CHAPTER 1

Version History

Date	Maintainer	Version
1 November 2018	Bruce Bullis	Version 13.0
16 July 2018	Zac Lam	Version 13.0 pre-release
13 November 2017	Zac Lam	Version 12.0
6 April 2017	Zac Lam	Version CC 2017.1
4 November 2016	Zac Lam	Version CC 2017
4 August 2015	Zac Lam	Version CC 2015
16 June 2014	Zac Lam	Version CC 2014
21 October 2013	Zac Lam	Version CC October release
16 July 2013	Zac Lam	Version CC
19 June 2012	Zac Lam	Version CS6 release 2
30 April 2012	Zac Lam	Version CS6 release 1
2 May 2011	Zac Lam	Version CS5.5
28 April 2010	Zac Lam	Version CS5
21 September 2009	Zac Lam	Version CS4
5 October 2007	Zac Lam	Version CS3
13 July 2006	Zac Lam	Version 2.0 release 2
17 January 2006	Zac Lam	Version 2.0 release 1
25 May 2004	Zac Lam	Version 1.5
21 August 2003	Zac Lam	Version 1.0 (Premiere Pro)
9 February 1996	Brian Andrews	Version 4.2
13 February 1995	Matt Foster, Nick Schlott	Version 4.0 - first Windows release
19 July 2002	Zac Lam & Bruce Bullis	Version 6.5
10 May 2001	Bruce Bullis	Version 6 release 2
10 December 2000	Bruce Bullis & Eric Sanders	Version 6 release 1
20 April 1998	Brian Andrews	Version 5

CHAPTER 2

Introduction

Welcome to the Adobe® Premiere® Pro CC Software Development Kit!

This is a living document, and is constantly being updated and edited. The latest release of the SDK is available at: <https://www.adobe.io/apis/creativecloud/premierepro.html>.

If you have questions about the APIs described in this document, or about integration with Premiere Pro, your question may already be answered on the Premiere Pro SDK forum at: <https://forums.adobe.com/community/premiere/sdk>.

CHAPTER 3

What Premiere Plug-Ins Do

Premiere APIs provide access to many points of the video editing pipeline.

Recording from an external device, device control, media import and export, video effects and transitions, playback to external hardware, and integration with control surfaces can all be performed by plug-ins.

The Premiere Pro Software Development Kit enables developers to create plug-ins for Premiere Pro, After Effects, Audition, Media Encoder, Character Animator, and Premiere Elements.

The required development environment for the Premiere Pro SDK for Windows is Microsoft Visual Studio 2015 Update 3 on Windows 7 or Windows 10 64-bit. When setting up Visual Studio you may need to adjust some installation settings to install the components for compiling 64-bit plug-ins. On macOS, the minimum environment is Xcode 7.3 on macOS 10.12 or later.

The SDK includes sample projects for these development environments. On Windows, projects can often be updated to more current versions of Microsoft Visual Studio by simply opening the project and approving the automatic conversion. The sample code is written in C++. Other compilers and programming languages are not supported. We cannot assist with platform API programming issues not central to Premiere Pro plug-in programming.

If this is your first time developing a Premiere plug-in, you can skip *Whats New*.

If you are developing on macOS, see a quickstart video on building a plug-in using a similar SDK (on macOS): adobe.ly/2sjMDwM and then go directly to *Where Do I Start*.

5.1 What's New in 13.0

The only significant change to Premiere Pro's C++ APIs for 13.0 is the addition of color-space specifiers to the Importer API. The `ColorProfileRec` structure is deprecated; instead, Importers will describe supported colorspace (in response to `imGetIndColorSpace`) using a `ColorSpaceRec`.

5.2 What's New in 12.0

5.2.1 Effects and Transitions

GPU Effects & Transitions built using this SDK are now compatible with After Effects 15.0 and later. The sample GPU effect projects have been updated so that they load in both Premiere Pro and After Effects.

The newly provided *PrGPU SDK Macros* and device functions allow you to write kernels that will compile on multiple GPU compute languages - OpenCL, CUDA, and Metal.

Multiple effects and transitions can now be implemented in a single plug-in binary, by defining multiple entry points in software at runtime. The new method for registering entry points will be a replacement for the PiPL resource, and is currently only supported in Premiere Pro. The sample effects and transitions demonstrate this new method, while *Plug-In Property Lists (PiPL) Resource* remains, for backwards-compatibility in PPro, and compatibility with AE.

Sequence Info Suite is now at version 5, adding the new call `GetImmersiveVideoVRConfiguration()`, which returns the VR video settings of the specified sequence.

New selector available for *Export Info Suite*: `kExportInfo_SourceBitrate`. This returns the source's bitrate in kbps, and is not available for all source types. `exParamType` can now be of type `exParamType_thumbnail`. A new flag `exParamFlag_verticalAlignment` can now be set so that property name and value controls are displayed vertically rather than side-by-side.

5.3 What's New in CC 2017.1

5.3.1 Importers

Importers that support captions can make use of the `mayHaveCaptions` flag in `imFileInfoRec8`, for better performance. Also, a `imImageInfoRec` is now added to `imInitiateAsyncClosedCaptionScanRec`, just for the width and height parameters.

5.3.2 Exporters

Exporters can advertise whether they support color profile embedding. There are also APIs to set color profile in the exporter, and a flag that controls whether profile is to be embedded. The color profile is passed to an exporter via `exDoExportRec`, for it to embed in the output media according to format standards. This is currently used for exports from After Effects through Media Encoder.

5.3.3 Transmit

New 10-bit and 12-bit RGB HLG formats have been added for expanded HDR support.

In *App Info Suite*, a new identifier has been added for Character Animator, which now supports transmit plug-ins.

5.3.4 VR Video Support

The Playmod Immersive Video Suite can be used to query whether or not ambisonics monitoring is on or not, in the VR Video Settings.

5.4 What's New in CC 2017

5.4.1 VR Video Support

Transmit plug-ins can have the VR perspective in the desktop Monitor driven by the Head-Mounted Display, so when the person with the Head-Mounted Display looks in a different direction, the desktop Monitor shows that same perspective. To do this, the transmit plug-in can use the new Playmod Immersive Video Suite to indicate that it supports tracking.

Once Premiere sees the transmitter supports tracking, when the user activates the VR viewer, the new menu item, “Track Head-Mounted Display” will become active, and can be toggled to begin tracking. The transmitter should call `NotifyDirection()` as frequently it wants with updated info. Premiere will pick up the new position on the next frame draw.

For importers, `imFileInfoRec8` has now been expanded so that if an importer detects that a clip contains VR video, it can inform Premiere.

5.4.2 New Sample Projects

This SDK includes a new render path for the ProcAmp sample for Metal. This sample requires macOS 10.11.4 and later.

We've also added a sample GPU effect called Vignette, donated by Bart Walczak. This effect has OpenCL, CUDA, and software render paths. Software rendering in Premiere Pro includes

8-bit/32-bit RGB/YUV software render paths. Software rendering in After Effects includes 8-bit and 32-bit smart rendering.

And lastly, the Control Surface sample is now cross-platform.

5.4.3 New Panel/Scripting Capabilities

Scripting, the processing underlying HTML5 panels, is consistently being improved upon. In this release, we've added scripting functions to add/modify effect keyframes. See the sample panel code on GitHub:

<https://github.com/Adobe-CEP/Samples/tree/master/PProPanel>

In particular, see the function `onPlayWithKeyframes()` in `jsx/Premiere.jsx`

5.4.4 Miscellaneous

In *Video Segment Render Suite*, new versions of various calls have been added with an additional boolean value that allows renders to skip rendering of non-intrinsic effects.

5.5 What's New in CC 2015.4

5.5.1 Effects and Transitions

GPU-accelerated rendering using Metal is now supported for third-party effects and transitions. `PrGPUDeviceFramework_Metal` has been added as one of the enum values in `PrGPUDeviceFramework`.

5.6 What's New in CC 2015.3?

5.6.1 Control Surfaces

New suites have been added for Control Surfaces to support the Lumetri Color panel. Most controls are supported, including the color wheels, but not including the Curves controls.

There is now a shared location for Control Surface plug-ins. On Mac:

`/Library/Application Support/Adobe/Common/Plug-ins/ControlSurface`, and

`~/Library/Application Support/Adobe/Common/Plug-ins/ControlSurface`

On Win:

`C:\Program Files\Adobe\Common\Plug-ins\ControlSurface`

5.6.2 Importers

Video duration can now be reported as a 64-bit integer, using the new `imFileInfoRec8.vidDurationInFrames`, to support longer file lengths. There is also a new suite function, `SetImporterInstanceStreamFileCount()`, for importers to specify how many files they open.

5.6.3 Exporters

New flags can be set in `exExporterInfoRec.flags`, to restrict an exporter from being used in a way that doesn't make sense. Now, an exporter can specify that video-only export is not supported. Also, an exporter can turn off the Publish tab if it chooses to.

5.6.4 Effects

Source settings effects should use the updated Source Settings suite with new

`SetIsSourceSettingsEffect()` function. They should make this call during *PF_Cmd*

GLOBAL_SETUP. This function was added to handle the case when the effect is applied to proxy video.

5.6.5 Misc

Using the *Sequence Info Suite*, a new call has been added, `GetProxyFlag()`, for a plug-in to know whether the proxy mode is on or off.

5.7 What's New in CC 2015.1?

5.7.1 Transmit

Native support for 12-bit Dolby PQ pixel formats, with Rec. 709, P3, and Rec. 2020 primaries, have been added.

5.8 What's New in CC 2015?

5.8.1 After Effects-Style Transitions

AE-style Transitions can now get and set transition start and end percentages. The user can change the start and end parameters in the Effect Controls panel. To allow a plugin to be informed of changes to these values, there are two new functions in the PF TransitionSuite: `RegisterTransitionStartParam()` and `RegisterTransitionEndParam()`, which register these parameters with the plug-in as float parameters. Once registered, the plug-in will receive *PF_Cmd_USER_CHANGED_PARAM* when these params change, as well as when the transition is first applied, so the plug-in can initialize them to the desired value.

AE-style Transitions can now retrieve GPU frames from arbitrary locations in the underlying clips. There is a new `PrGPUDependency_TransitionInputFrame`, and `PrGPUFilterFrameDependency` has a new member to specify whether frames from the incoming or outgoing clips are needed.

5.8.2 Source Settings = Effect + Importer

Source Settings for clips can now be implemented using effects that are tied to importers. This has the advantage of providing settings in the Effect Controls panel, rather than in a modal dialog. Editors can adjust Source Settings for multiple clips this way. These effects are used for the DPX source settings, CinemaDNG, etc.

To implement this, an importer should set `imImportInfoRec.hasSourceSettingsEffect` to true. Then in `imFileInfoRec8`, it should set `sourceSettingsMatchName` to the match name of the effect to be used for the Source Settings.

On the effects side, a new PF Source Settings Suite has been added to `PrSDKAESupport.h`, for effects using the After Effects API. This is how an effect registers a function to handle the Source Settings command.

A source settings effect is used primarily for the parameter UI and management. A source settings effect doesn't provide the actual frames. In fact, the effect isn't even called with `PF_Cmd_RENDER`. The frames come directly from the importer, which provides frames based on the settings as passed to the importer via prefs data.

When a clip is first imported, the effect is called with `PF_Cmd_SEQUENCE_SETUP`. It should call `PerformSourceSettingsCommand()` in the Source Settings Suite, to initialize the prefs. This causes the importer to get called with `imPerformSourceSettingsCommand`, where it can read the file and set the default prefs. `param1` of that function is `imFileAccessRec8*`, and `param2` is `imSourceSettingsCommandRec*`.

When the source settings effect parameters are changed, the effect gets called with `PF_Cmd_TRANSLATE_PARAMS_TO_PREFS`. The function signature is:

```
PF_Err TranslateParamsToPrefs(
    PF_InData*           in_data,
    PF_OutData*         out_data,
    PF_ParamDef*        params[],
    PF_TranslateParamsToPrefsExtra *extra)
```

With the new prefs, the importer will be sent `imOpenFile8`, `imGetInfo8`, `imGetIndPixelFormat`, `imGetPreferredFrameSize`, `imGetSourceVideo`, etc.

`imSourceSettingsCommandRec` and PF Source Settings Suite allow the effect to communicate directly with the importer, so that it can initialize its parameters properly, based on the source media. In the DPX source settings effect, for example, in `PF_Cmd_SEQUENCE_SETUP`, it calls `PF_SourceSettingsSuite->PerformSourceSettingsCommand()`, which calls through to the importer with the selector `imPerformSourceSettingsCommand`. Here, the importer opens the media, looks at the header and initializes the prefs based on the media. For

DPX, the initial parameters and default prefs are based on the bit depth of the video. These default prefs are passed back to the effect, which sets the initial param values and stashes a copy of them in `sequence_data` to use again for future calls to `PF_Cmd_SEQUENCE_RESETUP`.

5.8.3 Importers

For any importers that are using `imClipFrameDescriptorRec`, note that the structure definition has changed. Any importers that use this in both CC 2014 and CC 2015 or later will need to do a runtime check before accessing the members of this structure.

5.8.4 Exporters

Exporters can now use standard parameters for audio channel configuration, as used with the built-in QuickTime exporter. The new exporter parameters `ADBEAudioChannelConfigurationGroup` and `ADBEAudioChannelConfiguration` supercede `ADBEAudioNumChannels`. The new Export Audio Param Suite can be used to query/change the audio channel configuration.

The *Sequence Audio Suite* is now at version 2, revising `MakeAudioRenderer()` to take `PrAudioChannelLabel*` as a parameter.

5.8.5 Transmitters

Transmitters can get a few new bits of information to aid with A/V sync. In the *Playmod Audio Suite*, the new function `GetNextAudioBuffer2()` returns the actual time the rendered buffer is from.

Also, in `tmPlaybackClock`, the new members `inAudioOffset` and `inVideoOffset` have been added to specify the offset chosen by the user in the preferences.

The host accounts for these offsets automatically by sending frames early, but if a transmitter is manually trying to line up audio and video times, it can use this to know how far apart from each other they are supposed to be.

5.8.6 Miscellaneous

Legacy callbacks `bottlenecks->ConvolvePtr()` and `IndexMapPtr()` have had their parameter types updated to fix a bug. Any plug-ins that use these in both previous versions and CC 2015 will need to do a runtime check before calling this function.

Starting in CC 2015, we now provide installer hints for Mac. You'll find a new plist file "com. Adobe.Premiere Pro.paths.plist" at "/Library/Preferences". This contains hints for your Mac installer to know where to install plug-ins, and is similar to the registry entries we have been providing on Win.

5.8.7 New Sample Projects

This SDK includes updated GPU effect and transition samples that demonstrate GPU rendering. Thanks to Rama Hoetzlein from nVidia for the CUDA render path provided for the `SDK_CrossDissolve` sample!

A barebones Control Surface sample is now provided, too.

5.9 What's New in CC 2014 (8.2)?

Importers now have more visibility into the player's intent on a given async request, since the render context info is now passed in `imSourceVideoRec.inRenderContext`. Async importers can implement *aiSelectEfficientRenderTime* to specify if a frame request would be more efficient at another frame time, for example at I-frame boundaries. The *Video Segment Render Suite* has been updated to version 4, adding new calls that include `imRenderContext` as a parameter.

5.10 What's New in CC 2014 (8.1)?

Importers that support growing files now get a hint if the host knows the file has stopped growing:

```
imFileInfoRec8.ignoreGrowing.
```

Exporters can now get the list of source pixel formats used by the clips in a sequence that is being smart rendered. `GetExportSourceInfo(..., kExportInfo_SourcePixelFormat, ...)` provides this information.

5.11 What's New in CC 2014 (8.0.1)?

Importers can fill in `imImageInfoRec.codecDescription` to provide a string that will be displayed for clips in the Video Codec column of the Project panel.

5.12 What's New in CC 2014?

Importers can now choose the format they are rendering in, which allows importers to change pixel formats and quality based on criteria like enabled hardware and other source settings, such as HDR. To handle the negotiation, implement *imSelectClipFrameDescriptor*.

`imSourceVideoRec` now includes a quality attribute. *PPix Cache Suite* is now at version 6, adding `AddFrameToCache-WithColorProfile2()` and

`GetFrameFromCacheWithColorProfile2()`, which are the same as the ones added in version 5 with the addition of a `PrRenderQuality` parameter.

`imFileInfoRec8.highMemUsage` is no longer supported.

A new recorder return code was added, `rmRequiresRoyaltyContent`. Return this from `recmod_Startup8` or `recmod_StartRecord`, if the codec used is unlicensed.

OpenCL rendering now also uses the half-precision 16-bit floating point pixel format for rendering. GPU effects and transitions that support OpenCL should implement both 16f and 32f rendering.

A new plug-in API has been introduced for hardware Control Surfaces. This is the API that allows support for EUCON and Mackie devices to control audio mixing and basic transport controls. The API supports two-way communication with Premiere Pro, so that hardware faders, VU meters, etc are in sync with the application.

Premiere Pro is now localized in Russian and Brazilian Portuguese.

5.13 What's New in CC October 2013?

We've extended the After Effects API to support native transitions in Premiere Pro.

For device controllers, the new command *cmdSetDeviceHandler* was added. This command tells the device controller which panel is using the device controller – either the Capture panel, or Export to Tape panel.

For importers, `imInitiateAsyncClosedCaptionScanRec` now provides extra fields for the importer to fill in the estimated duration of all the captions. This is useful for certain cases where the embedded captions contain many frames of empty data.

We added version 2 of the *Export File Suite* to resolve a mismatch in seek modes.

5.14 What's New in CC July 2013?

The only significant additions made in the July 2013 update to version CC are in the device controller API.

5.15 What's New in CC?

5.15.1 New Edit to Tape Panel

You can think of this as the Export to Tape equivalent of the Capture panel for capturing, which provides a video preview and various settings in the PPro UI. Among the benefits are more seamless integration, a more familiar UI for users, integrated device presets, and some new capabilities like adding Bars and Tone / Black Video / Universal Counting Leader to the start of your layoff to tape. To use this new feature, read more about what's new in the device controller API.

5.15.2 New GPU Extensions for Effects and Transitions

New GPU Extensions to existing APIs allow effects and transitions to access video frames in GPU memory, when using the Mercury Playback Engine in a GPU-accelerated mode. See *GPU Effects & Transitions* for more information.

5.15.3 Closed Captioning Support in Importer and Exporter APIs

The importer and exporter APIs have been extended to support closed captioning embedded in media. Note that Premiere Pro can also import and export captions in a sidecar file (e.g. .mcc, .scc, or .xml) alongside any media file, regardless of the media file format.

5.15.4 Miscellaneous Improvements

- A new pixel format for native 10-bit RGB support - `PrPixelFormat_RGB_444_10u`, as well as `PrPixelFormat_UYVY_422_32f_*` formats
- VST 3 support allows many more audio plug-ins to run in Premiere Pro
- Windows installer improvements, by adding new registry values for preset and settings locations.
- Get the current build number via the *App Info Suite*
- Importers can now support audio beyond basic mono, stereo, and 5.1, without implementing multiple streams, and importers can return varying pixel formats depending on the clip settings. Read more about what's new for importers.
- Exporters can get the number of audio channels in the source, and check if the user has checked "Use Previews" in the Export Settings dialog. They can also move an existing settings parameter to a different location. Read more about what's new for exporters.
- The *Sequence Info Suite* can retrieve the field type, zero point, and whether or not the timecode is drop-frame
- New flags to the transition API as a hint to optimize rendering when a transition only has an input on one side
- The *Video Segment Suite* provides access to a new property: `Effect_ClipName`

Premiere Pro is now localized in Chinese.

5.16 What's New in CS6.0.x?

CS6.0.2 adds more support for growing files in importers. A transmitter can now label its audio channels for the Audio Output Mapping preferences.

CS6.0.1 gives device controllers a way to get the number of frames dropped during an insert edit, to abort an Export to Tape if desired. This method is already superceded by the new Edit to Tape panel functionality in CC.

5.17 What's New in CS6?

5.17.1 Transmit API

We are introducing the Transmit API as the preferred means for external hardware monitoring. This new API provides vastly simplified support for monitoring on external hardware. Transmit plug-ins offer more flexible usage, since they are not tied to the sequence Editing Mode, which cannot be changed once a sequence has been edited. Transmitters can be specified by the user in Preferences > Playback. Other plug-ins such as importers and effects with settings preview dialogs can send video out to the active transmitter, opening up new possibilities for hardware monitoring. For this first release, transmit plug-ins are supported in Premiere Pro, Encore, and Prelude. Not far down the road, we intend to stop supporting the player API, but we will continue to support it for CS6. See *Transmitters* for more details.

5.17.2 Exporter Enhancements

Exporters can now use “push” model compression. This can simplify export code and improve performance. The “pull” model is still supported, and required for legacy versions and Encore.

We've added the *Export Standard Param Suite*, which provides the standard parameters used in many built-in exporters. This can greatly reduce the amount of code needed to manage standard parameters for a typical exporter, and guarantee consistency with built-in exporters.

Exporters can now set tooltip strings for parameters. Multiple exporters are now supported in a single plug-in. And the Maximum Render Precision flag is now queried from the exporter, rather than being handled without the exporter's knowledge.

Exporters can now set events (error, warning, or info) for a specific encode in progress in the Adobe Media Encoder render queue, using the new *Exporter Utility Suite*. These events are displayed in the application UI, and are also added to the AME encoding log.

