.3. Ubuntu ships with Python 3.4, so everything is okay.

1. We also need pip, a package manager for Python packages, and virtualenv, which can create isolated Python environments for different projects:

   $ wget https://bootstrap.pypa.io/get-pip.py
   $ sudo python get-pip.py
   $ sudo pip install -U virtualenv

2. Now we need to create a virtual environment for mosaik and its dependencies. The common location for venvs is under ~/.virtualenvs/:

   $ virtualenv -p /usr/bin/python3 ~/.virtualenvs/mosaik
   $ source ~/.virtualenvs/mosaik/bin/activate

   Your command line prompt should now start with “(mosaik)” and roughly look like this: (mosaik)user@kubuntu:~$.

3. The final step is to install mosaik:

   (mosaik)$ pip install mosaik

   Mosaik should now be installed successfully.

2.1.1 Running the demo

Mosaik alone is not very useful (because it needs other simulators to perform a simulation), so we also provide a small demo scenario and some simple simulators as well as a mosaik binding for PYPOWER.

1. PYPOWER requires NumPy and SciPy. We also need to install the revision control tool git. You can use the packages shipped with Ubuntu. We use `apt-get` to install NumPy, SciPy, and h5py as well as git. By default, venvs are isolated from globally installed packages. To make them visible, we also have to recreate the venv and set the `--system-site-packages` flag:
2. You can now clone the mosaik-demo repository into a folder where you store all your code and repositories (we'll use ~/Code/):

   (mosaik)$ mkdir ~/Code
   (mosaik)$ git clone https://git@bitbucket.org/mosaik/mosaik-demo.git ~/Code/mosaik-demo

3. Now we only need to install all requirements (mosaik and the simulators) and can finally run the demo:

   (mosaik)$ cd ~/Code/mosaik-demo/
   (mosaik)$ pip install -r requirements.txt
   (mosaik)$ python demo.py

   If no errors occur, the last command will start the demo. The web visualisation shows the demo in your browser: http://localhost:8000. You can click the nodes of the topology graph to show a time series of their values. You can also drag them around to rearrange them.

   You can cancel the simulation by pressing Ctrl-C.

### 2.2 OS X

This guide is based on OS X 10.11 El Capitan.

1. Mosaik and the demo scenario require Python >= 3.3. OS X only ships with some outdated versions of Python, so we need to install a recent Python 2 and 3 first. The recommended way of doing this is with the packet manager homebrew. To install homebrew, we need to open a Terminal and execute the following command:

   $ ruby -e "$(curl -fsSL https://raw.githubusercontent.com/Homebrew/install/master/install)"

   The homebrew installer asks you to install the command line developer tools for "xcode-select". Install them. When you are done, go back to the terminal and press Enter so that the installer continues.

   If this doesn’t work for you, you’ll find more detailed instructions in the homebrew wiki.

   Once the installation is successful, we can install python and python3:

   $ brew install python python3

   This will also install the Python package manager pip.

2. Next, we need virtualenv which can create isolated Python environments for different projects:

   $ pip install -U virtualenv

3. Now we need to create a virtual environment for mosaik and its dependencies. The common location for venvs is under ~/.virtualenvs/:

   $ virtualenv -p /usr/local/bin/python3 ~/.virtualenvs/mosaik
   $ source ~/.virtualenvs/mosaik/bin/activate

   Your command line prompt should now start with “(mosaik)” and roughly look like this: (mosaik)user@macbook:~$.

4. The final step is to install mosaik:
mosaik Documentation, Release 2.5.1

(mosaik)$ pip install mosaik

Mosaik should now be installed successfully.

## 2.2.1 Running the demo

Mosaik alone is not very useful (because it needs other simulators to perform a simulation), so we also provide a small demo scenario and some simple simulators as well as a mosaik binding for PYPOWER.

1. To clone the demo repository, we need to install git. In order to compile NumPy, SciPy and h5py (which are required by PYPOWER and the database adapter) we also need to install gfortran which is included in gcc. You should deactivate the venv for this:

   (mosaik)$ deactivate
   $ brew install git gcc hdf5
   $ source ~/.virtualenvs/mosaik/bin/activate

2. For NumPy and SciPy we build binary wheel packages that we can later reuse without re-compiling everything. We'll store these wheels in `~/wheelhouse/`:

   (mosaik)$ pip install wheel
   (mosaik)$ pip wheel numpy
   (mosaik)$ pip install wheelhouse/numpy-1.10.1-cp35-cp35m-macosx_10_6_intel.macosx_10_9_intel.macosx_10_9_x86_64.macosx_10_10_intel.macosx_10_10_x86_64.whl
   (mosaik)$ pip wheel scipy
   (mosaik)$ pip install wheelhouse/scipy-0.16.0-cp35-cp35m-macosx_10_6_intel.macosx_10_9_intel.macosx_10_9_x86_64.macosx_10_10_intel.macosx_10_10_x86_64.whl
   (mosaik)$ pip wheel h5py
   (mosaik)$ pip install wheelhouse/h5py-2.5.0-cp35-cp35m-macosx_10_6_intel.macosx_10_9_intel.macosx_10_9_x86_64.macosx_10_10_intel.macosx_10_10_x86_64.whl

Note: The file names of the wheels (*.whl-files) may change when version-numbers change. Please check the output of `pip install` or the directory `~/wheelhouse/` for the exact file names.

2. You can now clone the mosaik-demo repository into a folder where you store all your code and repositories (we'll use `~/Code/`):

   (mosaik)$ mkdir ~/Code
   (mosaik)$ git clone https://git@bitbucket.org/mosaik/mosaik-demo.git ~/Code/mosaik-demo

3. Now we only need to install all requirements (mosaik and the simulators) and can finally run the demo:

   (mosaik)$ cd ~/Code/mosaik-demo/
   (mosaik)$ pip install -r requirements.txt
   (mosaik)$ python demo.py

   If no errors occur, the last command will start the demo. The web visualisation shows the demo in your browser: http://localhost:8000. You can click the nodes of the topology graph to show a time series of their values. You can also drag them around to rearrange them.

   You can cancel the simulation by pressing Ctrl-C.

## 2.3 Windows

2.3. Windows
This guide is based on Windows 7 or 8, 64bit.

1. Mosaik and the demo scenario require Python >= 3.3. By default, it will offer you a 32bit installer. You can find the Windows x86-64 MSI installer here.
   (a) When the download finished, double-click the installer.
   (b) Select Install for all users and click Next >.
   (c) The default installation path is okay. Click Next >.
   (d) In the Customize Python page, click on the Python node and select Entire feature will be installed on local hard drive. Make sure that Add python.exe to Path is enabled. Click Next >.
   (e) When Windows asks you to allow the installation, allow the installation. Wait. Click Finish.
   This also install the Python package manager pip.

2. We also need virtualenv which can create isolated Python environments for different projects.
   Open a terminal window: Press the Windows key (or click on the start menu) and enter cmd. Press Enter.
   Your terminal prompt should look like C:\Users\yourname>. Execute the following command to install virtualenv:
   ```
   C:\Users\yourname> pip install -U virtualenv
   ```
   **Note:** If your Windows account type is Standard User, you need to open the terminal with administrator privileges (right-click the Terminal icon, then open as Administrator). Make then sure that you are in your user directory:
   ```
   C:\Windows\system32> cd \Users\yourname
   C:\Users\yourname>
   ```

3. Now we need to create a virtual environment for mosaik and its dependencies. The common location for venvs is under Envs/ in your users directory:
   ```
   C:\Users\yourname> virtualenv -p C:\Python34\python.exe Envs\mosaik
   C:\Users\yourname> Envs\mosaik\Scripts\activate.bat
   ```
   Your command line prompt should now start with “(mosaik)” and roughly look like this: (mosaik) C:\Users\yourname>.

4. The final step is to install mosaik:
   ```
   (mosaik) C:\Users\yourname> pip install mosaik
   ```
   Mosaik should now be installed successfully.

### 2.3.1 Running the demo

Mosaik alone is not very useful (because it needs other simulators to perform a simulation), so we also provide a small demo scenario and some simple simulators as well as a mosaik binding for PYPOWER.
1. **PYPOWER** requires *NumPy* and *SciPy* and the database adapter requires *h5py*. Christoph Gohlke provides installers for them (*NumPy*, *SciPy*, *h5py*). Select the appropriate files for your Python installation (32bit or 64bit, Python version), e.g., `numpy-1.9.2+mkl-cp34-none-win_amd64.whl`, `scipy-0.15.1-cp34-none-win_amd64.whl`, `h5py-2.5.0-cp34-none-win_amd64.whl`.

**Note:** Run `python -c "import sys; print(sys.version)"` from the command prompt in order to get the system architecture and Python version.

If you have a 64bit Windows, but installed a 32bit Python, also use the 32bit versions of NumPy etc.

Download them into your downloads folder and install them via the following commands:

```bash
(mosaik) C:\Users\yourname> pip install Downloads\numpy-1.9.2+mkl-cp34-none-win_amd64.whl
(mosaik) C:\Users\yourname> pip install Downloads\scipy-0.15.1-cp34-none-win_amd64.whl
(mosaik) C:\Users\yourname> pip install Downloads\h5py-2.5.0-cp34-none-win_amd64.whl
```

2. Download and install *git*.

   **Restart the command** prompt (as Admin if necessary and make sure you are in the right directory again) and activate the virtualenv again:

   ```bash
   C:\Users\yourname> Envs\mosaik\Scripts\activate.bat
   ```

3. Clone the demo repository:

   ```bash
   (mosaik)C:\Users\yourname> git clone https://git@bitbucket.org/mosaik/mosaik-demo.git
   ```

3. Now we only need to install all requirements (mosaik and the simulators) and can finally run the demo:

   ```bash
   (mosaik)C:\Users\yourname> cd mosaik-demo
   (mosaik)C:\Users\yourname\mosaik-demo> pip install -r requirements.txt
   (mosaik)C:\Users\yourname\mosaik-demo> python demo.py
   ```

   An exception may be raised at the end of the installation, but as long as before that exception there was the output `Successfully installed PYPOWER mosaik-csv mosaik-householdsim ...`, everything is okay.

   The web visualisation shows the demo in your browser: [http://localhost:8000](http://localhost:8000). You can click the nodes of the topology graph to show a timeline of their values. You can also drag them around to rearrange them.

   You can cancel the simulation by pressing **Ctrl-C**. More exceptions may be raised. No problem. :-)

---

2.3. Windows
CHAPTER 3

Overview

This section describes how mosaik works without going into too much detail. After reading this, you should have a general understanding of what mosaik does and how to proceed in order to implement the mosaik API or to create a simulation scenario.

3.1 What’s mosaik supposed to do?

Mosaik’s main goal is to use existing simulators in a common context in order to perform a coordinated simulation of a given (Smart Grid) scenario.

That means that all simulators (or other tools and hardware-in-the-loop) involved in a simulation usually run in their own process with their own event loop. Mosaik just tries to synchronize these processes and manages the exchange of data between them.

To allow this, mosaik

1. provides an API for simulators to communicate with mosaik,
2. implements handlers for different kinds of simulator processes,
3. allows the modelling of simulation scenarios involving the different simulators, and
4. schedules the step-wise execution of the different simulators and manages the exchange of data (data-flows) between them.

Although mosaik is written in Python 3, its simulator API completely language agnostic. It doesn’t matter if your simulator is written in Python 2, Java, C, matlab or anything else.

3.1.1 A simple example
We have simulators for households (blue icon) and for photovoltaics (green). We’re also gonna use a load flow analysis tool (grey), and a monitoring and analysis tool (yellow).

First, we have to implement the mosaik API for each of these “simulators”. When we are done with this, we can create a scenario where we connect the households to nodes in the power grid. Some of the households will also get a PV module. The monitoring / analysis tool will be connected to the power grid’s transformer node. When we connect all these entities, we also tell mosaik about the data-flows between them (e.g., active power feed-in from the PV modules to a grid node).

When we finally start the simulation, mosaik requests the simulators to perform simulation steps and exchanges data between them according to the data-flows described in the scenario. For our simple example, that would roughly look like this:

1. The household and PV simulator perform a simulation step for an interval \([0, t]\).
2. Mosaik gets the values for, e.g., \(P\) and \(Q\) (active and reactive power) for every household and every PV module.
3. Mosaik sets the values \(P\) and \(Q\) for every node of the power grid based on the data it collected in step 2. The load flow simulator performs a simulation step for \([0, t]\) based on these inputs.
4. Mosaik collects data from the load flow simulator, sends it to the monitoring tool and lets it also perform a simulation step for \([0, t]\).
5. Now the whole process is repeated for \([t, t+i]\) and so forth until the simulation ends.

In this example, all simulators had the same step size \(t\), but this is not necessary. Every simulator can have its one step size (which may even vary during the simulation). It is also possible that a simulator (e.g., a control strategy) can set input values (e.g., a schedule) to another simulator (e.g., for “intelligent” consumers).

### 3.2 Mosaik’s main components

Mosaik consists of four main components that implement the different aspects of a co-simulation framework:

1. **The mosaik Sim API** defines the communication protocol between simulators and mosaik.
   
   Mosaik uses plain network sockets and JSON encoded messages to communicate with the simulators. We call this the **low-level API**. For some programming languages there also exists a **high-level API** that implements everything networking related and offers an abstract base class. You then only have to write a subclass and implement a few methods.
   
   Read more . . .

2. **The Scenario API** provides a simple API that allows you to create your simulation scenarios in pure Python (yes, no graphical modelling!).
   
   The scenario API allows you to start simulators and instantiate models from them. This will give you entity sets (sets of entities). You can then connect the entities with each other in order to establish data-flows between the simulators.
   
   Mosaik allows you both, connecting one entity at a time as well as connecting whole entity sets with each other.
   
   Read more . . .

3. **The Simulator Manager** (or shorter, SimManager) is responsible for handling the simulator processes and communicating with them.
   
   It is able to a) start new simulator processes, b) connect to already running process instances, and c) import a simulator module and execute it in-process if it’s written in Python 3.
   
   The in-process execution has some benefits: it reduces the amount of memory required (because less processes need to be started) and it avoids the overhead of (de)serializing and sending messages over the network.
External processes, however, can be executed in parallel which is not possible with in-process simulators.

*Read more . . .*

4. Mosaik’s **simulator** uses the event-discrete simulation library **SimPy** for the coordinated simulation of a scenario.

Mosaik is able to handle simulators with different step sizes. A simulator may even vary its step size during the simulation.

Mosaik is able to track the dependencies between the simulators and only lets them perform a simulation step if necessary (e.g., because its data is needed by another simulator). It is also able to let multiple simulators perform their simulation step in parallel if they don’t depend on each other’s data.

*Read more . . .*
Mosaik as a co-simulation tool organizes the data exchange between simulators and to coordinates the execution of the connected simulators. This part is called mosaik-core.

Mosaik-core without any connected simulators doesn’t do much. This is why we provide some simple and free simulators so that it is possible to start with a working Smart-Grid simulation. These simulators belong to a part of mosaik’s ecosystem called mosaik-components.

Mosaik is developed following the “lean and mean” principle. That means that we try to keep the software as simple as possible in order to keep it efficient and easy to maintain. In order to make it easier to set up and run experiments with mosaik we provide some tools that help building scenarios, connecting simulators or to visualize and analyze the simulation results. These tools are located in the mosaik-tools-library.

Elements of the mosaik ecosystem:
mosaik-tools
4.1 Odysseus

Odysseus is a framework for in-memory data stream management that is designed for online processing of big data. Large volumes of data such as continuously occurring events or sensor data can be processed in real time. In combination with mosaik Odysseus can be used to process, visualise and store the results of mosaik during a simulation.

4.1.1 Process data

Odysseus allows to process data streams with different operators. For instance, the operators SELECT and PROJECT can be used to filter the data, aggregations for specific periods of time can be calculated and key-value data can be transformed in relational data and the other way round. Multiple operators are connected with each other, to form so-called operator-graphs. An example of such a graph is shown below:

The query for this graph can be found in the tutorial.

4.1.2 Visualise data

All data can be visualised in lists, tables or graphs. For more complex visualisation, dashboards can be created and individually customised:
4.1.3 Store data

Odysseus also offers connectors to transform data to different formats and databases, which makes it suitable to store simulation data.

Further information about how to install Odysseus and how to use it with mosaik can be found in the tutorial.
In the **basic tutorial** you’ll learn how you can integrate simulators and control strategy into the mosaik ecosystem as well as how you create simulation scenarios and execute them.

In the first part, we’ll implement the Sim API for a simple example simulator. We’ll also create a simulation scenario in which that simulator will send its data to `mosaik-hdf5` which will store it in an HDF5 database.

In the second part, we’ll also integrate a simple control mechanism into mosaik. We’ll then create a scenario in which that control mechanism controls the example simulator from part one.

The **Odysseus tutorial** you’ll learn how to connect the data-stream-management-tool Odysseus to mosaik. The second part shows some examples on how to use Odysseus. This tutorial may also be of some use when you want to connect any other component via ZeroMQ.

The **Java API tutorial** shows you how to use the Java API. This API is intended to connect simulators written in Java to mosaik. You can use the Java-API also as a RCP-Server if you want to run your Java-simulator on a separate machine.

Basic tutorial

## 5.1 Integrating a simulation model into the mosaik ecosystem

In this section we’ll first implement a simple example simulator. We’ll then implement mosaik’s SimAPI step-by-step.

### 5.1.1 The simulator

We want to implement a simulator for a very simple model with a discrete step size of 1. Our model will have the following behavior:

- \( val_0 = init_val \)
- \( val_i = val_{i-1} + \delta \) for \( i \in \mathbb{N}, i > 0, \delta \in \mathbb{Z} \)

That simply means our model has a value \( val \) to which we add some \( \delta \) (which is a positive or negative integer) at every simulation step. Our model has the (optional) input \( \delta \) which can be used by control mechanisms to alter the behavior of the model. It has the output \( val \) which is its current value. Here is a possible implementation of that simulation model in Python:

```python
# simulator.py

"""
This module contains a simple example simulator.
"""
```

In the basic tutorial you’ll learn how you can integrate simulators and control strategy into the mosaik ecosystem as well as how you create simulation scenarios and execute them.

In the first part, we’ll implement the Sim API for a simple example simulator. We’ll also create a simulation scenario in which that simulator will send its data to `mosaik-hdf5` which will store it in an HDF5 database.

In the second part, we’ll also integrate a simple control mechanism into mosaik. We’ll then create a scenario in which that control mechanism controls the example simulator from part one.

The Odysseus tutorial you’ll learn how to connect the data-stream-management-tool Odysseus to mosaik. The second part shows some examples on how to use Odysseus. This tutorial may also be of some use when you want to connect any other component via ZeroMQ.

The Java API tutorial shows you how to use the Java API. This API is intended to connect simulators written in Java to mosaik. You can use the Java-API also as a RCP-Server if you want to run your Java-simulator on a separate machine.

Basic tutorial

## 5.1 Integrating a simulation model into the mosaik ecosystem

In this section we’ll first implement a simple example simulator. We’ll then implement mosaik’s SimAPI step-by-step.

### 5.1.1 The simulator

We want to implement a simulator for a very simple model with a discrete step size of 1. Our model will have the following behavior:

- \( val_0 = init_val \)
- \( val_i = val_{i-1} + \delta \) for \( i \in \mathbb{N}, i > 0, \delta \in \mathbb{Z} \)

That simply means our model has a value \( val \) to which we add some \( \delta \) (which is a positive or negative integer) at every simulation step. Our model has the (optional) input \( \delta \) which can be used by control mechanisms to alter the behavior of the model. It has the output \( val \) which is its current value. Here is a possible implementation of that simulation model in Python:

```python
# simulator.py

"""
This module contains a simple example simulator.
"""
```
Fig. 5.1: Schematic diagram of our example model. You can change the \textit{delta} input and collect the \textit{val} output.

```python
class Model:
    """Simple model that increases its value \textit{\texttt{val}} with some \textit{\texttt{delta}} every step.
You can optionally set the initial value \textit{\texttt{init_val}}. It defaults to \texttt{''0''}.
"""
    def __init__(self, init_val=0):
        self.val = init_val
        self.delta = 1
    def step(self):
        """Perform a simulation step by adding \textit{\texttt{delta}} to \textit{\texttt{val}}."
        self.val += self.delta

class Simulator(object):
    """Simulates a number of `Model` models and collects some data."""
    def __init__(self):
        self.models = []
        self.data = []
    def add_model(self, init_val):
        """Create an instances of `Model` with \texttt{\textit{init_val}}."
        model = Model(init_val)
        self.models.append(model)
        self.data.append([])  # Add list for simulation data
    def step(self, deltas=None):
        """Set new model inputs from \textit{\texttt{deltas}} to the models and perform a simulation step.
\textit{\texttt{deltas}} is a dictionary that maps model indices to new delta values for the model."""
```

Chapter 5. Tutorials
if deltas:
    # Set new deltas to model instances
    for idx, delta in deltas.items():
        self.models[idx].delta = delta

    # Step models and collect data
    for i, model in enumerate(self.models):
        model.step()
        self.data[i].append(model.val)

if __name__ == '__main__':
    # This is how the simulator could be used:
    sim = Simulator()
    for i in range(2):
        sim.add_model(init_val=0)
        sim.step()
    sim.step({0: 23, 1: 42})
    print('Simulation finished with data: ')
    for i, inst in enumerate(sim.data):
        print('%d: %s' % (i, inst))

If you run this script, you'll get the following output:

Simulation finished with data:
0: [1, 24]
1: [1, 43]

5.1.2 Setup for the API implementation

So lets start implementing mosaik’s Sim API for this simulator. We can use the Python high-level API for this. This package eases our workload, because it already implements everything necessary for communicating with mosaik. It provides an abstract base class which we can sub-class. So we only need to implement four methods and we are done.