Make sure your presets go in the right location in the new AME Preset Browser. Read additional details of what's new in *Exporters*.

5.17.3 Stereoscopic Video Pipeline

We are also adding API support for stereoscopic video throughout the render pipeline. This affects importers, effects built using the After Effects API, and exporters.

5.17.4 Other Changes

Importers can now support growing files in Premiere Pro. We have also added a way for importers to specify all their source files to be copied by Collect Files in After Effects. There is also a new function in the Media Accelerator Suite to validate the content state of a media accelerator. See additional details of what's new in *Importers*.

For **Recorders**, the parent window handle is now properly passed in during *recmod_ShowOptions* when a recorder should display its modal setup dialog.

For **Players**, *pmPlayerSettings* has a new member, *mPrimaryDisplayFullScreen*, which indicates whether or not the player should display fullscreen.

Device controllers have a new callback, *DroppedFrameProc*, to provide the feature to abort and Export to Tape if frames are dropped.

New video segment properties were added:

- *kVideoSegmentProperty_MediaClipScaleToFramePolicy*,
- *kVideoSegmentProperty_AdjustmentAdjustmentMediaIsOpaque*,
- *kVideoSegmentProperty_AdjustmentOperatorsHash*,
- *kVideoSegmentProperty_Media_InPointMediaTimeAsTicks*,
- *kVideoSegmentProperty_Media_OutPointMediaTimeAsTicks*,
- *kVideoSegmentProperty_Clip_TrackItemStartAsTicks*,
- *kVideoSegmentProperty_Clip_TrackItemEndAsTicks*,
- *kVideoSegmentProperty_Clip_EffectiveTrackItemStartAsTicks*,
- *kVideoSegmentProperty_Clip_EffectiveTrackItemEndAsTicks*

The *Memory Manager Suite* is now at version 4. *AdjustReservedMemorySize* provides a way to adjust the reserved memory size relative to the current size. This may be easier for the plug-in, rather than maintaining the absolute memory usage and updating it using the older *ReserveMemory* call.

MPEG-4 pixel formats and full-range Rec. 709 MPEG-2 and MPEG-4 formats have now been added for native support in the render pipeline.

5.18 What's New in CS5.5?

Importers can now support color management, when running in After Effects. Now, even nonsynthetic importers can explicitly provide peak audio data. And a new return value allows an importer to specify that it is dependent on a library that needs to be activated. See additional details of what's new in *Importers*.

Players can now support closed captioning. See additional details of what's new in the players chapter.

Exporters now have a call to request a rendered frame and then conform it to a specific pixel format. See additional details of what's new in *Exporters*.

We have opened up a new **Export Controller** API that can drive any exporter to output a file in any format and perform custom post-processing operations. Developers wanting to integrate Premiere Pro with an asset management system will want to use this API instead of the exporter API. See *Export Controllers* for more details.

A new pair of pixel formats was added to natively support full-range Rec. 601 4:2:0 YUV planar video, both progressive and interlaced: *PrPixelFormat_YUV_420_MPEG2_FRAME_PICTURE_PLANAR_8u_601_FullRange* and *PrPixelFormat_YUV_420_MPEG2_FIELD_PICTURE_PLANAR_8u_601_FullRange*.

The *Video Segment Suite* now provides a new call to retrieve a segment node for a requested time. There are also a few new properties for media nodes:

StreamIsContinuousTime, *ColorProfileName*, *ColorProfileData*, and *ScanlineOffsetToImproveVerticalCentering*.

The *Sequence Info Suite* now provides a call to get the sequence frame rate, which may be useful for effects.

The *Image Processing Suite* has a new call to set the aspect ratio flag of a DV frame.

5.19 What's New in CS5?

Importers now have access to the resolution, pixel aspect ratio, timebase, and audio sample rate of the source clip from a setup dialog. Custom importers can use a new call to update a clip after it has modified by the user in the setup dialog. Please refer to *Importers* for more info on what's new.

Recorders can now provide audio metering during preview and capture. Read more about what's new in *Recorders*.

Exporters and **players** can automatically take advantage of GPU acceleration, if available on the end-user's system. Each project now has a setting for the renderer that the user can choose in the project settings dialog. When renders occur through the *Sequence Render Suite* or the Playmod Render Suite, they now go through the renderer chosen for the current project. This allows third-party exporters and players to use the built-in GPU acceleration available in the new Mercury Playback Engine.

Exporters and players can now handle any pixel format, with the new *Image Processing Suite*. Exporters and players that parse segments and perform their own rendering can now call the host for subtree rendering. See the *Video Segment Render Suite* for details.

If you provide an installer for an exporter, note that custom presets created in Premiere Pro are now visible in AME and vice-versa.

5.19.1 Encore CS5

3rd-party exporters can now be used to transcode assets to MPEG-2 or Blu-ray compliant files. Please refer to the Guidelines for Exporters in Encore for instructions on how to set up your exporter so that Encore can use it for transcoding.

5.19.2 Mac 64-Bit and Cocoa

It is invalid to unload any bundle that uses Cocoa because of restrictions in the Objective-C runtime which do not support unregistering classes. If a plugin uses Cocoa, it must call `CFRetain` on its own bundle, otherwise it will cause a crash when the application is closing and tries to unload the plug-ins.

5.20 What's New in CS4?

5.20.1 New Renderer API and Custom Pixel Formats

The new renderer API provides a way to take over and accelerate rendering of segments. Just as a player can choose which segments to accelerate, so a renderer can choose which segments to accelerate. Renderers may accelerate any segment, in any sequence, in any project.

Renderers also provide a way to add completely custom pixel formats to the render pipeline. Supporting a custom pixel format in an importer, a renderer, and an exporter is the new way to implement smart rendering, by passing custom compressed data from input to output.

5.20.2 Sequence Preview Formats

Sequence preview file formats are now defined by Sequence encoder preset files. Without any presets installed, you will not be able to create a new sequence using your custom editing mode.

5.20.3 Separate Processes During Export

When choosing export settings, the settings UI is displayed by Premiere Pro. When the user confirms the settings, the clip or sequence is passed to Media Encoder. From Media Encoder, frames from the clip or sequence can be retrieved and rendered without further participation from Premiere Pro. For a clip export, Media Encoder uses any installed importers to get source frames. For sequence export, Media Encoder uses a process called PProHeadless, to import and render frames to be exported.

Since there are so many processes involved during export, it is important that plug-ins be accessible to all processes, by being installed in the common plug-ins folder. PProHeadless Plugin Loading.log provides information on the PProHeadless process. PProHeadless is also used when the user creates a dynamic link to a .prproj that is not opened in Premiere Pro.

5.20.4 XMP metadata

There are built-in XMP metadata handlers for known filetypes. These handlers write and read metadata to and from the file, without going through the importer. *imSetTimeInfo8* is no longer called, since this is set by the XMP handler for that filetype.

5.20.5 More Pixel Format Flexibility

Effects, transitions, and exporters no longer need to support 8-bit RGB at a minimum. So, for example, an effect can be written to process floating point YUV only. If necessary, Premiere will make an intermediate conversion so that the effect will receive the pixel format it supports.

5.21 Legacy API

Legacy API features, such as selectors and callbacks that are superseded by new ones, are deprecated, but are supported, unless indicated.

CHAPTER 6

Where Do I Start

Read about the sample projects. Decide which one is closest to the functionality you want to provide. Build the plug-in into the shared plug-ins folder.

Launch Premiere Pro with the debugger attached, and set breakpoints at the plug-in's entry point to see all communication between Premiere Pro and the plug-in.

The documentation is intended as a reference with detailed explanation where appropriate, but studying the interaction between Premiere Pro and plug-ins is the best way to understand it.

Write plug-ins by modifying sample plug-in source code. This will greatly simplify your efforts, and make it easier for us to help you. Feel free to explore and experiment with the API on your own once you're familiar with it, but please, resist the temptation to start from scratch; you'll only force yourself to repeat other developers' mistakes, including our own.

If you run into behavior that seems wrong, see if you can reproduce the behavior using one of the unmodified sample projects. This can save you a lot of time, if you can determine whether the bug behavior was introduced by your modifications, or was already there to begin with.

Document Overview

This introduction information is common to all the plug-in types.

All developers should read this chapter, and browse through chapters two and three before diving too deep into plug-in development.

Resources is a short chapter that describes the Premiere Pro-specific resources used by plug-ins, including the Plug-in Property List (PiPL).

Universals documents concepts, data types, and structures used throughout the APIs. It also describes suites and functions used by more than one type of plug-in.

Hardware introduces Media Abstraction, used by hardware integrators and software developers to integrate with Premiere and accelerate specific workflows.

The remainder of the document describes specific *Premiere Pro Plug-In Types*.

This document is designed to be read non-linearly. You can browse through the topics from the bookmarks that appear in the left-hand panel in Acrobat, or the right-hand panel in the Preview application on macOS. A simple search for a well-chosen keyword will also turn up much information on any given topic.

7.1 Documentation Conventions

Functions, structure names and general C/C++ code are in Courier; `MyStruct.member` and `MyFunction()`

Underlined text in light blue is hyperlinked. Premiere selectors are italicized; *imGetPrefs*.

Getting Support and Providing Feedback

Please read relevant sections of this document and view the included sample code before requesting assistance. Please direct questions regarding installation, configuration, or use of Adobe products to Adobe Technical Support.

Having a solid understanding of digital video concepts is vital to developing plug-ins. This documentation assumes you understand basic video topics such as resolution, frame rates, field interlacing, pixel aspect ratio, bit depth, timecode, compression, color spaces, etc. You must also understand how your plug-in will fit into a user's workflow in Premiere Pro. If you aren't yet familiar with Premiere Pro or video editing concepts, we recommend the Adobe Premiere Pro Classroom in a Book.

To report a bug or submit a feature request for Premiere Pro, please visit: <http://www.adobe.com/products/wishform.html>

Since this form can be used to submit bugs and features for all Adobe products, make sure you have the right product selected.

We encourage you to use the Premiere Pro SDK forum to ask questions on the API and general integration. For development questions that you'd rather keep confidential, you may contact API Engineering directly. Your feedback can improve the API and SDK to streamline future development.

Premiere Pro Plug-In Types

Type	Description
<i>Importers</i>	Import video and audio media into Premiere. Synthetic importers, a subset, dynamically synthesize media without creating an actual file on disk. Custom importers, dynamically synthesize media to disk.
<i>Recorders</i>	Records from a (usually hardware) source to disk. If necessary, provides a plug-in-defined settings dialog. Displays the video overlay in the preview area of the Capture panel. Any audio preview should be played directly by the recorder. The captured file is passed to Premiere after capture by its file path. The recorder can optionally provide the timecode of the captured file to Premiere Pro.
<i>Export Controllers</i>	Can drive any exporter to generate a file in any format and perform custom post-processing operations. Developers wanting to integrate Premiere Pro with an asset management system will want to use this API instead of the exporter API.
<i>Exporters</i>	Allows the user to output media to disk.
<i>Transmitters</i>	Sends video, audio, and closed captioning to any external device during playback and editing.
<i>Video Filters</i>	We strongly recommend using the After Effects SDK to develop effects plug-ins. Most of the effects included in Premiere Pro are After Effects plug-ins. Process a series of video frames with parameters that can be animated over time.
<i>GPU Effects & Transitions</i>	Process two video sources into a single destination over time. This API is based on the After Effects API, with certain functions to enable transition functionality in Premiere Pro.
<i>Device Controllers</i>	Control an external device (video tape recorder, camera, etc.) during Capture and Edit To Tape.
<i>Control Surfaces</i>	Interface with a hardware control surface to support audio mixing, basic transport controls, and the Lumetri Color panel. The API supports two-way communication with Premiere Pro, so that motorized hardware faders, VU meters, etc can be in sync with the application.

9.1 Other Supported Plug-In Standards

Type	Description
Adobe After Effects API	Premiere Pro supports a portion of the AE API. The After Effects SDK is not included in the Premiere Pro SDK. The last chapter in the After Effects SDK Guide.pdf, included in the After Effects SDK, contains information on known differences with how Premiere Pro supports the AE API.
VST	Starting in CC, Premiere supports version 3 of the VST specification for audio effects. In CS6.x and previous versions, support was limited to version 2.4.
ASIO	An ASIO driver is often provided in addition to a transmit plug-in, to provide audio output during editing, playback, and Export To Tape. Prior to CS6, an ASIO driver was required to support audio input for voiceover recording in the audio mixer. On macOS, a Core Audio component may be provided rather than an ASIO driver.
Core Audio	macOS only. May be provided instead of an ASIO driver.

9.1.1 Plug-in Support Across Adobe Video and Audio Applications

This chart shows which third-party plug-ins are supported by the various Video and Audio applications.

	Premiere Pro	After Effects	Media Encoder	Animation	Character Animator	After Effects Prelude
After Effects AEGPs		X				
After Effects effects	X	X				
After Effects transitions	X					
ASIO	X	X		X		X
Control Surfaces	X			X		
CoreAudio	X	X		X		X
Premiere device controllers	X					
Premiere export controllers	X					
Premiere exporters	X	X	X	X		
Premiere importers	X	X	X	X		X
Premiere recorders	X					
Premiere transmitters	X	X			X	X
Premiere video filters	X					
QuickTime codecs	X	X	X	X		X
Transitions	X					
VfW codecs	X	X	X	X		X
VST audio effects	X			X		

Encore can use third-party exporters to transcode assets to MPEG-2 or Blu-ray compliant files.

Please refer to *Guidelines for Exporters in Encore* for instructions on how to set up your exporter so that Encore can use it for transcoding.

9.1.2 Premiere Elements Plug-in Support

Premiere Elements uses the same core libraries for plug-in support that Premiere Pro does, although Premiere Elements is 32-bit, whereas Premiere Pro is 64-bit starting with CS5.

Premiere Elements version	Equivalent Premiere Pro API version
12	CS6
11	CS5.5
10	CS5.5
9	CS5
8	CS4

It's always important to test the plug-in fully in each application before advertising compatibility.

Check out *Guidelines for Exporters in Premiere Elements* for instructions on how to set up your exporter to be used in Premiere Elements.

9.1.3 What Exactly Is a Premiere Plug-in?

Premiere plug-ins contain a single entry point of a type specific to each API.

Plug-ins are DLLs on Windows, and Carbon or Cocoa Bundles on macOS.

Plug-ins in the \Plug-ins[language] folder, and any of its subfolders, will be loaded at launch.

Plug-ins can have private resources.

Only one plug-in per file is parsed, unlike After Effects and Photoshop plug-ins, which can contain multiple entry points.

CHAPTER 10

Sample Projects

10.1 Descriptions

Name	Description
SDK File Importer	<p>This importer supports .sdk media files.</p> <p>To use the importer, choose File > Import, and select an .sdk file. Such files may be created using the SDK Exporter.</p> <p>It supports uncompressed 8-bit RGB with or without alpha, and packed 10-bit YUV (v410). It supports mono, stereo, and 5.1 audio at arbitrary sample rates and 32-bit float. It supports trimming using the Project Manager, Properties and Data Rate Analysis, Unicode filenames, the avoidAudioConform flag, and can read video frames asynchronously. It also features a test harness for multistream audio, which can be turned on by uncommenting the MULTISTREAM_AUDIO_TESTING define in the header.</p>
Synth Import	<p>This synthetic importer generates 8-bit YUV and RGB, video only.</p> <p>To use it, choose File > New > SDK Synthetic Importer.</p> <p>When the clip is created, it demonstrates a sample settings dialog, which can be displayed again by double-clicking the clip in the Project Panel or Timeline Panel.</p> <p>Every time the settings dialog is displayed, it creates new footage in memory. It creates ten seconds of footage at 24 fps. The video consists of horizontal lines of random colors.</p> <p>No file is created on disk for an example of that, see the Custom Importer.</p>
SDK Custom Import	<p>This custom importer creates a clip similar to the Synth Import sample, but generates it to disk, rather than memory.</p> <p>To use it, choose File > New > SDK Custom Importer.</p> <p>Or, import an existing .sdkc clip from the File > Import dialog.</p> <p>On Windows, newly generated files with .sdkc file extensions are created in C:WindowsTemp. On macOS, they are created on the Desktop.</p> <p>After the sample settings dialog, it optionally displays a background frame from the timeline (useful for titlers).</p> <p>The generated footage is between 2 and 30 frames at 24 fps, with a random resolution between 32 and 720 pixels wide and between 32 and 480 high, at DV NTSC pixel aspect ratio.</p>
Recorder	<p>This recorder pretends to capture .sdk files.</p> <p>To select it, choose Project > Project Settings > Capture > Capture Format: SDK Record.</p> <p>To simulate a capture, there must be a valid .sdk file at C:premiere.sdk, and the SDK File Importer must also be installed.</p>
32	<p>When the record button is pressed, a capture is simulated, and when capture is finished, the file at C:premiere.sdk is copied to the file specified in the Save Captured File dialog, and automatically imported into the project.</p> <p>It demonstrates a simple implementation of two capture options buttons, audio capture settings directly in the Project Settings > Capture panel. Unicode filenames, and changing the capture format mid-stream.</p>

10.2 How To Build the SDK Sample Projects

The required development environment is described in *SDK Audience*.

See a quickstart video on building an effect using a similar SDK (on macOS): adobe.ly/2sjMDwM

We've combined the sample projects into a single master project, stored in the Examples folder of the SDK.

For macOS it is BuildAll.xcodeproj; for Windows, it is _BuildAll.sln.

You'll need to specify some settings so that the plug-ins are built into a folder where they will be loaded by the application you are developing for.

We recommend plug-ins be built into the following folder for macOS: `/Library/Application Support/Adobe/Common/Plug-ins/[version]/MediaCore/`

Version is locked at 7.0 for all CC versions, or CSx for earlier versions.

For example: `/Library/Application Support/Adobe/Common/Plug-ins/7.0/MediaCore/`

or: `/Library/Application Support/Adobe/Common/Plug-ins/CS6/MediaCore/`

and the following path for Windows:

`[Program Files]\Adobe\Common\Plug-ins\[version]\MediaCore\`

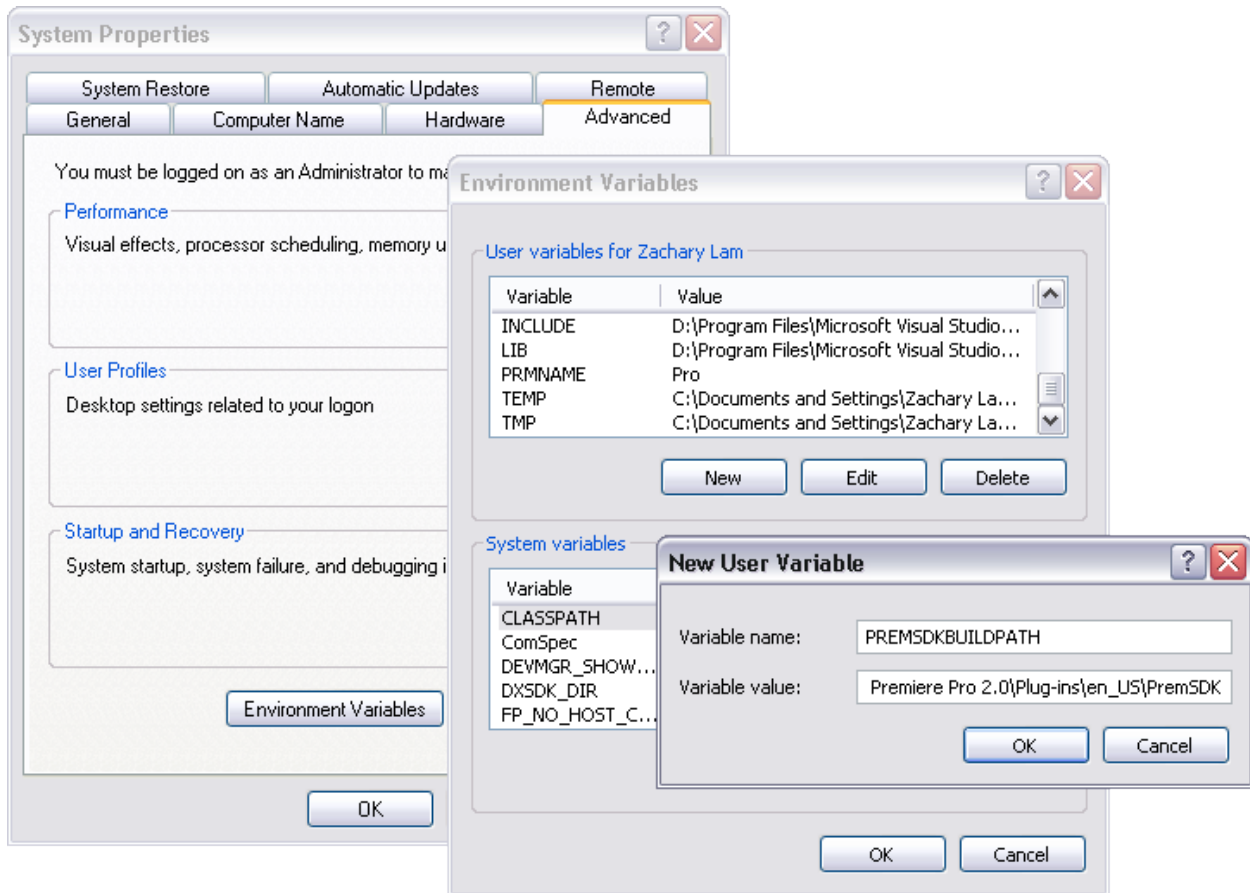

for example: `C:\Program Files\Adobe\Common\Plug-ins\7.0\MediaCore\`

or: `C:\Program Files\Adobe\Common\Plug-ins\CS6\MediaCore\`

Note that this Windows path is only recommended for development purposes. Windows installers should follow the guidelines here.