If you already installed mosaik and the demo, you already have this package installed in your mosaik virtualenv.

We start by creating a new simulator_mosaik.py and import the module containing the mosaik API as well as our simulator:

# simulator_mosaik.py

""
Mosaik interface for the example simulator.
""

import mosaik_api

import simulator

5.1.3 Simulator meta data

Next, we prepare the meta data dictionary that tells mosaik which models our simulator implements and which parameters and attributes it has. Since this data usually constant, we defines this at module level (which improves readability):
We added our “Model” model with the parameter init_val and the attributes delta and val. At this point we don’t care if they are read-only or not. We just list everything we can read or write. The public flag should usually be True. You can read more about it in the Sim API docs. From this information, mosaik deduces that our model could be used in the following way:

```python
model = ExampleModel(init_val=42)
p = model.val
print(model.val)
p = model.delta
print(model.delta)
```

### 5.1.4 The Simulator class

The package mosaik_api defines a base class Simulator for which we now need to write a sub-class:

```python
class ExampleSim(mosaik_api.Simulator):
    def __init__(self):
        super().__init__(META)
        self.simulator = simulator.Simulator()
        self.eid_prefix = 'Model_
        self.entities = () # Maps EIDs to model indices in self.simulator
```

In our simulator’s __init__() method (the constructor) we need to call Simulator.__init__() and pass the meta data dictionary to it. Simulator.__init__() will add some more information to the meta data and set it as self.meta to our instance.

We also initialize our actual simulator class, set a prefix for our entity IDs and prepare a dictionary which will hold some information about the entities that we gonna create.

We can now start to implement the four API calls init, create, step and get_data:

### 5.1.5 init()

This method will be called exactly once after the simulator has been started. It is used for additional initialization tasks (e.g., it can handle parameters that you pass to a simulator in your scenario definition). It must return the meta data dictionary self.meta:

```python
def init(self, sid, eid_prefix=None):
    if eid_prefix is not None:
        self.eid_prefix = eid_prefix
    return self.meta
```

The first argument is the ID that mosaik gave to that simulator instance. In addition to that, you can define further (optional) parameters which you can later set in your scenario. In this case, we can optionally overwrite the eid_prefix that we defined in __init__().
5.1.6 create()

create() is called in order to initialize a number of simulation model instances (entities) within that simulator. It must return a list with some information about each entity created:

```python
def create(self, num, model, init_val):
    next_eid = len(self.entities)
    entities = []

    for i in range(next_eid, next_eid + num):
        eid = '%s%d' % (self.eid_prefix, i)
        self.simulator.add_model(init_val)
        self.entities[eid] = i
        entities.append({'eid': eid, 'type': model})

    return entities
```

The first two parameters tell you how many instances of which model you should create. As in init(), you can specify additional parameters for your model. They must also appear in the params list in the simulator meta data or mosaik will reject them. In this case, we allow setting the initial value init_val for the model instances.

For each entity, we create a new entity ID \(^1\) and a model instance. We also create a mapping (self.entities) from the entity ID to our model. For each entity we create we also add a dictionary containing its ID and type to the entities list which is returned to mosaik. In this example, it has num entries for the model model, but it may get more complicated if you have, e.g., hierarchical models.

5.1.7 step()

The step() method tells your simulator to perform a simulation step. It returns to mosaik the time at which it wants to do its next step. It receives its current simulation time as well as a dictionary with input values from other simulators (if there are any):

```python
def step(self, time, inputs):
    # Get inputs
    deltas = {}
    for eid, attrs in inputs.items():
        for attr, values in attrs.items():
            model_idx = self.entities[eid]
            new_delta = sum(values.values())
            deltas[model_idx] = new_delta

    # Perform simulation step
    self.simulator.step(deltas)

    return time + 60  # Step size is 1 minute
```

In this example, the inputs could be something like this:

```json
{
    'Model_0': {
        'delta': {'src_eid_0': 23},
    },
    'Model_1': {
        'delta': {'src_eid_1': 42},
    },
}
```

\(^1\) Although entity IDs can be plain integers, it is advisable to use something more meaningful to ease debugging and analysis.
The inner dictionaries containing the actual values may contain multiple entries if multiple source entities provide input for another entity. The simulator receiving these inputs is responsible for aggregating them (e.g., by taking their sum, minimum or maximum. Since we are not interested in the source’s IDs, we convert that dict to a list with `values.values()` before we calculate the sum of all input values.

After we converted the inputs to something that our simulator can work with, we let it finally perform its next simulation step.

The return value `time + 60` tells mosaik that we wish to perform the next step in one minute (in simulation time).

### 5.1.8 get_data()

The `get_data()` call allows other simulators to get the values of the `delta` and `val` attributes of our models (the attributes we listed in the simulator meta data):

```python
def get_data(self, outputs):
    models = self.simulator.models
    data = {}
    for eid, attrs in outputs.items():
        model_idx = self.entities[eid]
        data[eid] = {}
        for attr in attrs:
            if attr not in self.meta['models']['ExampleModel']['attrs']:
                raise ValueError('Unknown output attribute: %s' % attr)
            # Get model.val or model.delta:
            data[eid][attr] = getattr(models[model_idx], attr)

    return data
```

The `outputs` parameter contains the query and may in our case look like this:

```json
{
    'Model_0': ['delta', 'value'],
    'Model_1': ['value'],
}
```

The expected return value would then be:

```json
{
    'Model_0': {'delta': 1, 'value': 24},
    'Model_1': {'value': 3},
}
```

In our implementation we loop over each entity ID for which data is requested. We then loop over all requested attributes and check if they are valid. If so, we dynamically get the requested value from our model instance via `getattr(obj, 'attr')`. We store all values in the `data` dictionary and return it when we are done.

### 5.1.9 Making it executable

The last step is adding a `main()` method to make our simulator executable (e.g., via `python -m simulator_mosaik HOST:PORT`). The package `mosaik_api` contains the method `start_simulation()` which creates a socket, connects to mosaik and listens for requests from it. You just call it in your `main()` and pass an instance of your simulator class to it:

```python
def main():
    return mosaik_api.start_simulation(ExampleSim())
```
Simulators running on different nodes than the mosaik instance are supported explicitly with the mosaik Python-API v2.4 upward via the `remote` flag. A simulator with the `start_simulation()` method in its `main()` can then be called e.g. via

```
python simulator_mosaik -r HOST:PORT
```

in the command line. The mosaik scenario, started independently, can then connect to the simulator via the statement `connect: HOST:PORT` in its “sim_config” (Configuration). Note that it may make sense to introduce a short waiting time into your scenario to give you enough time to start both processes. Alternatively, the remote connection of simulators supports also a timeout (via the `timeout` flag, e.g. `-t 60` in the command line call will cause your simulator to wait for 60 seconds for an initial message from mosaik).

5.1.10 Summary

We have now implemented the mosaik Sim API for our simulator. The following listing combines all the bits explained above:

```python
# simulator_mosaik.py

""
Mosaik interface for the example simulator.
""

import mosaik_api
import simulator

META = {
    'models': {
        'ExampleModel': {
            'public': True,
            'params': ['init_val'],
            'attrs': ['delta', 'val'],
        },
    },
}

class ExampleSim(mosaik_api.Simulator):
    def __init__(self):
        super().__init__(META)
        self.simulator = simulator.Simulator()
        self.eid_prefix = 'Model_'
        self.entities = {}

    def init(self, sid, eid_prefix=None):
        if eid_prefix is not None:
            self.eid_prefix = eid_prefix
        return self.meta

    def create(self, num, model, init_val):
        next_eid = len(self.entities)
```

5.1. Integrating a simulation model into the mosaik ecosystem 25
entities = []

for i in range(next_eid, next_eid + num):
    eid = '%s%d' % (self.eid_prefix, i)
    self.simulator.add_model(init_val)
    self.entities[eid] = i
    entities.append({'eid': eid, 'type': model})

return entities

def step(self, time, inputs):
    # Get inputs
    deltas = {}
    for eid, attrs in inputs.items():
        for attr, values in attrs.items():
            model_idx = self.entities[eid]
            new_delta = sum(values.values())
            deltas[model_idx] = new_delta

    # Perform simulation step
    self.simulator.step(deltas)

    return time + 60  # Step size is 1 minute

def get_data(self, outputs):
    models = self.simulator.models
    data = {}
    for eid, attrs in outputs.items():
        model_idx = self.entities[eid]
        data[eid] = {}
        for attr in attrs:
            if attr not in self.meta['models']['ExampleModel']['attrs']:
                raise ValueError('Unknown output attribute: $s' % attr)

            # Get model.val or model.delta:
            data[eid][attr] = getattr(models[model_idx], attr)

    return data

def main():
    return mosaik_api.start_simulation(ExampleSim())

if __name__ == '__main__':
    main()

We can now start to write our first scenario, which is exactly what the next section is about.

5.2 Creating and running simple simulation scenarios

We will now create a simple scenario with mosaik in which we use also use a simple data collector to get some nice output from our simulation. That means, we will instantiate a few ExampleModels and a data monitor. We will then connect the model instances to that monitor and simulate that for some time.
5.2.1 Configuration

You should define the most important configuration values for your simulation as “constants” on top of your scenario file. This makes it easier to see what’s going on and change the parameter values.

Two of the most important parameters that you need in almost every simulation are the simulator configuration and the duration of your simulation:

```python
# Sim config. and other parameters
SIM_CONFIG = {
    'ExampleSim': {
        'python': 'simulator_mosaik:ExampleSim',
    },
    'Collector': {
        'cmd': 'python collector.py $(addr)',
    },
}
END = 10 * 60  # 10 minutes
```

The `sim config` specifies which simulators are available and how to start them. In the example above, we list our `ExampleSim` as well as `Collector` (the names are arbitrarily chosen). For each simulator listed, we also specify how to start it.

Since our example simulator is, like mosaik, written in Python 3, mosaik can just import it and execute it in-process. The line `python': 'simulator_mosaik:ExampleSim' tells mosaik to import the package `simulator_mosaik` and instantiate the class `ExampleSim` from it.

The data collector will be started as external process which will communicate with mosaik via sockets. The line `cmd': 'python collector.py $(addr)' tells mosaik to start the simulator by executing the command `python collector.py`. Beforehand, mosaik replaces the placeholder `%{addr}` with its actual socket address `HOSTNAME:PORT` so that the simulator knows where to connect to.

The section about the Sim Manager explains all this in detail.

Here is the complete file of the data collector:

```python
""
A simple data collector that prints all data when the simulation finishes.
""

import collections
import pprint

import mosaik_api

META = {
    'models': {
        'Monitor': {
            'public': True,
            'any_inputs': True,
            'params': [],
            'attrs': [],
        },
    },
}

class Collector(mosaik_api.Simulator):
```

5.2. Creating and running simple simulation scenarios
```python
def __init__(self):
    super().__init__(META)
    self.eid = None
    self.data = collections.defaultdict(lambda: collections.defaultdict(list))
    self.step_size = None

def init(self, sid, step_size):
    self.step_size = step_size
    return self.meta

def create(self, num, model):
    if num > 1 or self.eid is not None:
        raise RuntimeError('Can only create one instance of Monitor.')
    self.eid = 'Monitor'
    return [{'eid': self.eid, 'type': model}]

def step(self, time, inputs):
    data = inputs[self.eid]
    for attr, values in data.items():
        for src, value in values.items():
            self.data[src][attr].append(value)
    return time + self.step_size

def finalize(self):
    print('Collected data:
    for sim, sim_data in sorted(self.data.items()):
        print('- %s:' % sim)
        for attr, values in sorted(sim_data.items()):
            print(' - %s: %s' % (attr, values))

if __name__ == '__main__':
    mosaik_api.start_simulation(Collector())
```

### 5.2.2 The World

The next thing we do is instantiating a `World` object. This object will hold all simulation state. It knows which simulators are available and started, which entities exist and how they are connected. It also provides most of the functionality that you need for modelling your scenario:

```python
import mosaik

world = mosaik.World(SIM_CONFIG)
```

### 5.2.3 The scenario

Before we can instantiate any simulation models, we first need to start the respective simulators. This can be done by calling `World.start()`. It takes the name of the simulator to start and, optionally, some simulator parameters which will be passed to the simulators `init()` method. So let’s start the example simulator and the HDF5 database adapter:

```python```
examplesim = world.start('ExampleSim', eid_prefix='Model_')
collector = world.start('Collector', step_size=60)

We also set the `eid_prefix` for our example simulator and some configuration values for the database. It will collect data every minute until the simulation ends. What gets returned by `World.start()` is called a model factory.

We can use this factory object to create model instances within the respective simulator. In your scenario, such an instance is represented as an `Entity`. The model factory presents the available models as if they were classes within the factory’s namespace. So this how we can create one instance of our example model and one database instance:

```python
model = examplesim.ExampleModel(init_val=2)
monitor = collector.Monitor()
```

The `init_val` parameter that we passed to `ExampleModel` is the same as in the `create()` method of our Sim API implementation. Similarly, the database has a parameter for its filename.

Now, we need to connect the example model to the monitor. That’s how we tell mosaik to send the outputs of the example model to the monitor:

```python
world.connect(model, monitor, 'val', 'delta')
```

The method `World.connect()` takes one entity pair – the source and the destination entity, as well as a list of attributes or attribute tuples. If you only provide single attribute names, mosaik assumes that the source and destination use the same attribute name. If they differ, you can instead pass a tuple like `(‘val_out’, ‘val_in’)`.

Usually, you will neither create single entities nor connect single entity pairs, but work with large(r) sets of entities. Mosaik allows you to easily create multiple entities with the same parameters at once. It also provides some utility functions for connecting sets of entities with each other. So lets create two more entities and connect them to our monitor:

```python
import mosaik.util
more_models = examplesim.ExampleModel.create(2, init_val=3)
mosaik.util.connect_many_to_one(world, more_models, monitor, 'val', 'delta')
```

Instead of instantiating the example model directly, we called its static method `create()` and passed the number of instances to it. It returns a list of entities (nine in this case). We used the utility function `mosaik.util.connect_many_to_one()` to connect all of them to the database. This function has a similar signature as `World.connect()`, but the first two parameters are a `world` instance and a set (or list) of entities that are all connected to the `dest_entity`.

Mosaik also provides the function `mosaik.util.connect_randomly()`. This method randomly connects one set of entities to another set. These two methods should cover most use cases. For more special ones, you can implement custom functions based on the primitive `World.connect()`.

### 5.2.4 The simulation

In order to start the simulation, we call `World.run()` and specify for how long we want our simulation to run:

```python
world.run(until=END)
```

Executing the scenario script will then give us the following output:
Starting "ExampleSim" as "ExampleSim-0" ...  
Starting "Collector" as "Collector-0" ...  
Starting simulation. 
Progress: 5.00%  
Progress: 10.00%  
Progress: 15.00%  
Progress: 20.00%  
Progress: 25.00%  
Progress: 30.00%  
- delta: [1, 1, 1, 1, 1, 1, 1, 1, 1, 1]  
- val: [4, 5, 6, 7, 8, 9, 10, 11, 12, 13]  
- ExampleSim-0.Model_2:  
- delta: [1, 1, 1, 1, 1, 1, 1, 1, 1, 1]  
- val: [4, 5, 6, 7, 8, 9, 10, 11, 12, 13]  

5.2.5 Summary  

This section introduced you to the basic of scenario creation in mosaik. For more details you can check the guide to scenarios. 

For your convenience, here is the complete scenario that we created in this tutorial. You can use this for some more experiments before continuing with this tutorial:

```python
# demo_1.py
import mosaik
import mosaik.util

# Sim config. and other parameters
SIM_CONFIG = {
    'ExampleSim': {
        'python': 'simulator_mosaik:ExampleSim',
    },
    'Collector': {
        'cmd': 'python collector.py $(addr)s',
    },
}
END = 10 * 60  # 10 minutes

# Create World
world = mosaik.World(SIM_CONFIG)

# Start simulators
examplesim = world.start('ExampleSim', eid_prefix='Model_')
collector = world.start('Collector', step_size=60)

# Instantiate models
model = examplesim.ExampleModel(init_val=2)
monitor = collector.Monitor()

# Connect entities
world.connect(model, monitor, 'val', 'delta')

# Create more entities
more_models = examplesim.ExampleModel.create(2, init_val=3)
mosaik.util.connect_many_to_one(world, more_models, monitor, 'val', 'delta')
```
The next part of the tutorial will be about integrating control mechanisms into a simulation.

## 5.3 Adding a control mechanism to a scenario

Now that we integrated our first simulator into mosaik and tested it in a simple scenario, we should implement a control mechanism and mess around with our example simulator a little bit.

As you remember, our example models had a `value` to which they added something in each step. Eventually, their value will end up being very high. We’ll use a multi-agent system to keep the values of our models in [-3, 3]. The agents will monitor the current `value` of their respective models and when it reaches -3/3, they will set `delta` to -1/1 for their model.

Implementing the Sim API for control strategies is very similar to implementing it for normal simulators. We start again by importing the `mosaik_api` package and defining the simulator meta data:

```python
# controller.py

MetA = {
    'models': {
        'Agent': {
            'public': True,
            'params': [],
            'attrs': ['val_in'],
        },
    },
}
```

Our control mechanism will use agents to control other entities. The agent has no parameters and only one attribute for incoming values.

Let’s continue and implement `mosaik_api.Simulator`:

```python
class Controller(mosaik_api.Simulator):
    def __init__(self):
        super().__init__(META)
        self.agents = []
```

Again, nothing special is going on here. We pass our meta data dictionary to our super class and set an empty list for our agents.

Since our agent doesn’t have any parameters, we don’t need to implement `init()`. The default implementation will return the meta data, so there’s nothing we need to do in this case.

Implementing `create()` is also straightforward:

```python
def create(self, num, model):
    n_agents = len(self.agents)
    entities = []
    for i in range(n_agents, n_agents + num):
```
Every agent gets an ID like “Agent_*<num>*”. Because there might be multiple `create()` calls, we need to keep track of how many agents we already created in order to generate correct entity IDs. We also create a list of `{'eid': 'Agent_<num>', 'type': 'Agent'}` dictionaries for mosaik.

You may have noticed that we, in contrast to our example simulator, did not actually instantiate any real simulation models this time. We just pretend to do it. This okay, since we’ll implement the agent’s “intelligence” directly in `step()`:

```
def step(self, time, inputs):
    commands = {}
    for agent_eid, attrs in inputs.items():
        values = attrs.get('val_in', {})
        for model_eid, value in values.items():
            if value >= 3:
                delta = -1
            elif value <= -3:
                delta = 1
            else:
                continue

            if agent_eid not in commands:
                commands[agent_eid] = {}
            if model_eid not in commands[agent_eid]:
                commands[agent_eid][model_eid] = {}
            commands[agent_eid][model_eid]['delta'] = delta
```

After finishing the loop, the `commands` dict may look like this:

```
{
    'Agent_0': {'Model_0': {'delta': 1}},
    'Agent_2': {'Model_2': {'delta': -1}}
}
```

`Agent_0` sets for `Model_0` the new `delta = 1`. `Agent_2` sets for `Model_2` the new `delta = -1`. `Agent_1` did not set a new `delta`.

So now that we created all commands – how do they get to the example simulator? The way via `get_data()` is not possible since it would require a circular data-flow like `connect(model, agent); connect(agent, model)` which mosaik cannot resolve (You can read the details if you are curious why).
Instead, we use one of the *asynchronous requests* that you can perform within `step()`, namely `set_data()`. The `Simulator` makes these requests available via the `mosaik` attribute:

```python
yield self.mosaik.set_data(commands)
# this works only for Python versions >=3.3.
```

The `set_data()` actively sends the commands to mosaik which will pass them to the example simulator in its next step.

**Note:** `yield??` If you are new to Python and don’t know what the `yield` keyword does: Don’t worry! In this case, it will just block the execution of `step()` until all commands are sent to mosaik. After that, the method will normally continue its execution.

When all commands were sent to mosaik, we are done with our step and return the time for our next one (which should be in one minute).

That’s it. Since there’s no data to be retrieved, we don’t need to implement `get_data()`. The default implementation will raise an error for us if it should be called accidentally.

Here is the complete code for our (very simple) controller / mutli-agent system:

```python
# controller.py

""
A simple demo controller.
""

import mosaik_api

META = {
    'models': {
        'Agent': {
            'public': True,
            'params': [],
            'attrs': ['val_in'],
        },
    },
}

class Controller(mosaik_api.Simulator):
    def __init__(self):
        super().__init__(META)
        self.agents = []

    def create(self, num, model):
        n_agents = len(self.agents)
        entities = []
        for i in range(n_agents, n_agents + num):
            eid = 'Agent_%d' % i
            self.agents.append(eid)
            entities.append({'eid': eid, 'type': model})

        return entities

    def step(self, self, time, inputs):
```

5.3. Adding a control mechanism to a scenario
commands = {}
for agent_eid, attrs in inputs.items():
    values = attrs.get('val_in', {})
    for model_eid, value in values.items():
        if value >= 3:
            delta = -1
        elif value <= -3:
            delta = 1
        else:
            continue
        if agent_eid not in commands:
            commands[agent_eid] = {}  
        if model_eid not in commands[agent_eid]:
            commands[agent_eid][model_eid] = {}
        commands[agent_eid][model_eid]['delta'] = delta
        yield self.mosaik.set_data(commands)
        # this works only for Python versions >=3.3.
        # For older versions use: raise StopIteration(time + 60)
        return time + 60

def main():
    return mosaik_api.start_simulation(Controller())

if __name__ == '__main__':
    main()

Next, we’ll create a new scenario to test our controller.

5.4 Integrating a control mechanism

The scenario that we’re going to create in this last part of the tutorial will be similar to the one we created before but incorporate the control mechanism that we just created.

Again, we start by setting some configuration values and creating a simulation world:

```python
# demo_2.py
import mosaik
import mosaik.util

# Sim config. and other parameters
SIM_CONFIG = {
    'ExampleSim': {
        'python': 'simulator_mosaik:ExampleSim',
    },
    'ExampleCtrl': {
        'python': 'controller:Controller',
    },
    'Collector': {
        'cmd': 'python collector.py $(addr)s',
    },
}
```
END = 10 * 60  # 10 minutes

# Create World
world = mosaik.World(SIM_CONFIG)

We added *ExampleCtrl* to the sim config and let all simulators be executed in-process with mosaik.

We can now start one instance of each simulator:

```python
# Start simulators
examplesim = world.start('ExampleSim', eid_prefix='Model_')
examplectrl = world.start('ExampleCtrl')
collector = world.start('Collector', step_size=60)
```

We’ll create three model instances and one agent, and one database:

```python
# Instantiate models
models = [examplesim.ExampleModel(init_val=i) for i in range(-2, 3, 2)]
agents = examplectrl.Agent.create(len(models))
monitor = collector.Monitor()
```

We use a list comprehension to create three model instances with individual initial values (-2, 0 and 2). For instantiating the same amount of agent instances we use `create()` which does the same as a list comprehension but is a bit shorter.

We finally connect each model to an agent (one-to-one):

```python
# Connect entities
for model, agent in zip(models, agents):
    world.connect(model, agent, ('val', 'val_in'), async_requests=True)
```

The important thing here is the `async_requests=True` argument that we pass to `connect()`. This tells mosaik that our control mechanism may do async requests (e.g., setting data to the models).

Finally, we can connect the models to the monitor and run the simulation:

```python
mosaik.util.connect_many_to_one(world, models, monitor, 'val', 'delta')
```

```python
# Run simulation
world.run(until=END)
```

In the output, you can clearly see the effect of our control mechanism:

```
Starting "ExampleSim" as "ExampleSim-0" ...
Starting "ExampleCtrl" as "ExampleCtrl-0" ...
Starting "Collector" as "Collector-0" ...
Starting simulation.
Progress: 3.33%
Progress: 6.67%
Progress: 10.00%
Progress: 13.33%
Progress: 16.67%
Progress: 20.00%
- delta: [1, 1, 1, -1, -1, -1, -1, -1, -1, 1]
- val: [1, 2, 3, 2, 1, 0, -1, -2, -3, -2]
- ExampleSim-0.Model_2:
  - delta: [1, -1, -1, -1, -1, -1, -1, 1, 1, 1]
  - val: [3, 2, 1, 0, -1, -2, -3, -2, -1, 0]
```

This is the complete scenario:

5.4. Integrating a control mechanism
# demo_2.py
import mosaik
import mosaik.util

# Sim config. and other parameters
SIM_CONFIG = {
    'ExampleSim': {
        'python': 'simulator_mosaik:ExampleSim',
    },
    'ExampleCtrl': {
        'python': 'controller:Controller',
    },
    'Collector': {
        'cmd': 'python collector.py $(addr)',
    },
}
END = 10 * 60  # 10 minutes

# Create World
world = mosaik.World(SIM_CONFIG)

# Start simulators
examplesim = world.start('ExampleSim', eid_prefix='Model_')
examplectrl = world.start('ExampleCtrl')
collector = world.start('Collector', step_size=60)

# Instantiate models
models = [examplesim.ExampleModel(init_val=i) for i in range(-2, 3, 2)]
agents = examplectrl.Agent.create(len(models))
monitor = collector.Monitor()

# Connect entities
for model, agent in zip(models, agents):
    world.connect(model, agent, ('val', 'val_in'), async_requests=True)
mosaik.util.connect_many_to_one(world, models, monitor, 'val', 'delta')

# Run simulation
world.run(until=END)

Congratulations, you have mastered the mosaik tutorial. The following sections provide a more detailed description of everything you learned so far.

## 5.5 Cyclic data-flow

Sometimes the simulated system requires cyclic data-flows between components without any control mechanisms involved. In such a case using async_requests reduces the scenario flexibility since it forces you to specify data exchange within a simulator’s interface (via set_data).

With version 2.5.0 mosaik provides an alternative way to establish cyclic data-flows between simulators. This is done via time_shifted connections. They are functionally similar to the async_request concept, but require no adjustment of simulator interfaces. Furthermore, they can work with cyclic data-flows involving any number of simulators (not just cyclic interactions between two simulators). As an example, take three simulators A, B and C that are to be connected in the way A B, B C, C A. After establishing the first two connections, mosaik will prohibit the third one since it might lead to deadlocks. It is allowed, however, when established via
world.connect(src, dest, ('c_out', 'a_in'), time_shifted=True, initial_data={'c_out': 0})

This connection will always be handled after all other connections and provide data to A only for its next time step. This way, deadlocks are avoided. However, input data for the initial step of A has to be provided. This is done via the initial_data argument. In this case, the initial data for `a_in` is 0.

Odysseus tutorial

5.6 Connecting mosaik and Odysseus

In this first part of the tutorial we cover the two ways to connect mosaik and Odysseus, the second part is about how to use Odysseus to process, visualize and store simulation data.

You can choose between two different solutions to connect mosaik and Odysseus. Both have their advantages and disadvantages and therefore, the right choice depends on your use case. We recommend to use the SimAPI version for beginners.

No matter which connection we use, we first have to download Odysseus Server and Studio Client. For the first start of Odysseus Studio the default user “System” and password “manager” have to be used, the tenant can be left empty.

5.6.1 Connecting via mosaik protocol handler

The easiest way to connect to mosaik is to use the mosaik protocol handler in Odysseus, which is available as installable feature in Odysseus Studio. It uses the mosaik API through remote procedure calls (RPC) and offers a close coupling of mosaik and Odysseus. With this, a blocked simulation in mosaik or a blocked processing in Odysseus will block the other system as well. If this is a problem in your use case, you should look in the section Connecting via ZeroMQ.

First we have to install the following features in odysseus:

- wrapper / mosaik
- server / key value processing

After installing the features we create a new Odysseus project and in the project a new Odysseus script file (more information on Odysseus projects and script files can be found in this tutorial). To use mosaik as source we can use the mosaik operator which contains a standard configuration of mandatory parameters. The script-code in the Odysseus query language PQL looks like this:

```
#PARSER PQL
#METADATA TimeInterval
#QUERY
mosaikCon := MOSAIK({SOURCE = 'mosaik', type='simapi'})
```

This is for the standard configuration. If you want to change something, for example to use another port, you need a more detailed configuration:

```
#PARSER PQL
#METADATA TimeInterval
#QUERY
mosaikCon1 := ACCESS({TRANSPORT = 'TCPServer',
                      PROTOCOL = 'mosaik',
                      SOURCE = 'mosaik',
                      DATAHANDLER = 'KeyValueObject',
                      WRAPPER = 'GenericPush',
                      OPTIONS = [
                                  ['port', '5555'],
                                  ['mosaikPort', '5554']},
```

5.6. Connecting mosaik and Odysseus
As we can see the protocol ‘mosaik’ is chosen. When the query is started, the mosaik protocol handler in Odysseus opens a TCP server for receiving data from mosaik.

Before we can receive data, we have to adapt our mosaik scenario. Here we take the mosaik-demo as an example. The Odysseus simulator is treated just like any other component in mosaik. It has to be added to the SIM_CONFIG parameter. For the connection to the simulator the connect command is used and the IP address and port of Odysseus have to be specified:

```python
sim_config = {
    'Odysseus': {
        'connect': '127.0.0.1:5554',
    }
}
```

After that, we have to initialize the simulator and connect it to all components whose data we want to receive in Odysseus. For the mosaik-demo, we have to add the following lines of code to the scenario definition:

```python
# Start simulators
odysseusModel = world.start('Odysseus', step_size=60*15)

# Instantiate models
odysseus = odysseusModel.Odysseus.create(1)
ody = odysseus[0]

# Connect entities
connect_many_to_one(world, nodes, ody, 'P', 'Vm')
connect_many_to_one(world, houses, ody, 'P_out')
connect_many_to_one(world, pvs, ody, 'P')
```

Now we have set up everything to receive mosaik's data in Odysseus. To begin transferring data we have to start first the query in Odysseus and then the simulation in mosaik.

For more information on how to use Odysseus visit part two.

### 5.6.2 Connecting via ZeroMQ

In contrast to the close coupling via mosaik protocol handler the coupling via ZeroMQ is more loose. Mosaik sends all data as data stream with ZeroMQ and Odysseus can even be closed and restarted during the simulation without affecting mosaik. This behaviour holds the risk of loosing data so it should only be used if this doesn’t cause problems.

First we have to install the following features for Odysseus:

- wrapper / Zero MQ
- server / key value processing
- wrapper / mosaik (only if you want to use the mosaik operator)

After installing the feature we create a new Odysseus project and in the project a new Odysseus script file. The messages sent by mosaik are formatted in JSON format and sent via ZeroMQ. So we have to choose the corresponding ZeroMQ transport handler and JSON protocol handler:

```python
#PARSER PQL
#METADATA TimeInterval
#QUERY
mosaikCon3 := ACCESS({TRANSPORT = 'ZeroMQ',
                        PROTOCOL = 'JSON',
                         
```

---

**mosaik Documentation, Release 2.5.1**

[72x748]mosaik Documentation, Release 2.5.1

[190x696]`byteorder', 'LITTLE_ENDIAN'

[72x674]As we can see the protocol 'mosaik' is chosen. When the query is started, the mosaik protocol handler in Odysseus opens a TCP server for receiving data from mosaik.

Before we can receive data, we have to adapt our mosaik scenario. Here we take the mosaik-demo as an example. The Odysseus simulator is treated just like any other component in mosaik. It has to be added to the SIM_CONFIG parameter. For the connection to the simulator the connect command is used and the IP address and port of Odysseus have to be specified:

```python
sim_config = {
    'Odysseus': {
        'connect': '127.0.0.1:5554',
    }
}
```

After that, we have to initialize the simulator and connect it to all components whose data we want to receive in Odysseus. For the mosaik-demo, we have to add the following lines of code to the scenario definition:

```python
# Start simulators
odysseusModel = world.start('Odysseus', step_size=60*15)

# Instantiate models
odysseus = odysseusModel.Odysseus.create(1)
ody = odysseus[0]

# Connect entities
connect_many_to_one(world, nodes, ody, 'P', 'Vm')
connect_many_to_one(world, houses, ody, 'P_out')
connect_many_to_one(world, pvs, ody, 'P')
```

Now we have set up everything to receive mosaik's data in Odysseus. To begin transferring data we have to start first the query in Odysseus and then the simulation in mosaik.

For more information on how to use Odysseus visit part two.

### 5.6.2 Connecting via ZeroMQ

In contrast to the close coupling via mosaik protocol handler the coupling via ZeroMQ is more loose. Mosaik sends all data as data stream with ZeroMQ and Odysseus can even be closed and restarted during the simulation without affecting mosaik. This behaviour holds the risk of loosing data so it should only be used if this doesn’t cause problems.

First we have to install the following features for Odysseus:

- wrapper / Zero MQ
- server / key value processing
- wrapper / mosaik (only if you want to use the mosaik operator)

After installing the feature we create a new Odysseus project and in the project a new Odysseus script file. The messages sent by mosaik are formatted in JSON format and sent via ZeroMQ. So we have to choose the corresponding ZeroMQ transport handler and JSON protocol handler:

```python
#PARSER PQL
#METADATA TimeInterval
#QUERY
mosaikCon3 := ACCESS({TRANSPORT = 'ZeroMQ',
                        PROTOCOL = 'JSON',
                         
```
SOURCE = 'mosaik',
DATAHANDLER = 'KeyValueObject',
WRAPPER = 'GenericPush',
OPTIONS = [
    ['host', '127.0.0.1'],
    ['readport', '5558'],
    ['writeport', '5559'],
    ['byteorder', 'LITTLE_ENDIAN']
])

If you use the standard configuration you can use the short version (feature “wrapper / mosaik” has to be installed):

#PARSER PQL
#METADATA TimeInterval
#QUERY
mosaikCon2 := MOSAIK({SOURCE = 'mosaik', type='zeromq'})

After setting up Odysseus we have to install the mosaik-zmq adapter in our mosaik virtualenv. It is available on bitbucket and PyPI. To install it we have to activate our mosaik virtualenv and execute (if there are errors during installation have a look at the readme on bitbucket):

pip install mosaik-zmq

The mosaik-zmq adapter is treated in mosaik like any other component of the simulation. If we use the mosaik demo for an example we have to add the new simulator to the SIM_CONFIG parameter:

sim_config = {
    'ZMQ': {
        'cmd': 'mosaik-zmq %(addr)s',
    },
}

Also we have to initialize the ZeroMQ simulator and connect it to other components:

# Start simulators
zmqModel = world.start('ZMQ', step_size=15*60, duration=END)

# Instantiate models
zmq = zmqModel.Socket(host='tcp://*:5558', port=5558, socket_type='PUB')

# Connect entities
connect_many_to_one(world, nodes, zmq, 'P', 'Vm')
connect_many_to_one(world, houses, zmq, 'P_out')
connect_many_to_one(world, pvs, zmq, 'P')

For more information on how to use Odysseus visit part two.

5.7 Using Odysseus to process, visualize and store simulation data

This tutorial will give some examples on how you can use Odysseus to process, visualize and store the data from mosaik. More information about connecting mosaik and Odysseus can be found in the first part of the tutorial and more about Odysseus in general can be found in its documentation. If you have no experience with Odysseus you should first visit the tutorials in its documentation. Simple query processing and selection, projection and map should explain the basics.
5.7.1 Processing

Mosaik sends data in JSON format and so the key-value-object has to be used as datatype for receiving in Odysseus. But most operators in Odysseus are based on relational tuples with a fixed schema, so it can be useful to transform arriving key-value objects to relational tuples. For this the `keyvaluetotuple` operator can be used. It creates relational tuples with the given attributes and omits all data, which is not included in the schema:

```java
tuples = KEYVALUETOTUPLE({
    SCHEMA = [
        ['odysseus_0.Vm.PyPower-0.0-tr_sec', 'Double'],
        ['odysseus_0.Vm.PyPower-0.0-node_b1', 'Double'],
        ['odysseus_0.Vm.PyPower-0.0-node_b2', 'Double'],
        ['odysseus_0.Vm.PyPower-0.0-node_b3', 'Double'],
        ['odysseus_0.Vm.PyPower-0.0-node_b4', 'Double'],
        ['timestamp', 'STARTTIMESTAMP']
    ],
    TYPE = 'mosaik',
    mosaikCon
})
```

For better handling we can rename the attributes with the `rename` operator:

```java
renamedTuples = RENAME({aliases = ['tr_sec_Vm', 'node1_Vm', 'node2_Vm', 'node3_Vm', 'node4_Vm', 'timestamp']}, tuples)
```

We can also add computations to the data with a `map` operator. The expressions parameter contains first the computation and second the new name for every attribute. In this example the deviation of voltage to the nominal voltage of 230 V is calculated (more information about the offered functions can be found here):

```java
voltageDeviation = MAP({EXPRESSIONS = [
    ['abs(230 - tr_sec_Vm)', 'dev_tr_sec_Vm'],
    ['abs(230 - Node1_Vm)', 'dev_Node1_Vm'],
    ['abs(230 - Node2_Vm)', 'dev_Node2_Vm'],
    ['abs(230 - Node3_Vm)', 'dev_Node3_Vm'],
    ['abs(230 - Node4_Vm)', 'dev_Node4_Vm']
]}, renamedTuples)
```

By using the `aggregate` operator we are able to calculate e.g. the average values. We have to add a `timewindow` operator first to have the right timestamps for aggregating.

```java
windowedTuples = TIMEWINDOW({SIZE = [5, 'MINUTES']}, voltageDeviation)
aggregatedTuples = AGGREGATE({
    AGGREGATIONS = [
        ['AVG', 'dev_tr_sec_Vm', 'AVG_dev_tr_sec_P'],
        ['AVG', 'dev_Node1_Vm', 'AVG_dev_Node1_P'],
        ['AVG', 'dev_Node2_Vm', 'AVG_dev_Node2_P'],
        ['AVG', 'dev_Node3_Vm', 'AVG_dev_Node3_P'],
        ['AVG', 'dev_Node4_Vm', 'AVG_dev_Node4_P']
    ],
    windowedTuples
})
```

5.7.2 Visualisation

To visualize data in Odysseus dashboards can be used, which can contain different graphs. For the data stream shown in the section above an exemplary dashboard could look like the following picture:

More information about dashboards in Odysseus can be found in the documentation.
5.7.3 Storing

If we want to save the results of our Odysseus query, we can use the `sender` operator to export it, e.g. to a csv file:

```java
send = SENDER(
    SINK='writeCSV',
    transport='File',
    wrapper='GenericPush',
    protocol='CSV',
    dataHandler='Tuple',
    options=[
        ['filename', '${WORKSPACEPROJECT}\output2.csv']
    ], aggregatedTuples)
```

Odysseus also offers adapters to store the processed data to different databases (e.g. mysql, postgres and oracle). More details can be found here.

Java API tutorial

5.8 Integrating a Model in Java

What do we do if we want to connect a simulator to mosaik which ist written in Java? In this tutorial we will describe how to create a simple model in Java and integrate it into mosaik using the mosaik-Java high level API. We will do this with the help of our simple model from the Python tutorial, i.e. we will try to replicate the first part of the Python tutorial as close as possible.

5.8.1 Getting the Java API

First you have to get the sources of the mosaik-API for Java which is provided on Bitbucket. Clone it and put it in the development environment of your choice.

5.8.2 Creating the model

Next we create a Java class for our model. Our example model has exact the same behaviour as our simple model in the Python tutorial. To distinguish it from the Python-model we call it `JModel`. The only difference to the Python-model is that in Java we need two constructors (with and without init value) and getter and setter methods to access the variables `val` and `delta`.

```java
class JModel {
    private float val;
    private float delta = 1;

    public JModel() {
        this.val = 0;
    }

    public JModel(float initVal) {
        this.val = initVal;
    }

    public float get_val() {
        return this.val;
    }
}
```
public float get_delta() {
    return this.delta;
}

public void set_delta(float delta) {
    this.delta = delta;
}

public void step() {
    this.val += this.delta;
}

5.8.3 Creating the simulator

A simulator provides the functionality that is necessary to manages instances of our model and to execute the models. We need a method addModel to create instances of our model and an ArrayList models to store them. The step method executes a simulation for each model instance. To access the values and deltas we need getter and setter methods. In our example the class implementing these functionalities is called JSimulator.

```java
class JSimulator {
    private final ArrayList<JModel> models;

    public JSimulator() {
        this.models = new ArrayList<JModel>();
    }

    public void add_model(Number init_val) {
        JModel model;
        if (init_val == null) {
            model = new JModel();
        } else {
            model = new JModel(init_val.floatValue());
        }
        this.models.add(model);
    }

    public void step() {
        for (int i = 0; i < this.models.size(); i++) {
            JModel model = this.models.get(i);
            model.step();
        }
    }

    public float get_val(int idx) {
        JModel model = this.models.get(idx);
        return model.get_val();
    }

    public float get_delta(int idx) {
        JModel model = this.models.get(idx);
        return model.get_delta();
    }

    public void set_delta(int idx, float delta) {
        JModel model = this.models.get(idx);
        model.set_delta(delta);
    }
```
5.8.4 Implementing the mosaik API

Finally we need to implement the mosaik-API methods. In our example this is done in a class called JExampleSim. This class has to extend the abstract class Simulator from mosaik-java-api which is the Java-equivalent to the Simulator class in Python. The class Simulator provides the four mosaik-API-calls init(), create(), step(), and getData() which we have to implement. For a more detailed explanation of the API-calls see the API-documentation.

But first we have to put together the meta-data containing information about models, attributes, and parameters of our simulator. ‘models’ are all models our simulator provides. In our case this is only JModel. ‘public’: true tells mosaik that it is allowed to create models of this class. ‘params’ are parameter that are passed during initialisation, in our case this is init_val. ‘attrs’ is a list of values that can be exchanged.

```java
private static final JSONObject meta = (JSONObject) JSONValue.parse("{
" + "'api_version': " + Simulator.API_VERSION + ",",
" + "'models': {
" + "'JModel': {
" + "'public': true,"
" + "'params': ['init_val'],
" + "'attrs': ['val', 'delta']
" + "}
" + "}").replace("‘", "\""));
```

First method is init() that returns the meta data. In addition it is possible to pass arguments for initialization. In our case there is eid_prefix which will be used to name instances of the models:

```java
public Map<String, Object> init(String sid, Map<String, Object> simParams) {
 if (simParams.containsKey("eid_prefix")) {
 this.eid_prefix = simParams.get("eid_prefix").toString();
 }
 return JExampleSim.meta;
}
```

create() creates new instances of the model JModel by calling the add_model-method of JSimulator. It also assigns ID (eid) to the models, so that it is able to keep track of them. It has to return a list with the name (eid) and type of the models. You can find more details about the return object in the API-documentation.

```java
@Override
public List<Map<String, Object>> create(int num, String model, Map<String, Object> modelParams) {
 JSONArray entities = new JSONArray();
 for (int i = 0; i < num; i++) {
 String eid = this.eid_prefix + (this.idCounter + i);
 if (modelParams.containsKey("init_val")) {
 Number init_val = (Number) modelParams.get("init_val");
 this.simulator.add_model(init_val);
 }
 JSONObject entity = new JSONObject();
 entity.put("eid", eid);
 entity.put("type", model);
 entity.put("rel", new JSONArray());
 entities.add(entity);
 this.entities.put(eid, this.idCounter + i);
 }
 return entities;
}
```

5.8. Integrating a Model in Java 43
step() tells the simulator to perform a simulation step. It passes the time, the current simulation time, and inputs, a JSON data object with input data from preceding simulators. The structure of inputs is explained in the API-documentation. If there are new delta-values in inputs they are set in the appropriate model instance. Finally it calls the simulator’s step()-method which, on its part, calls the step()-methods of the individual model-instances.