In Xcode, set the build location for the project in File > Project Settings. Press the Advanced button. Under Build Location choose Custom, select Absolute, and set the Products path.

In Visual Studio, for convenience, we have set the Output File for all sample projects to use the base path set by the environment variable `PREMSDKBUILDPATH`. You'll need to set this as a user environment variable for your system, and shown in the screenshot below.

1. On Windows 7, right-click *My Computer* > *Properties*, and in the left sidebar choose *Advanced System Settings*.
2. In the dialog that appears, hit the *Environment Variables* button.
3. In the *User variables*, create a new variable named `PREMSDKBUILDPATH`, with the path as described above. (e.g. “C:\Program Files\Adobe\CommonPlug-ins[version]\MediaCore”).
4. Log out of Windows, and log back in so that the variable will be set.

When compiling the plug-ins, if you see a link error such as:

“Cannot open file “[MediaCore plug-ins path]plugin.prm”, make sure to launch Visual Studio in administrator mode. In your Visual Studio installation, right-click `devenv.exe`, *Properties* > *Compatibility* > *Privilege Level*, click “Run this program as an administrator”.

It’s not recommended to copy plug-ins into the plug-in folder after you’ve built them, because that won’t allow you to debug the plug-ins while the host application is running.

Debugging Plug-Ins

Once you've got the plug-in building directly into the plug-ins folder as explained above, here's how to specify Premiere Pro as the application to run during debug sessions:

On Windows:

1. In the Visual Studio solution, in the Solution Explorer panel, choose the project you want to debug
2. Right-click it and choose Set as StartUp Project
3. Right-click it again and choose Properties
4. In Configuration Properties > Debugging > Command, provide the path to the executable file of the host application the plug-ins will be running in (this may be Premiere Pro or After Effects)
5. From there you can either hit the Play button, or you can launch the application and later at any point choose Debug > Attach to Process. . .

On macOS:

1. In Xcode, in the Project Navigator, choose the xcodeproj you want to debug
2. Choose Product > Scheme > Edit Scheme. . .
3. Under Run, in the Info tab, for Executable, choose the host application the plug-ins will be running in (this may be Premiere Pro or After Effects)
4. From there you can either hit the Play button to build and run the current scheme, or you can launch the application and later at any point choose Debug > Attach to Process.

Another way to do this in Visual Studio is by placing a line of code:

```
_asm int 3;
```

or:

```
DebugBreak();
```

You will then receive the Microsoft error reporting message, but if you hit the Debug button you will enable Just-In-Time Debugging and can attach to the process.

12.1 Plug-in Caching

On its first launch, Premiere Pro loads all the plug-ins, reads the *Plug-In Property Lists (PiPL) Resource*, and sends any startup selectors to determine the plug-ins' capabilities. To speed up future application launches, it saves some of these capabilities in what we call the plug-in cache (the registry on Windows, a Property List file on macOS).

The next time the application is launched, the cached data is used wherever possible, rather than loading all the plug-ins on startup. Using this cached data will make the application launch faster, but for a small set of plug-ins that need to be initialized every time, it may be undesirable. These include plug-ins that need to get run-time information that might change in between app launches (i.e. installed codec lists), and plug-ins that check for hardware and need to be able to fail. So we give your plug-in control final say over whether or not it is reloaded each time.

By default, importers, recorders, and exporters are not cached. Exporters can be cached by setting `exExporterInfoRec.isCacheable` to non-zero during *exSelStartup*. Importers and recorders can be cached by returning `*IsCacheable` instead of `*NoError` (e.g. for importers, `imIsCacheable` instead of `imNoError`) on the startup selector.

By default, legacy video filters and device controllers are cached by default. To specify that legacy video filters must be reloaded each time, rather than cached, Premiere filters should respond to *fsCacheOnLoad*.

12.2 Resolving Plug-in Loading Problems

There are various tools to help in the development process.

On Windows only, you can force Premiere to reload all the plug-ins by holding down shift on startup. The plug-in cache on macOS may be deleted manually from the user folder, at `~/Library/Preferences/com.Adobe.Premiere Pro [version].plist`.

For plug-in loading issues, you may first check one of the plug-in loading logs.

On Windows: `[user folder]\AppData\Roaming\Adobe\Premiere Pro\[version number]\Plugin Loading.log`

On macOS, this is: `~/Library/Application Support/Adobe/Premiere Pro/[version number]/Plugin Loading.log`

Your plug-in will be listed by path and filename, and the log will contain details on what happened during the plug-in loading process. Starting in CC 2017, it now logs any error codes returned from an effect on *PF_Cmd_GLOBAL_SETUP*.

If the log says a plug-in has been marked as Ignore, the most common culprit is a library dependency that could not be loaded. If your plug-in uses some image processing or proprietary code library, is it installed on the system, and in the right place? On Windows, a tool such as Dependency Walker (*depends.exe*) is helpful to check a plug-in's dependencies.

12.3 Library Linkage

On Windows, we strongly recommend dynamically linking to libraries, rather than static linking. In Visual Studio, the runtime library linkage setting is in *C/C++ > Code Generation > Runtime Library*.

We ask developers to compile with the */MD* flag (or */MDd* for debug builds), and not with the */MT* flag.

Failure to do so can contribute to the problem where the Premiere Pro process can run out of fiber-local storage slots, and subsequent plug-ins fail to load.

12.4 No Shortcuts

The Premiere Pro plug-in loader does not follow Windows shortcuts. Although it does follow macOS symbolic links, we recommend against using symbolic links in the plug-ins folder, since the plug-in loader checks the timestamp of the symbolic link rather than the timestamp of the plug-in pointed to.

Explanation: If you use a symbolic link and the plug-in fails to load once (for example, if the plug-in pointed to isn't there) it will be marked to ignore when Premiere launches. Even if the plug-in is restored to the proper location, the plug-in loader will check the modification time of

the symbolic link, rather than the plug-in pointed to, and continue to ignore the plug-in until the modification date of the symbolic link is updated. So plug-ins should be placed directly in a plug-ins folder or subfolder.

Plug In Installation

Plug-ins must have an installer. This simplifies installation by the user, provides more compact distribution, and ensures all the pieces are installed correctly.

Create a container folder for your plug-in(s) to minimize user confusion.

Don't unintentionally overwrite existing plug-ins, or replace newer versions.

The installer should find the default installation directories as described below.

It is also appreciated when an installer allows the user to specify an alternate directory.

Plug-ins should be installed in the common plug-in location.

Supported Premiere and After Effects plug-ins installed here will be loaded by Premiere Pro, After Effects, Audition, and Media Encoder.

Other plug-in types, such as QuickTime and Vfw codecs should be installed at the operating system level.

13.1 Windows

Starting in CC, each version of Premiere Pro will create a unique registry key that provide locations of folders of interest for third-party installations for that version.

For example, here are the registry values **for CC 2015.3:**

Key: HKEY_LOCAL_MACHINE/Software/Adobe/Premiere Pro/10.0/

Value name: CommonPluginInstallPath

Value data: C:\Program Files\Adobe\Common\Plug-ins\7.0\MediaCore\\ (or whatever the proper MediaCore plug-ins folder is; note that this is the same as what the After Effects installer provides for a corresponding registry key)

Starting in CC 2015.3, **control surface plug-ins** should be installed here:

/Library/Application Support/Adobe/Common/Plug-ins/ControlSurface/

For sequence presets:

Value name: SequencePresetsPath

Value data: [Adobe Premiere Pro installation path]\Settings\SequencePresets\\

For sequence preview presets:

Value name: SequencePreviewPresetsPath

Value data: [Adobe Premiere Pro installation path]\Settings\EncoderPresets\SequencePreview\\

For exporter presets:

Value name: CommonExporterPresetsPath

Value data: [User folder]AppDataRoamingAdobeCommonAME7.0Presets\

Effects presets:

Value name: PluginInstallPath

Value data: [Adobe Premiere Pro installation path]\Adobe Premiere Pro CC\Plug-ins\Common

Third-party installers can start from this path, and then modify the string to build the path to the language-specific effect presets.

Prior to CC, the only path given in the registry was the common plug-in path for the most recently installed version of Premiere Pro:

HKEY_LOCAL_MACHINE/Software/Adobe/Premiere Pro/CurrentVersion

Value name: Plug-InsDir

Value data: REG_SZ containing the full path of the plug-in folder.

As an example: C:\Program Files\Adobe\Common\Plug-ins\CS6\MediaCore\\

The best way to locate other preset folders was to start from the root path for Premiere Pro in the registry at

HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\App Paths\ Adobe Premiere Pro.exe.

Then, just add the proper subdirectories as described in the macOS section.

13.2 macOS

Starting in CC 2015, we now provide installer hints for Mac. You'll find a new plist file "com. Adobe.Premiere Pro.paths.plist" at "/Library/Preferences". This contains hints for your Mac installer to know where to install plug-ins, and is similar to the registry entries we have been providing on Win.

The **common plug-in location** is at:

/Library/Application Support/Adobe/Common/Plug-ins/[version]/MediaCore/

Starting in CC 2015.3, **control surface plug-ins** should be installed here:

/Library/Application Support/Adobe/Common/Plug-ins/ControlSurface/

Following OS X Code Signing guidelines, plug-ins should be installed in this separate shared location rather than in the application bundle.

For sequence presets:

```
/Settings/SequencePresets/[Your specific folder]/
```

Sequence preview presets:

```
/Settings/EncoderPresets/SequencePreview/[Your editing mode GUID]/
```

Encoder presets:

```
/MediaIO/systempresets/[Your exporter folder]/
```

Effects presets:

```
/Plug-ins/[language subdirectory]/Effect Presets/ (see Localization for the list of language codes)
```

Editing modes:

```
/Settings/Editing Modes/
```

13.3 Plug-in Naming Conventions

On Windows, Premiere Pro plug-ins must have the file extension “.prm”. On macOS, they have the file extension “.bundle”. Other supported plug-in standards use their conventional file extensions: “.aex” for After Effects plug-ins, “.dll” for VST plug-ins.

While it is not required for your plug-in to load, naming your plug-ins using the plug-in type as a prefix (e.g. ImporterSDK, FilterSDK, etc.) will help reduce user confusion.

13.4 Plug-in Blacklisting

Have a plug-in that works fine in one CS application, but has problems in another CS application? Now, specific plug-ins can be blocked from being loaded by MediaCore in specific applications, using blacklists. Note that this does not work for After Effects plug-ins loaded by AE, although it does work for AE plug-ins loaded in Premiere Pro.

In the plug-ins folder, look for the appropriate blacklist file, and append the the filename of the plug-in to the file (e.g. BadPlugin, not BadPlugin.prm). If the file doesn’t exist, create it first. “Blacklist.txt” contains names of plug-ins blacklisted from all apps. Plug-ins can be blocked from loading in specific apps by including them in “Blacklist Adobe Premiere Pro.txt”, or “Blacklist After Effects.txt”, etc.

13.5 Creating Sequence Presets

Not to be confused with encoder presets or sequence preview encoder presets, sequence presets are the successor to project presets. They contain the video, audio, timecode, and track layout information used when creating a new sequence.

If you wish to add Sequence Presets for the New Sequence dialog, save the settings with a descriptive name and comment. Emulate our settings files. Install the presets as described in this section.

13.6 Application-level Preferences

For Windows 7 restricted user accounts, the only place that code has guaranteed write access to a folder is inside the user documents folder and its subfolders.

```
..Users[user name]AppDataRoamingAdobePremiere Pro[version]\
```

This means that you cannot save data or documents in the application folder. There is currently no plug-in level API for storing preferences in the application prefs folder. Plug-ins can create their own preferences file in the user's Premiere prefs directory like so:

```
HRESULT herr = SHGetKnownFolderPath(FOLDERID_RoamingAppData, 0, NULL, &
↳preferencesPath);
strcat(preferencesPath, "\\Adobe\\Premiere Pro\\[version]\\MyPlugin.preferences");
```

On MacOS: `NSSearchPathForDirectoriesInDomains(NSApplicationSupportDirectory, NSLocalDomainMask, ...)`

This should get you started getting the Application Support folder which you can add onto to create something like:

```
/Library/Application Support/Adobe/Premiere Pro/[version]/ MyPlugin.
preferences
```

13.7 Dog Ears

Premiere Pro's built-in player has a mode to display statistics, historically known as "dog ears", which can be useful in debugging and tuning performance of importers, effects, transitions, and transmitters. The statistics include frames per second, frames dropped during playback, pixel format rendered, render size, and field type being rendered.

You can bring up the debug console in Premiere Pro. You can do this via Ctrl/Cmd-F12. To enable the dog ears, type this:

```
debug.set EnableDogEars=true
```

to disable, use this:

```
debug.set EnableDogEars=false
```

If the enter keystroke seems to go to the wrong panel, this is an intermittent panel focus problem. Click the Tools or Info panel before typing in the Console panel, and the enter key will be processed properly.

Once enabled, the player displays the statistics as black text on a partially transparent background. This allows you to still see the underlying video (to some extent) and yet also read the text. When you turn off dog ears, the setting may not take effect until you switch or reopen your current sequence.

Note if you are developing a transmitter, displaying dog ears will result in duplicate calls to `PushVideo` for the same frame. This happens because the player routinely updates the dog ears on a timer even when the frame hasn't changed for updated stats. As of CS6, this triggers a `PushVideo` to active transmitters as a side effect.

The language used by Premiere Pro is decided by the user during installation.

Plug-ins can determine this setting from the following locations:

On Windows, in the registry at `HKEY_CURRENT_USER\Software\Adobe\Premiere Pro\[version]`, in a key named "Language".

On macOS, at `~/Library/Preferences/com.Adobe.Premiere Pro.[version].plist`, at `Root > Language`.

The string will be set to one of the values below by Premiere Pro at startup.

Language	String
English	en_US
French	fr_FR
German	de_DE
Italian	it_IT
Japanese	ja_JP
Spanish	es_ES
Korean	ko_KR
Chinese (new in CC)	zh_CN
Russian (new in CC 2014)	ru_RU
Brazilian Portugese (new in CC 2014)	pt_BR

Changing the string will not change the language Premiere Pro runs in, unless you override the application language by placing a file in the following location:

Windows: `[App installation folder]\lang-override.txt`

macOS: `[App Installation folder]/[Premiere Pro application package]/Contents/lang-override.txt`

When a plug-in receives a selector it doesn't recognize, it should always return the code specific to the plug-in type that means the selector is not supported (i.e. `imUnsupported`, `rmUnsupported`, etc).

In this way, new selectors can be added to the API and legacy plug-ins will automatically answer whether or not they support it.

15.1 Structure Alignment

All the sample projects include `PrSDKTypes.h`.

This header sets the proper (single-byte) structure alignment and specifies the necessary (C-style) external linkage.

CHAPTER 16

Resources

There are two types of special resources that are specific to Premiere plug-ins: the PiPL and the IMPT. This chapter describes these resources, and how certain plug-in types use them.

Plug-In Property Lists (PiPL) Resource

For many plug-in types, Premiere loads a PiPL (Plug-in Property List) resource. The PiPL is described in a file with a “.r” extension.

The complete PiPL syntax is described in PiPL.r.

You’ll notice that PiPLs are really old. A vestige of 68k macOS programming, they spread to Windows.

However, if you develop from the sample projects, you shouldn’t have to do anything to get them to build properly for Latin languages.

17.1 Which Types of Plug-ins Need PiPLs?

Exporters, players, and recorders do not need PiPLs.

Standard importers do not need PiPLs. Synthetic and custom importers use a basic PiPL to specify their name, and the match name that Premiere uses to identify them. The name appears in the File > New menu.

Device controllers use a basic PiPL to specify their name and the match name that Premiere uses to identify them.

Video filters use an extended PiPL to specify their name, the match name that Premiere uses to identify them, the bin they go in, how they handle pixel aspect ratio, whether or not they have randomness, and their parameters.

For more information on the `ANIM_FilterInfo` and `ANIM_ParamAtom`, see the resources section in *Video Filters*.

17.2 A Basic PiPL Example

```
#define plugInName "SDK Custom Import"
#define plugInMatchName "SDK Custom Import"

resource 'PiPL' (16000) {
{
    // The plug-in type
    Kind {PrImporter},

    // The name as it will appear in a Premiere menu, this can be localized
    Name {plugInName},

    // The internal name of this plug-in - do not localize this. This is used for both
    ↪Premiere and After Effects plug-ins.
    AE_Effect_Match_Name {plugInMatchName}

    // Transitions and video filters define more PiPL attributes here
}
};
```

17.3 How PiPLs Are Processed By Resource Compilers

On macOS, .r files are processed natively by Xcode, as a Build Phase of type Build Carbon Resources. This step is already set for the sample projects.

On Windows, .r files are processed with CnvtPiPL.exe, which creates an .rcp file based upon custom build steps in the project. The .rcp file is then included in the .rc file along with any other resources the plug-in uses. These custom build steps are already in place in the sample projects.

To view them, open up the sample project in .NET. In the Solution Explorer, right-click the .r file and choose Properties. In the dialog, choose the Custom Build Step folder. The Command

Line contains the script for executing the CnvtPiPL.exe. Unless you are using a different compiler than the support compiler, or adding support for Asian languages, you should not need to modify the custom build steps. This script may also be found as a text file in the SDK at \Examples\ ResourcesWinCustom Build Steps.txt. This text file also describes the additional switches used for Asian languages.

CHAPTER 18

IMPT Resource

Premiere Pro looks for an IMPT resource to identify a plug-in as an importer.

Before Premiere Pro 1.0, the IMPT resource was also used to declare the file extension supported by an importer.

Since file extensions are now declared during `imGetIndFormat`, the drawtype four character code in the IMPT resource is no longer used by Premiere Pro.

However, a unique drawtype fourcc is needed for the importer to function properly in After Effects on macOS.

Do not use `0x4D4F6F76`. This is already reserved by After Effects.

```
1000 IMPT DISCARDABLE BEGIN
0x12345678 // Put your own unique hexadecimal code here
END
```

CHAPTER 19

Universals

This chapter covers topics that are common to more than one type of Premiere plug-in. We start by discussing fundamental concepts and common data structures. The rest of the chapter discusses the various function suites that are available to plug-ins.

There are two different representations of time: `scale over sampleSize`, and `ticks`.

20.1 `scale over sampleSize`

The first representation of time uses `value/scale/sampleSize` components, either separated, or combined in a `TDB_TimeRecord` structure. `scale over sampleSize` defines the timebase. For example, to represent the NTSC standard of 29.97 frames per second, `scale / sampleSize = 30000 / 1001`. To represent the PAL standard of 25 frames per second, `25 / 1`.

To represent the 24p standard of 23.976, `23976 / 1000`, or `24000 / 1001`. To represent most other timebases, use `sampleSize = 1`, and `scale` is the frame rate (e.g. 15, 24, 30 fps, etc). Another way of thinking about `scale` and `sampleSize` is that `sampleSize` is the duration of a frame of video, and `scale` is that duration of a second of video.

`value` is the time in the timebase given by `scale over sampleSize`. So, for example, 30 frames with a `sampleSize` of 1001 have a value of 30030.

To convert `value` to seconds, divide by `scale`. To convert `value` to frames, divide by `sampleSize`.

Sometimes, as when handling audio-only media, `sampleSize` refers to a sample of audio, and `sampleSize = 1`. In this case, `scale` is the audio sampling rate (22050, 32000, 44100, 48000 Hz, etc).

20.2 `PrTime`

Most newer areas of the API use a tick-based time value that is stored in a signed 64-bit integer. Variables that use this new format are of type `PrTime`. When a frame rate is represented as a `PrTime`, the frame rate is the number of ticks in a frame duration.

The current number of ticks per second must be retrieved using the callback in the *Time Suite*. This rate is guaranteed to be constant for the duration of the application's run-time.

CHAPTER 21

Video Frames

Premiere stores each video frame in a `PPix` structure. A `PPixHand` is a handle to a `PPix`. This structure should not be accessed directly, but manipulated using various suites such as the *PPix Suite*, *PPix 2 Suite*, *PPix Creator Suite*, and *PPix Creator 2 Suite*.

Far from being just a boring buffer of RGB data, `PPixes` can contain a significant amount of information about a video frame, including: rectangle bounds (width, height), pixel aspect ratio, pixel format, field dominance, alpha interpretation, color space, gamma encoding, and more.

In the pixel buffer itself, there may be padding between neighboring horizontal rows of pixels. So when iterating through the pixels in the buffer, don't assume that the first pixel on the next line is stored immediately after the last pixel on the current line. Honor the `rowbytes`, which is a measure of the size in bytes of a row of pixels, including any extra padding.

Frames are guaranteed to be 16-byte aligned.

Pixel Formats And Color Spaces

As of CC, Premiere supports 69 different pixel formats, not including raw and custom formats.

Why so many? Each pixel format has its unique advantages and disadvantages. 8-bit formats are compact, but lack quality. 32-bit ones are more accurate, but overkill in some situations.

Compressed formats are great for storing raw frames, but bad for effects processing. And so on... In summary, choose wisely!

22.1 What Format Should I Use?

Starting in CS4, plug-ins no longer need to support 8-bit BGRA at a minimum. If required, Premiere can make intermediate format conversions in the render pipeline, although these intermediate conversions will be avoided if possible.

Previously in CS3 and earlier, all plug-ins except importers needed to support 8-bit per channel BGRA, even if they supported other formats.

When choosing which pixel formats to support, there are different factors to consider, depending on the plug-in type.

22.1.1 Importers

Importers typically should provide frames in a format closest to the source format.

If needed, Premiere can convert any compressed format to a 8-bit or 32-bit uncompressed format. Keeping the format compressed as long as possible as it passes through the render pipeline will save memory and bandwidth.

Starting in Premiere Pro CC 2014, importers can now choose the format they are rendering in. This allows importers to change pixel formats and quality based on criteria like enabled hardware and other source settings, such as HDR. To handle the negotiation, implement *imSelectClipFrameDescriptor*.

22.1.2 Effects

Effects should support the uncompressed format(s) that works best with the effect's pixel processing algorithm.

If the algorithm is based on RGB pixel calculations, provide a fast render path using 8-bit BGRA, and optionally a high-quality render path using 32-bit BGRA. If the algorithm is Y'UV-based, use the VUYA pixel formats.

22.1.3 Exporters and Transmitters

Exporters and transmitters should request frames in a format closest to the output format. New in CS5, `PrPixelFormat_Any` can be used in exporter render requests.

Any render function that takes a list of pixel formats can now be called with just two formats - the desired 4:4:4:4 pixel format, and `PrPixelFormat_Any`. This allows the host to avoid frame conversions and decompressions in many very common cases. The best part is that the plug-in doesn't need to

understand all the possible pixel formats to make use of this. It can use the *Image Processing Suite* to copy/convert from any a `PPix` of any format to a separate memory buffer, which is a copy that would likely need to be done anyway.

After the request is made, Premiere analyzes the preferred format of all importers and effects that are used to produce a single rendered frame, as well as the list of requested formats, and chooses the best format to use on a per-segment basis.

If the requestor supports more than one format, and the importers and effects used for various clips in the sequence support different formats, the render may use different formats for each segment.

Premiere Pro's built-in Rec. 601 to 709 color space conversion can be slow. So if the majority of the sources and effects use the Rec 601 color space, and if the exporter or transmitter can handle the 601 to 709 conversion quickly on its own, it may be faster to do the color space conversion in the exporter or transmitter.

22.1.4 Other Considerations

For high-bit depth support, the 32f formats are the recommended route, rather than the 16u formats. For example, an exporter that supports 10-bit Y'UV should ask for frames in 32f Y'UV format, and then convert the 32f to 10u.

The ARGB formats can be natively used in the After Effects render pipeline, and are used by After Effects effect plug-ins that do not specifically support any other pixel format. However, in Premiere Pro, these ARGB formats will require byte-swapping, and shouldn't be used.

22.2 Byte Order

BGRA, ARGB, and VUYA are written in order of increasing memory address from left to right. Uncompressed formats have a lower-left origin, meaning the first pixel in the buffer describes the pixel in the lower-left corner of the image. Compressed formats have format-specific origins. Use calls in the *Image Processing Suite* to get details on any format.

8-bit and 16-bit BGRA formats do not contain super whites or super blacks.

The 16-bit formats use channels that go from black at 0 to white at 32768, like After Effects and Photoshop 16-bit formats.

22.2.1 Unpacked, Uncompressed

PrPixelFormat	Bits / Channel	Format / FourCC	Additional Details
BGRA_4444_8u	8	RGB	
VUYA_4444_8u	8	Y'UV	
VUYA_4444_8u_709	8	Y'UV	Rec. 709 color space. New in Premiere Pro 4.1.
BGRA_4444_16u	16	RGB	
BGRA_4444_32f	32	RGB	
VUYA_4444_32f	32	Y'UV	
VUYA_4444_32f_709	32	Y'UV	Rec. 709 color space. New in Premiere Pro 4.1.

22.2.2 Unpacked, Uncompressed, native After Effects support only

PrPixelFormat	Bits / Channel	Format / FourCC	Additional Details
ARGB_4444_8u	8	RGB	For native After Effects support. For native Premiere Pro support, use BGRA.
ARGB_4444_16u	16	RGB	
ARGB_4444_32f	32	RGB	

22.2.3 Unpacked, Uncompressed, with implicit alpha

PrPixelFormat	Bits / Channel	Format / FourCC	Additional Details
BGRX_4448_8u	8u	RGB	Implicitly opaque alpha channel. The actual data may be left filled with garbage, which allows optimized processing by both the plug-in and host, with the understanding the the alpha channel is opaque. New in Premiere Pro CS5.
VUYX_4448_8u	8u	Y'UV	
VUYX_4448_8u_709	8u	Y'UV	
XRGB_4448_8u	8u	RGB	
BGRX_44416_16u	16u	RGB	
XRGB_44416_16u	16u	RGB	
BGRX_44432_32f	32f	RGB	
VUYX_44432_32f	32f	Y'UV	
VUYX_44432_32f_709	32f	Y'UV	
XRGB_44432_32f	32f	RGB	
BGRP_4448_8u	8u	RGB	Premultiplied alpha. New in Premiere Pro CS5.
VUYP_4448_8u	8u	Y'UV	
VUYP_4448_8u_709	8u	Y'UV	
PRGB_4448_8u	8u	RGB	
BGRP_44416_16u	16u	RGB	
PRGB_44416_16u	16u	RGB	
BGRP_44432_32f	32f	RGB	
VUYP_44432_32f	32f	Y'UV	
VUYP_44432_32f_709	32f	Y'UV	
PRGB_44432_32f	32f	RGB	

22.2.4 Linear RGB

PrPixelFormat	Bits / Channel	Format / FourCC	Additional Details
BGRA_4444_32f	32f	Linear RGB	These RGB formats have a gamma of 1, rather than the standard 2.2. New in Premiere Pro CS5.
BGRP_4444_32f	32f	Linear RGB	
BGRX_4444_32f	32f	Linear RGB	
ARGB_4444_32f	32f	Linear RGB	
PRGB_4444_32f	32f	Linear RGB	
XRGB_4444_32f	32f	Linear RGB	

22.2.5 Packed, Uncompressed formats

PrPixelFormat	Bits / Channel	Format FourCC /	Additional Details
RGB_444_10u			New in Premiere Pro CC. Full range 10-bit 444 RGB little-endian
YUYV_422_8u_601	8	'YUY2'	New in Premiere Pro CS4.
YUYV_422_8u_709	8	'YUY2'	Rec. 709 color space. New in Premiere Pro CS4.
UYVY_422_8u_601	8	'UYVY'	New in Premiere Pro CS4.
UYVY_422_8u_709	8	'UYVY'	Rec. 709 color space. New in Premiere Pro CS4.
V210_422_10u_601	10	'v210'	New in Premiere Pro CS4.
V210_422_10u_709	10	'v210'	Rec. 709 color space. New in Premiere Pro CS4.
UYVY_422_32f_601	32	'UYVY'	New in Premiere Pro CC.
UYVY_422_32f_709	32	'UYVY'	New in Premiere Pro CC.

22.2.6 Compressed Y'UV

PixelFormat	Bits / Channel	Format / FourCC	Additional Details
NTSCDV25	8	DV25 / 'dvsd'	
PALDV25	8	DV25 / 'dvsd'	
NTSCDV50	8	DV50 / 'dv50'	
PALDV50	8	DV50 / 'dv50'	
NTSCDV100_720p	8	DV100 720p / 'dvh1'	
PALDV100_720p	8	DV100 720p / 'dvh1'	
NTSCDV100_1080i	8	DV100 1080i / 'dvh1'	
PALDV100_1080i	8	DV100 1080i / 'dvh1'	
YUV_420_MPEG2_FRAME_PICTURE	8	YUV420P	Progressive Rec. 601 color space
YUV_420_MPEG2_FIELD_PICTURE	8	YUV420P	Interlaced Rec. 601 color space
YUV_420_MPEG2_FRAME_PICTURE	8	YUV420P	New in 6.0: Full Range CS5.5. Progressive Rec. 601 color space, full range Y'UV
YUV_420_MPEG2_FIELD_PICTURE	8	YUV420P	New in 6.0: Full Range CS5.5. Interlaced Rec. 601 color space, full range Y'UV
YUV_420_MPEG2_FRAME_PICTURE	8	YUV420P	Progressive Rec. 709 color space
YUV_420_MPEG2_FIELD_PICTURE	8	YUV420P	Interlaced Rec. 709 color space
YUV_420_MPEG2_FRAME_PICTURE	8	YUV420P	New in 7.0: Full Range CS6. Progressive Rec. 709 color space, full range Y'UV. Matricies scaled from 709 by each component's excursion (Y is scaled by 219/255 and UV scaled by 224/256)
YUV_420_MPEG2_FIELD_PICTURE	8	YUV420P	New in 7.0: Full Range CS6. Interlaced Rec. 709 color space, full range Y'UV
YUV_420_MPEG4_FRAME_PICTURE	8	YUV420P	New in 6.0: Premiere Pro CS6. Progressive Rec. 601 color space
YUV_420_MPEG4_FIELD_PICTURE	8	YUV420P	New in 6.0: Premiere Pro CS6. Interlaced Rec. 601 color space
YUV_420_MPEG4_FRAME_PICTURE	8	YUV420P	New in 6.0: Premiere Pro CS6. Progressive Rec. 601 color space, full range Y'UV

22.2.7 Miscellaneous

PrPixelFormat	Bits / Channel	Format / FourCC	Additional Details
Raw	?	?	Raw, opaque data, with no rowbytes or height

22.3 Custom Pixel Formats

New in CS4, custom pixel formats are supported. Plug-ins can define a pixel format which can pass through various aspects of our pipeline, but remain completely opaque to the built-in renderers. Use the macro `MAKE_THIRD_PARTY_CUSTOM_PIXEL_FORMAT_FOURCC` in the *Pixel Format Suite*. Please use a unique name to avoid collisions.

The format doesn't need to be registered in any sense. They can just be used in the same way the current pixel formats are used, though in many cases they will be ignored.

The first place the new pixel formats can appear in the render pipeline is at the importer level. Importers can advertise the availability of these pixel formats during *imGetIndPixelFormat*, just as they would for any other format. Note that importers must also support a non-custom pixel format, for the case where the built-in renderer is used, which would not be prepared to handle an opaque pixel format added by a third-party.

In the importer, use the new *CreateCustomPPix* call in the *PPix Creator 2 Suite*, and specify a custom pixel format and a memory buffer size, and the call will pass back a PPix of the requested format. These PPixes can then be returned from an importer, like any other. The memory for the PPix will be allocated by MediaCore, and must be a flat data structure as they will need to be copied between processes.

However, because the data itself is completely opaque, it can easily be a reference to another pixel buffer, as long as the reference can be copied. For example, the buffer could be a constant 16 bytes, containing a GUID which can be used to access a memory buffer by name in another process.

To query for available custom pixel formats from the player, use the *GetNumCustomPixelFormat* and *GetCustomPixelFormat* calls in the *Clip Render Suite*. The custom pixel formats will not returned by the regular calls to get the supported frame formats, mostly to prevent them from being used.

The other *Clip Render Suite* functions will accept requests for custom pixel formats and will return these custom PPixes like any others.

With the *Clip Render Suite*, a third-party player can directly access these custom PPixes from a matched importer.

22.3.1 Smart Rendering

Smart rendering involves passing compressed frames from the importer to the exporter, to bypass any unnecessary decompression and recompression, which reduces quality and performance.

The way to implement this is by passing custom PPixes between an importer, exporter, and usually a renderer.

In the rare case of exporting a single clip, using the *Clip Render Suite* in the exporter to request custom PPixes from the importer is sufficient. But in the more common case of exporting a sequence, a renderer that supports the custom pixel format is required.

When an exporter running in Media Encoder parses the segments in the sequence, it only has a very high-level view. It sees the entire sequence as a single clip (which is actually a temporary project file that has been opened using a Dynamic Link to the PProHeadless process), and it sees any optional cropping or filters as applied effects.

So when the exporter parses that simple, high-level sequence, if there are no effects, it should use the MediaNode's ClipID with the *Clip Render Suite* to get frames directly from the PProHeadless process. In the PProHeadless process, the renderer can step in and parse the real sequence in all its glory.

It can use the *Clip Render Suite* to get the frames in the custom pixel format directly from the importer, and then set the custom PPix as the render result. This custom PPix then is available to the exporter, in a pristine, compressed PPix.

Pixel Aspect Ratio

Pixel Aspect Ratio (PAR) is usually represented as a rational number, with a numerator and a denominator. Note that several PAR values were changed in CS4 to match broadcast standards. Here are some examples of pixel aspect ratios:

- NTSC DV 0.9091 PAR is (10, 11)
- NTSC DV Widescreen 1.2121 PAR is (40, 33)
- PAL DV 1.0940 PAR is (768, 702)
- PAL DV 1.4587 PAR is (1024, 702)
- Square 1.0 PAR is (1,1)

In certain legacy structures, PAR is represented as a single 32-bit integer, such as in `recCapInfoRec.pixelAspectRatio`.

This uses a representation where the numerator is bit-shifted 16 to the left, and OR'd with the denominator. For example NTSC DV 0.9091 PAR is `(10 << 16) | 11`.

There are different constants defined for fields. These constants are now largely interchangeable in CS4, since the conflicting constants for the old compiler API have been removed.

Exporters, Players, Video Segment Suite, etc	Recorders
<code>prFieldsNone</code>	<code>kMALFieldsNone</code>
<code>prFieldsUpperFirst</code>	<code>kMALFieldsUpperFirst</code>
<code>prFieldsLowerFirst</code>	<code>kMALFieldsLowerFirst</code>
<code>prFieldsUnknown</code>	<code>kMALFieldsUnknown</code>
<code>prFieldsAny</code>	<code>kMALFieldsInvalid</code>
<code>prFieldsInvalid</code>	

25.1 32-bit Float, Uninterleaved Format

All audio calls to and from Premiere use arrays of buffers of 32-bit floats to pass audio. Audio is not interleaved, rather separate channels are stored in separate buffers. So the structure for stereo audio looks like this:

```
float* audio[2];
```

where `audio[0]` is the address of a buffer `N` samples long, and `audio[1]` is the address of a second buffer `N` samples long. `audio[0]` contains the left channel, and `audio[1]` contains the right channel. `N` is the number of sample frames in the buffer.

Since Premiere uses 32-bit floats for each audio sample, it can represent values above 0 dB. 0 dB corresponds to +/- 1.0 in floating point. A floating point sample can be converted to a 16-bit short integer by multiplying by 32767.0 and casting the result to a short.

E.g.:

```
sample16bit[n] = (short int) (sample32bit[n] * 32767.0)
```

The plug-in is responsible for converting to and from the 32-bit uninterleaved format when reading a file that uses a different format. There are calls to convert between formats in the *Audio Suite*. For symmetry in the `int <-> float` conversions, we recommend you use the utility functions provided.

25.2 Audio Sample Types

Since 32-bit floats are the only audio format ever passed, there is no option of sample type or bit depth. However, file formats do use a variety of sample types and bit depths, so `AudioSampleTypes` define a variety of possible formats.

These formats are used to set members in structures passed to Premiere to define the user interface, and do not affect the format of the audio passed to and from Premiere.

PrAudioSampleType	Description
kPrAudioSampleType_8BitInt	8-bit integer
kPrAudioSampleType_8BitTwosInt	8-bit integer, two's complement
kPrAudioSampleType_16BitInt	16-bit integer
kPrAudioSampleType_24BitInt	24-bit integer
kPrAudioSampleType_32BitInt	32-bit integer
kPrAudioSampleType_32BitFloat	32-bit floating point
kPrAudioSampleType_64BitFloat	64-bit floating point
kPrAudioSampleType_16BitIntBigEndian	16-bit integer, big endian
kPrAudioSampleType_24BitIntBigEndian	24-bit integer, big endian
kPrAudioSampleType_32BitIntBigEndian	32-bit integer, big endian
kPrAudioSampleType_32BitFloatBigEndian	32-bit floating point, big endian
kPrAudioSampleType_Compressed	Any non-PCM format
kPrAudioSampleType_Packed	Any PCM format with mixed sample types
kPrAudioSampleType_Other	A sample type not in this list
kPrAudioSampleType_Any	Any available sample type (used by exporters)

25.3 Audio Sample Frames

A sample frame is a unit of measurement for audio. One audio sample frame describes all channels of one sample of audio. Each sample is a 32-bit float. Thus, the storage requirement of an audio sample frame in bytes is equal to 4 * number of channels.

25.4 Audio Sample Rate

PrAudioSample is a prInt64

25.5 Audio Channel Types

Premiere currently supports four different audio channel types: mono, stereo, 5.1, and max channel.

Greater than 5.1 channel support was originally added in Premiere Pro 4.0.1, with partial support for a 16 channel master audio track, only for importing OMFs and playing out to hardware.

In CS6, 16-channel audio export was added.

Starting in CC, the audio channel support is increased to 32 channels.

PrAudioChannelType	Description
kPrAudioChannelType_Mono	Mono
kPrAudioChannelType_Stereo	<p>Stereo. The order of the stereo channels is:</p> <ul style="list-style-type: none"> • kPrAudioChannelLabel_FrontLeft, • kPrAudioChannelLabel_FrontRight.
kPrAudioChannelType_51	<p>5.1 audio.</p> <p>The order of the 5.1 channels is:</p> <ul style="list-style-type: none"> • kPrAudioChannelLabel_FrontLeft, • kPrAudioChannelLabel_FrontRight, • kPrAudioChannelLabel_BackLeft, • kPrAudioChannelLabel_BackRight, • kPrAudioChannelLabel_FrontCenter, • kPrAudioChannelLabel_LowFrequency
kPrAudioChannelType_MaxChannel	<p>New in CC.</p> <p>kMaxAudioChannelCount, defined as 32 channels as of CC.</p> <p>All channels use kPrAudioChannelLabel_Discrete.</p>

Memory Management

Premiere Pro has a media cache in which it stores imported frames, intermediate frames (intermediate stages of a render), fully rendered frames, and audio.

This is sized based on a specific percentage of physical memory, taking into account if multiple Production Premium applications like After Effects, Encore, etc are also running.

PPro manages this cache itself, so as it adds new items to the cache, it flushes least recently used items.

26.1 What Really is a Memory Problem?

Often, users monitoring memory usage are alarmed when they see memory growing to a specific point during a render or playback. When the memory doesn't drop right back down after a render or playback, they might think they have found a memory leak. However, keeping in mind the function of the Premiere Pro media cache, this behavior is to be expected.

On the other hand, memory contention between plug-ins and the rest of Premiere Pro can lead to memory problems. If a plug-in allocates a significant amount of memory and the Premiere Pro media cache has not accounted for it, this means there is less free memory available after the media cache grows to the predefined size. Even if Premiere Pro does not completely run out of memory, limited memory can cause memory thrashing as memory is moved around to make room for video frames, which in turn can cause poor performance.

26.2 Solutions for Memory Contention

The best approach to reduce memory contention is to reduce the memory requirements of each plug-in. However, if the memory requirements of a plug-in are significant, it should also use the *Memory Manager Suite* to report any memory usage that would not already be accounted for.

Frames allocated using the *PPix Creator Suite* are accounted for, but any memory allocated using the old PPix and Memory functions are not automatically accounted for.

CHAPTER 27

Basic Types Structures

These types and structures are defined in PrSDKTypes.h and PrSDKStructs.h, and are used throughout the Premiere API.

Premiere defines cross-platform types for convenience when developing plug-ins for both Windows and Mac OS.

Name	Description
prColor	An unsigned 32-bit integer that stores an RGB color. This type is useful for the 8-bpc colors retrieved by the color picker in a video effect or transition. Color channels are stored as BGRA, in order of increasing memory address from left to right.
prWnd	A Windows HWND or Mac OS NSView*
prParentWnd	A Windows HWND or Mac OS NSWindow*
prOffscreen	A Windows HDC
prRect	A Windows RECT or Mac OS Rect. Use the utility function prSetRect to set the dimensions of a prRect struct. This should be used because Mac OS Rect members have a different ordering than Windows RECT members.
prFloatRect	<pre>typedef struct { float left; float top; float right; float bottom; } prFloatRect;</pre>
prRgn	A Windows HRGN
prPoint, LongPoint	<pre>typedef struct { csSDK_int32 x; csSDK_int32 y; } prPoint, LongPoint;</pre> <p>LongPoint is deprecated, but still used for a couple of Bottleneck callbacks</p>
prFPoint	<pre>typedef struct { double x; double y; } prFPoint64;</pre>
prPixel	(Deprecated)
prPixelAspectRatio	(Deprecated)
PPix, *PPixPtr, **PPixHand	Holds a video frame or field, and contains related attributes such as pixel aspect ratio and pixel format. Manipulate PPixs using the <i>PPix Suite</i> , never directly.
TDB_TimeRecord	A time database record representing a time value in the context of a video frame rate. <pre>typedef struct { TDB_Time value; TDB_TimeScale scale; TDB_SampSize sampleSize; } TDB_TimeRecord;</pre>
prBool	Can be either kPrTrue or kPrFalse
PrMemoryPtr, *PrMemoryHandle	A char*
PrTimelineID, PrClipID	A 32-bit signed integer.
prUTF8Char	An 8-bit unsigned integer.
PrSDKString	An opaque data type that should be accessed using the new <i>String Suite</i> .
80 rParam	Used for exporting Chapter 27: Basic Types Structures <pre>struct PrParam { PrParamType mType;</pre>

There are different sets of function suites available to Premiere plug-ins. *SweetPea Suites* are the more modern suites that have been added for most new functionality. The *piSuites* are still needed for various functionality that has not all been superseded by *SweetPea Suites*.