```java
public long step(long time, Map<String, Object> inputs) {
    //go through entities in inputs
    for (Map.Entry<String, Object> entity : inputs.entrySet()) {
        //get attrs from entity
        Map<String, Object> attrs = (Map<String, Object>) entity.getValue();
        //go through attrs of the entity
        for (Map.Entry<String, Object> attr : attrs.entrySet()) {
            //check if there is a new delta
            String attrName = attr.getKey();
            if (attrName.equals("delta")) {
                //sum up deltas from different sources
                Object[] values = ((Map<String, Object>) attr.getValue()).values().toArray();
                float value = 0;
                for (int i = 0; i < values.length; i++) {
                    value += ((Number) values[i]).floatValue();
                }
                //set delta
                String eid = entity.getKey();
                int idx = this.entities.get(eid);
                this.simulator.set_delta(idx, value);
            }
        }
    }
    //call step-method
    this.simulator.step();
    return time + this.stepSize;
}
```

dataGet() gets the simulator’s output data from the last simulation step. It passes outputs, a JSON data object that describes which parameters are requested. getdata() goes through outputs, retrieves the requested values from the appropriate instances of JModel and puts it in data. The structure of outputs and data is explained in the API-documentation.

```java
public Map<String, Object> getData(Map<String, List<String>> outputs) {
    Map<String, Object> data = new HashMap<String, Object>();
    //*outputs* lists the models and the output values that are requested
    //go through entities in outputs
    for (Map.Entry<String, List<String>> entity : outputs.entrySet()) {
        String eid = entity.getKey();
        List<String> attrs = entity.getValue();
        HashMap<String, Object> values = new HashMap<String, Object>();
        int idx = this.entities.get(eid);
        //go through attrs of the entity
        for (String attr : attrs) {
            if (attr.equals("val")) {
                values.put(attr, this.simulator.get_val(idx));
            }
        }
    }
    return data;
}
```
else if (attr.equals("delta")) {
    values.put(attr, this.simulator.get_delta(idx));
}
}
data.put(eid, values);
}
return data;

5.8.5 Connecting the simulator to mosaik

We use the same scenario as in our Python example demo1. The only thing we have to change is the way we connect our simulator to mosaik. There are two ways to do this:

- **cmd**: mosaik calls the Java API by executing the command given in cmd. Mosaik starts the Java-API in a new process and connects it to mosaik. This works only if your simulator runs on the same machine as mosaik.

- **connect**: mosaik connects to the Java-API which runs as a TCP server. This works also if mosaik and the simulator are running on different machines.

For more details about how to connect simulators to mosaik see the section about the Sim Manager in the mosaik-documentation.

**Connecting the simulator using cmd**

We have to give mosaik the command how to start our Java simulator. This is done in SIM_CONFIG. The marked lines show the differences to our Python simulator.

```
# Sim config. and other parameters
SIM_CONFIG = {
    'JExampleSim': {
        'cmd': 'java -cp JExampleSim.jar de.offis.mosaik.api.JExampleSim %(addr)s',
    },
    'Collector': {
        'cmd': 'python collector.py %(addr)s',
    },
}
END = 10 * 60  # 10 minutes
```

The placeholder %(addr)s is later replaced with IP address and port by mosaik. If we now execute demo_1.py we get the same output as in our Python-example.

**Note**: The command how to start the Java simulator may differ depending on your operating system. If the command is complex, e. g. if it contains several libraries, it is usually better to put it in a script and than call the script in cmd.

**Connecting the simulator using connect**

In this case the Java API acts as TCP server and listens at the given address and port. Let’s say the simulator runs on a computer with the IP-address 1.2.3.4. We can now choose a port that is not assigned by default. In our example we choose port 5678. Make sure that IP-address and port is accessible from the computer that hosts mosaik (firewalls etc.).
Note: Of course you can run mosaik and your simulator on the same machine by using 127.0.0.1:5678 (localhost). You may want to do this for testing and experimenting. Apart from that the connection with cmd (see above) is usually the better alternative because you don’t have to start the Java part separately.

We have to tell mosaik how to connect to the simulator. This is done in SIM_CONFIG in our scenario (demo1):

```python
# Sim config. and other parameters
SIM_CONFIG = {
    'JExampleSim': {
        'connect': '1.2.3.4:5678',
    },
    'Collector': {
        'cmd': 'python collector.py %s
    },
}
END = 10 * 60  # 10 minutes
```

The marked lines show the differences to our Python simulator. Our simulator is now called JExampleSim and we need to give the simulator’s address and port after the connect key word.

Now we start JExampleSim. To tell the mosaik-Java-API to run as TCP-server is done by starting it with “server” as second argument. The first command line argument is IP-address and port. The command line in our example looks like this:

```bash
java -cp JExampleSim.jar de.offis.mosaik.api.JExampleSim 1.2.3.4:5678 server
```

If we now execute demo_1.py we get the same output as in our Python-example.

Note: You can find the source code used in this tutorial in the mosaik-source-files in the folder docs/tutorial/code.
The mosaik API defines the communication protocol between mosaik and the simulators it couples. We differentiate between a *low-level* and a *high-level* version of the API.

The low-level API uses plain network sockets to exchange JSON encoded messages.

The high-level API is an implementation of the low-level API in a specific programming language. It encapsulates all parts related to networking (socket handling, an event loop, message (de)serialization) and provides an abstract base class with a few methods that have to be implemented in a subclass. A high-level API implementation is currently available for Python and Java. Implementations for other languages will be added when needed.

The figure below depicts the differences between the two API levels.
This section provides a general overview which API calls exist and when mosaik calls them. The following sections will go into more detail.

When the connection between a simulator and mosaik is established, mosaik will first call `init()`, optionally passing some global parameters to the simulator. The simulator returns some meta data describing itself.

Following this, mosaik may call `create()` multiple times in order to instantiate one of the models that the simulator implements. The return value contains information describing the entities created.

The end of `create` phase and the beginning of the `step` (or simulation) phase is marked by a call to `setup_done()`.
At this point, all entities are created and all relations between them are established.

When the simulation has been started, mosaik repeatedly calls `step()`. This allows the simulator to step forward in time. It returns the time at which it wants to perform its next step.

Finally, mosaik sends a `stop()` message to every simulator to request its shut-down.

The following figure depicts the sequence of these messages:

After `create()` or `step()` have been called, there may be an arbitrary amount of `get_data()` calls where mosaik requests the current values of some entities’ attributes:
These methods are usually sufficient to connect simple simulators to mosaik. However, control strategies, visualizations or database adapters may need to actively query mosaik for additional data. Thus, while a simulator is executing a simulation step, it may make asynchronous requests to mosaik. It can get the current simulation progress (get_progress()), collect information about the simulated topology (get_related_entities()), query other entities for data (get_data()) and set data for other entities (set_data()).
The next two section explain the low-level API and the Python high-level API in more detail.

6.2 The low-level API

The low-level API uses standard TCP sockets. If mosaik starts a simulator, that simulator needs to connect to mosaik. If mosaik connects to a running instance of a simulator, that simulator obviously needs to provide a server socket that mosaik can connect to.

Network messages consists of a four bytes long header and a payload of arbitrary length. The header is an unsigned integer (uint32) in network byte order (big-endian) and stores the number of bytes in the payload. The payload itself is a UTF-8 encoded JSON list containing the message type, a message ID and the actual content:
Messages send between mosaik and a simulator must follow the request-reply pattern. That means, that every request that one party makes must be responded by the other party. Request use the message type 0, replies uses 1 for success or 2 to indicate a failure. The message ID is an integer that is unique for every request that a network socket makes. Replies (no matter if successful or failed) need to use the message ID of the corresponding request.

The content of a request roughly map to a Python function call:

```
[function, [arg0, arg1, ...], {kwarg0: val0, kwarg1: val1}]
```

Thereby, `function` is always a string. The type of the arguments and keyword arguments may vary depending on the function.

The content of replies is either the return value of the request, or an error message or stack trace. Error messages and stack traces should always be strings. The return value for successful requests depends on the function.

**6.2.1 Example**

We want to perform the following function call on the remote site: `my_func('hello', 'world', times=23) --> 'the return value'`. This would map to the following message payload:

```
[0, 1, ["my_func", ["hello", "world"], {"times": 23}]]
```

Our message is a request (message type 0), the message ID is 1 and the content is a JSON list containing the function name as well as its arguments and keyword arguments.

The complete message sent via the network will be:

```
\x00\x00\x00\x36[1, 1, ["my_func", ["hello", "world"], {"times": 23}]]
```

In case of success, the reply's payload to this request could look like this:

```
[1, 1, "the return value"]
```

In case of error, this could be the reply's payload:

```
[2, 1, "Error in your code line 23: ..."]
```

The actual network messages would be:

```
\x00\x00\x00\x1a[1, 1, "the return value"]
\x00\x00\x00\x1a[2, 1, "Error in your code line 23: ..."]
```

All commands that mosaik may send to a simulator are described in-depth in the next section. All asynchronous requests that a simulator may make are described in *Asynchronous requests*.

API calls:

- init
• create
• setup_done
• step
• get_data
• stop

Async. requests:
• get_progress
• get_related_entities
• get_data
• set_data

6.2.2 API calls

This section describes the API calls init(), create(), setup_done(), step(), get_data() and stop(). In addition to these, a simulator may optionally expose additional functions (referred to as extra methods). These methods can be called at composition time (when you create your scenario).

init

["init", [sim_id], {**sim_params}] -> meta

The init call is made once to initialize the simulator. It has one positional argument, the simulator ID, and an arbitrary amount of keyword arguments (sim_params).

The return value meta is an object with meta data about the simulator:

```
{
    "api_version": "x.y",
    "models": {
        "ModelName": {
            "public": true|false,
            "params": ["param_1", ...],
            "attrs": ["attr_1", ...],
            "any_inputs": true|false,
        },
        ...,
        "extra_methods": ["do_cool_stuff", "set_static_data"
    ]
}
```

The api_version is a string that defines which version of the mosaik API the simulator implements. Since mosaik API version 2.2, the simulator’s major version (“x”, in the snippet above) has to be equal to mosaik’s. Mosaik will cancel the simulation if a version mismatch occurs.

models is an object describing the models provided by this simulator. The entry public determines whether a model can be instantiated by a user (true) or if it is a sub-model that cannot be created directly (false). params is a list of parameter names that can be passed to the model when creating it. attrs is a list of attribute names that can be accessed (reading or writing). If the optional any_inputs flag is set to true, any attributes can be connected to the model, even...
if they are not *attrs*. This may, for example, be useful for databases that don’t know in advance which attributes of an entity they’ll receive.

*extra_methods* is an optional list of methods that a simulator provides in addition to the standard API calls (*init()*, *create()* and so on). These methods can be called while the scenario is being created and can be used for operations that don’t really belong into *init()* or *create()*.

**Example**

Request:

```json
["init", ["PowerGridSim-0"], {"step_size": 60}]
```

Reply:

```json
{
   "api_version": "2.2",
   "models": {
      "Grid": {
         "public": true,
         "params": ["topology_file"],
         "attrs": []
      },
      "Node": {
         "public": false,
         "params": [],
         "attrs": ["P", "Q"]
      },
      "Branch": {
         "public": false,
         "params": [],
         "attrs": ["I", "I_max"]
      }
   }
}
```

**create**

```json
["create", [num, model], {**model_params}] -> entity_list
```

Create *num* instances of *model* using the provided *model_params*

*num* is an integer for the number of model instances to create.

*model* needs to be a public entry in the simulator’s *meta[‘models’]* (see *init)*.

*model_params* is an object mapping parameters (from *meta[‘models’][model][‘params’]*, see *init*) to their values.

Return a (nested) list of objects describing the created model instances (entities). The root list must contain exactly *num* elements. The number of objects in sub-lists is not constrained:

```json
[
   {
      "eid": "eid_1",
      "type": "model_name",
      "rel": ["eid_2", ...],
      "children": <entity_list>
   }
]
```
The entity ID (eid) of an object must be unique within a simulator instance. For entities in the root list, type must be the same as the model parameter. The type for objects in sub-lists may be anything that can be found in meta['models'] (see init). rel is an optional list of related entities; “related” means that two entities are somehow connect within the simulator, either logically or via a real data-flow (e.g., grid nodes are related to their adjacent branches). The children entry is optional and may contain a sub-list of entities.

**Example**

Request:

```json
["create", [1, "Grid"], {"topology_file": "data/grid.json"}]
```

Reply:

```json
[
  {
    "eid": "Grid_1",
    "type": "Grid",
    "rel": [],
    "children": [
      {
        "eid": "node_0",
        "type": "Node",
      },
      {
        "eid": "node_1",
        "type": "Node",
      },
      {
        "eid": "branch_0",
        "type": "Branch",
        "rel": ["node_0", "node_1"]
      }
    ]
  }
]
```

**setup_done**

```json
["setup_done", [], {}] -> null
```

Callback that indicates that the scenario setup is done and the actual simulation is about to start.

At this point, all entities and all connections between them are know but no simulator has been stepped yet. Implementing this method is optional.

*Added in mosaik API version 2.2.*

**Example**

Request:
null

step

Perform the next simulation step from time `time` using input values from `inputs` and return the new simulation time (the time at which `step` should be called again).

`time` and the time returned are integers. Their unit is `seconds` (counted from simulation start).

`inputs` is a dict of dicts mapping entity IDs to attributes and dicts of values (each simulator has to decide on its own how to reduce the values (e.g., as its sum, average or maximum):

```
{
    "eid_1": {
        "attr_1": {'src_full_id_1': val_1_1, 'src_full_id_2': val_1_2, ...),
        "attr_2": {'src_full_id_1': val_2_1, 'src_full_id_2': val_2_2, ...),
        ...
    },
    ...
}
```

Example

Request:

```
[ 
    "step", 
    [time, inputs], {}
] -> time_next_step
```

Reply:

120

get_data

Return the data for the requested attributes in `outputs`
`outputs` is an object mapping entity IDs to lists of attribute names whose values are requested:
The return value needs to be an object of objects mapping entity IDs and attribute names to their values:

```json
{
    "eid_1": {
        "attr_1": "val_1",
        "attr_2": "val_2",
        ...
    },
    ...
}
```

**Example**

Request:

```json
["get_data", [{"branch_0": ["I"]}], {}]
```

Reply:

```json
{
    "branch_0": {
        "I": 42.5
    }
}
```

**stop**

```json
["stop", [], {}] -> null
```

Immediately stop the simulation and terminate.

This call has no parameters and no reply is required.

**Example**

Request:

```json
["stop", [], {}]
```

Reply:

```
no reply required
```

### 6.2.3 Asynchronous requests

**get_progress**

```json
["get_progress", [], {}] -> progress
```

Return the current overall simulation progress in percent.
Example

Request:

["get_progress", [], {}]

Reply:

23.42

get_related_entities

["get_related_entities", [entities], {}] -> related_entities

Return information about the related entities of entities.

If entities omitted (or null), return the complete entity graph, e.g.:

```
{
    "nodes": {
        "sid_0.eid_0": {"type": "A"},
        "sid_0.eid_1": {"type": "B"},
        "sid_1.eid_0": {"type": "C"},
    },
    "edges": [
        ["sid_0.eid_0", "sid_1.eid0", {}],
        ["sid_0.eid_1", "sid_1.eid0", {}],
    ],
}
```

If entities is a single string (e.g., sid_1.eid_0), return an object containing all entities related to that entity:

```
{
    "sid_0.eid_0": {"type": "A"},
    "sid_0.eid_1": {"type": "B"},
}
```

If entities is a list of entity IDs (e.g., ["sid_0.eid_0", "sid_0.eid_1"]), return an object mapping each entity to an object of related entities:

```
{
    "sid_0.eid_0": {
        "sid_1.eid_0": {"type": "B"},
    },
    "sid_0.eid_1": {
        "sid_1.eid_1": {"type": "B"},
    },
}
```

Example

Request:

["get_related_entities", ["grid_sim_0.node_0", "grid_sim_0.node_1"] {}]

Reply:
get_data

`["get_data", [attrs], {}] -> data`

Get the data for the requested attributes in `attrs`. `attrs` is an object of (fully qualified) entity IDs mapping to lists of attribute names:

```

{        "sim_id.eid_1": ["attr_1", "attr_2", ...],
        ...
}
```

The return value is an object mapping the input entity IDs to data objects mapping attribute names to their respective values:

```

{        "sim_id.eid_1": {
            "attr_1": "val_1",
            "attr_2": "val_2",
            ...
        },
        ...
}
```

**Example**

Request:

```
["get_data", [["grid_sim_0.branch_0": ["I"]]], {}]
```

Reply:

```

{        "grid_sim_0.branch_0": {
            "I": 42.5
        }
}
```

set_data

`["set_data", [data], {}] -> null`

Set `data` as input data for all affected simulators.

6.2. The low-level API
data is an object mapping source entity IDs to objects which in turn map destination entity IDs to objects of attributes and values ({{"src_full_id": {"dest_full_id": {"attr1": "val1", "attr2": "val2"}}}})

Example

Request:
```
[
   "set_data",
   [
   "mas_0.agent_0": {"pvsim_0.pv_0": {"P_target": 20, "Q_target": 3.14}},
   "mas_0.agent_1": {"pvsim_0.pv_1": {"P_target": 21, "Q_target": 2.718}}
   ],
]
```

Reply:
```
null
```

6.3 The high-level API

Currently, there are high-level API for Python and Java. Implementations for C# and MatLab will be available soon.

6.3.1 Installation

The Python implementation of the mosaik API is available as a separate package and can easily be installed via pip:
```
pip install mosaik-api
```

It supports Python 2.7, >= 3.3 and PyPy.

For the use of the Java-API please refer to the Java-tutorial.

6.3.2 Usage

You create a subclass of `mosaik_api.Simulator` which implements the four API calls `init()`, `create()`, `step()` and `get_data()`. You can optionally override `configure()` and `finalize()`. The former allows you to handle additional command line arguments that your simulator may need. The latter is called just before the simulator terminates and allows you to perform some clean-up.

You then call `mosaik_api.start_simulation()` from your `main()` function to get everything set-up and running. That function handles the networking as well as serialization and de-serialization of messages. Commands from the low-level API are translated to simple function calls. The return value of these functions is used for the reply.

For example, the message
```
["create", [2, "Model", {"param1": 15, "param2": "spam"}]]
```

will result in a call
create(2, 'Model', param1=15, param2='spam')

### API calls

```python
class mosaik_api.Simulator (meta):
    This is the base class that you need to inherit from and implement the API calls.

    meta
    Meta data describing the simulator (the same that is returned by `init()`).
    ```
    
    
    ```
    
    
    ```
    ```
    
    The `api_version` is a string that defines which version of the mosaik API the simulator implements. Since mosaik API version 2.3, the simulator’s major version (“x”, in the snippet above) has to be equal to mosaik’s. Mosaik will cancel the simulation if a version mismatch occurs.

    `models` is a dictionary describing the models provided by this simulator. The entry `public` determines whether a model can be instantiated by a user (True) or if it is a sub-model that cannot be created directly (False). `params` is a list of parameter names that can be passed to the model when creating it. `attrs` is a list of attribute names that can be accessed (reading or writing). If the optional `any_inputs` flag is set to `true`, any attributes can be connected to the model, even if they are not `attrs`. This may, for example, be useful for databases that don’t know in advance which attributes of an entity they’ll receive.

    `extra_methods` is an optional list of methods that a simulator provides in addition to the standard API calls (`init()`, `create()` and so on). These methods can be called while the scenario is being created and can be used for operations that don’t really belong into `init()` or `create()`.

### mosaik

An RPC proxy to mosaik.

```python
init (sid, **sim_params)
```

Initialize the simulator with the ID `sid` and apply additional parameters (`sim_params`) sent by mosaik.

Return the meta data `meta`.

If your simulator has no `sim_params, you don’t need to override this method.

```python
create (num, model, **model_params)
```

Create `num` instances of `model` using the provided `model_params`.

`num` is an integer for the number of model instances to create.

`model` needs to be a public entry in the simulator’s `meta['models']`.

`model_params` is a dictionary mapping parameters (from `meta['models'][model]['params']`) to their values.
Return a (nested) list of dictionaries describing the created model instances (entities). The root list must contain exactly `num` elements. The number of objects in sub-lists is not constrained:

```python
[
  {
    'eid': 'eid_1',
    'type': 'model_name',
    'rel': ['eid_2', ...],
    'children': [
      {'eid': 'child_1', 'type': 'child'},
      ...
    ],
  },
  ...
]
```

The entity ID (`eid`) of an object must be unique within a simulator instance. For entities in the root list, `type` must be the same as the `model` parameter. The type for objects in sub-lists may be anything that can be found in `meta['models']`. `rel` is an optional list of related entities; “related” means that two entities are somehow connect within the simulator, either logically or via a real data-flow (e.g., grid nodes are related to their adjacent branches). The `children` entry is optional and may contain a sub-list of entities.

**setup_done()**
Callback that indicates that the scenario setup is done and the actual simulation is about to start.

At this point, all entities and all connections between them are know but no simulator has been stepped yet.

Implementing this method is optional.

*Added in mosaik API version 2.3*

**step(time, inputs)**
Perform the next simulation step from time `time` using input values from `inputs` and return the new simulation time (the time at which `step()` should be called again).

`time` and the time returned are integers. Their unit is `seconds` (from simulation start).