Whenever possible, use *SweetPea Suites*.

There are also function suites more specific to certain plug-in types. The *Bottleneck Functions* are useful for transitions and video filters. Other suites available to only one plug-in type are documented in the appropriate chapter for that plug-in type.

29.1 Overview

Suites common to more than one plug-in type are documented in this chapter below.

Suites that are only used by one plug-in type are documented in the chapter on that plug-in type.

Below is a table of all suites available in Premiere Pro:

Suite Name	Relevant to Plug-in Type
Accelerated Render Invocation Suite	Exporters
<i>App Info Suite</i>	All
<i>Application Settings Suite</i>	All
<i>Async File Reader Suite</i>	Importers
Async Operation Suite	All
<i>Audio Suite</i>	Importers, Exporters
<i>Captioning Suite</i>	Device Controllers, Exporters, Transmitters
<i>Clip Render Suite</i>	Exporters
<i>Deferred Processing Suite</i>	Importers
<i>Error Suite</i>	All except Exporters starting in CS6
<i>Export File Suite</i>	Exporters
<i>Export Info Suite</i>	Exporters
<i>Export Param Suite</i>	Exporters
<i>Export Progress Suite</i>	Exporters
<i>Export Standard Param Suite</i>	Exporters
<i>Exporter Utility Suite</i>	Exporters
<i>File Registration Suite</i>	Importers, Transitions, Video Filters
<i>Flash Cue Marker Data Suite</i>	Exporters
<i>GPU Device Suite</i>	GPU Effects and Transitions
<i>Image Processing Suite</i>	All
Importer File Manager Suite	Importers

Continued on next page

Table 1 – continued from previous page

Suite Name	Relevant to Plug-in Type
<i>Legacy Callback Suites</i>	All
<i>Marker Suite</i>	Exporters
Media Accelerator Suite	Importers
<i>Memory Manager Suite</i>	All
<i>Palette Suite</i>	Exporters
<i>Pixel Format Suite</i>	All
<i>Playmod Audio Suite</i>	Transmitters
Playmod Device Control Suite	None (Deprecated)
<i>Playmod Overlay Suite</i>	Transmitters
Playmod Render Suite	None (Deprecated)
<i>PPix Cache Suite</i>	Importers
<i>PPix Creator Suite</i>	All
<i>PPix Creator 2 Suite</i>	All
<i>PPix Suite</i>	All
<i>PPix 2 Suite</i>	All
Quality Suite	None (Deprecated)
<i>RollCrawl Suite</i>	Exporters
Scope Render Suite	None (Deprecated)
<i>Sequence Audio Suite</i>	Exporters
<i>Sequence Info Suite</i>	Importers, Transitions, Video Filters
<i>Sequence Render Suite</i>	Exporters
Stock Image Suite	None (Deprecated)
<i>String Suite</i>	All
<i>Threaded Work Suite</i>	All
<i>Time Suite</i>	All
<i>Transmit Invocation Suite</i>	All
<i>Video Segment Render Suite</i>	Exporters
<i>Video Segment Suite</i>	Exporters
<i>Window Suite</i>	All

29.2 Acquiring and Releasing the Suites

All SweetPea suites are accessed through the Utilities Suite. Plug-ins can acquire the suites like so:

```
SPBasicSuite *SPBasic = NULL;
PrSDKPixelFormatSuite *PixelFormatSuite = NULL;

SPBasic = stdParmsP->piSuites->utilFuncs->getSPBasicSuite();

if (SPBasic)
{
    SPBasic->AcquireSuite ( kPrSDKPixelFormatSuite,
                          kPrSDKPixelFormatSuiteVersion,
                          (const void**) &PixelFormatSuite);
}
```

Don't forget to release the suites when finished!

```

if (SPBasic && PixelFormatSuite)
{
    SPBasic->ReleaseSuite ( kPrSDKPixelFormatSuite,
                          kPrSDKPixelFormatSuiteVersion);
}

```

29.2.1 Versioning

Generally from version to version, the changes made to a suite are additive, so it is recommended to work with the most recent version of a suite if possible. However the latest version of a suite may not be supported by older versions of Premiere Pro or other host applications. Attempting to acquire suites that are unsupported by the host application will result in a NULL pointer being returned from `AcquireSuite`.

For a plug-in to support multiple versions, it may choose to use a specific older version of the suite that is supported across those multiple versions. Alternatively, it may check the version of the host application (using the *App Info Suite*), and use the new suites where available, or the older suites when running in an older version. To acquire a specific older version of a suite, rather than requesting `kPrSDKPixelFormatSuiteVersion` in the example above, use a specific version number instead.

29.3 App Info Suite

Useful for plug-ins that are shared between different applications, such as After Effects plug-ins, Premiere exporters, transmitters, and importers, where it may be important to know which host, version, or language the plug-in is currently running in. Note that this suite is not available to AE effects running in AE.

This suite provides the host application and version number. For a version such as 6.0.3, it will return `major = 6`, `minor = 0`, and `patch = 3`. See `PrSDKAppInfoSuite.h`.

Starting in version 2 of the suite, introduced in CC, the suite has a new selector to retrieve the build number. Speed-Grade CC supports this suite starting with the July 2013 update.

In version 3, starting in CC 2014, the suite has a new selector to retrieve the language as a NULL-terminated string identifying the locale used in the host application. For example: “en_US”, “ja_JP”, “zh_CN”.

29.4 Application Settings Suite

New in CS4. This suite provides calls to get the scratch disk folder paths defined in the current project, where the captured files and preview files are created. It also provides a call to get the project file path. All paths are passed back as `PrSDKStrings`. Use the new *String Suite* to extract the strings to UTF-8 or UTF-16. See `PrSDKApplicationSettingsSuite.h`.

29.5 Audio Suite

Calls to convert to and from the native audio format used by the Premiere API, at various bit depths. See `PrSDKAudioSuite.h`.

29.6 Captioning Suite

This suite enables a device controller, exporter, player, or transmitter to get the closed captioning data attached to a sequence. This suite provides the data in either Scenarist (CEA-608, *.scc) and MacCaption (CEA-708, *.mcc) formats. In the case of CEA-708, it includes not just the text to display, but it's also the position information, and background, font, etc. If the transmitter or player just wants to overlay the captioning data on a frame, it can use the *Playmod Overlay Suite* instead.

29.7 Clip Render Suite

New in 2.0. Use this suite in the player or renderer, to request source frames directly from the importer. There are calls to find the supported frame sizes and pixel formats, so that the caller can make an informed decision about what format to request. Frames can be retrieved synchronously or asynchronously. Asynchronous requests can be cancelled, for example if the frames have passed their window of playback. See `PrSDKClipRenderSuite.h`.

Starting in CS4, this suite includes calls to find any custom pixel format supported by a clip, and to get frames in those custom pixel formats.

An exporter can use this suite to request frames from the renderer in a compressed pixel format.

29.8 Error Suite

Uses a single callback for errors, warnings, and info. This callback will activate a flashing icon in the lower left-hand corner of the main application window, which when clicked, will open up the new Events Window containing the error information. See `PrSDKErrorSuite.h`.

Starting in version 3 of the suite, introduced in CS4, the suite supports UTF-16 strings. Starting in CS6, exporters should use the *Exporter Utility Suite* to report events.

29.9 File Registration Suite

Used for registering external files (such as textures, logos, etc) that are used by a plug-in instance but do not appear as footage in the Project Window. Registered files will be taken into account when trimming or copying a project using the Project Manager. See `PrSDKFileRegistrationSuite.h`.

29.10 Flash Cue Marker Data Suite

New in CS4. Specific utilities to read Flash cue points. Use in conjunction with the *Marker Suite*. See `PrSDK-FlashCueMarkerDataSuite.h`.

29.11 Image Processing Suite

New in CS5. Various calls to get information on pixel formats and process frames. The `ScaleConvert()` call is the way to copy-convert from a buffer of any supported pixel format to a separate memory buffer.

In version 2, new in CS5.5, we have added `StampDVFrameAspect()`, which allows a plug-in to set the aspect ratio of a DV frame. This was added to supplement `ScaleConvert()`, which doesn't have an aspect ratio parameter.

29.12 Marker Suite

New in CS4. New way to read markers of all types. See `PrSDKMarkerSuite.h`.

29.13 Memory Manager Suite

New in Premiere Pro 2.0. Calls to allocate and deallocate memory, and to reserve an amount of memory so that it is not used by the host. See `PrSDKMemoryManagerSuite.h`.

In CS6, the suite is now at version 4. `AdjustReservedMemorySize` provides a way to adjust the reserved memory size relative to the current size. This may be easier for the plug-in, rather than maintaining the absolute memory usage and updating it using the older `ReserveMemory` call.

29.13.1 ReserveMemory

A plug-in instance can call `ReserveMemory` as a request to reserve space so that Premiere's media cache does not use it. Each time `ReserveMemory` is called, it updates Premiere Pro on how many bytes the plug-in instance is currently reserving. The amount specified is absolute, rather than cumulative. So to release any reserved memory to be made available to Premiere Pro's media cache, call it with a size of 0. However, it's not needed to reset this when exporters are destructed on `exSDK_EndInstance`, since the media manager will be deleting all the references anyways.

`ReserveMemory` changes the maximum size of Premiere's Media Cache. So if the cache size starts at 10 GB, and you reserve 1 GB, then the cache will not grow beyond 9 GB. `ReserveMemory` will reserve a different amount of memory, depending on the amount of available memory in the system, and what other plug-in instances have already reserved. The media cache needs a minimum amount of memory to play audio, render, etc.

Starting in version 2 of the suite, introduced in CS4, there are calls to allocate/deallocate memory. This is necessary for exporters, which are not passed the legacy `memFuncs`.

29.14 Pixel Format Suite

See the table of supported pixel formats. `GetBlackForPixelFormat` returns the minimum (black) value for a given pixel format. `GetWhiteForPixelFormat` returns the maximum (white) value for a given pixel format. Pixel types like YUYV actually contain a group of two pixels to specify a color completely, so the data size returned in this case will be 4 bytes (rather than 2). This call does not support MPEG-2 planar formats.

ConvertColorToPixelFormattedData converts an BGRA/ARGB value into a value of a different pixel type. These functions are not meant to convert entire frames from one colorspace to another, but may be used to convert a single color value from a filter color picker or transition border. To convert frames between pixel formats, see the *Image Processing Suite*.

New in Premiere Pro 4.0.1, MAKE_THIRD_PARTY_CUSTOM_PIXEL_FORMAT_FOURCC () defines a custom pixel format.

29.15 Playmod Overlay Suite

New in CS5.5. A transmitter can ask Premiere Pro to render the overlay for a specific time. As of CS6, this is only used for closed captioning.

To render the closed captioning overlay, it is not necessary to know anything about the closed captioning data, whether it is CEA-608 or CEA-708. RenderImage will simply produce a PPixHand.

The reason why it's not called Closed Captioning Overlay Suite is because going forward we want to use it as a general suite that provides all kinds of overlays. That way, when we add more overlay types in the future, you don't need to worry about updating your player each time to mirror the implementation on your side. In the future, we will likely use this same suite to render static overlays, such as safe areas. To support those, even if VariesOverTime returns false, you can call HasVisibleRegions at time 0.

Version 2 in CC 2014 removes CalculateVisibleRegions ().

29.15.1 RenderImage

Render the overlay into an optionally provided BGRA PPixHand. RenderImage does not composite the overlay onto an existing frame, it just renders the overlay into the visible regions. After rendering the overlay at the player's display size, you will then need to composite that result over the frame.

If the user has zoomed the video, it could be wasteful to render a full-sized overlay image and then scale it. For better performance, the overlay can be rendered at the actual display size. The inDisplayWidth, inDisplayHeight and inLogicalRegion parameters provide this extra information needed to optimize for scaling in the UI.

As an example, let's say the sequence is 720x480 at 0.9091 PAR, and the Sequence Monitor is set to show the full frame at square PAR. Set inLogicalRegion to (0, 0, 720, 480), and inDisplayWidth to 654 and inDisplayHeight to 480.

If the Monitor zoom level was set to 50%, then the inLogicalRegion should stay the same, but display width and height should be set to 327x240. If zoomed to 200%, display width and height should be set to 1308x960. To pan around (as opposed to showing the entire frame), the logical region should be adjusted to represent the part of the sequence frame currently being displayed.

```
prSuiteError (*RenderImage) (
    PrPlayID      inPlayID,
    PrTime        inTime,
    const prRect* inLogicalRegion,
    int           inDisplayWidth,
    int           inDisplayHeight,
    prBool        inClearToTransparentBlack,
    PPixHand*     ioPPix);
```

Parameter	Description
inLogicalRegion	The non-scaled region of the source PPix to overlay
inDisplayWidth	Width and height of PPix, if provided in ioPPix, scaled to account for Monitor zoom and PAR
inDisplayHeight	
inClearToTransparentBlack	If <code>prBool</code> is true, the frame will first be cleared to transparent black before render
ioPPix	The frame into which to draw the overlay. If NULL, the host will allocate the PPix. If provided, the PPix must be BGRA, square pixel aspect ratio, and sized to inDisplayWidth & inDisplayHeight.

29.15.2 GetIdentifier

```
prSuiteError (*GetIdentifier)(
    PrPlayID      inPlayID,
    PrTime        inTime,
    const prRect* inLogicalRegion,
    int           inDisplayWidth,
    int           inDisplayHeight,
    prBool        inClearToTransparentBlack,
    prPluginID*   outIdentifier);
```

29.15.3 HasVisibleRegions

```
prSuiteError (*HasVisibleRegions)(
    PrPlayID      inPlayID,
    PrTime        inTime,
    const prRect* inLogicalRegion,
    int           inDisplayWidth,
    int           inDisplayHeight,
    prBool*       outHasVisibleRegions);
```

29.15.4 VariesOverTime

```
prSuiteError (*VariesOverTime)(
    PrPlayID inPlayID,
    prBool*  outVariesOverTime);
```

29.16 PPix Cache Suite

Used by an importer, player, or renderer to take advantage of the host application's PPix cache. See `PrSDKPPix-CacheSuite.h`.

Starting in version 2 of this suite, introduced in Premiere Pro 4.1, `AddFrameToCache` and `GetFrameFromCache` now have two extra parameters, `inPreferences` and `inPreferencesLength`. Now frames are differentiated within the cache, based on the importer preferences, so when the preferences change, the host will not use the old frame when it gets a frame request.

Version 4, new in CS5.0.3, adds `ExpireNamedPPixFromCache()` and `ExpireAllPPixesFromCache()`, which allow a plug-in to remove one or all PPixes from the Media Cache, which can be useful if the media is changing due to being edited in a separate application.

To expire an individual frames expired using `ExpireNamedPPixFromCache()`, the identifier must be known. The plug-in may specify an identifier using `AddNamedPPixToCache()`. If a frame is in the cache with multiple names, and you expire any one of those names, then the frame will be expired. Alternatively, for rendered frames, the identifier may be retrieved using `GetIdentifierForProduceFrameAsync()` in the *Video Segment Render Suite*.

Clearing the cache will not interfere with any outstanding requests, because each request holds dependencies on the needed frames.

Version 5, new in CS5.5, adds the new color profile-aware calls `AddFrameToCacheWithColorProfile()` and `GetFrameFromCacheWithColorProfile()`.

Version 6, new in CC 2014, adds `AddFrameToCacheWithColorProfile2()` and `GetFrameFromCacheWithColorProfile2()`, which are the same as the ones added in version 5 with the addition of a `PrRenderQuality` parameter.

29.17 PPix Creator Suite

Includes callbacks to create and copy PPixes. See also the *PPix Creator 2 Suite*.

29.17.1 CreatePPix

Creates a new PPix. The advantage of using this callback is that frames allocated are accounted for in the media cache, and are 16-byte aligned.

`ppixNew` and `newPtr` don't allocate memory in the media cache, or perform any alignment.

```
prSuiteError (*CreatePPix) (  
    PPixHand*          outPPixHand,  
    PrPPixBufferAccess inRequestedAccess,  
    PrPixelFormat      inPixelFormat,  
    const prRect*     inBoundingRect);
```

Parameter	Description
<code>PPixHand *outPPixHand</code>	The new PPix handle if the creation was successful. NULL otherwise.
<code>PrPPixBufferAccess inRequestedAccess</code>	Requested pixel access. Read-only is not allowed (doesn't make sense). <code>PrPPixBufferAccess</code> values are defined in <i>PPix Suite</i> .
<code>PrPixelFormat inPixelFormat</code>	The pixel format of this PPix

29.17.2 ClonePPix

Clones an existing PPix.

It will ref-count the PPix if only read access is requested and the PPix to copy from is read-only as well, otherwise it will create a new one and copy.

```
prSuiteError (*ClonePPix) (
    PPixHand          inPPixToClone,
    PPixHand*         outPPixHand,
    PrPPixBufferAccess inRequestedAccess);
```

Parameter	Description
PPixHand inPPixToClone	The PPix to clone from.
PPixHand *outPPixHand	The new PPix handle if the creation was successful. NULL otherwise.
PrPPixBufferAccess inRequestedAccess	Requested pixel access. Only read-only is allowed right now. PrPPixBufferAccess values are defined in <i>PPix Suite</i> .

29.18 PPix Creator 2 Suite

More callbacks to create PPixs, including raw PPixs.

Starting in version 2 of this suite, introduced in Premiere Pro 4.0.1, there is a new CreateCustomPPix call to create a PPix in a custom pixel format. See PrSDKPPixCreator2Suite.h.

29.19 PPix Suite

Callbacks and enums pertaining to PPixs. See also *PPix 2 Suite*.

29.19.1 PrPPixBufferAccess

Can be either:

- PrPPixBufferAccess_ReadOnly,
- PrPPixBufferAccess_WriteOnly,
- PrPPixBufferAccess_ReadWrite

29.19.2 Dispose

This will free this PPix. The PPix is no longer valid after this function is called.

```
prSuiteError (*Dispose) (
    PPixHand inPPixHand);
```

Parameter	Description
PPixHand inPPixHand	The PPix handle to dispose.

29.19.3 GetPixels

This will return a pointer to the pixel buffer.

```
prSuiteError (*GetPixels) (
    PPixHand          inPPixHand,
    PrPPixBufferAccess inRequestedAccess,
    char**            outPixelAddress);
```

Parameter	Description
PPixHand inPPixHand	The PPix handle to operate on.
PrPPixBufferAccess inRequestedAccess Most PPixs do not support write access modes.	Requested pixel access.
char** outPixelAddress	The output pixel buffer address. May be NULL if the requested pixel access is not supported.

29.19.4 GetBounds

This will return the bounding rect.

```
prSuiteError (*GetBounds) (
    PPixHand inPPixHand,
    prRect*  inoutBoundingRect);
```

Parameter	Description
PPixHand inPPixHand	The PPix handle to operate on.
prRect* inoutBoundingRect	The address of a bounding rect to be filled in.

29.19.5 GetRowBytes

This will return the row bytes of the PPix.

```
prSuiteError (*GetRowBytes) (
    PPixHand          inPPixHand,
    csSDK_int32*      outRowBytes);
```

Parameter	Description
PPixHand inPPixHand	The PPix handle to operate on.
csSDK_int32* outRowBytes	Returns how many bytes must be added to the pixel buffer address to get to the next line.

29.19.6 GetPixelAspectRatio

This will return the pixel aspect ratio of this PPix.

```
prSuiteError (*GetPixelAspectRatio) (
    PPixHand          inPPixHand,
    csSDK_uint32*     outPixelAspectRatioNumerator,
    csSDK_uint32*     outPixelAspectRatioDenominator);
```

Parameter	Description
PPixHand inPPixHand	The PPix handle to operate on.
PrPixelFormat* outPixelFormat	Returns the pixel format of this PPix

29.19.7 GetUniqueKey

This will return the unique key for this PPix.

Returns	If
error	the buffer size is too small (call GetUniqueKeySize to get the correct size)
error	the key is not available
success	the key data was filled in

```
prSuiteError (*GetUniqueKey) (
    PPixHand      inPPixHand,
    unsigned char* inoutKeyBuffer,
    size_t        inKeyBufferSize);
```

Parameter	Description
PPixHand inPPixHand	The PPix handle to operate on.
unsigned char* inoutKeyBuffer	Storage for the key to be returned.
size_t inKeyBufferSize	Size of buffer

29.19.8 GetUniqueKeySize

This will return the unique key size. This will not change for the entire run of the application.

```
prSuiteError (*GetUniqueKeySize) (
    size_t* outKeyBufferSize);
```

Parameter	Description
size_t* outKeyBufferSize	Returns the size of the PPix unique key.

29.19.9 GetRenderTime

This will return the render time for this PPix.

```
prSuiteError (*GetRenderTime) (
    PPixHand      inPPixHand,
    csSDK_int32*  outRenderMilliseconds);
```

Parameter	Description
PPixHand inPPixHand	The PPix handle to operate on.
csSDK_int32* outRenderMilliseconds	Returns the render time in milliseconds. If the frame was cached, the time will be zero.

29.20 PPix 2 Suite

A call to get the size of a PPix. Starting in version 2 of this suite, introduced in CS4, there is a new `GetYUV420PlanarBuffers` call to get buffer offsets and rowbytes of YUV_420_MPEG2 pixel formats. See `PrSDKKPPix2Suite.h`.

29.21 RollCrawl Suite

Used by a player or renderer to obtain the pixels for a roll/crawl. The player or render can then move and composite it using accelerated algorithms or hardware. See `PrSDKRollCrawlSuite.h`.

29.22 Sequence Info Suite

New in CS4. Calls to get the frame size and pixel aspect ratio of a sequence. This is useful for importers, transitions, or video filters, that provide a custom setup dialog with a preview of the video, so that the preview frame can be rendered at the right dimensions. See `PrSDKSequenceInfoSuite.h`.

Version 2, new in CS5.5, adds `GetFrameRate()`.

Version 3, new in CC, adds `GetFieldType()`, `GetZeroPoint()`, and `GetTimecodeDropFrame()`.

29.23 String Suite

New in CS4. Calls to allocate, copy, and dispose of `PrSDKStrings`. See `PrSDKStringSuite.h`.

29.24 Threaded Work Suite

New in CS4. Calls to register and queue up a threaded work callback for processing on a render thread. If you queue multiple times, it is possible for multiple threads to call your callback. If this is a problem, you'll need to handle this on your end.

29.25 Time Suite

A SweetPea suite that includes the following structure, callbacks, and enum:

29.25.1 pmPlayTimebase

Member	Description
csSDK_uint32 scale	rate of the timebase
csSDK_int32 sampleSize	size of one sample
csSDK_int32 fileDuration	number of samples in file

29.25.2 PrVideoFrameRates

Member	Description
kVideoFrameRate_24Drop	24000 / 1001
kVideoFrameRate_24	24
kVideoFrameRate_PAL	25
kVideoFrameRate_NTSC	30000 / 1001
kVideoFrameRate_30	30
kVideoFrameRate_PAL_HD	50
kVideoFrameRate_NTSC_HD	60000 / 1001
kVideoFrameRate_60	60
kVideoFrameRate_Max	0xFFFFFFFF

29.25.3 GetTicksPerSecond

Get the current ticks per second. This is guaranteed to be constant for the duration of the runtime.

```
prSuiteError (*GetTicksPerSecond) (
    PrTime*   outTicksPerSec);
```

29.25.4 GetTicksPerVideoFrame

Get the current ticks in a video frame rate. inVideoFrameRate may be any of the PrVideoFrameRates enum.

```
prSuiteError (*GetTicksPerVideoFrame) (
    PrVideoFrameRates inVideoFrameRate,
    PrTime*           outTicksPerFrame);
```

29.25.5 GetTicksPerAudioSample

Get the current ticks in an audio sample rate.

```
+=====+
| Returns | If | +=====+
| kPrTimeSuite_RoundedAudioRate | the requested audio sample rate is not an even
divisor of the base tick count and therefore times in this rate will not be exact. |
+-----+
| kPrTimeSuite_Success | otherwise | +-----+
```

```
prSuiteError (*GetTicksPerAudioSample) (
    float   inSampleRate,
    PrTime* outTicksPerSample);
```

29.26 Video Segment Render Suite

This suite uses the built-in software path for rendering, and supports subtree rendering. This means the plug-in can ask the host to render a part of the segment, and then still handle the rest of the rendering. This is useful if, for example, one of the layers has an effect that the plug-in cannot render itself. The plug-in can have the host render that layer, but then handle the other layers along with the compositing.

In version 2, new in CS5.5, the new call `SupportsInitiateClipPrefetch()` can be used to query whether or not a clip supports prefetching.

In version 3, new in CS6, the function signatures have been modernized, using `inSequenceTicksPerFrame` rather than `inFrameRateScale` and `inFrameRateSampleSize`.

29.27 Video Segment Suite

This suite provides calls to parse a sequence and get details on video segments. All the queryable node properties are in `PrSDKVideoSegmentProperties.h`. These properties will be returned as `PrSDKStrings`, and should be managed using the *String Suite*. The segments provide a hash value that the caller can use to quickly determine whether or not a segment has changed. This hash value can be maintained even if a segment is shifted in time

In version 4, new in CS5.5, the new call `AcquireNodeForTime()` passes back a segment node for a requested time. There are also a few new properties for media nodes: `StreamIsContinuousTime`, `ColorProfileName`, `ColorProfileData`, and `ScanlineOffsetToImproveVerticalCentering`.

In version 5, new in CC, a new video segment property is available: `Effect_ClipName`. In version 6, new in CC 2014, `AcquireFirstNodeInTimeRange()` and

`AcquireOperatorOwnerNodeID()` were added, along with the new node type `kVideoSegment_NodeType_AdjustmentEffect`.

The basic structure of the video segments is that of a tree structure. There is a `Compositor` node with `n` inputs. Each of those inputs is a `Clip` node, which has one input which is a `Media` node, and it also has `n` `Operators`, which are effects.

So, a simple example, three clips in a stack, the top one with three effects looks like this:

```
Segment
  Compositor Node
    Clip Node
      Media Node (bottom clip) Clip Node
    Clip Node
      Media Node (middle clip) Clip Node
    Clip Node
      Media Node (top clip)
      Clip Operators (Blur, Color Corrector, Motion)
```

To get a good idea of the segment structure, try the SDK player, create a sequence using the SDK Editing Mode, and watch the text overlay in the Sequence Monitor as you perform edits.

See `PrSDKVideoSegmentSuite.h` and `PrSDKVideoSegmentProperties.h`.

29.28 Window Suite

New in CS4. This is the new preferred way to get the handle of the mainframe window, especially for exporters, who don't have access to the legacy *piSuites*.

30.1 piSuites

These callbacks are available to all plug-ins, although many of these callbacks are only appropriate for specific plug-in types.

```
typedef struct {  
    int piInterfaceVer;  
    PlugMemoryFuncsPtr memFuncs;  
    PlugWindowFuncsPtr windFuncs;  
    PlugppixFuncsPtr ppixFuncs;  
    PlugUtilFuncsPtr utilFuncs;  
    PlugTimelineFuncsPtr timelineFuncs;  
} piSuites, *piSuitesPtr;
```

Member	Description
<code>piInterfaceVer</code>	API version <ul style="list-style-type: none"> • Premiere Pro CS4 - PR_PISUITES_VERSION_9 • Premiere Pro CS3 - PR_PISUITES_VERSION_8 • Premiere Pro 2.0 - PR_PISUITES_VERSION_7 • Premiere Pro 1.5.1 - PR_PISUITES_VERSION_6 • Premiere Pro 1.5 - PR_PISUITES_VERSION_5 • Premiere Pro 1.0 - PR_PISUITES_VERSION_4 • Premiere 6.x - PR_PISUITES_VERSION_3 • Premiere 5.1 - PR_PISUITES_VERSION_2 • Premiere 5.0 - PR_PISUITES_VERSION_1
<code>memfuncs</code>	Pointer to memory functions
<code>windFuncs</code>	Pointer window functions
<code>ppixFuncs</code>	Pointer PPix functions
<code>utilFuncs</code>	Pointer to utility functions. In the <code>utilFuncs</code> , the <code>getSPBasicSuite</code> callback provides access to the <i>SweetPea Suites</i> , which are used for most of the newer functions.
<code>timelineFuncs</code>	Pointer to timeline functions

30.1.1 Memory Functions

Memory and handle allocation. Where possible, use the *PPix Creator Suite* for PPix-specific allocation.

Strings passed to and from Premiere in API structures are always null-terminated C strings.

Function	Description
newPtr	Allocates a block of memory, returns a pointer to the new block. <code>char* newPtr (csSDK_uint32 size);</code>
newPtrClear	Equivalent to newPtr, but initializes the memory to 0. <code>char* newPtrClear (csSDK_uint32 size);</code>
setPtrSize	Resizes an allocated memory block. <code>void setPtrSize (PrMemoryPtr *ptr, csSDK_uint32 newsize);</code>
getPtrSize	Returns size in bytes of an allocated memory block. <code>csSDK_int32 getPtrSize (char *ptr);</code>
disposePtr	Frees an allocated memory block. <code>void disposePtr (char *ptr);</code>
newHandle	Allocates a block of memory, returning a handle to it. <code>char** newHandle (csSDK_uint32 size);</code>
newHandleClear	Equivalent to newHandle, but initializes the memory to 0. <code>char** newHandleClear (csSDK_uint32_ ↪size);</code>
setHandleSize	Resizes an allocated memory handle. <code>csSDK_int16 setHandleSize (char **PrMemoryHandle, csSDK_uint32 newsize);</code>
getHandleSize	Returns the size (in bytes) of an allocated block. <code>csSDK_int32 getHandleSize (char_ ↪**PrMemoryHandle);</code>
disposeHandle	Disposes of a previously allocated handle. <code>void disposeHandle (char_ ↪**PrMemoryHandle);</code>
lockHandle unlockHandle	These legacy functions are deprecated and should no longer be used.

30.1.2 Window Functions

Window management routines. Superseded by the *Window Suite*.

Function	Description
updateAllWindows	Updates all windows. Windows only, doesn't work on Mac OS. <code>void updateAllWindows (void);</code>
getMainWnd	Returns the main application HWND. <code>void getMainWnd (void);</code>

30.1.3 PPix Functions

Used to manipulate a PPix. Superseded by the *PPix Creator Suite* for PPix allocation and the *PPix Suite* for general PPix functions.

Function	Description
ppixGetPixels	Returns a pointer to the array of pixels contained in a PPix. <code>char* ppixGetPixels (PPixHand pix);</code>
ppixGetBounds	Returns the bounds of a PPix. <code>void ppixGetBounds (PPixHand pix; prRect *bounds);</code>
ppixGetRowbytes	Returns the rowbytes of a PPix so you can properly parse the pixels returned by ppixGetPixels. <code>int ppixGetRowbytes (PPixHand pix);</code>
ppixNew	Allocates and returns a handle to a new PPix, with specified bounds. Since this is an older call, the pixel format is hardcoded to BGRA_4444_8u. <code>PPixHandle ppixNew (prRect *bounds);</code>
ppixDispose	Frees a PPixHand. <code>void ppixDispose (PPixHand pix);</code>
ppixLockPixels ppixUnlockPixels	These legacy functions are deprecated and should no longer be used.
ppixGetPixelAspectRatio	Passes back the pixel aspect ratio of a PPixHand. Premiere populates the longs with the PAR numerator and denominator. <code>int ppixGetPixelAspectRatio (PPixHand pix, csSDK_uint32 *num, csSDK_uint32 *den);</code>
ppixGetAlphaBounds	Passes back the alpha bounds of a PPixHand. <code>void ppixGetAlphaBounds (PPixHand pix, prRect *alphaBounds);</code>

30.1.4 Utility Functions

Function	Description
getSerialNumber	<p>Passes back Premiere's serial number.</p> <pre>void getSerialNumber (char* buffer);</pre> <ul style="list-style-type: none"> buffer: must be at least 40 characters long.
getFileTimebase	<p>Passes back a file's timebase in a TDB_TimeRecord (allocated by the plug-in). If the file is already in the sequence, it is preferable to get a file's timebase using the <i>Video Segment Suite</i> to get the kVideoSegmentProperty_Media_StreamFrameRate.</p> <p>Note: Know your formats. Don't ask an audio only format for video, you may get unexpected results.</p> <pre>csSDK_int32 getFileTimebase (prFileSpec *filespec, csSDK_int32 audioOnly, TDB_TimeRecord *result);</pre> <ul style="list-style-type: none"> filespec: description of the file, use before getFileVideo audioOnly: if non-zero, return the audio timebase. If zero, return the video timebase. result: the returned timebase
getFileVideo	<p>Gets a frame of video (at a specified time) from a file. If the file is already in the sequence, it is preferable to get a file's video using the <i>Clip Render Suite</i>.</p> <pre>csSDK_int32 getFileVideo (prFileSpec *filespec, csSDK_int32 frame, PPixHand thePort, prRect *bounds, csSDK_int32 flags);</pre> <ul style="list-style-type: none"> filespec: the description of the file frame: the frame to retrieve thePort: where the frame will be delivered, allocate prior to calling bounds: the boundary of the port flags: unused
getFileVideoBounds	<p>Passes back the bounds of a file. If the file is already in the sequence, it is preferable to get a file's video bounds using the <i>Clip Render Suite</i>.</p> <pre>csSDK_int32 getFileVideoBounds (prFileSpec *filespec, prRect *bounds);</pre>
getSPBasicSuite	<p>This very important call returns the SweetPea suite that allows plug-ins to acquire and release all other <i>SweetPea Suites</i>.</p> <pre>SPBasicSuite* getSPBasicSuite();</pre>
getFileExtString	<p>Passes back the list of valid extensions/filter strings given a class of media (see file types constants below)</p> <pre>csSDK_int32 (*plugGetFileExtStringFunc)(csSDK_uint32 fileTypes, char *inBuffer,</pre>

30.1. piSuites

30.1.5 Timeline Functions

Function	Description
getClipVideo	<p>Superseded by the <i>Clip Render Suite</i>, which provides asynchronous import.</p> <p>Retrieves a frame from a clip in a segment tree returned from the <i>Video Segment Suite</i>.</p> <p>It can be used by to retrieve and store a still frame, such as a title, for playback.</p> <p>This call is expensive; use it carefully.</p> <pre>csSDK_int32 getClipVideo (csSDK_int32 frame, PPixHand thePort, prRect *bounds, csSDK_int32 flags, PrClipID clipData);</pre> <ul style="list-style-type: none"> • frame: the frame number you're requesting • thePort: allocate using the <i>PPix Creator Suite</i> before calling • bounds: the boundaries of video to return • flags: either <code>kGCVFlag_UseFilePixelAspectRatio</code> or <code>0</code>. Setting it to <code>kGCVFlag_UseFilePixelAspectRatio</code> will return a PPix stamped with the PAR of the file. Setting it to <code>0</code> will return a PPix adjusted to the PAR of the project and stamped accordingly. It scales, but does not stretch the PPix to fit the destination PPix that is passed in. So if the destination PPix is larger than the frame asked for, the frame will maintain its frame aspect ratio, letterboxing or pillarboxing the frame with transparent black. To import a frame at its native dimensions, use <code>getClipVideoBounds</code>, allocate the destination PPix using the dimensions returned, and pass the PPixHand and the dimensions into <code>getClipVideo</code>. If the frame size is not the same as the sequence size, the frame must be positioned in the composite by the plug-in. • clipData: the clipData handle found in <code>prtFileRec</code>
getWorkArea	<p>Passes back two longs with the start and end of the current work area (read-only).</p> <p>Set <code>timelineData</code> to the <code>timelineData</code> of the current sequence.</p> <pre>csSDK_int32 getWorkArea (PrTimelineID timelineData, csSDK_int32 *workAreaStart, csSDK_int32 *workAreaEnd);</pre>
getCurrentTimebase	<p>Passes back the current timebase of the timeline (scale + <code>sampleSize</code>).</p>
30.1. piSuites	<pre>void getCurrentTimebase(PrTimelineID timelineData, csSDK_uint32 *scale, csSDK_int32 *sampleSize);</pre> <ul style="list-style-type: none"> • timelineData: the <code>timelineData</code> of the cur-

30.2 Bottleneck Functions

The pointer to the legacy bottleneck functions is passed only to transitions and video filters.

These functions are not exposed for other plug-in types.

These functions are not aware of different pixel formats, and are intended only for 8-bit BGRA processing.

Sample usage:

```
((*theData)->bottleNecks->StretchBits) (*srcpix,  
                                         *dstpix,  
                                         &srbox,  
                                         &srbox,  
                                         0,  
                                         NULL);
```

Function	Description
StretchBits	<p>Stretches and copies an image, including the alpha channel.</p> <p>When the destination is larger than the source, it performs bilinear interpolation for smooth scaling.</p> <pre>void StretchBits (PPixHand srcPix, PPixHand dstPix, prRect srcRect, prRect dstRect, int mode, prRgn rgn);</pre> <p>StretchBits only works on 8-bit PPixs. srcRect is the area of the source PPix to copy; dstRect is used to scale the copy.</p> <p>Valid modes are cbBlend, cbInterp, and cbMaskHdl</p> <p>For cbBlend, the low byte of the mode defines the amount of blend between the source and destination in a range of 0-255.</p> <p>Example:</p> <p>To blend 30% of the source with the destination, use cbBlend (30*255/100)</p> <p>While much slower than cbBlend, cbInterp mode does bilinear interpolation when resizing a source PPix to a larger destination, resulting in a much smoother image. cbMaskHdl tells StretchBits that prRgn is a handle to a 1-bit deep buffer the same size as the source and destination PPixs, to be used as a mask.</p> <p>Pass 0 for no clipping. The prRgn parameter is only used on Windows.</p>
DistortPolygon	<p>Maps the source rectangle to a four-point polygon in the destination.</p> <pre>void DistortPolygon (PPixHand src, PPixHand dest, prRect *srcbox, prPoint *dstpts);</pre> <p>When scaling up, DistortPolygon uses bilinear interpolation; it uses pixel averaging when scaling down.</p>
MapPolygon	<p>Maps a four-point src polygon into a four-point polygon (dstpts).</p> <p>If the source polygon is a rectangle, it is equivalent to DistortPolygon.</p> <pre>void MapPolygon (PPixHand src, PPixHand dest, prPoint *srcpts, prPoint *dstpts);</pre>
DistortFixed	<p>Equivalent to DistortPolygon, using fixed-point coordinates.</p> <pre>void DistortFixed (PPixHand src, PPixHand dest, prRect *srcbox, LongPoint *dstpts);</pre>
30.2. Bottleneck Functions	109
FixedToFixed	<p>Equivalent to MapPolygon, using fixed-point coordinates.</p>

CHAPTER 31

Hardware

To integrate hardware with Premiere Pro, you may consider developing up to five types of plug-ins: importers, recorders, exporters, transmitters, and device controllers. Premiere Pro provides the user interface for the capture, timeline, monitor, and export panels; the plug-ins provide the functionality behind the interface.

Hardware Integration Components

32.1 Importers

Importers are used whenever frames of video or audio from a clip are needed. To give Premiere Pro the ability to read media that uses a new format or codec, develop an importer. See *Importers* for more information.

32.2 Recorders

Users may choose a recorder in Project > Project Settings > General > Capture Format. Recorders are used to grab frames from a hardware source and write them to a file, to be imported for editing. See *Recorders* for more information.

32.3 Exporters

Exporters are used whenever Premiere Pro renders preview files, or performs an export on a clip or sequence. To give Premiere Pro the ability to write media that uses a new format or codec, develop an exporter. The exporter used to render preview files in the timeline is set in Sequence > Sequence Settings > Preview File Format. The exporter used for exports is chosen when the user selects File > Export > Media > File Type. See *Exporters* for more information.

32.4 Transmitters

A transmitter handles the display of video on any external A/V hardware and secondary output. To give Premiere Pro the ability to play video out to hardware for preview and final playout, write a transmitter. See *Transmitters* for more information.

ClassID, Filetype and Subtype

All plug-in types that support media must identify unique classID, filetype, and subtype.

These are all four character codes, or ‘fourCCs’.

Identifier	Purpose
filetype	Identifies the plug-in’s associated file type(s). Plug-ins create lists of filetypes they support.
subtype	Differentiates between files of the same filetype. Identifies the codec or compression to be used.
classID	With the new editing mode system starting in CS4, the classID is far less important. It is used as part of the identification for exporters in the Editing Mode XML. And plug-ins may share information with most other plug-ins running in the same process using the <i>Class-Data Functions</i> .

ClassData Functions

All plug-in types that support media can use these callbacks to share information associated with their classID.

For example, these plug-ins can confirm their hardware is present and operational using the ClassData functions.

They all call `getClassData` during initialization. If `getClassData` returns 0, the module checks for and initialize the hardware.

It then calls `setClassData` to store information about the current context. Use handles, not pointers, for storing info.

```
typedef struct {
    SetClassDataFunc  setClassData;
    GetClassDataFunc  getClassData;
} ClassDataFuncs, *ClassDataFuncsPtr;
```

Function	Description
<code>setClassData</code>	<p>Writes class data, destroys previous data.</p> <pre>int setClassData (unsigned int theClass, void *info);</pre> <ul style="list-style-type: none"> • <code>theClass</code> - the class being set. Use a unique 4-byte code. • <code>info</code> - the class data to be set. It can be used as a pointer or a handle. <p>Note that all plug-ins that share the data must use the same data structure.</p>
<code>getClassData</code>	<p>Retrieves the class data for the given class.</p> <pre>int getClassData (unsigned int theClass);</pre> <ul style="list-style-type: none"> • <code>theClass</code> - the class for which to retrieve data.

Importers

Importers provide video, audio and/or closed captioning from the media source. This source can be a single file, a set of files, a communication link between another application, etc.

Standard importers appear as choices in the File > Import dialog, in the Files of type drop-down menu. Importers can support movies, still images, series of still images, and/or audio. If your importer provides enhanced support for a format already supported by another importer that ships with Premiere, set a high value in `imImportInfoRec.priority` to give your importer the first opportunity to handle the file.