`inputs` is a dict of dicts mapping entity IDs to attributes and dicts of values (each simulator has do decide on its own how to reduce the values (e.g., as its sum, average or maximum):

```python
{
  'dest_eid': {
    'attr': {'src_fullid': val, ...},
    ...,
  },
  ...
}
```

**get_data(outputs)**
Return the data for the requested attributes in `outputs`

`outputs` is a dict mapping entity IDs to lists of attribute names whose values are requested:

```python
{
  'eid_1': ['attr_1', 'attr_2', ...],
  ...
}
```

The return value needs to be a dict of dicts mapping entity IDs and attribute names to their values:
```json
{
    'eid_1': {
        'attr_1': 'val_1',
        'attr_2': 'val_2',
        ...,
    },
    ...,
}
```

`configure(args, backend, env)`

This method can be overridden to configure the simulation with the command line `args` as created by `docopt`.

`backend` and `env` are the `simpy.io` backend and environment used for networking. You can use them to start extra processes (e.g., a web server).

The default implementation simply ignores them.

`finalize()`

This method can be overridden to do some clean-up operations after the simulation finished (e.g., shutting down external processes).

The `mosaik-api` package provides an example simulator that demonstrates how the API can be implemented.

### Asynchronous requests

The asynchronous requests can be called via the `MosaikRemote` proxy `self.mosaik` from within `step()`. They don’t return the actual results but an `event` (similar to a `future` of `deferred`). The event will eventually hold the actual result. To wait for that result to arrive, you simply yield the event, e.g.:

```python
def step(self, time, inputs):
    progress = yield self.mosaik.get_progress()
    # ...
```

`MosaikRemote.get_progress()`

Return the current simulation progress from `sim_progress`.

`MosaikRemote.get_related_entities(entities=None)`

Return information about the related entities of `entities`.

If `entities` omitted (or `None`), return the complete entity graph, e.g.:

```json
{
    'nodes': {
        'sid_0.eid_0': {'type': 'A'},
        'sid_0.eid_1': {'type': 'B'},
        'sid_1.eid_0': {'type': 'C'},
    },
    'edges': [
        ['sid_0.eid_0', 'sid_1.eid0', {}],
        ['sid_0.eid_1', 'sid_1.eid0', {}],
    ],
}
```

If `entities` is a single string (e.g., `sid_1.eid_0`), return a dict containing all entities related to that entity:

```json
{
    'sid_0.eid_0': {'type': 'A'},
    'sid_0.eid_1': {'type': 'B'},
}
```
If `entities` is a list of entity IDs (e.g., `['sid_0.eid_0', 'sid_0.eid_1']`), return a dict mapping each entity to a dict of related entities:

```
{
    'sid_0.eid_0': {
        'sid_1.eid_0': {'type': 'B'},
    },
    'sid_0.eid_1': {
        'sid_1.eid_1': {'type': 'B'},
    },
}
```

**MosaikRemote.get_data** *(attrs)*

Return the data for the requested attributes `attrs`.

`attrs` is a dict of (fully qualified) entity IDs mapping to lists of attribute names (`{'sid/eid': ['attr1', 'attr2']}`).

The return value is a dictionary, which maps the input entity IDs to data dictionaries, which in turn map attribute names to their respective values: (`{'sid/eid': {'attr1': val1, 'attr2': val2}}`).

**MosaikRemote.set_data** *(data)*

Set data as input data for all affected simulators.

`data` is a dictionary mapping source entity IDs to destination entity IDs with dictionaries of attributes and values (`{'src_full_id': {'dest_full_id': {'attr1': 'val1', 'attr2': 'val2'}}}`).

The `mosaik-api` package provides an example “multi-agent system” that demonstrates how to perform asynchronous requests can be implemented.

**Starting the simulator**

To start your simulator, you just need to create an instance of your `Simulator` sub-class and pass it to `start_simulation()`:

```
mosaik_api.start_simulation(simulator, description='', extra_options=None)
```

Start the simulation process for simulation.

`simulation` is the instance of your API implementation (see `Simulator`).

`description` may override the default description printed with the help on the command line.

`extra_option` may be a list of options for docopt (example: `['-e, --example Enable example mode']`). Commandline arguments are passed to `Simulator.configure()` so that your API implementation can handle them.

Here is an example with a bit more context:

```
import mosaik_api

element_meta = {
    'models': {
        'A': {
            'public': True,
            'params': ['init_val'],
            'attrs': ['val_out', 'dummy_out'],
        },
    },
}
```
```python
class ExampleSim(mosaik_api.Simulator):
    def __init__(self):
        super().__init__(example_meta)

        sim_name = 'ExampleSimulation'

def configure(self, args, backend, env):
    # Here you could handle additional command line arguments

def init(self, sid):
    # Initialize the simulator
    return self.meta

    # Implement the remaining methods (create, step, get_data, ...)

def main():
    import sys

    description = 'A simple example simulation for mosaik.'
    extra_options = [
        '--foo Enable foo',
        '--bar BAR The bar parameter',
    ]

    return mosaik_api.start_simulation(ExampleSim(), description, extra_options)

if __name__ == '__main__':
    sys.exit(main())
```

6.3. The high-level API
Modeling or composing a scenario in mosaik comprises three steps:

1. Starting simulators,
2. Instantiating models within the simulators, and
3. Connecting the model instances of different simulators to establish the data flow between them.

This page will show you how to create simple scenarios in these three steps. It will also provide some recipes that allow you to create more complex scenarios.

## 7.1 The setup

The central class for creating scenarios is `mosaik.scenario.World` (for your convenience, you can also import `World` directly from `mosaik`). This class stores all data and state that belongs to your scenario and its simulation. It also provides various methods that allow you to start simulators and establish the data flows between them.

In this tutorial, we’ll create a very simple scenario using the example simulation that is provided with the Python implementation of the simulator API.

We start by importing the `mosaik` package and creating a `World` instance:

```python
>>> import mosaik
...
>>> sim_config = {
... 'ExampleSim': {'python': 'example_sim.mosaik:ExampleSim'},
... }

>>> world = mosaik.World(sim_config)
```

As we start simulator instances by using `world`, it needs to know what simulators are available and how to start them. This is called the `sim config` and is a dict that contains every simulator we want to use together with some information on how to start it.

In our case, the only simulator is the `ExampleSim`. It will be started by importing the module `example_sim.mosaik` and instantiating the class `ExampleSim`. This is only possible with simulators written in Python 3. You can also let mosaik start simulator as external processes or let it connect to already running processes. The `simulator manager docs` explain how this all works and give you some hints when to use which method of starting a simulator.

In addition to the `sim config` you can optionally pass another dictionary to `World` in order to overwrite some general parameters for mosaik (e.g., the host and port number for its network socket or timeouts). Usually, the defaults work just well.
7.2 Starting simulators

Now that the basic set-up is done, we can start our simulators:

```python
>>> simulator_0 = world.start('ExampleSim', step_size=2)
Starting "ExampleSim" as "ExampleSim-0" ...
>>> simulator_1 = world.start('ExampleSim')
Starting "ExampleSim" as "ExampleSim-1" ...
```

To start a simulator, we call `World.start()` and pass the name of the simulator. Mosaik looks up that name in its `sim config`, starts the simulator for us and returns a `ModelFactory`. This factory allows us to instantiate simulation models within that simulator.

In addition to the simulator name, you can pass further parameters for the simulators. These parameters are passed to the simulator via the `init()` API call.

7.3 Instantiating simulation models

Simulators specify a set of public models in their meta data (see `init()` API call). These models can be accessed with the `ModelFactory` that `World.start()` returns as if they were normal Python classes. So to create one instance of `ExampleSim`'s model `A` we just write:

```python
>>> a = simulator_0.A(init_val=0)
```

This will create one instance of the `A` simulation model and pass the model parameter `init_val=0` to it (see `create()` API call). Let's see what it is that gets returned to us:

```python
>>> print(a)
Entity('ExampleSim-0', '0.0', 'ExampleSim', A)
>>> a.sid, a.eid, a.full_id
('ExampleSim-0', '0.0', 'ExampleSim-0.0.0')
>>> a.sim_name, a.type
('ExampleSim', 'A')
>>> a.children
[]
```

A model instance is represented in your scenario as an `Entity`. The entity belongs to the simulator `ExampleSim-0`, has the ID `0.0` and its type is `A`. The entity ID is unique within a simulator. To make it globally unique, we prepend it with the simulator ID. This is called the entity’s full ID (see `Entity.full_id`). You can also get a list of its child entities (which is empty in this case).

In order to instantiate multiple instances of a model, you can either use a simple list comprehension (or for loop) or call the static method `create()` of the model:

```python
>>> a_set = [simulator_0.A(init_val=i) for i in range(2)]
>>> b_set = simulator_1.B.create(3, init_val=1)
```

The list comprehension is more verbose but allows you to pass individual parameter values to each instance. Using `create()` is more concise but all three instance will have the same value for `init_val`. In both cases you’ll get a list of entities (aka `entity sets`).

7.4 Connecting entities

If we would now run our simulation, both, `simulator_0` and `simulator_1` would run in parallel and never exchange any data. To change that, we need to connect the models providing input data to entities requiring this data. In our case,
we will connect the val_out attribute of the \textit{A} instances with the val_in attribute of the \textit{B} instances:

```python
>>> a_set.insert(0, a)  # Put our first A instance to the others
>>> for a, b in zip(a_set, b_set):
...    world.connect(a, b, ('val_out', 'val_in'))
```

The method \texttt{World.connect()} takes the source entity, the destination entity and an arbitrary amount of (source attribute, dest. attribute) tuples. If the name of the source attributes equals that of the destination attribute, you can alternatively just pass a single string (e.g., \texttt{connect(a, b, 'attr')}).

You can only connect entities that belong to different simulators with each other (that's why we created two instances of the \texttt{ExampleSim}).

You are also not allowed to created circular dependencies (e.g., connect \textit{a} to \textit{b} and then connect \textit{b} to \textit{a}). To allow a bidirectional exchange of data, which is required for things like control strategies, there is another mechanism that is explained in one of the next sections (\textit{How to achieve bi-directional data-flows}).

### 7.5 Running the simulation

When all simulators are started, models are instantiated and connected, we can finally run our simulation:

```python
>>> world.run(until=10)
Starting simulation.
Simulation finished successfully.
```

This will execute the simulation from time 0 until we reach the time \texttt{until} (in simulated seconds). The \textit{scheduler section} explains in detail what happens when you call \texttt{run()}. To wrap it all up, this is how our small example scenario finally looks like:

```python
# Setup
import mosaik

sim_config = {
    'ExampleSim': {'python': 'example_sim.mosaik:ExampleSim'},
}

world = mosaik.World(sim_config)

# Start simulators
simulator_0 = world.start('ExampleSim', step_size=2)
simulator_1 = world.start('ExampleSim')

# Instantiate models
a_set = [simulator_0.A(init_val=i) for i in range(3)]
b_set = simulator_1.B.create(3, init_val=1)

# Connect entities
for a, b in zip(a_set, b_set):
    world.connect(a, b, ('val_out', 'val_in'))

# Run simulation
world.run(until=10)
```
7.6 How to achieve bi-directional data-flows

Bi-directional data-flows are important when you want to integrate, for example, control strategies. However, this trivial approach is not allowed in mosaik:

```python
# Send battery's active power value to the controller
world.connect(battery, controller, 'P')
# Controller sends back a schedule to the battery
world.connect(controller, battery, 'schedule')
```

The problem with this is that mosaik cannot know whether to compute `battery.P` or `controller.schedule` first.

To solve this problem, you only connect the battery’s `P` to the controller and let the control strategy set the new schedule via the asynchronous request `set_data`. To indicate this in your scenario, you set the `async_request` flag of `World.connect()` to `True`:

```python
world.connect(battery, controller, 'P', async_requests=True)
```

This way, mosaik will push the value for `P` from the battery to the controller. It will then wait until the controller’s `step` is done before the next step for the battery will be computed.

The `step` implementation of the controller could roughly look like this:

```python
class Controller(Simulator):
    def step(self, t, inputs):
        schedule = self._get_schedule(inputs)
        yield self.mosaik.set_data(schedule)
        return t + self.step_size
```

7.7 How to filter entity sets

When you create large-scale scenarios, you often work with large sets of entities rather then single ones. This section provides some examples how you can extract a sub-set of entities from a larger entity set based on arbitrary criteria.

Let’s assume that we have created a power grid with mosaik-pypower:

```python
grid = pypower.Grid(gridfile='data/grid.json').children
```

Since mosaik-pypower’s `Grid` entity only serves as a container for the buses and branches of our power grid, we directly bound its `children` to the name `grid`. So `grid` is now a list containing a `RefBus` entity and multiple `Transformer`, `PQBus` and `Branch` entities.

So how do we get a list of all transformers? This way:

```python
transformers = [e for e in grid if e.type == 'Transformer']
```

How do we get the single `RefBus`? This way:

```python
refbus = [e for e in grid if e.type == 'RefBus'][0]
```

Our `PQBus` entities are named like `Busbar_<i>` and `ConnectionPoint_<i>` to indicate to which buses we can connect consumers and producers and to which we shouldn’t connect anything. How do we get a list of all `ConnectionPoint` buses? We might be tempted to do it this way:

```python
conpoints = [e for e in grid if e.eid.startswith('ConnectionPoint_')]
```
The problem in this particular case is, that `mosaik-pypower` prepends a “grid ID” to each entity ID, because it can handle multiple grid instances at once. So our entity IDs are actually looking like this: `<grid_idx>-ConnectionPoint_<i>`. Using regular expressions, we can get our list:

```python
import re

regex_conpoint = re.compile(r'\d+-ConnectionPoint_\d+')
conpoints = [e for e in grid if regex_conpoint.match(e.eid)]
```

If we want to connect certain consumers or producers to defined nodes in our grid (e.g., your boss says: “This PV module needs to be connected to `ConnectionPoint_23`!”), creating a dict instead of a list is a good idea:

```python
remove_grididx = lambda e: e.eid.split('-', 1)[1]  # Little helper function
cps_by_name = {remove_grididx(e): e for e in grid if regex_conpoint.match(e)}
```

This will create a mapping where the string ‘`ConnectionPoint_23`’ maps to the corresponding `Entity` instance.

This was just a small selection of how you can filter entity sets using list/dict comprehensions. Alternatively, you can also use the `filter()` function or a normal `for` loop. You should also take a look at the `itertools` and `functools` modules. You’ll find even more functionality in specialized packages like PyToolz.

### 7.8 How to create user-defined connection rules

The method `World.connect()` allows you to only connect one pair of entities with each other. When you work with larger entity sets, you might not want to connect every entity manually, but use functions that take to sets of entities and connect them with each other based on some criteria.

The most common case is that you want to randomly connect the entities of one set to another, for example, when you distribute a number of PV modules over a power grid.

For this use case, `mosaik` provides `mosaik.util.connect_randomly()`. It takes two sets and connects them either evenly or purely randomly:

```python
world = mosaik.World(sim_config)
grid = pypower.Grid(gridfile=GRID_FILE).children
pq_buses = [e for e in grid if e.type == 'PQBus']
pvs = pvsim.PV.create(20)

mosaik.util.connect_randomly(world, pvs, pq_buses, 'P')
mosaik.util.connect_randomly(world, pvs, pq_buses, 'P', evenly=False, max_connects=3)
```

Another relatively common use case is connecting a set of entities to one other entities, e.g., when you want to connect a number of controllable energy producers to a central scheduler:

```python
from itertools import chain

def connect_many_to_one(world, src_set, dest_entity, *attrs, async_requests=False):
    for src_entity in src_set:
`
world.connect(src_entity, dest_entity, *attrs,
            async_requests=async_requests)

pvs = pvsim.PV.create(30)
chps = chpsim.CHP.create(20)
controller = cs.Scheduler()

# Connect all producers to the controller, remember to set the
# "async_requests" flag.
connect_many_to_one(world, chain(pvs, chps), controller, 'P',
                     async_requests=True)

Connection rules are oftentimes highly specific for a project. connect_randomly() is currently the only function that is useful and complicated enough to ship it with mosaik. But as you can see in the connect_many_to_one example, writing your own connection method is not that hard.

### 7.9 How to retrieve static data from entities

Sometimes, the entities don’t contain all the information that you need in order to decide which entity connect to which, but your simulation model could provide that data. An example for this might be the maximum amount of active power that a producer is able to produce.

Mosaic allows you to query a simulator for that data during composition time via `World.get_data()`:

```python
>>> example_simulator = world.start('ExampleSim')
Starting "ExampleSim" as "ExampleSim-2" ...
>>> entities = example_simulator.A.create(3, init_val=42)
>>> data = world.get_data(entities, 'val_out')
>>> data[entities[0]]
{'val_out': 42}
```

The entities that you pass to this function don’t need to belong to the same simulator (instance) as long as they all can provide the required attributes.

### 7.10 How to access topology and data-flow information

The `World` contains to `networkx` Graphs which hold information about the data-flows between simulators and the simulation topology that you created in your scenario. You can use these graphs, for example, to export the simulation topology that mosaik created into a custom data or file format.

`World.df_graph` is the directed datatflow graph for your scenarios. It contains a note for every simulator that you started. The simulator ID is used to label the nodes. If you established a data-flow between two simulators (by connecting at least two of their entities), a directed edge between two nodes is inserted. The edges contain the `async_requests` flag (see *How to achieve bi-directional data-flows*) and a list of the data-flows.

The data-flow graph may, for example, look like this:

```python
world.df_graph.node == {
    'PvSim-0': {},
    'PyPower-0': {},
}
world.df_graph.edge == {
    'PvSim-0': {'PypPower-0': {
      'async_requests': False,
    }}
```
World.entity_graph is the undirected entity graph. It contains a node for every entity. The full entity ID ('sim_id.entity_id') is used as node label. Every node also stores the simulator name and entity type. An edge between two entities is inserted

- if they are somehow related within a simulator (e.g., a PyPower branch is related to the two PyPower buses to which it is adjacent) (see create); or
- if they are connected via World.connect()

The entity graph may, for example, look like this:

```python
world.entity_graph.node == {
    'PvSim_0.PV_0': {'sim': 'PvSim', 'type': 'PV'},
    'PvSim_0.PV_1': {'sim': 'PvSim', 'type': 'PV'},
    'PyPower_0.branch_0': {'sim': 'PyPower', 'type': 'Branch'},
    'PyPower_0.bus_0': {'sim': 'PyPower', 'type': 'PQBus'},
    'PyPower_0.bus_1': {'sim': 'PyPower', 'type': 'PQBus'},
}
world.entity_graph.edge == {
    'PvSim_0.PV_0': {'PyPower_0.bus_0': {}},
    'PvSim_0.PV_1': {'PyPower_0.bus_1': {}},
    'PyPower_0.branch_0': {'PyPower_0.bus_0': {}, 'PyPower_0.bus_1': {}},
    'PyPower_0.bus_0': {'PvSim_0.PV_0': {}, 'PyPower_0.branch_0': {}},
    'PyPower_0.bus_1': {'PvSim_0.PV_1': {}, 'PyPower_0.branch_0': {}},
}
```

The get_related_entities API call also uses and returns (parts of) the entity graph. So you can access it in your scenario definition as well as from with a simulator, control strategy or monitoring tool.

Please consult the networkx documentation for more details about working with graphs and directed graphs.

### 7.11 How to destroy a world

When you are done working with a world, you should shut it down properly:

```python
>>> world.shutdown()
```

This will, for instance, close mosaik’s socket and allows new World instances to reuse the same port again.

World.run() automatically calls World.shutdown() for you.

### 7.12 How to do real-time simulations

It is very easy to do real-time (or “wall-clock time”) simulations in mosaik. You just pass an rt_factor to World.run() to enable it:

```python
world.run(until=10, rt_factor=1)
```
A real-time factor of 1 means, that 1 simulation time unit (usually a simulation second) takes 1 second of real time. Thus, if you set the real-time factor to 0.5, the simulation will run twice as fast as the real time. If you set it to 1/60, one simulated minute will take one real-time second.

It may happen that the simulators are too slow for the real-time factor chosen. That means, they take longer than, e.g., one second to compute a step when a real-time factor of one second is set. If this happens, mosaik will by default just print a warning message to stdout. However, you can also let your simulation crash in this case by setting the parameter `rt_strict` to True. Mosaik will then raise a `RuntimeError` if your simulation is too slow:

```
world.run(until=10, rt_factor=1/60, rt_strict=True)
```

### 7.13 How to call extra methods of a simulator

A simulator may optionally define additional API methods (see `init`) that you can call from your scenario. These methods can implement operations, like setting some static data to a simulator, which don’t really fit into `init()` or `create()`.

These methods are exposed via the model factory that you get when you start a simulator. In the following example, we’ll call the `example_method()` that the example simulator shipped with the mosaik Python API:

```python
>>> world = mosaik.World({'ExampleSim': {'...    'python': 'example_sim.mosaik:ExampleSim'}})
>>> es = world.start('ExampleSim')
Starting "ExampleSim" as "ExampleSim-0" ...