Synthetic importers synthesize source material, rather than reading from disk. They appear in the File > New menu.

Custom importers are a special type of synthetic importer, implemented to better support titlers. Custom importers can create files on disk; synthetic importers don't. Custom importers either create new media or import existing media handled by the importer. After the file is created, the media is treated like a standard file by the host application. Additionally, the media can be modified by the importer when the user double-clicks on it in the Project Panel.

Importer Type	Reads from disk	Creates clips	Menu Location
Standard	Yes	No	File > Import
Synthetic	No	Yes	File > New
Custom	Yes	Yes	File > New File > Import

If you've never developed an importer before, you can skip *What's New*, and go directly to *Getting Started*.

36.1 What's New in Premiere Pro CC 2019 (13.0)

We've begun adding colorspace support to Premiere Pro's APIs, beginning with Importers.

36.2 What's New in Premiere Pro CC 2014

Importers can now choose the format they are rendering in, which allows importers to change pixel formats and quality based on criteria like enabled hardware and other Clip Source Settings, such as HDR. To handle the negotiation, implement *imSelectClipFrameDescriptor*.

imSourceVideoRec now includes a quality attribute. *PPix Cache Suite* is now at version 6, adding *AddFrameToCache-WithColorProfile2()* and

GetFrameFromCacheWithColorProfile2(), which are the same as the ones added in version 5 with the addition of a *PrRenderQuality* parameter.

imFileInfoRec8.highMemUsage is no longer supported.

36.3 What's New in Premiere Pro CC October 2013 release?

imInitiateAsyncClosedCaptionScanRec now provides extra fields for the importer to fill in the estimated duration of all the captions. This is useful for certain cases where the embedded captions contain many frames of empty data.

36.4 What's New in Premiere Pro CC?

Starting in CC, importers can support closed captioning that is embedded in the source media. Note that Premiere Pro can also import and export captions in a sidecar file (e.g. .mcc, .scc, or

.xml) alongside any media file, regardless of the media file format. This does not require any specific work on the importer side. The importer only needs to add support if it will support embedded closed captions.

Importers can now support audio beyond basic mono, stereo, and 5.1, without implementing multiple streams (existing importers do not need to be updated). The importer specifies a channel layout by implementing the new *imGetAudioChannelLayout* selector. Otherwise the channel layout will be assumed to be discrete.

The clip preferences are now passed with *imIndPixelFormatRec*, so that an importer can choose to return varying pixel formats depending on the Clip Source Settings.

36.5 What's New in Premiere Pro CS6.0.2?

This release adds more support for growing files by adding a new flag, *imFileInfoRec8.mayBeGrowing*.

36.6 What's New in Premiere Pro CS6?

Importers can now bring in stereoscopic footage as a single clip with separate left and right channels.

With some additional work, importers can now support growing files. The refresh rate for growing files is set by the user in Preferences > Media > Growing Files. The importer should get the refresh rate using the new call *GetGrowingFileRefreshInterval()* in the Importer File Manager Suite. Call *RefreshFileAsync()* to refresh the file.

A new selector, *imQueryInputFileList*, was added to support Collect Files in After Effects for file types that use more than a single file. In *imImportInfoRec*, a new member, *canProvideFileList*, specifies whether the importer can provide a list of all files for a copy operation. If the importer does not implement this selector, the host will assume the media just uses a single file at the original imported media path.

The Media Accelerator Suite is now at version 4. *FindPathInDatabaseAndValidateContentState* provides a new way to find existing media accelerators, making sure they are up-to-date.

Importers can now choose whether or not they want to provide peak audio data on a clip-by-clip basis.

The importer-wide setting still remains in *imImportInfoRec.canProvidePeakAudio*, but an importer can override the general setting by setting *imFileInfoRec8.canProvidePeakAudio* appropriately.

36.7 What's New in Premiere Pro CS5.5?

Importers can now support color management, when running in After Effects. The importer should set *imImageInfoRec.colorProfileSupport* to *imColorProfileSupport_Fixed*, and then describe the color profiles supported by the clip using the new *imGetIndColorProfile* selector. When importing the frame, specify the color profile in *imSourceVideoRec.selectedColorProfileName*. The *PPix Cache Suite* has been updated to differentiate between color profiles as well.

New `canProvidePeakAudio` flag to allow an importer to provide peak audio data by responding to `imGetPeakAudio`.

The new return value, `imRequiresProtectedContent`, allows an importer to be disabled if a library it depends on has not been activated.

36.8 What's New in Premiere Pro CS5?

When an importer's settings dialog is opened, the importer now has access to the resolution, pixel aspect ratio, time-base, and audio sample rate of the source clip, in `imGetPrefsRec`.

Custom importers can now use a new call in the Importer File Manager Suite,

`RefreshFileAsync()`, to be able to update a clip after it is modified in `imGetPrefs8`.

Two new selectors have been added. `imQueryDestinationPath` allows importers that trim or copy files to be able to change the destination path of the trimmed or copy file. `imQueryContentState` gives the host an alternate way of checking the state of a clip, for clips that have multiple source files. A new return value, `inFileNotAvailable` can be returned from `imQueryContentState` if the clip is no longer available because it is offline or has been deleted.

As a convenience, when a file is opened, an importer can tell Premiere Pro how much memory to reserve for the importer's usage, rather than calling `ReserveMemory` in the *Memory Manager Suite*. The importer should pass back this value in `imFileOpenRec8.outExtraMemoryUsage`.

Several new return values are available for more descriptive error reporting:

- `imBadHeader`,
- `imUnsupportedCompression`,
- `imFileOpenFailed`,
- `imFileHasNoImportableStreams`,
- `imFileReadFailed`,
- `imUnsupportedAudioFormat`,
- `imUnsupportedVideoBitDepth`,
- `imDecompressionError`, and
- `imInvalidPreferences`

36.9 What's New in Premiere Pro CS4?

For CS4 only, importers are loaded and called from a separate process. As a result of being in a separate process, (1) all importers must do their own file handling, (2) `privateData` is no

longer accessible from `imGetPrefs8`, and (3) the compressed frame selectors such as `imGetCompressedFrame` are no longer supported (this may now be achieved using custom pixel formats and a renderer plug-in).

To debug importers, attach to the `ImporterProcessServer` process. There is also a separate `Importer Process Plugin Loading.log`.

All legacy selectors have been removed, and are now longer supported. All structures used only in these legacy selectors have been removed as well.

There are built-in XMP metadata handlers for known filetypes. These handlers write and read metadata to and from the file, without going through the importer. *imSetTimeInfo8* is no longer called, since this is set by the XMP handler for that filetype.

All file-based importers (which does not include synthetics) are required to do their own file handling now, rather than having Premiere Pro open the files. The *imCallbackFuncs: OpenFileFunc* and *ReleaseFileFunc* are no longer supported.

Due to the out-of-process importing, *privateData* is not accessible during *imGetPrefs8*, and has been removed from *imGetPrefsRec*.

imGetFrameInfo, *imDisposeFrameInfo*, *imGetCompressedFrame*, and *imDisposeCompressedFrame* are no longer supported. Supporting a custom pixel format in an importer, a renderer, and an exporter is the new way to implement smart rendering, by passing custom compressed data from input to output.

New *imFrameNotFound* return code. Returned if an importer could not find the requested frame (typically used with async importers).

New in Premiere Pro 4.1, importer prefs are now part of *imSourceVideoRec*, passed to both *imGetSourceVideo* and the async import calls

New in Premiere Pro 4.1, there is a new *filepath* member in *imFileInfoRec8*. For clips that have audio in files separate from the video file, set the filename here, so that UMIDs can properly be generated for AAFs.

36.10 What's New in Premiere Pro CS3?

Importers can specify an initial poster frame for a clip in *imImageInfoRec*.

Importers can specify subtype names during the new *imGetSubTypeNames* selector. This selector is sent after each *imGetIndFormat*, which gives an importer the opportunity to enumerate all the fourCCs and display names (e.g. "Cinepak") of their known compression types for a specific filetype. The importer can return *imUnsupported*, or create an array of *imSubTypeDescriptionRec* records (pairs of fourCCs and codec name strings) for all the codecs/subtypes it knows about.

Importers that open their own files should specify how many files they keep open between *imOpenFile8* and *imQuietFile* using the new Importer File Manager Suite, if the number is not equal to one. Importers that don't open their own files, or importers that only open a single file should not use this suite. Premiere's File Manager now keeps track of the number of files held open by importers, and limits the number open at a time by closing the least recently used files when too many are open. On Windows, this helps memory usage, but on Mac OS this addresses a whole class of bugs that may occur when too many files are open.

Importers can also specify that certain files have very high memory usage, by setting *imFileInfoRec8.highMemUsage*. The number of files allowed to be open with this flag set to true is currently capped at 5.

Importers can now specify an arbitrary matte color for premultiplied alpha channels in *imImageInfoRec.matteColor*. Importers can state that they are uncertain about a clip's pixel aspect ratio, field type, or alpha info in *imImageInfoRec.interpretationUncertain*.

The *imInvalidHandleValue* is now -1 for Mac OS.

Importers can specify a transform matrix for frames by setting *imImageInfoRec.canTransform = kPrTrue*, and then during *imImportImage*, when *imImportImageRec.applyTransform* is non-zero, use *imImportImageRec.transform*, and *destClipRect* to calculate the transform - This code path is currently not called by Premiere Pro. After Effects uses this call to import Flash video.

New in Premiere Pro 3.1, the new capability flag, `imImportInfoRec.canSupplyMetadataClipName`, allows an importer to set the clip name from metadata, rather than the filename. The clip name should be set in `imFileInfoRec8.streamName`. This is useful for clips recorded by some new file-based cameras.

New in Premiere Pro 3.1, the new *imGetFileAttributes* selector allows an importer to provide the clip creation date in the new `imFileAttributesRec`.

37.1 The Basics of Import

For each clip, importers can tell Premiere the resolutions and pixel formats they can decode video frames to.

Premiere will request video frames as needed during scrubbing, playback, or export.

Audio will be requested right when the clip is imported, if audio conforming or peak file generation is necessary.

If audio conforming is not necessary, audio frames will be requested as needed during scrubbing, playback, or export.

Premiere requests audio in arrays of 32-bit float, uninterleaved format.

37.2 Try the Sample Importer Plug-ins

Choose which one of the three sample importers matches closest with your desired functionality.

Build that one, or if you are still not sure, build all three! Step through the code in your debugger to learn order of events.

Start your importer by modifying one of the SDK samples.

37.3 *imGetSourceVideo* VERSUS *imImportImage*

For synchronous import, there are two different selectors an importer can use to provide frames to the host.

Why? *imGetSourceVideo* is best for media that has specific resolutions.

Importers that support *imGetSourceVideo* can import frames at their native resolution or specify preferred resolutions, rather than having to scale the frames to an arbitrary size.

imImportImage is only useful for resolution-independent video, such as vector-based graphics.

Choose the one that fits the media your importer will support.

The SDK importer demonstrates *imGetSourceVideo* because resolution dependent video is much more common.

The synthetic importer sample demonstrates *imImportImage* because it generates video on-the-fly and doesn't have a preference as to video resolution.

`imImageInfoRec.supportsGetSourceVideo` should be set to true if the importer wants to support *imGetSourceVideo*.

37.4 Asynchronous Import

Importers can optionally support asynchronous calls to read frames for better performance. `imImageInfoRec.supportsAsyncIO` should be set to true if the importer wants to support asynchronous import. The importer can implement *imCreateAsyncImporter*, which tells the importer to create an asynchronous importer object using the data provided, and store it in `imAsyncImporterCreationRec`.

This async importer object must implement a separate entry point from a standard importer because it does not follow the same rules as a standard importer.

All calls to `AsyncImporterEntry` are reentrant, except for the *aiClose* selector. *aiClose* will only be called once, but may be called while other calls are still executing. No calls will be made after *aiClose* is called.

Here is an overview of the lifetime of an async importer:

1. The host calls *imOpenFile* and *imGetInfo* on the standard importer.
2. The host calls *imCreateAsyncImporter* on the standard importer. At this time, the standard importer creates the private data for the async importer. The async importer **MUST NOT** contain a link to the standard importer, as their lifetimes are now decoupled. The async importer, therefore, must contain copies of all relevant private data from the creator importer. The importer preferences are also guaranteed to not change during the lifetime of the async importer.
3. The host uses the async importer to perform i/o.
4. The host closes the async importer, forgetting about it. This will happen whenever the app loses focus, or when the async importer is no longer needed.

37.5 privateData

Don't use global variables to store data. Use `privateData` instead. Each clip can have its own `privateData`. The host application will automatically pass the correct `privateData` to the appropriate importer instance.

For `privateData`, create a handle to the custom structure you wish to store (during `imGetInfo8` or `imGetPrefs8`.) and save the handle to the `privateData` member of the structure passed in.

The importer is responsible for allocating and deallocating the memory for `privateData` using Premiere's memory functions.

Free the allocated `privateData` during *imCloseFile* or *imShutdown*, as appropriate.

37.6 Clip Source Settings

This data is unique to each clip instance, and can be used to store clip-wide data that affects the appearance of video and/or audio in the clip, usually user-modifiable.

For example, Clip Source Settings for a titler/graphics importer could contain all the data describing the text and shapes for that clip.

For a raw video clip, it could contain metadata that affects how the video is developed prior to import.

Starting in Premiere Pro CC 2014, importers can now choose the format they are rendering in, which allows importers to change pixel formats and quality based on criteria like enabled hardware and other Clip Source Settings, such as HDR.

To handle the negotiation, implement `imSelectClipFrameDescriptor`.

Clip Source Settings can be shown on file creation (for synthetic or custom importers) or when a clip is double-clicked.

Settings data should be stored in a disk-safe prefs structure, which is defined by the importer.

Premiere will allocate the prefs based on the `prefsLength` returned from the first call to `imGetPrefs8`.

Premiere will deallocate the prefs when it is no longer needed.

Once prefs has been allocated, the importer should show its setup dialog during all subsequent calls to `imGetPrefs8`, and store any setup dialog settings in prefs.

Like `privateData`, each clip has its own prefs, and the host application automatically passes the correct prefs to the appropriate importer instance.

If the user changes the Clip Source Settings in a way such that the frames should be reimported, then the importer should use the Importer File Manager Suite to call `RefreshFileAsync()` on the main file.

This is demonstrated in the SDK Custom Importer sample code.

37.6.1 Showing a Video Preview in the Settings Dialog

If a clip is placed in the timeline, and its settings dialog is opened by double-clicking in the timeline, then the import can get frames from the timeline of the settings dialog. Only the rendered frames on layers beneath the current clip or timeline location are available. Use the `getPreviewFrameEx` callback with the time given by `tdbTimeLocation` in `imGetPrefsRec`. `timelineData` is also valid during `imGetPrefs8`.

37.7 File Handling

Basic importers that bring in media from a single file can rely on the host to provide basic file handling. If a clip has child files or a custom file system, an importer can provide its own file handling. Set `canOpen`, `canSave`, and `canDelete` to true during `imInit`, and respond to `imOpenFile8`, `imQuietFile`, `imCloseFile`, `imSaveFile8`, `imDeleteFile8`.

Use the *Async File Reader Suite* for cross-platform file operations.

37.7.1 Quieting versus Closing a File

When the application loses focus, importers receive `imQuietFile` for each file it has been asked to open. Update any `PrivateData` and close the file. If the project is closed, `imCloseFile` is sent, telling the importer to free any `PrivateData`. If the importer didn't store any `PrivateData`, it will not receive `imCloseFile`.

37.7.2 Growing Files

When Premiere Pro attempts to refresh a growing file (after N seconds, as determined by the preferences value), it quiets the existing importer instance, and opens a new one pointing to the same file. In response, the Importer should report the current (new) duration and, once it's determined whether the file is still growing, set `imFileInfoRec.mayBeGrowing` appropriately.

37.7.3 Importing from Streaming Sources

For importing video from a streaming source, in order to pretend that the file is a local file or available on the network, create a placeholder file like `video_proxy.abc`.

Inside this file, include info that lets your importer know it is your own type, and the http path, like this:

“MyCompany ABC streaming format placeholder file <https://myurl.com/video.abc>”

Your importer would open the local `video_proxy.abc` file, check the header and find it is your own placeholder file, and then access the real contents at the http location included. To create the local

`.abc` files, you could use a custom importer that presents a OS dialog to choose the remote file, or a Premiere panel to do so. The Panel SDK can be found here:

<https://github.com/Adobe-CEP/Samples/tree/master/PProPanel>

If the filetype is an existing filetype supported by Premiere Pro, then set a high value in `imImportInfoRec.priority` to give your importer the first opportunity to handle the file.

For your filetype to be visible in the Proxy > Attach Proxies window, set `imIndFormatRec.flags |= xfiIsMovie` (this flag is labeled obsolete, but still needed for this case)

If your importer supports different fractional resolutions and decode qualities, the fractional resolutions can be enumerated in response to the selector `imGetPreferredFrameSize`, and the decode quality hint is sent on import requests to your importer (for example in `imSourceVideoRec.inQuality`).

37.8 Audio Conforming and Peak File Generation

When a clip that contains audio is imported into Premiere, one or two types of files may be generated:

First, a separate `.pek` file is always created. This contains peak audio samples for quick access when Premiere needs to draw the audio waveform, for example in the Source Monitor or Timeline panel.

Second, the audio may be conformed into a separate `.cfa` file. The conformed audio is in an interleaved 32-bit floating point format that matches the sequence audio sample rate, to maximize the speed at which Premiere can render audio effects and mix it without sacrificing quality.

Both of these files can be generated through sequential calls for audio using `imImportAudio7`. Audio conforming cannot be disabled through the Premiere menus or API. However, if an importer can provide random-access, uncompressed audio of the clip, Premiere will not conform the audio. All compressed audio data must be conformed.

Specifically, it is important to set these flags to avoid conforming: `imImportInfoRec.avoidAudioConform = kPrTrue`; `imFileInfoRec8.accessModes |= kRandomAccessImport`;

Starting in CS5.5, peak audio data can also optionally be provided by the importer, if the importer implements a faster way to read the peak audio data from the clip. By setting `imImportInfoRec.canProvidePeakAudio` to non-zero, the importer will be sent `imGetPeakAudio` whenever this data is requested. Starting in CS6, if an importer wants to provide peak audio data on a clip-by-clip basis, it can set `imFileInfoRec8.canProvidePeakData` accordingly.

The location of the .cfa and .pek files is determined by the user-specified path in Edit > Preferences > Media > Media Cache Files. When the project is closed, the files will be cleaned up. If the source clip is not saved in the project, the associated conformed audio files will be deleted.

Importers can get audio for scrubbing, playing and other timeline operations before conforming has completed, resulting in responsive audio feedback during conforming. To do this, they must support both random access and sequential access audio importing. The `kSeparateSequentialAudio` access mode should be set in `imFileInfoRec8.accessModes`.

37.9 Quality Levels

Importers can optionally support two different quality modes, with the `imDraftMode` flag that is used in `imImportImageRec`.

37.10 Closed Captioning

Starting in CC, importers can support closed captioning that is embedded in the source media. The built-in QuickTime importer provides this capability. Note that Premiere Pro can also import and export captions in a sidecar file (e.g. .mcc, .scc, or .xml) alongside any media file, regardless of the media file format. This does not require any specific work on the importer side.

To support embedded closed captioning, set `imImportInfoRec.canSupportClosedCaptions` to true. The importer should handle the following selectors: `imInitiateAsyncClosedCaptionScan`, `imGetNextClosedCaption`, and `imCompleteAsyncClosedCaptionScan`.

`imInitiateAsyncClosedCaptionScan` will be called for every file that is imported through an importer that sets `canSupportClosedCaptions` to true. The plug-in should at this point determine whether or not there is closed captioning data for this file. If not, then the plug-in should simply return `imNoCaptions`, and everything is done. If the plug-in didn't report an error for that call, then `imGetNextClosedCaption` will be called until the plug-in returns `imNoCaptions`. After which, `imCompleteAsyncClosedCaptionScan` will be called informing the importer that the host is done requesting captions.

Both `imGetNextClosedCaption` and `imCompleteAsyncClosedCaptionScan` may be called from a different thread from which `imInitiateAsyncClosedCaptionScan` was originally called. To help facilitate this, `outAsyncCaptionScanPrivateData` during `imInitiateAsyncClosedCaptionScan` can be allocated by the importer to be used for the upcoming calls, which can be deallocated

in `imCompleteAsyncClosedCaptionScan`.

37.11 N-Channel Audio

Starting in CC, for audio configurations beyond mono, stereo, and 5.1, an importer can specify a channel layout by implementing the new `imGetAudioChannelLayout` selector. Otherwise the channel layout will be assumed to be discrete. For support prior to CC, the importer needs to import them as multiple streams.

37.12 Multiple Streams

Importers can support multiple streams of audio and/or video. For most filetypes with a single video and a simple audio configuration (mono, stereo, or 5.1), only a single stream is necessary. Multiple streams can be useful for stereoscopic footage, layered file types (like Photoshop PSD files), or clips with complex audio configuration (such as 4 mono audio channels). The following describes the general case of multiple streams. For stereoscopic importers, please refer to the description further down.