>>> # Now brace yourself ...
>>> es.example_method(23)
23

>>> world.shutdown()
```
The simulator manager (or just *sim manager*) is responsible for starting and handling the external simulator processes involved in a simulation as well as for the communication with them.

Usually, these simulators will be started as separate sub-processes which will then connect to mosaik via network sockets. This has two benefits:

1. Simulators can be written in any language.
2. Simulation steps can be performed in parallel, if two processes don’t depend on each others data.

Simulators written in Python 3 can, for performance reasons, be imported and executed like normal Python modules. This way, all Sim API calls will be plain functions calls without the overhead of network communication and message (de)serialization. However, since Python only runs in one thread at a time, this will also prevent parallel execution of simulators.

When a (Python 3) simulator is computationally inexpensive, running it in-process may give you good results. If it performs a lot of expensive computations, it may be better to start separate processes which can then do these computations in parallel. In practice, you should try and profile both ways in order to get the maximum performance out of it.

Sometimes, both ways won’t work because you simply cannot start the simulator process by yourself. This might be the reason for hardware-in-the-loop or if a simulator needs to run on a separate machine. In these cases, you can simply let mosaik connect to a running instance of such a simulator.

Internally, all three kinds of simulator processes (in-process with mosaik, started by mosaik, connected to by mosaik) are represented by *SimProxy* objects so that they all look the same to the other components of mosaik:
The sim manager gets its configuration via the `World`'s `sim_config` argument. The `sim_config` is a dictionary containing simulator names and description of how to start them:

```python
>>> import mosaik

>>> sim_config = {
...     'SimA': {
...         'python': 'package.module:SimClass',
...     },
...     'SimB': {
...         'cmd': 'java -jar simB.jar %%(addr)s',
...         'cwd': 'simB/dist/',
...     },
...     'SimC': {
...         'connect': 'localhost:5678',
...     }
... }

>>> world = mosaik.World(sim_config)

>>> world.shutdown()
```

In the example above, we declare three different simulators. You can freely choose a name for a simulator. Its configuration should either contain a `python`, `cmd` or `connect` entry:

Since mosaik 2.3.0 it is possible to pass environment variables to sub-processes. Using the key `env` in `sim_config` allows you to set new environment variables. That could look like this:

```python
>>> import mosaik

>>> sim_config = {
...     'SimA': {
...         'python': 'package.module:SimClass',
...         'env': {
...             'PYTHONPATH': 'src/',
...         },
...     }
... }
```

Chapter 8. The simulator manager
... },
... },
... }

```python
>>> world = mosaik.World(sim_config)
>>> world.shutdown()
```

**python**  This tells mosaik to run the simulator in process. As a value, you need to specify the module and class name of the simulator separated by a colon. In the example, mosaik will import `package.module` and instantiate `sim = package.module.SimClass()`. This only works for simulators written in Python 3.

**cmd**  This tells mosaik to execute the specified command `cmd` in order to start a new sub-process for the simulator.

You can use the placeholder `%{python}` to use the same Python interpreter and virtualenv that mosaik currently uses (see `sys.executable`).

In order to create a socket connection to mosaik the simulator needs to know the address of mosaik’s server socket. Mosaik will pass this address (in the form `host:port`) as a command line argument, so you need to include the placeholder `%{addr}` in your command. Mosaik will replace this with the actual address.

You can optionally specify a current working directory (`cwd`). If it is present, mosaik will change to that directory before executing `cmd`. Its default value is `.'`.

In our example, mosaik would execute:

```
$ cd simB/java
$ java -jar simB.jar localhost:5555
```

in order to start `SimB`.

**Note:** Please use the `cwd` command and for paths in the `cmd` call only the UNIX/Linux path notation with slashes even if you are using windows. Do not use backslashes or double backslashes.

**connect**  This tells mosaik to establish a network connection to a running simulator instance. It will simply connect to `host:port` for `SimC`
When you defined your scenario and start the simulation, mosaik’s scheduler becomes active. It manages the execution of all involved simulators, keeps them in sync and handles the data-flows between them.

Mosaik runs the simulation by stepping simulators through time. The time has internally no unit attached, but by convention, seconds are used. If all simulators involved in your scenario agree on another unit (e.g., minutes or milliseconds), this can be used as well.

### 9.1 Anatomy of a step

When the simulation starts, all simulators are at time 0. Mosaik tracks the current simulation time for every simulator individually. When it asks a simulator to perform its next step, it passes its current simulation time \( t_{\text{now}} \) to it. After its step, the simulator returns the time at which it wants to perform its next step \( t_{\text{next}} \). Thus, a simulator’s step size doesn’t need to be constant but can vary during the simulation.

The data that a simulator computes during a step is valid for the right-open interval \( [t_{\text{now}}, t_{\text{next}}) \) as shown in the following figure.

![Fig. 9.1: Schematic execution of a simulator A. \( t_{\text{now}} \), \( t_{\text{next}} \) and the validity interval for its first step 0 are shown. The figure also shows that the step size of a simulator may vary during the simulation.](image)

### 9.2 Synchronization and data-flows

If there are data-flows between two simulators (because you connected some of their entities), a simulator can only perform a step if all input data has been computed.
Let’s assume we created a data-flow from a simulator $A$ to a simulator $B$ and $B$ wants to perform a step from $t_{\text{now}(B)}$. Mosaik determines which simulators provide input data for $B$. This is only $A$ in this example. In order to provide data for $B$, $A$ needs to step far enough to produce data for $t_{\text{now}(B)}$, that means $t_{\text{next}(A)} > t_{\text{now}(B)}$ as the following figure illustrates.

![Figure 9.2: (a) $B$ cannot yet step because $A$ has not progressed far enough yet ($t_{\text{next}(A)} \leq t_{\text{now}(B)}$). (b) $B$ can perform its next step, because $A$ now has progressed far enough ($t_{\text{next}(A)} > t_{\text{now}(B)}$).](image)

If this condition is met for all simulators providing input for $B$, mosaik collects all input data for $B$ that is valid at $t_{\text{now}(B)}$ (you could say it takes one snapshot of the global simulation state). It passes this data to $B$. Based upon this (and only this) data, $B$ performs its step $[t_{\text{now}(B)}, t_{\text{next}(B)}]$.

This is relatively easy to understand if $A$ and $B$ have the same step size, as the following figures shows:

If $B$ had a larger step size then $A$, $A$ would produce new data while $B$ steps. $B$ would still only use the data that was valid at $t_{\text{now}(B)}$, because it only “measures” its inputs once at the beginning of its step:

On the other hand, if $A$ had a larger step size then $B$, we would reuse the same data from $A$ multiple times as long as it is valid:

The last two examples may look like special cases, but they actually arise from the approach explained above.
Fig. 9.3: In this example, A and B have the same step size. Mosaik steps them in an alternating order starting with A, because it provides the input data for B.

Fig. 9.4: In this example, B has a larger step size. It doesn’t consume all data that A produces, because it only gets data once at the beginning of its step.

Fig. 9.5: In this example, A has a larger step size. B reuses the same data multiple times because it is still valid.
9.2.1 How data flows through mosaik

After a simulator is done with its step, mosaik determines, based on the data-flows that you created in your scenario, which data other simulators need from it. It makes a `get_data()` API call to the simulator and stores the data that this call returns in an internal buffer. It also memorizes for which period of time this data is valid.

Before a simulator steps, mosaik determines in a similar fashion what input data the simulator needs. Mosaik checks its internal data buffer if input data from all simulators is available. If not, it waits until all simulators stepped far enough to provide that data. All input data is then passed to the `inputs` parameter of the `step()` API call.

It is important to understand that simulators don’t talk to each other directly but that all data flows through mosaik were it can be cached and managed.

9.3 Cyclic data-flows

Cyclic data-flows are necessary to model situations in which a control mechanism (C) controls another entity (E) based on its state, e.g. by sending commands or a schedule.

It is not possible to perform both data-flows (the state from E to C and the commands/schedule from C to E) at the same time because they depend on each other (yes, this is similar to the chicken or egg dilemma).

The cycle can be resolved by first stepping E (e.g., from \( t = 0 \) to \( t = 1 \)). E’s state for that interval can then be used as input for C’s step for the same interval. The commands/schedule that C generates for E will then be used in E’s next step.

![Diagram](image)

Fig. 9.6: In this example, a controlled entity E provides state data to the controller C. The commands or schedule from C is used by E in its next step.

This resolution of the cycle makes sense if you think how this would work in real life. The controller would measure the data from the controlled unit at a certain point \( t \). It would then do some calculation which take a certain amount of time \( \Delta t \) which would be send to the controlled unit at \( t + \Delta t \).

However, mosaik is not able to automatically resolve that cycle. That’s why you are not allowed to `connect(E, C)` and `connect(C, E)` in a scenario. Instead you have to `connect(E, C, async_requests=True)` and use the asynchronous callback `set_data()` in C’s `step()` implementation in order to send the commands or schedule from C to E.

You can take a look at our discussion of design decisions to learn why cyclic data-flows are handled this way.
9.4 Stepping and simulation duration

By now you should have a general idea of how mosaik handles data-flows between simulators. You should also have the idea that simulators only perform a step when all required input data is available. But what if they don’t need any? In this section you’ll learn about the algorithm that mosaik uses to determine whether a simulator can be stepped or not.

The general idea behind this is laziness. A simulator will only step if it really needs to. This is usually, because someone else needs its data. This becomes problematic if your simulator is the only one in the simulation (e.g., for testing purposes) or at the end of a data-flow chain.

This is how it works:

1. Should there be a next step at all? *  
   *Yes*: Go to step 2.  
   *No*: Stop the simulator.  
   *We’ll explain how to answer this question below.*

2. Are there simulators that need data from us?  
   *Yes*: Go to step 3.  
   *No*: Go to step 4.

3. Does a depending simulator require new data from us?  
   *Yes*: Go to step 4.  
   *No*: Wait until someone does. Then go to step 4.

4. Is all required input data from other simulators available?  
   *Yes*: Go to step 5.  
   *No*: Wait until all data is available. Then go step 5.

5. Collect all required input data.

6. Send collected input data to simulator, perform the simulation step and get the time for the next step.

7. Get all data from the simulator that other simulators need.

8. Notify simulators that already wait for that data.

So how do we determine whether a simulator must perform another step or if it is done?

When we start the simulation, we pass a time unto which our simulation should run \( \text{world.run(until=END)} \). Usually a simulator is done if the time of its next step is larger then the value of \( \text{until} \). This is, however, not true for all simulators in a simulation. If no one needs the data of a simulator step, why perform this step?

So the actual algorithm is as follows:

If a simulator has no outgoing data-flows (no other simulator needs its data) it simulates until the condition \( t_{\text{next}} > t_{\text{until}} \) is met.

Else, if a simulator needs to provide data for other simulators, it keeps running until all of these simulators have stopped.

The algorithm explained above allows mosaik to perform as little simulation steps as possible and only perform these steps when necessary.
This is a list of some questions we recently got. If you cannot find an answer for your questions here, you are welcome to post it on our mailing list.

### 10.1 General questions

#### 10.1.1 Are there graphical tools for scenario design?

An environment for graphical analysis as well as scenario design is currently developed and will presumably be released in 2015. However, we argue that graphical tools are not feasible for the design of large and complex scenarios. For most applications the more flexible scenario design by code is advantageous.

#### 10.1.2 Where can I find a mosaik Tutorial/Manual?

There is none yet but it’s quite on top of our to-do list. You’ll soon find one here.

#### 10.1.3 Is there a mosaik-Wiki?

We like Wikis but consider them the wrong tool for documenting software (and we are not alone with that). There are a lot of other resources, though:

- All documentation is concentrated here, at Read the Docs.
- Source code and issues are managed by Bitbucket.
- Discussion takes place in our mailing list.
- News are spread through our blog.

There’s not much that a wiki could add here.

### 10.2 Coupling models with mosaik

#### 10.2.1 Can I use continuous models with mosaik?

Yes. Since mosaik 2 you can even use a variable step size for your simulator that can dynamically change during the simulation.
10.2.2 Can I use mosaik only with Python programs?

No, mosaik can be used with any language that provides network sockets and ways to (de)serialize JSON.

Since implementing network event loops and message (de)serialization is repetitive work and unnecessary overhead, we provide so called high-level APIs for certain languages that provide a base class that you can inherit and just need to implement a few methods representing the API calls.

Currently, a high-level API is only available for Python, but implementations for Java and other languages will follow soon.

10.2.3 Can I use my MATLAB/Simulink models with mosaik? How do I do it?

Yes, you can. We will provide an example soon. In the end, if you manage to let your model communicate via sockets and are capable of serializing/deserializing JSON data objects you can use it with mosaik (see Can I use mosaik only with Python programs? for details).

10.3 The mosaik demo

10.3.1 I can only see active power values in the web visualization. Does mosaik also support reactive power values with PyPower?

Of course, it only depends on your models. The basic models distributed with mosaik 2 only produce active power outputs ($\cos \phi = 1$), so we don’t display reactive power.

10.3.2 What are the power grid’s parameters? How are the cables’/lines’ parameters formatted?

Check https://bitbucket.org/mosaik/mosaik-pypower under “input file format”. Typically, line values are given in $R$ per km and $X$ per km.

10.3.3 Port 8000 on my local machine is already in use. How can I see the visualization with WebVis?

Port 8000 is used as default when using WebVis. You can overwrite the default value in demo.py.

```python
... sim_config = {
    ... 'WebVis': {
        'cmd': 'mosaik-web -s 0.0.0.0:8000 $(addr)s',
    },
}
...```

11.2 Development setup and tests

This guide will show you how to set up a development environment for mosaik or components of its ecosystem (like the Python API), how to run the tests, check the code coverage and quality, and build the documentation.

11.2.1 General advice

- You should use Linux or OS X as your main development platform – most tools are working much better there than on Windows. However, you should still make sure that mosaik keeps working on Windows. :-)  
- You should create a separate virtualenv for each project, that you are going to work on (e.g., one for mosaik, another one for mosaik-api-python and so forth). This will make it easier for you to track their dependencies.  
- You should install and use virtualenvwrapper. It will make working with multiple virtualenvs much easier.  
- You may need to change some absolute paths from the code blocks depending on your system.  
- I’ll only explain the necessary steps for mosaik, because its the most complex project (e.g., mosaik-api-python has no separate documentation).  
- You should have worked through the general installation instructions and got the demo running. Afterwards delete the virtualenv mosaik (rmvirtualenv mosaik) – you can later recreate it as mosaik-demo.

11.2.2 Installation

Change to the directory where you keep your code and clone the mosaik-repository. Create a virtualenv with a Python 3 interpreter and install all development dependencies. Finally, install mosaik in editable mode:

```
$ cd ~/Code
$ git clone ssh://git@bitbucket.org/mosaik/mosaik.git
$ cd mosaik
$ mkvirtualenv -p /usr/bin/python3 mosaik
(mosaik)$ pip install -r requirements.txt
(mosaik)$ pip install -e .  # Install mosaik in "editable"
```

An “editable” installation just means, that changes you introduce in the repository are automatically reflected in your installation (and thus in your tests).

11.2.3 Tests and coverage

To run all tests, simply execute py.test:

```
$ py.test
```

It will automatically run all code examples in the docs/ as well as the actual tests from mosaik/test/. Pytest’s behavior can be controlled via the [pytest] section in the setup.cfg file and via command line arguments (see its documentation or py.test --help).

You should also regularly check the code/branch coverage:
$ py.test --cov=mosaik

You can also generate HTML files from your source that highlight uncovered lines:

$ py.test --cov=mosaik --cov-report=html
$ [kde-]open htmlcov/index.html

Take a look at the docs of pytest-cov for more help.

Before making a release (and in between) you should make sure that the tests are passing on all supported Python versions. You do this with tox. ‘Tox’ config file tox.ini will show you which versions we support. Every interpreter listed here (e.g., Python 3.3 or PyPy) should be installed on your system. Running tox is than very easy:

$ tox
...
_______ summary ________
py33: commands succeeded
py34: commands succeeded
congratulations :)

11.2.4 Coding style

Mosaik follows – as most Python projects – relatively strict coding standards.

• All source files are encoded with UTF-8
• LF (\n) is used to represent a new line (Unix style).
• Four spaces are used for indentation (three spaces for reStructuredText directives).
• Trailing whitespaces should always be stripped.
• Lines should be no longer than 79 characters.
• Python files should be formatted according to PEP 8 and PEP 257.

You should regularly run flake8 to perform PEP8 style checks and and run some analyses to find things like unused imports:

$ flake8 mosaik

It takes its configuration from setup.cfg.

11.2.5 Build the documentation

We use Sphinx to create mosaik’s documentation:

$ cd docs/
$ make html

This will build the documentation to docs/_build/html.

When you push new revisions to mosaik’s main repo (bitbucket.org/mosaik/mosaik) the official documentation is automatically updated via a hook.

11.3 Release Process

This process describes the steps to execute in order to release a new version of mosaik.

11.3. Release Process
11.3.1 Preparations

1. Make a new release of mosaik-api-python if required. Use this guide as an orientation.

2. Close all tickets for the next version.

3. Check all dependencies for new versions and update the exact version of all entries in requirements.txt.
   Update the minimum required versions of dependencies in setup.py if (and only if) necessary.

4. Run tox from the project root. All tests for all supported versions must pass:

   ```
   $ tox
   [...] summary [...]
   py33: commands succeeded
   py34: commands succeeded
   congratulations :)
   ```

5. Build the docs (HTML is enough). Make sure there are no errors and undefined references.

   ```
   $ cd docs/
   $ make clean html
   $ cd ..
   ```

6. Check if all authors are listed in AUTHORS.txt.

7. Update the change logs (CHANGES.txt and docs/about/history.rst). Only keep changes for the current major release in CHANGES.txt and reference the history page from there.

8. Commit all changes:

   ```
   $ git commit -m 'Updated change log for the upcoming release.'
   ```

9. Update the version number in mosaik/_version.py, setup.py and docs/conf.py and commit:

   ```
   $ git commit -m 'Bump version from x.y.z to a.b.c'
   ```

   **Warning:** Do not yet tag and push the changes so that you can safely do a rollback if one of the next steps fails and you need change something!

10. Write a draft for the announcement mail with a list of changes, acknowledgements and installation instructions. Everyone in the team should agree with it.

11.3.2 Build and release

1. Test the release process. Build a source distribution and a wheel package and test them:

   ```
   $ python setup.py sdist bdist_wheel
   $ ls dist/
   mosaik-a.b.c-py2.py3-none-any.whl mosaik-a.b.c.tar.gz
   ```

   Try installing them:

   ```
   $ rm -rf /tmp/mosaik-sdist  # ensure clean state if ran repeatedly
   $ virtualenv -p /usr/bin/python3 /tmp/mosaik-sdist
   $ /tmp/mosaik-sdist/bin/pip install dist/mosaik-a.b.c.tar.gz
   $ /tmp/mosaik-sdist/bin/python
   >>> import mosaik  # doctest: +SKIP
   >>> mosaik.__version__  # doctest: +SKIP
   'a.b.c'
   ```
and

$ rm -rf /tmp/mosaik-wheel  # ensure clean state if ran repeatedly
$ virtualenv -p /usr/bin/python3 /tmp/mosaik-wheel
$ /tmp/mosaik-wheel/bin/pip install dist/mosaik-a.b.c-py2.py3-none-any.whl
$ /tmp/mosaik-wheel/bin/python
>>> import mosaik  # doctest: +SKIP
>>> mosaik.__version__  # doctest: +SKIP
'a.b.c'

2. Create or check your accounts for the test server and PyPI. Update your ~/.pypirc with your current credentials:

[distutils]
index-servers =
    pypi
test

[test]
repository: https://test.pypi.org/legacy/
username: <your test user name goes here>
password: <your test password goes here>

[pypi]
repository: https://upload.pypi.org/legacy/
username: <your production user name goes here>
password: <your production password goes here>

3. Upload the distributions for the new version to the test server and test the installation again:

$ twine upload -r test dist/mosaik*a.b.c*
$ pip install -i https://testpypi.python.org/pypi mosaik

4. Check if the package is displayed correctly: https://testpypi.python.org/pypi/mosaik

5. Finally upload the package to PyPI and test its installation one last time:

$ twine upload -r pypi dist/mosaik*a.b.c*
$ pip install -U mosaik

6. Check if the package is displayed correctly: https://pypi.python.org/pypi/mosaik

11.3.3 Post release

1. Push your changes:

$ git tag a.b.c
$ git push ssh://git@bitbucket.org/mosaik/mosaik.git

2. Remove the build/ directory:

$ rm -r build/

3. Activate the documentation build for the new version.

4. Make sure, the demo works with the new release.

5. Send the prepared email to the mailing list.

6. Create blog post for mosaik.offis.de.
11.4 Requirements

This document lists all requirements for mosaik’s development. The main goals are:

1. **Couple existing simulators**, schedule their (step-wise) execution and manage the data exchange between them.
   
   These simulators may range from open-source software to closed-source and commercial software as well as from simulators that can directly integrate the mosaik API to simulators that offer their own API and that cannot be started or directly controlled by mosaik.

2. **Allow easy creation and execution of large-scale simulation scenarios**.

   *Large-scale* means scenarios comprising thousands or ten thousands of simulated entities. As few lines of code as possible should be required to describe a scenario and connect all entities involved.

   Once a scenario is defined, it should be easy to run the simulation.

3. **Maintainability is most important.**

   Developers will not be able to contribute to mosaik forever. New developers must be able to quickly understand how mosaik works in order to fix things and add features.

   Thus, the source code of mosaik must be as readable as possible. Everything should be documented (API docs and guides describing the ideas and concepts behind the different parts of mosaik). There should also be as little different technologies (and libraries to a certain point) involved as possible.

4. **Runtime performance is important, too, but not as much as maintainability.**

5. **Stability and robustness**: Large simulations (comprising thousands of entities over a period of several months or a year of simulation time) may take a while. Mosaik should not crash in the middle of a simulation, so everything needs to be tested as good as possible.

The following sections describe these requirements in more detail.

11.4.1 Types of simulators and models

1. **Heterogeneous implementations**: It must be possible to integrate simulators with different implementations (i.e., programming languages, frameworks, tools).

2. **Different temporal resolutions**: Mosaik must be able to compose simulations from models with differing temporal resolutions.

3. **Multiple paradigms**: Mosaik must be able to compose simulation models that use different paradigms with respect to the handling of time (e.g., discrete event or continuous).

4. **Simulators written in Python (like mosaik)** should be able to run in the same process as mosaik, so that no networking is required in order to communicate with them.

5. **Mosaik must be able to start and stop (open-source) simulators** that can directly implement the mosaik API. It should always use the fastest possible method to communicate with them; e.g., inter-process communication if the simulator runs on the same machine or sockets if it runs on another machine.

6. **COTS integration**: It must be possible to write adapters that translate between the mosaik API and the API provided by commercial or closed-source simulators.

   Mosaik also needs to handle simulators that it cannot start itself but can only connect to a running instance of them.

7. **Real-time simulators**: Mosaik must be able to work with real-time (wall-clock) simulators; e.g., real-time power grid simulators.
11.4.2 Integrating simulators

1. Simulator self-description: Mosaik must provide a way for simulators to describe their capabilities, models, inputs, outputs, and so on. This self-description will later be used for creating scenarios.

2. Mosaik API: There must be an (easy and well documented) API that simulators can implement in order to communicate with mosaik.

3. Control strategies (like multi-agent systems) should use the same API as simulators.

11.4.3 Scenario definition

1. Defining scenarios should happen directly in Python to not introduce another technology that has to be maintained and because Python syntax is as easy as an arbitrary DSL. Furthermore, Python is much more flexible and powerful than a simple DSL.

2. Connecting entities: On the lowest level, mosaik must be able to connect two single entities. On a higher level, mosaik must be able to automatically connect two sets of entities based on their inputs and outputs. For example, PV modules with a $P$ and $Q$ output can be connected to power grid nodes with a $P$ and $Q$ input.

3. Filtering of entity sets: Mosaik must also offer means to automatically filter sets of entities based on their attributes or on existing connections to other entities.

4. Cyclic Data-flow Support: mosaik must offer a way to deal with cyclic data flows, e.g. between a controllable energy producer and a control strategy which generates schedules based on the current feed-in.

5. Physical Topology Access: mosaik must allow the control strategies and simulators to query/traverse the physical topology created during the composition process.

6. Intra-Model Topology Access: a simulator must offer the possibility to get access to the relations between the entities of a model (e.g., how nodes and lines in a power grid are interconnected) for building the complete physical topology.

7. Moving entities: Mosaik must support the specification of scenarios with moving resources like electric vehicles which may be connected to varying nodes in the power grid based on their current state.

8. Scenario variants: Mosaik must offer means to easily create scenario variants to e.g., simulate a scenario for summer and winter months.

11.4.4 Execution

1. Mosaik must be able to report the progress of a simulation.

2. Data logging: mosaik must log data that is provided by the simulators for later evaluation. It must also be possible to filter what goes into the database when creating a scenario. Otherwise, the database might grow too large and contain mostly irrelevant data for the research question at hand.

3. It should be possible to distribute the simulator instances over multiple processes on the same machine and over multiple different machines or servers.

4. Mosaik should be usable as a library. That means, that the user who creates a scenario makes calls to mosaik’s functionality to execute their scenario. This will allow them to easily test the scenario and hook into mosaik e.g., for debugging purposes.

5. Mosaik should be able to run as a framework. That means that a mosaik process loads a scenario and executes a defined entry point (the scenario’s main method). This allows to start a mosaik master process that manages the execution of multiple scenarios in parallel and that offers a web GUI to monitor these simulations.
6. Configure log messages for every component independently: Simulation developers, scenario experts and mosaik core developers usually are interested in different kinds of debug output. It should thus be possible to change log levels for mosaik’s various components independently.

11.5 Discussion of design decisions

On this page, we discuss some of the design decisions that we made. This should explain why some features are (not) present and why they work the way that they work.

**Note:** For the sake of readability, some concepts are simplified in the following sections. For example, the snippet `connect(A, B)` means we’re connecting some entities of a simulator A to some entities of simulator B; simulator and entity are used as if they were the same concept; `A.step()` means, that mosaik calls the step() function of simulator/entity A.

11.5.1 Circular data-flows

Circular data-flows were one of the harder problems to solve.

When you connect the entities of two simulators with each other, mosaik tracks the new dependency between these simulators:

```python
connect(A, B)
```

A would now provide input data for B. When mosaik runs the simulation, the step for a certain time `t` would first be computed for A and then for B with the inputs of A.

In order to connect control strategies (like multi-agent systems) with to-be-controlled entities, you usually need a circular data-flow. The entity provides state information for the controller which in turn sends new commands or schedules to the controlled entity. The naïve way of doing this would be:

```python
connect(A, B, 'state')
connect(B, A, 'schedule')
```

A would receive schedules via the inputs of `A.step()`. In `A.step()`, it would compute new state information which mosaik would get via `A.get_data()`. Mosaik would forward this to the inputs of `B.step()`. `B.step()` would calculate some schedules, which mosaik would again get via `B.get_data()` and pass to `A.step()` …

The question that arise here is: Which simulator do we step first – A or B? Mosaik has no clue. You could say that A needs to step first, because the data-flow from A to B was established first. However, if you re-arrange your code and (accidentally) flip both lines, you would get a different behavior and a very hard to find bug.

What do we learn from that? We need to explicitly tell mosaik how to resolve these cycles and prohibit normal circular data-flows as in the snippet above.

If you remember mosaik 1, your next approach would be as follows:

```python
connect(A, B, 'state')
connect(B, A, 'schedule', delay=True)
```

This would tell mosaik how to resolve the cycle and throw an error if you accidentally flip both lines.

Theoretically, we could be done here. But we aren’t. The data-flows in the example above are passive, meaning that A and B compute data hoping that someone will use them. This abstraction works reasonably well for normal simulation models, but control mechanism usually have an active roll. They actively decide whether or not to send commands to the entities they control.
Accordingly, mosaik provides ways for control mechanisms and monitoring tools to actively collect more data from the simulation and set data to other entities. These means are implemented as *asynchronous requests* that a simulator can perform during its step. Similar to the cyclic data-flows, this requires you to tell mosaik about it to prevent some scheduling problems:

```python
connect(A, B, async_requests=True)
```

This prevents A from stepping too far into the future so that B can get additional data from or set new data to A in `B.step()`. Since you can set data via an asynchronous request, you can implement cyclic data-flows with it:

```python
connect(A, B, 'state', async_requests=True)
```

The implementation of `A.step()` and `A.get_data()` would be the same. In `B.step()` you would still receive the state information from A and compute the schedules. However, you wouldn’t store them somewhere so that `B.get_data()` can return them. Instead, you would just pass them actively to `set_data()`. Mosaik stores that data in the same buffer in which it would store data that it retrieved via `B.get_data()`.

So to wrap this up, there would be two possibilities to achieve cyclic data-flows:

1. **Passive controller:**
   ```python
   connect(A, B, 'state')
   connect(B, A, 'schedules', delay=True)
   ```

   `B.step()` computes schedules and caches them somewhere. Mosaik gets these schedules via `B.get_data()` and sends them to A.

   If you forget to set the `delay=True` flag, mosaik will raise an error at *composition time*.

   If you forget the second `connect()`, nothing will happen with the schedules. You may not notice this for a while.

2. **Active controller:**
   ```python
   connect(A, B, 'state', async_requests=True)
   ```

   `B.step()` computes schedules and immediately passes them to `set_data()`. Mosaik sends them to A.

   If you forget to set the `async_requests=True` flag, mosaik will raise an error at *simulation time*.

So, two ways to achieve basically the same thing. What does the *Zen of Python* say to this?

*"There should be one-- and preferably only one --obvious way to do it."*

Since the asynchronous requests can be used for other purposes as well and thus, cannot simply be stripped away, we chose the second way and excluded the first possibility.

### 11.6 Logo and corporate identity

This page contains download links to the mosaik logos and lists the official mosaik colors.

#### 11.6.1 Normal logo

This is the large version of the logo.
SVG for the web

Letters converted to objects so that it nicely renders on all devices.

SVG for Inkscape

This is the Inkscape master file for the logo. In order to edit it in Inkscape, you need to install the Aller font.

11.6.2 Simple logo

The simple variant of the logo should be used when the display size for the logo is so small, that the icons would not be recognizable very well, e.g. in the headers of letters or papers.
PNG, 512 × 280 px, with transparency

SVG for the web

Letters converted to objects so that it nicely renders on all devices.

SVG for Inkscape

This is the Inkscape master file for the logo. In order to edit it in Inkscape, you need to install the Aller font.

11.6.3 Icon

This version should be used for (program) Icons.
11.6.4 Colors

Value ranges RGB: [0-255] [0-255] [0-255]

Value ranges HSB/HSL: [0-359]° [0-100]% [0-100]%

mosaik logo

These colors are usually only used in the logo.

11.6. Logo and corporate identity
The API reference provides detailed descriptions of mosaik’s classes and functions. It should be helpful if you plan to extend mosaik with custom components.

12.1 mosaik — The ende-user API

This module provides convenient access to all classes and functions required to create scenarios and run simulations. Currently, this is only `mosaik.scenario.World`.

12.2 mosaik.exceptions — mosaik specific error types

This module provides mosaik specific exception types.

```python
class mosaik.exceptions.ScenarioError
    This exception is raised if something fails during the creation of a scenario.

class mosaik.exceptions.SimulationError(msg, exc=None)
    This exception is raised if a simulator cannot be started or if a problem arises during the execution of a simulation.
```

12.3 mosaik.scenario — Classes related to the scenario creation

This module provides the interface for users to create simulation scenarios for mosaik.

The `World` holds all necessary data for the simulation and allows the user to start simulators. It provides a `ModelFactory` (and a `ModelMock`) via which the user can instantiate model instances (entities). The method `World.run()` finally starts the simulation.

```python
class mosaik.scenario.World(sim_config, mosaik_config=None, debug=False)
    The world holds all data required to specify and run the scenario.
    It provides a method to start a simulator process (`start()`) and manages the simulator instances.
    You have to provide a `sim_config` which tells the world which simulators are available and how to start them.
    See `mosaik.simmanager.start()` for more details.
    `mosaik_config` can be a dict or list of key-value pairs to set additional parameters overriding the defaults:
```
Here, `addr` is the network address that mosaik will bind its socket to. `start_timeout` and `stop_timeout` specify a timeout (in seconds) for starting/stopping external simulator processes.

If `execution_graph` is set to `True`, an execution graph will be created during the simulation. This may be useful for debugging and testing. Note, that this increases the memory consumption and simulation time.

**sim_config = None**
The config dictionary that tells mosaik how to start a simulator.

**config = None**
The config dictionary for general mosaik settings.

**sims = None**
A dictionary of already started simulators instances.

**env = None**
The SimPy.io networking `Environment`.

**srv_sock = None**
Mosaik’s server socket.

**df_graph = None**
The directed data-flow graph for this scenario.

**shifted_graph = None**
A second directed data-flow graph for flows that are shifted in time to enable cyclic data dependencies.

**entity_graph = None**
The graph of related entities. Nodes are `(sid, eid)` tuples. Each note has an attribute `entity` with an `Entity`.

**sim_progress = None**
Progress of the current simulation.

**start**( `sim_name`, **sim_params**) 
Start the simulator named `sim_name` and return a `ModelFactory` for it.

**connect**( `src`, `dest`, *`attr_pairs`, *, `async_requests=False`, `time_shifted=False`, `initial_data=None`) 
Connect the `src` entity to `dest` entity.

Establish a data-flow for each `(src_attr, dest_attr)` tuple in `attr_pairs`. If `src_attr` and `dest_attr` have the same name, you can optionally only pass one of them as a single string.

Raise a `ScenarioError` if both entities share the same simulator instance, if at least one (src. or dest.) attribute in `attr_pairs` does not exist, or if the connection would introduce a cycle in the data-flow (e.g., `A → B → C → A`).

If the `dest` simulator may make asynchronous requests to mosaik to query data from `src` (or set data to it), `async_requests` should be set to `True` so that the `src` simulator stays in sync with `dest`.

An alternative to asynchronous requests are time-shifted connections. Their data flow is always resolved after normal connections so that cycles in the data-flow can be realized without introducing deadlocks. For such a connection `time_shifted` should be set to `True` and `initial_data` should contain a dict with input data for the first simulation step of the receiving simulator.
An alternative to using async_requests to realize cyclic data-flow is given by the time_shifted kwarg. If set to True it marks the connection as cycle-closing (e.g. C → A). It must always be used with initial_data specifying a dict with the data sent to the destination simulator at the first step (e.g. `{'src_attr': value}).

get_data(entity_set, *attributes)
Get and return the values of all attributes for each entity of an entity_set.

The return value is a dict mapping the entities of entity_set to dicts containing the values of each attribute in attributes:

```python
{Entity(...): {
    'attr_1': 'val_1',
    'attr_2': 'val_2',
    ...
},
...
}
```

run(until, rt_factor=None, rt_strict=False)
Start the simulation until the simulation time until is reached.

In order to perform real-time simulations, you can set rt_factor to a number > 0. An rt-factor of 1 means that 1 simulation time unit (usually a second) takes 1 second in real-time. An rt-factor of 0.5 will let the simulation run twice as fast as real-time.

If the simulators are too slow for the rt-factor you chose, mosaik prints by default only a warning. In order to raise a RuntimeError, you can set rt_strict to True.

Before this method returns, it stops all simulators and closes mosaik’s server socket. So this method should only be called once.

shutdown()
Shut-down all simulators and close the server socket.

class mosaik.scenario.ModelFactory(world, sim)
This is a facade for a simulator sim that allows the user to create new model instances (entities) within that simulator.

For every model that a simulator publicly exposes, the ModelFactory provides a ModelMock attribute that actually creates the entities.

If you access an attribute that is not a model or if the model is not marked as public, an ScenarioError is raised.

class mosaik.scenario.ModelMock(world, name, sim)
Instances of this class are exposed as attributes of ModelFactory and allow the instantiation of simulator models.

You can call an instance of this class to create exactly one entity: sim.ModelName(x=23). Alternatively, you can use the create() method to create multiple entities with the same set of parameters at once: sim.ModelName.create(3, x=23).

create(num, **model_params)
Create num entities with the specified model_params and return a list with the entity dicts.

The returned list of entities is the same as returned by mosaik_api.Simulator.create(), but the simulator is prepended to every entity ID to make them globally unique.

class mosaik.scenario.Entity(sid, eid, sim_name, type, children, sim)
An entity represents an instance of a simulation model within mosaik.
sid
The ID of the simulator this entity belongs to.

eid
The entity's ID.

sim_name
The entity's simulator name.

type
The entity’s type (or class).

children
An entity set containing subordinate entities.

sim
The SimProxy containing the entity.

full_id
Full, globally unique entity id sid.eid.

12.4 mosaik.scheduler — Coordinate and execute simulators

This module is responsible for performing the simulation of a scenario.

mosaik.scheduler.run(world, until, rt_factor=None, rt_strict=False)
Run the simulation for a World until the simulation time until has been reached.

Return the final simulation time.

See mosaik.scenario.World.run() for a detailed description of the rt_factor and rt_strict arguments.

mosaik.scheduler.sim_process(world, sim, until, rt_factor, rt_strict)
SimPy simulation process for a certain simulator sim.

mosaik.scheduler.step_required(world, sim)
Return an Event that is triggered when sim needs to perform its next step.

The event will already be triggered if the simulator is a “sink” (no other simulator depends on its outputs) or if another simulator is already waiting for it.

world is a mosaik World.

mosaik.scheduler.wait_for_dependencies(world, sim)
Return an event (simpy.events.AllOf) that is triggered when all dependencies can provide input data for sim.

Also notify any simulator that is already waiting to perform its next step.

world is a mosaik World.

mosaik.scheduler.get_input_data(world, sim)
Return a dictionary with the input data for sim.

The dict will look like:

```python
{
    'eid': {
        'attrname': {'src_eid_0': val_0, ... 'src_eid_n': val_n},
        ...
    },
```
For every entity, there is an entry in the dict and each entry is itself a dict with attributes and a list of values. This is, because we may have inputs from multiple simulators (e.g., different consumers that provide loads for a node in a power grid) and cannot know how to aggregate that data (sum, max, ...?).

`world` is a mosaik `World`.

`mosaik.scheduler.step`(`world`, `sim`, `inputs`)  
 Advance (step) a simulator `sim` with the given `inputs`. Return an event that is triggered when the step was performed.

`inputs` is a dictionary, that maps entity IDs to data dictionaries which map attribute names to lists of values (see `get_input_data()`).

`mosaik.scheduler.get_outputs`(`world`, `sim`)  
 Get all required output data from a simulator `sim`, notify all simulators that are waiting for that data and prune the data flow cache. Return an event that is triggered when all output data is received.

`world` is a mosaik `World`.

`mosaik.scheduler.get_progress`(`sims`, `until`)  
 Return the current progress of the simulation in percent.

### 12.5 mosaik.simmanager — Management of external processes

The simulation manager is responsible for starting simulation processes and shutting them down. It also manages the communication between mosaik and the processes.

It is able to start pure Python simulators in-process (by importing and instantiating them), to start external simulation processes and to connect to already running simulators and manage access to them.

`mosaik.simmanager.start`(`world`, `sim_name`, `sim_id`, `sim_params`)  
 Start the simulator `sim_name` based on the configuration in `world.sim_config`, give it the ID `sim_id` and pass the parameters of the dict `sim_params` to it.

The sim config is a dictionary with one entry for every simulator. The entry itself tells mosaik how to start the simulator:

```python
{
    'ExampleSimA': {
        'python': 'example_sim.mosaik:ExampleSim',
    },
    'ExampleSimB': {
        'cmd': 'example_sim $(addr)s',
        'cwd': '.',
    },
    'ExampleSimC': {
        'connect': 'host:port',
    },
}
```

`ExampleSimA` is a pure Python simulator. Mosaik will import the module `example_sim.mosaik` and instantiate the class `ExampleSim` to start the simulator.

`ExampleSimB` would be started by executing the command `example_sim` and passing the network address of mosaik as command line argument. You can optionally specify a `current working directory`. It defaults to ..

`ExampleSimC` can not be started by mosaik, so mosaik tries to connect to it.

12.5. mosaik.simmanager — Management of external processes
The function returns a `mosaik_api.Simulator` instance.

It raises a `SimulationError` if the simulator could not be started.

Return a `SimProxy` instance.

`mosaik.simmanager.start_inproc` (world, sim_name, sim_config, sim_id, sim_params)

Import and instantiate the Python simulator `sim_name` based on its config entry `sim_config`.

Return a `LocalProcess` instance.

Raise a `ScenarioError` if the simulator cannot be instantiated.

`mosaik.simmanager.start_proc` (world, sim_name, sim_config, sim_id, sim_params)

Start a new process for simulator `sim_name` based on its config entry `sim_config`.

Return a `RemoteProcess` instance.

Raise a `ScenarioError` if the simulator cannot be instantiated.

`mosaik.simmanager.start_connect` (world, sim_name, sim_config, sim_id, sim_params)

Connect to the already running simulator `sim_name` based on its config entry `sim_config`.

Return a `RemoteProcess` instance.

Raise a `ScenarioError` if the simulator cannot be instantiated.

```python
class mosaik.simmanager.SimProxy (name, sid, meta, world)

Handler for an external simulator.

It stores its simulation state and own the proxy object to the external simulator.

stop ()

Stop the simulator behind the proxy.

The default implementation does nothing.

class mosaik.simmanager.LocalProcess (name, sid, meta, inst, world)

Proxy for internal simulators.

stop ()

Yield a triggered event but do nothing else.

class mosaik.simmanager.RemoteProcess (name, sid, meta, proc, rpc_con, world)

Proxy for external simulator processes.

stop ()

Send a stop message to the process represented by this proxy and wait for it to terminate.

class mosaik.simmanager.MosaikRemote (world, sim_id)

This class provides an RPC interface for remote processes to query mosaik and other processes (simulators) for data while they are executing a step() command.

get_progress ()

Return the current simulation progress from sim_progress.

get_related_entities (entities=None)

Return information about the related entities of entities.

If entities omitted (or `None`), return the complete entity graph, e.g.:

```json
{
  'nodes': {
    'sid_0.eid_0': {'type': 'A'},
    'sid_0.eid_1': {'type': 'B'},
    'sid_1.eid_0': {'type': 'C'},
  }
}```
If `entities` is a single string (e.g., `sid_1.eid_0`), return a dict containing all entities related to that entity:

```python
{
    'sid_0.eid_0': {'type': 'A'},
    'sid_0.eid_1': {'type': 'B'},
}
```

If `entities` is a list of entity IDs (e.g., `['sid_0.eid_0', 'sid_0.eid_1']`), return a dict mapping each entity to a dict of related entities:

```python
{
    'sid_0.eid_0': {
        'sid_1.eid_0': {'type': 'B'},
    },
    'sid_0.eid_1': {
        'sid_1.eid_1': {'type': 'B'},
    },
}
```

**get_data** *(attrs)*

Return the data for the requested attributes `attrs`.

`attrs` is a dict of (fully qualified) entity IDs mapping to lists of attribute names (`{'sid/eid': ['attr1', 'attr2']}`).

The return value is a dictionary, which maps the input entity IDs to data dictionaries, which in turn map attribute names to their respective values: (`{'sid/eid': {'attr1': val1, 'attr2': val2}}`).

**set_data** *(data)*

Set `data` as input data for all affected simulators.

`data` is a dictionary mapping source entity IDs to destination entity IDs with dictionaries of attributes and values (`{'src_full_id': {'dest_full_id': {'attr1': 'val1', 'attr2': 'val2'}}}`).

12.6 mosaik.util — Utility classes and functions
About mosaik

The latest version of mosaik is 2.5.1 and it is licensed under LGPL.

Contents:

13.1 Acknowledgments

A lot of people were involved in the creation of mosaik and mosaik wouldn’t be what it is today without any of them:

- Martin Tröschel and Astrid Nieße had the original idea for a tool that lets you integrate existing simulators to perform large-scale Smart Grid simulations. They also accompanied mosaik’s development many years as group and project leaders and provided the necessary time and resources for mosaik’s development.
- Steffen Schütte wrote his PhD around mosaik. He and Stefan Scherfke are the primary authors of mosaik 1.
- Ontje Lünsdorf not only contributed code to mosaik 1, but also a lot of ideas. He held countless discussions with Steffen and Stefan whose results often greatly improved mosaik.
- Stefan Scherfke is the primary author of mosaik 2.0 and 2.1.
- Sebastian Rohjans and Sebastian Lehnhoff accompanied mosaik’s development as group and scientific leaders. They also put lots of effort into making mosaik open-source software.
- Okko Nannen and Florian Schlögl joined the team in May / July 2014.

We’d also like to thank everyone who worked with mosaik and gave us feedback to make it better.

13.2 The history of mosaik

Our work on mosaik started on July 15th, 2010 – at least, the initial commit happened on that day. Since then, we’ve come a long way . . .

13.2.1 2.5.1 - 2018-11-29

- [NEW] When calling the world.start() command for a simulator, users can now set a predefined value for the posix flag (e.g. True) to prevent automatic detection of the operating system. This facilitates the creation of some co-simulation cases across OS (e.g. Windows and Linux).
13.2.2 2.5.0 - 2018-09-05

• [NEW] Connection option “time_shifted” added as alternative to async_requests. This will make creating cyclic
data dependencies between simulators more usable since usage of set_data with an API implementation will no
longer be needed.

13.2.3 2.4.0 - 2017-12-06

• [NEW] Compatible to the new versions of networkx, simpy and simpy.io
• [CHANGE] python 3.4, 3.5 and 3.6 are currently supported python 3.3 is no longer supported
• [FIX] Various bug fixes

13.2.4 2.3.0 - 2016-04-26

• [NEW] Allow passing environment vars to sup processes
• [FIX] Fixed a bug in the version validation which raised an error when using a floating point for the version

13.2.5 2.2.0 - 2016-02-15

• [NEW] API version 2.2: Added an optional “setup_done()” method.
• [CHANGE] API version validation: The API version is no longer an integer but a “major.minor” string. The
major part has to math with mosaiks major version. The minor part may be lower or equal to mosaik’s minor
version.
• [FIX] Various minor fixes and stability improvements.
• [FIX] Various documentation updates and fixes.

13.2.6 2.1 – 2014-10-24

• [NEW] Mosaik can now perform real-time simulations. Before, this functionality needed to be implemented
by simulators. Now it’s just World.run(until=x, rt_factor=y), where rt_factor defines the
simulation speed relative to the wall-clock time (issue #24).
• [NEW] Simulators can now expose extra methods via their API that can be called from a mosaik scenario.
This allows you to, e.g., store static data in a data base. These extra API methods need to be specified in the
simulator’s meta data (issue #26).
• [NEW] util.connect_many_to_one() helper function.
• [NEW] More and better documentation:
  – Tutorial for integrating simulators, control strategies and for creating scenarios.
  – Sim API description
  – Scenario API description
  – Sim Manager documentation
  – Scheduler documentation
  – Discussion of design decisions
• [NEW] Added `util.sync_call()` which eases calling proxied methods of a simulator synchronously.

• [CHANGE] The `rel` attribute in the entity description returned by `create()` is now optional.

• [CHANGE] Moved proxied methods from `SimProxy` to `SimProxy.proxy` in order to avoid potential name clashes with other attributes.

• [CHANGE] Check a simulator’s models and extra API methods for potential name clashes with the built-in API methods.

• [CHANGE] The argument `execution_graph` of `World` was renamed to `debug`. The execution graph now also stores the time after a simulation step (in addition to the time before the step).

• [FIX] issue #22: The asynchronous requests `get_data()` and `set_data()` now check if the `async_requests` flag was set in `World.connect()`.

• [FIX] issue #23: `finalize()` is now called for in-process Python simulators.

• [FIX] issue #27: Dramatically improved simulation performance (30 times as fast in some cases) if simulators use different step sizes (e.g. 1 minute and 1 hour) by improving some internal data structures.

---

### 13.2.7 2.0 – 2014-09-22

• [NEW] Updated documentation

• [CHANGE] Separated mosaik’s package and API version. The former stays a string with a semantic version number; the later is now a simple integer (issue #17).

• [CHANGE] Start/stop timeout for simulators was raised from 2 to 10 seconds.

• [CHANGE] Updated the mosaik logo. It now uses the flat colors and has some improved icon graphics.

• [CHANGE] Renamed `mosaik.simulator` to `mosaik.scheduler`.

• [CHANGE] Entity and the World’s entity graph now store their simulator name.

• [FIX] issue #16: Mosaik now always prints the name of the simulator if it closes its socket.

---

### 13.2.8 2.0a4 – 2014-07-31

• [NEW] The model meta data may now contain the `any_inputs` which, if set to `True`, allows any attribute to be connected to that model (useful for databases and alike).

• [CHANGE] The dictionary of input values in the API’s `step()` call now also contains the source of a particular value. This is also useful for databases. This may break existing simulators.

• [CHANGE] “.” is now used as separator in full entity IDs instead of “/” (issue #19).

---

### 13.2.9 2.0a3 – 2014-06-26

• [NEW] Hierarchical entities: Entities can now have a list of child entities (issue #14).

• [NEW] The `World` class now has a `get_data()` method that allows you to get data from entities while creating a scenario.

• [NEW] `World.connect(a, b, ('X', 'X'))` can now be simplified to `World.connect(a, b, 'X')`.

• [NEW] Attribute `Entity.full_id` which uniquely identifies an entity: `<sid>/<eid>`
• [NEW] Attribute `ModelFactory.meta` which is the meta data dictionary of a simulator.

• [NEW] `World()` now accepts a configuration dictionary which can, e.g., specify the network address for mosaik.

• [NEW] Overview section for the docs

• [NEW] Description of the mosaik API in the docs

• [CHANGE] When you create entities, mosaik checks if the model parameters actually exists and raises an error if not (issue #9).

• [CHANGE] The mosaik API’s `init()` function now receives the simulator ID as first argument (issue #15).

• [CHANGE] The behavior of the `get_related_entities()` RPC that simulators can perform has been changed.

• [CHANGE] Various internal improvements

• [FIX] issue #18. Improved the error message if a Python simulator could not be imported.

• [REMOVED] Attribute `Entity.rel`.

13.2.10 2.0a2 – 2014-05-05

• [NEW] Preliminary documentation and installation instructions (https://mosaik.readthedocs.org)

• [NEW] Simulators can now set data to other simulators using the asynchronous request `set_data` (issue #1).

• [NEW] There is now a start timeout for external processes (issue #11).

• [CHANGE] Mosaik now raises an error if a simulator uses the wrong API version (issue #4).

• [CHANGE] Mosaik prints everything to `stdout` instead of using the Python logging module (issue #7).

• [FIX] issue #3. Local (in-process) Simulators can now also perform async. requests to mosaik (`get_progress`, `get_related_entities`, `get_data`, `set_data`).

• [FIX] issue #8. Cleaned up the code a bit.

13.2.11 2.0a1 – 2014-03-26

• Mosaik 2 is a complete rewrite of mosaik 1 in order to improve its maintainability and flexibility. It is still an early alpha version and neither feature complete nor bug free.

• Removed features:
  – The `mosl` DSL (including Eclipse xtext and Java) are now gone. Mosaik now only uses Python.
  – Mosaik now longer has executables but is now used as a library.
  – The platform manager is gone.
  – Mosaik no longer includes a database.
  – Mosaik no longer includes a web UI.

• Mosaik now consists of four core components with the following feature sets:
  – mosaik API
• The API has been cleaned up and simplified.
• Simulators and control strategies share the same API.
• There are only four calls from mosaik to a simulator: init, create, step and get_data.
• Simulators / processes can make asynchronous requests to mosaik during a step: get_progress, get_related_entities, get_data.
• ZeroMQ with JSON is replaced by plain network sockets with JSON.

- Scenarios:
  • Pure Python is now used to describe scenarios. This offers you more flexibility to create complex scenarios.
  • Scenario creation simplified: Start a simulator to get a model factory. Use the factory to create model instances (entities). Connect entities. Run simulation.
  • Connection rules are based on a primitive connect function that only connects two entities with each other. On top of that, any connection strategy can be implemented.

- Simulation Manager:
  • Simulators written in Python 3 can be executed in process.
  • Simulators can be started as external processes.
  • Mosaik can connect to an already running instance of a simulator. This can be used as a replacement for the now gone platform manager.

- Simulation execution:
  • The simulation is now event-based. No schedule and no synchronization points need to be computed.
  • Simulators can have different and varying step sizes.

• Mosaik ecosystem:
  - A high-level implementation of the mosaik 2 API currently only exists for Python. See https://bitbucket.org/mosaik/mosaik-api-python.
  - mosaik-web is a simple visualization for mosaik simulations. See https://bitbucket.org/mosaik/mosaik-web.
  - mosaik-pypower is an adapter for the PYPOWER load flow analysis library. See https://bitbucket.org/mosaik/mosaik-pypower and https://github.com/rwl/PYPOWER.
  - mosaik-csv and mosaik-householdsim are simple demo simulators that you can use to “simulate” CSV data sets and load-profile based households. See https://bitbucket.org/mosaik/mosaik-csv and https://bitbucket.org/mosaik/mosaik-householdsim.
  - There is a repository containing a simple demo scenario for mosaik. See https://bitbucket.org/mosaik/mosaik-demo.

13.2.12 1.1 – 2013-10-25

• [NEW] New API for control strategies.
• [NEW] Mosaik can be configured via environment variables.
• [NEW] Various changes and improvements implemented during Steffen’s dissertation.
Mosaik 1 was nearly a complete rewrite of the previous version and already incorporated many of the concepts and features described in Steffen Schütte's Phd thesis.

It used mosl, a DSL implemented with Eclipse and xtext, to describe simulators and scenarios. Interprocess communication was done with ZeroMQ and JSON encoded messages.

This was the first actual version of mosaiq that actually worked. However, the simulators we were using at that time were hard coded into the simulation loop and we used XML-RPC to communicate with the simulators.
Privacy Policies

We welcome you to our website. We would like to inform you about the management of your personal data in accordance with Art. 13 General Data Protection Regulation (GDPR).

Controller
The controller responsible for the described data collection and processing is OFFIS e.V., Escherweg 2, 26121 Oldenburg/Germany.

Usage Data
When you visit our website, the data collected from the use of the website is temporarily stored on our web server for statistical purposes in order to improve the quality of our website. This data set contains:

- the page, from which the data is requested
- the name of the data file,
- the date and time of the query,
- the amount of data transferred,
- the access status (file transmitted, file not found),
- a description of the type of browser used,
- the IP address of the requesting computer shortened to such an extent that no reidentification of any persona data is possible.

The listed usage data is stored anonymously. The legal basis for the processing of this personal data is provided for in Art. 6 para. 1 lit. f GDPR.

Data Transfer to Third Parties
We do not transfer your personal data to third parties.

Cookies
We use cookies on our website. Cookies are small pieces of data that are stored and read in your end-device. A distinction is made between session cookies, which are deleted when you close your browser, and permanent cookies, which are stored even after your visit has expired. Cookies may contain data that enables the recognition of the device being used. However, in some cases cookies only contain information on certain settings which are not personal data.

We use session cookies and permanent cookies on our website. The data is processed in accordance to Art. 6 para. 1 lit. f GDPR and in the interest of optimizing or enabling user guidance and improving our website presence.

Please be aware that you can set your browser to inform you when cookies are being stored or used on the website you are visiting. Thus, any use of cookies is transparent to you. You have the possibility to delete your browser
configuration at any time and prevent any use of new cookies. In the event you refuse the use of cookies, please note that our websites may not be displayed optimally and some functions are then no longer technically available.

**Data Security**

To avoid unauthorized access to your data, we have implemented technical and organizational measures. We use encryption technologies on our website. Your data will be transferred to our servers and back again via a connection that is protected by a TLS encryption technology. You can recognize that you are browsing on an encryption secured website by the lock-symbol shown in the address bar of your browser and by the address bar starting with https://.

**Your Rights as a User**

As a website user, the GDPR grants you certain rights when processing your personal data.

1. **Right of access (Art. 15 GDPR):** You have the right to obtain confirmation as to whether or not personal data concerning you is being processed, and, where that is the case access to the personal data and the information specified in Art. 15 GDPR.

2. **Right to rectification and erasure (Art. 16 and 17 GDPR):** You have the right to obtain without undue delay the rectification of inaccurate personal data concerning you and, if necessary, the right to have incomplete personal data completed. You also have the right to obtain an erasure of the personal data concerning you without undue delay, if one of the reasons listed in Art. 17 GDPR applies, e.g. if the data is no longer necessary for the intended purpose.

3. **Right to restriction of processing (Art. 18 GDPR):** If one of the conditions set forth in Art. 18 GDPR applies, you shall have the right to restrict the processing of your data to mere storage, e.g. if you revoke consent, to the processing, for the duration of a possible examination.

4. **Right to data portability (Art. 20 GDPR):** In certain situations, listed in Art. 20 GDPR, you have the right to receive the personal data concerning you in a structured, common and machine-readable format or demand a transmission of the data to another third party.

5. **Right to object (Art. 21 GDPR):** If the data is processed pursuant to Art. 6 para. 1 lit. f GDPR (data processing for the purposes of the legitimate interests), you have the right to object to the processing at any time for reasons arising out of your particular situation. We will then no longer process personal data, unless there are demonstrably compelling legitimate grounds for processing, which override the interests, rights and freedoms of the person concerned, or the processing serves the purpose of asserting, exercising or defending legal claims.

6. **Right to lodge a complaint with a supervisory authority:** Pursuant to Art. 77 GDPR, you have the right to lodge a complaint with a supervisory authority if you consider the processing of the data concerning you infringing data protection regulations. The right to lodge a complaint may be invoked in particular in the Member State of your habitual residence, place of work or the place of the alleged infringement.

**Contact Details of the Data Protection Officer**

Please contact our data protection officer if you have any further questions, suggestions or wishes regarding data protection:

Datenschutzerklärung

Wir nehmen den Schutz Ihrer persönlichen Daten sehr ernst. Ihre Daten werden im Rahmen der gesetzlichen Vorschriften geschützt. Personenbezogene Daten werden auf unseren Internetseiten nur im notwendigen Umfang erhoben. In keinem Fall werden die erhobenen Daten verkauft oder aus anderen Gründen an Dritte weitergegeben.

Verantwortlicher

Verantwortlich für die hier erläuterte Datenverarbeitung ist der OFFIS e.V., Escherweg 2, 26121 Oldenburg.

Erhebung und Verarbeitung von Daten

- welche Datei angefordert wurde,
- der Name der Datei,
- das Datum und die Uhrzeit der Anforderung,
- die übertragene Datenmenge,
- der Zugriffsstatus (Datei nicht gefunden, Datei übertragen etc.),
- der Typ des verwendeten Webbrowsers und
- die IP-Adresse des Internetseitenbesuchers

Sämtliche dieser Daten werden ausschließlich anonymisiert gespeichert und ausgewertet. Zu diesem Zweck wird die IP-Adresse des Systems, von dem aus die Internetseite oder Datei angefordert wurde, geeignet anonymisiert. Rechtsgrundlage ist Art. 6 Abs. 1 lit. f DSGVO (Datenschutz-Grundverordnung). Es ist somit weder ein Rückschluss auf eine bestimmte Person möglich, noch erfolgt eine Zusammenführung mit anderen Daten.

Cookies

Darüber hinaus verwenden wir weitere Cookies, um unsere Internetseiten besser auf Ihre Wünsche ausrichten und um statistische Daten über die Nutzung unserer Internetseiten erheben zu können. Durch diese Cookies werden keine Daten erhoben, die einen Rückschluss auf eine bestimmte Person ermöglichen. Auch die Installation dieser Cookies wird durch eine entsprechende Browser-Einstellung verhindert. Einmal gesetzte Cookies können Sie jederzeit selbst löschen, indem Sie den entsprechenden Menüpunkt in Ihrem Internet-Browser aufrufen oder die Cookies auf Ihrer Festplatte löschen. Einzelheiten hierzu finden Sie im Hilfemenü Ihres Internet-Browsers. Weitergehende personenbezogene Daten werden nur erfasst, wenn Sie diese Angaben freiwillig, z.B. im Rahmen einer Anfrage oder Registrierung, machen.

Datensicherheit

Verwendung der Daten
Wir beachten den Grundsatz der zweckgebundenen Datenverwendung und erheben, verarbeiten und speichern Ihre personenbezogenen Daten nur für die Zwecke, für welche Sie uns diese mitgeteilt haben und für die technische Administration. Eine Weitergabe Ihrer persönlichen Daten an Dritte erfolgt ohne Ihre ausdrückliche Einwilligung nicht, sofern dies nicht zur Erbringung der Dienstleistung oder zur Vertragsdurchführung notwendig ist. Auch die Übermittlung an auskunftsberechtigte staatliche Institution und Behörden erfolgt nur im Rahmen der gesetzlichen Auskunftspflichten oder wenn wir durch eine gerichtliche Entscheidung zur Auskunft verpflichtet werden.

Lösung der Daten
Eine Lösung der gespeicherten personenbezogenen Daten erfolgt, wenn Sie Ihre Einwilligung zur Speicherung widerrufen, wenn deren Kenntnis zur Erfüllung des mit der Speicherung verfolgten Zwecks nicht mehr erforderlich ist oder wenn deren Speicherung aus sonstigen gesetzlichen Gründen unzulässig ist.

Ihre Rechte als Nutzer
Bei Verarbeitung Ihrer personenbezogenen Daten gewährt die DSGVO Ihnen als Webseitennutzer bestimmte Rechte:

1. Auskunftsrecht (Art. 15 DSGVO): Sie haben das Recht eine Bestätigung darüber zu verlangen, ob sie betreffende personenbezogene Daten verarbeitet werden; ist dies der Fall, so haben Sie ein Recht auf Auskunft über diese personenbezogenen Daten und auf die in Art. 15 DSGVO im einzelnen aufgeführten Informationen.

2. Recht auf Berichtigung und Löschung (Art. 16 und 17 DSGVO): Sie haben das Recht, unverzüglich die Berichtigung sie betreffender unrichtiger personenbezogener Daten und ggf. die Vervollständigung unvollständiger personenbezogener Daten zu verlangen. Sie haben zudem das Recht, zu verlangen, dass sie betreffende personenbezogene Daten unverzüglich gelöscht werden, sofern einer der in Art. 17 DSGVO im einzelnen aufgeführten Gründe zutrifft, z. B. wenn die Daten für die verfolgten Zwecke nicht mehr benötigt werden.

3. Recht auf Einschränkung der Verarbeitung (Art. 18 DSGVO): Sie haben das Recht, die Einschränkung der Verarbeitung zu verlangen, wenn eine der in Art. 18 DSGVO aufgeführten Voraussetzungen gegeben ist, z. B. wenn Sie Widerspruch gegen die Verarbeitung eingelegt haben, für die Dauer einer etwaigen Prüfung.

4. Recht auf Datenübertragbarkeit (Art. 20 DSGVO): In bestimmten Fällen, die in Art. 20 DSGVO im Einzelnen aufgeführt werden, haben Sie das Recht, die sie betreffenden personenbezogenen Daten in einem strukturierten, gängigen und maschinenlesbaren Format zu erhalten bzw. die Übermittlung dieser Daten an einen Dritten zu verlangen.

5. Widerspruchsrecht (Art. 21 DSGVO): Werden Daten auf Grundlage von Art. 6 Abs. 1 lit. f erhoben (Datenverarbeitung zur Wahrung berechtigter Interessen), steht Ihnen das Recht zu, aus Gründen, die sich aus Ihrer besonderen Situation ergeben, jederzeit gegen die Verarbeitung Widerspruch einzulegen. Wir verarbeiten die personenbezogenen Daten dann nicht mehr, es sei denn, es liegen nachweisbar zwingende schutzwürdige Gründe für die Verarbeitung vor, die die Interessen, Rechte und Freiheiten der betroffenen Person überwiegen, oder die Verarbeitung dient der Geltendmachung, Ausübung oder Verteidigung von Rechtsansprüchen.

Mehr zum Thema Datenschutz finden Sie *hier*.
Control strategy  A program that is intended to observe and manipulate the state of objects (simulated or real) of a power system or those that are somehow connected to the power system; for example a multi-agent system that controls the feed-in of decentralized producers.

Co-simulation  In co-simulation the different subsystems which form a coupled problem are modeled and simulated in a distributed manner. The modeling is done on the subsystem level without having the coupled problem in mind. The coupled simulation is carried out by running the subsystems in a black-box manner. During the simulation the subsystems will exchange data. (source: Wikipedia)

Data-flow  The exchange of data between two simulators or between the entities of two simulators.

Example: the (re)active power feed-in of a PV model that is sent to a node of a power system simulator.

Entity  Represents an instance of a Model within a mosaik simulation. Entities can be connected to establish a data-flow between them. Examples are the nodes and lines of a power grid or single electric vehicles.

Entity Set  A set or list of entities.

Framework  A software framework provides generic functionality that can be selectively changed and expanded by additional user-written code.

Model  A Model is a simplified representation of a real world object or system. It reproduces the relevant aspects of that object or system for its systematic analysis.

Scenario  Description of the system to be simulated. It includes the used models and their relations. It includes the state of the models and their data base. In the mosaik-context it includes also the simulators.

Simulation  The process of executing a scenario (and the simulation models).

Simulation Model  The representation of a model in programming code.

Simulator  A program that contains the implementation of one or more simulation models and is able to execute these models (that is, to perform a simulation).

Sometimes, the term simulator also refers all kinds of processes that can talk to mosaik, including actual simulators, control strategies, visualization servers, database adapters and so on.

Smart Grid  An electric power system that utilizes information exchange and control technologies, distributed computing and associated sensors and actuators, for purposes such as:

• to integrate the behaviour and actions of the network users and other stakeholders,

• to efficiently deliver sustainable, economic and secure electricity supplies.

(source: IEC)

Step  Mosaik executes simulators in discrete time steps. The step size of a simulator can be an arbitrary integer. It can also vary during the simulation.
Mosaik does not dictate a unit for the simulation time and step size. The convention is to use seconds, but it is no problems if all simulators used minutes or milli seconds – as long as all of them assume the same unit.