An importer describes each stream one-by-one during iterative calls to *imGetInfo8*. In response to each call, the importer describes one stream, and returns *imIterateStreams*, until it reaches the last stream, and then it returns *imBadStreamIndex*. Set *imFileInfoRec8-*

>streamsAsComp = kPrFalse, so that the set of streams appear as a single clip within Premiere Pro.

In *imGetInfo8*, save *streamIdx* in *privateData*, to have access to it later. That way, when called in *imImportAudio7*, the importer will know which stream of audio to pass back.

See the sample code in the SDK File Importer, which can be turned on by uncommenting back in the *MULTI-STREAM_AUDIO_TESTING* define in *SDK_File_Import.h*.

37.12.1 Stereoscopic Video

First, an importer must advertise multiple video streams. During *imGetInfo8*, the host passes in the stream index in *imFileInfoRec8.streamIdx*. If the clip has a second stream, then on index 0 the importer should return *imIterateStreams* and it will be called again for the second stream. On the second one you return *imNoErr*, as before. The nice thing is that this works in Premiere Pro CS5.5 and earlier - when two video streams are present, on import, they will just appear as two different project items.

Prior to CS6, an importer would need to have a *prefs* structure and on *imGetInfo8* it would need to store the stream index in that structure. With CS6 this is a lot simpler. Now, in the *imSourceVideoRec* (passed in *imGetSourceVideo*, and part of the *aiFrameRequest* for async importers), the host application passes in the *currentStreamIndex* (in the value formerly

known as *unused1*). This makes it much easier to just check when providing a *PPix* and differentiate the two streams.

Now, obviously, it is not desirable to have two project items. In order to get them merged, an importer needs to label the streams (the logic here is pretty simple, if there are multiple labeled video streams, it will appear as a single project item, and all views on that item will show the first stream). For this there is a new selector: *imQueryStreamLabel*. The struct passed to the importer has its *privateData*, *prefs* data, and the stream index, and the label needs to be passed back in a *PrSDKString*. If you're not familiar with *PrSDKStringSuite*, it's fairly obvious how to use. In this case you'll be allocating a string, passing either UTF-8 data, or UTF-16 data.

In *PrSDKStreamLabel.h* we define two labels: *kPrSDK_StreamLabelStereoscopicLeft* and *kPrSDKStreamLabelStereoscopic_Right*. By convention, we expect Left to be stream 0 and Right to be stream 1. This is purely for consistency - if we have multiple stereo clips from multiple importers, we would want the thumbnails to all be consistent. If we stick to this convention, then the thumbnails will all be Left.

To integrate well with other third-parties, we strongly encourage using these labels for stereoscopic importers. However, the entire *StreamLabel* mechanism is intentionally left quite general. You could use whatever labels you want in your importers and effects, and when you request the video segments you can pass whatever label you would like. If you have other uses for this, we would be interested to hear about them, and we would welcome any bug reports.

37.13 Project Manager Support

The Project Manager in Premiere Pro allows users to archive projects, trim out unused media, or collect all source files to a single location. Importers are the most knowledgeable about the sources they work with. So Premiere Pro doesn't make any assumptions about the source media, but instead relies on the importers to handle the trimming and file size estimates. Only importers that specifically support trimming will trim and not copy when the Project Manager trims projects.

To support trimming, importers will want to set the `canCalcSizes` and `canTrim` flags during `imInit`, and support `imCalcSize8`, `imCheckTrim8`, and `imTrimFile8`.

If the each clip has more than one source file (such as audio channels in separate files), the importer should also set `canCopy` and support `imCopyFile`. Otherwise, the Project Manager will not know about the other source files.

External files, such as textures, logos, etc. that are used by an importer instance but do not appear as footage in Project panel, should be registered with Premiere Pro using the *File Registration Suite* during `imGetInfo8` or `imGetPrefs8`. Registered files will be taken into account when trimming or copying a project using the Project Manager.

37.14 Creating a Custom Importer

This variant of the importer API allows importers to dynamically create disk-based media while working within Premiere. A titler plug-in or similar should use this API. Once your clip is created, it is treated like any other standard file and will receive all standard missing file handling.

A Custom Importer **must** do the following:

- Set the following flags true in `imImportInfoRec`; `canCreate`, `canOpen`, `addToMenu`, `noFile`. This tells Premiere your plug-in will create a clip on disk at `imGetPrefs8` time.
- To determine when you need to create a new clip vs. modify an existing clip, check the `imFileAccessRec` filename. If it's identical to the plug-in display name (as set in the PiPL), create a new clip; otherwise modify the clip.
- If the user cancels from your dialog when creating a new clip, return `imCancel`.
- If the clip is modified, the importer needs to do a few things for Premiere to pick up the changes. Put your file access information in the supplied `imFileAccessRec`. Premiere will use this data to reference your clip from now on. Close the file handle after you create it. Return `imSetFile` after creating a file handle in `imGetPrefs8`, and call `RefreshFileAsync()` in the Importer

File Manager Suite to notify Premiere that the clip has been modified. Premiere will immediately call you to open the file and return a valid `imFileRef`. Respond to `imOpenFile8`, `imQuietFile`, `imCloseFile` at a minimum.

37.15 Real-Time Rolling and Crawling Titles

For RT rolls and crawls, a player and importer must be specially designed to work together. An importer can implement the appropriate functionality, but it is up to the player to take advantage of it.

Importers can make image data available for rolling and crawling titles, using `imImageInfoRec.isRollCrawl`. If the importer sets it to non-zero, this declares that the image is a title or other image that does roll/crawl, and that the importer supports the `imGetRollCrawlInfo` and `imRollCrawlRenderPage` selectors. `imGetRollCrawlInfo` is used to get info on the roll/crawl from the importer, and `imRollCrawlRenderPage` is used to get a rendered page of the roll/crawl.

37.16 Troubleshooting

37.16.1 How to Get First Crack at a File

To get the first opportunity to import a filetype also supported by a built-in importer (e.g. MPEG, AVI, QuickTime, etc), provide a different subtype and classID in order for your importer to be called for the types of files you support. `imImportInfoRec.priority` must be higher than any of the other importers for that filetype. Set this value to 100 or higher to override all built-in importers. Premiere Pro has more than one type of AVI importer and MPEG importer, which use this same prioritization mechanism. So your importer can override all of them and get the first shot at a filetype.

Just because you want to take over handling some files of a given filetype, it doesn't mean you have to handle all of them. To defer an unsupported subtype to a lower priority importer, return `imBadFile` during `imOpenFile8` or `imGetInfo8`. See the Media Abstraction chapter for more information on filetypes, subtypes, and classIDs.

37.16.2 Format repeated in menu?

To avoid having your importer appear multiple times in the file formats supported pop-up list, fill out the `formatName`, `formatShortName` and `platform` extension once and only once during your `imGetIndFormat`.

37.17 Resources

Importers must contain a IMPT resource. Premiere uses this to identify the plug-in as an importer. Also, depending on the type of importer (standard, synthetic, or custom), a PiPL may be required.

37.18 Entry Point

```
csSDK_int32 xImportEntry (  
    csSDK_int32 selector,  
    imStdParms *stdParms,  
    void *param1,  
    void *param2)
```

`selector` is the action Premiere wants the importer to perform. `stdParms` provides callbacks to obtain additional information from Premiere or to have Premiere perform tasks.

`param1` and `param2` vary with the selector; they may contain a specific value or a pointer to a structure. Return `imNoErr` if successful, or an appropriate return code.

37.19 Standard Parameters

A pointer to this structure is sent from the host application to the plug-in with every selector.

```
typedef struct {
    csSDK_int32      imInterfaceVer;
    imCallbackFuncs *funcs;
    piSuitesPtr      piSuites;
} imStdParms;
```

Member	Description
imInterfaceVer	Importer API version <ul style="list-style-type: none"> • Premiere Pro CC 2014 - IMPORTMOD_VERSION_15 • Premiere Pro CC - IMPORTMOD_VERSION_14 • Premiere Pro CS6.0.2 - IMPORTMOD_VERSION_13 • Premiere Pro CS6 - IMPORTMOD_VERSION_12 • Premiere Pro CS5.5 - IMPORTMOD_VERSION_11 • Premiere Pro CS5 - IMPORTMOD_VERSION_10 • Premiere Pro CS4 - IMPORTMOD_VERSION_9
funcs	Pointers to callbacks for importers
piSuites	Pointer to universal callback suites

37.20 Importer-Specific Callbacks

```
typedef struct {
    ClassDataFuncsPtr classFuncs;
    csSDK_int32      unused1;
    csSDK_int32      unused2;
} imCallbackFuncs;

typedef csSDK_int32 (*importProgressFunc) {
    csSDK_int32 partDone;
    csSDK_int32 totalToDo;
} void *trimCallbackID);
```

Function	Description
classFuncs	See ClassData functions.
importProgressFunc	Available in <code>imSaveFileRec</code> and <code>imTrimFileRec</code> during <code>imSaveFile8</code> and <code>imTrimFile8</code> . Callback function pointer for use during project archiving or trimming to call into Premiere and update the progress bar and check for cancellation. Either <code>imProgressAbort</code> or <code>imProgressContinue</code> will be returned. The <code>trimCallbackID</code> parameter is passed in the same structures.

Selector Table

Before implementing a handler for a certain selector, make sure that it is really necessary for your importer. Many selectors are optional, and only useful for certain special needs.

The Synth column indicates whether or not the selector is applicable to synthetic importers. Custom importers can respond to any of the selectors.

Selector	param1	param2	Synth
<i>imInit</i>	<i>imImportInfoRec*</i>	unused	Yes
<i>imShutdown</i>	unused	unused	Yes
<i>imGetIndFormat</i>	(int) index	<i>imIndFormatRec*</i>	Yes
<i>imGetSupports8</i>	unused	unused	Yes
<i>imGetSupports7</i>	unused	unused	Yes
<i>imGetInfo8</i>	<i>imFileAccessRec8*</i>	<i>imFileInfoRec8*</i>	Yes
<i>imCloseFile</i>	<i>imFileRef*</i>	(void*) PrivateData**	No
<i>imGetIndPixelFormat</i>	(int) index	<i>imIndPixelFormatRec*</i>	Yes
<i>imGetPreferredFrameSize</i>	<i>imPreferredFrameSizeRec*</i>	unused	Yes
<i>imSelectClipFrameDescriptor</i>	<i>imFileRef</i>	<i>imClipFrameDescriptorRec*</i>	Yes
<i>imGetSourceVideo</i>	<i>imFileRef</i>	<i>imSourceVideoRec*</i>	Yes
<i>imCreateAsyncImporter</i>	<i>imAsyncImporterCreationRec*</i>	unused	Yes
<i>imImportImage</i>	<i>imFileRef</i>	<i>imImportImageRec*</i>	Yes
<i>imImportAudio7</i>	<i>imFileRef</i>	<i>imImportAudioRec7*</i>	Yes
<i>imResetSequentialAudio</i>	<i>imFileRef</i>	<i>imImportAudioRec7*</i>	Yes
<i>imGetSequentialAudio</i>	<i>imFileRef</i>	<i>imImportAudioRec7*</i>	Yes
<i>imGetPrefs8</i>	<i>imFileAccessRec8*</i>	<i>imGetPrefsRec*</i>	Yes

The following selectors are optional, to provide custom file handling:

Selector	param1	param2	Synth
<i>imOpenFile8</i>	<i>imFileRef*</i>	<i>imFileOpenRec8*</i>	No
<i>imQuietFile</i>	<i>imFileRef*</i>	(void*) PrivateData**	No
<i>imSaveFile8</i>	<i>imSaveFileRec8*</i>	unused	No
<i>imDeleteFile</i>	<i>imDeleteFileRec*</i>	unused	No

The following selectors are optional, for better support copying and trimming files using the Project Manager:

Selector	param1	param2	Synth
<i>imCalcSize8</i>	<i>imCalcSizeRec*</i>	<i>imFileAccessRec8*</i>	No
<i>imCheckTrim8</i>	<i>imCheckTrimRec*</i>	<i>imFileAccessRec8*</i>	No
<i>imTrimFile8</i>	<i>imFileAccessRec8*</i>	<i>imTrimFileRec8*</i>	No
<i>imCopyFile</i>	<i>imCopyFileRec*</i>	unused	No
<i>imRetargetAccelerator</i>	<i>imAcceleratorRec*</i>	unused	No
<i>imQueryDestinationPath</i>	<i>imQueryDestinationPathRec*</i>	unused	No

The following selectors are used for embedded Closed Captioning support:

Selector	param1	param2	Synth
<i>imInitiateAsyncClosedCaptionScan</i>	<i>imFileRef</i>	<i>imInitiateAsyncClosedCaptionScanRec*</i>	No
<i>imGetNextClosedCaption</i>	<i>imFileRef</i>	<i>imGetNextClosedCaptionRec*</i>	No
<i>imCompleteAsyncClosedCaptionScan</i>	<i>imFileRef</i>	<i>imCompleteAsyncClosedCaptionScanRec*</i>	No

The following selectors are optional, useful for a subset of importers:

Selector	param1	param2	Synth
<i>imAnalysis</i>	<i>imFileRef</i>	<i>imAnalysisRec*</i>	Yes
<i>imDataRateAnalysis</i>	<i>imFileRef</i>	<i>imDataRateAnalysisRec*</i>	No
<i>imGetTimeInfo8</i>	<i>imFileRef</i>	<i>imTimeInfoRec8*</i>	No
<i>imSetTimeInfo8</i>	<i>imFileRef</i>	<i>imTimeInfoRec8*</i>	No
<i>imGetFileAttributes</i>	<i>imFileAttributesRec*</i>	unused	
<i>imGetMetaData</i>	<i>imFileRef</i>	<i>imMetaDataRec*</i>	No
<i>imSetMetaData</i>	<i>imFileRef</i>	<i>imMetaDataRec*</i>	No
<i>imGetRollCrawlInfo</i>	<i>imRollCrawlInfoRec*</i>	unused	Yes
<i>imRollCrawlRenderPage</i>	<i>rollCrawlRenderRec*</i>	unused	Yes
<i>imDeferredProcessing</i>	<i>imDeferredProcessingRec*</i>	unused	No
<i>imGetAudioChannelLayout</i>	<i>imFileRef</i>	<i>imGetAudioChannelLayoutRec*</i>	Yes
<i>imGetPeakAudio</i>	<i>imFileRef</i>	<i>imPeakAudioRec*</i>	Yes
<i>imQueryContentState</i>	<i>imQueryContentStateRec*</i>	unused	No
<i>imQueryStreamLabel</i>	<i>imQueryStreamLabelRec*</i>	unused	Yes
<i>imGetIndColorSpace</i>	ColorProfileRec	unused	Yes

Used only in After Effects:

Selector	param1	param2	Synth
<i>imGetSubTypeNames</i>	(csSDK_int32) fileType	<i>imSubTypeDescriptionRec*</i>	No
<i>imGetIndColorProfile</i>	(int) index	<i>imIndColorProfileRec*</i>	No
<i>imQueryInputFileList</i>	<i>imQueryInputFileListRec*</i>	unused	No

Selector Descriptions

This section provides a brief overview of each selector and highlights implementation issues. Additional implementation details are at the end of the chapter.

39.1 *imInit*

- param1 - *imImportInfoRec**
- param2 - unused

Sent during application startup.

Describe the importer's capabilities in the *imImportInfoRec*; all options are false by default.

The similarly named flags in *imIndFormatRec.flags* are obsolete and should not be used.

Set *hasSetup* to *kPrTrue* if the importer has a setup dialog, and *setupOnDbIClk* to *kPrTrue* to have that dialog display when the user double-clicks a file in the Project Panel; Premiere throws away any preview files generated for a file imported with this setting, even if no setup dialog is displayed.

Return *imIsCacheable* from *imInit* if a plug-in does not need to be called to initialize every time Premiere launched.

This will help reduce the time to launch the application.

39.1.1 Synthetic Importers

Setting *noFile* to *kPrTrue* indicates that the importer is synthetic.

Set *addToMenu* to *kPrTrue* to add the importer to the File > New menu.

39.1.2 Custom Importers

To create a custom importer, the following capabilities must be set.

See [Additional Details](#) for more info on custom importers.

```
noFile = kPrTrue;
hasSetup = kPrTrue;
canOpen = kPrTrue;
canCreate = kPrTrue;
addToMenu = imMenuNew;
```

39.2 imShutdown

- param1 - unused
- param2 - unused

Release all resources and perform any other necessary clean-up; sent when Premiere quits.

39.3 imGetIndFormat

- param1 - (int) index
- param2 - *imIndFormatRec**

Sent repeatedly, immediately after `imInit`; enumerate the filetypes the plug-in supports by populating the `imIndFormatRec`.

When finished, return `imBadFormatIndex`.

`imIndFormatRec.flags` are obsolete and should not be used.

39.3.1 Synthetic Importers

Because they have no file, synthetic importers only need to respond with the filetype established in their resource.

Create a separate plug-in for each synthetic file type.

39.4 imGetSupports8

- param1 - unused
- param2 - unused

A plug-in that supports the Premiere Pro 2.0 API (and beyond) must return `malSupports8`.

39.5 imGetSupports7

- param1 - unused
- param2 - unused

A plug-in that supports the Premiere Pro 1.0 API (and beyond) must return `malSupports7`.

39.6 imGetInfo8

- param1 - *imFileAccessRec8**
- param2 - *imFileInfoRec8**

Describe a clip, or a single stream of a clip if the clip has multiple streams.

Called when a specific file is instantiated.

Importer checks file validity, optionally allocates file instance data, and describes the properties of the file being imported by populating the `imFileInfoRec8`.

39.6.1 Synthetic Importers

You can create a still frame, a movie of a set duration, or an ‘infinite’ length movie, but cannot change the properties of a synthetic file once imported.

39.7 imCloseFile

- param1 - *imFileRef**
- param2 - `(void*) PrivateData**`

The specified file is no longer required; dispose of `privateData`.

Only sent if `privateData` was allocated during `imGetInfo8`.

39.8 imGetIndPixelFormat

- param1 - `(int) index`
- param2 - *imIndPixelFormatRec**

New optional selector called to enumerate the pixel formats available for a specific file.

This message will be sent repeatedly until all formats have been returned.

Pixel formats should be returned in the preferred order that the importer supports.

The Importer should return `imBadFormatIndex` after all formats have been enumerated.

`imUnsupported` should be returned on the first call if only *yawn* BGRA_4444_8u is supported.

What pixel formats should you support? Keep it real.

Just return the pixel format that most closely matches the data stored in your file.

If decoding to two or more formats can be done at about the same speed, declare support for both, but favor any pixel formats that are more compact, to save on memory and bandwidth.

39.9 `imGetPreferredFrameSize`

- param1 - *imFileRef*
- param2 - *imPreferredFrameSizeRec**

Provide the frame sizes preferred by the importer.

39.10 `imSelectClipFrameDescriptor`

- param1 - *imFileRef*
- param2 - *imClipFrameDescriptorRec**

New in Premiere Pro CC 2014.

If the importer can provide multiple formats, describe the format it will provide here.

This allows importers to change pixel formats based on criteria like enabled hardware and other source settings, such as HDR.

39.11 `imGetSourceVideo`

- param1 - *imFileRef*
- param2 - *imSourceVideoRec**

Get the host an unscaled frame of video.

This selector will be sent instead of `imImportImage` if `supportsGetSourceVideo` is set to true during `imGetInfo8`.

39.12 `imCreateAsyncImporter`

- param1 - *imAsyncImporterCreationRec**
- param2 - unused

Create an asynchronous importer object using the data provided, and store it in `imAsyncImporterCreationRec`.

39.13 imImportImage

- param1 - *imFileRef*
- param2 - *imImportImageRec**

Note: In most cases, `imGetSourceVideo` is the better choice.

Before going down this route, read the discussion [here](#).

Give the host a frame of video; populate the `imImportImageRec` buffer with pixel data, or (if you've set `canDraw` to true during `imInit`) draw to the screen in the provided window using platform-specific calls to do so.

You must scale the image data to fit the window; Premiere relies on the import module for properly scaled frames.

39.14 imImportAudio7

- param1 - *imFileRef*
- param2 - *imImportAudioRec7**

Replacement for `imImportAudio` that uses new `imAudioInfoRec7`.

Called to import audio using the new 32-bit float, uninterleaved audio format.

Fill `imImportAudioRec7->buffer` with the number of sample frames specified in `imImportAudioRec7->size`, starting from `imImportAudioRec7->position`.

Always return 32-bit float, uninterleaved samples as described in *Universals*.

You may use the calls in the *Audio Suite* to do some common conversions.

39.15 imGetPrefs8

- param1 - *imFileAccessRec8**
- param2 - *imGetPrefsRec**

Only sent if clip filetype uses a setup dialog within Premiere.

Premiere sends this selector when the user imports (or creates, if synthetic) a file of your type, or when double-clicking on an existing clip.

You must have set `hasSetup = true` during `imInit` to receive this selector.

Storing preferences is a two step process.

If the pointer in `imGetPrefsRec.prefs` is NULL, set `prefsLength` to the size of your preferences structure and return `imNoErr`.

Premiere sends `imGetPrefs` again; display your dialog, and pass the preferences pointer back in `imGetPrefsRec.prefs`.

Starting in Premiere Pro 1.5, the importer can get a frame from the timeline beneath the current clip or timeline location.

This is useful for titler plug-ins.

Use the `getPreviewFrameEx` callback with the time given by `TDB_TimeRecord` `tdbTimeLocation` in `imGetPrefsRec`.

39.15.1 Synthetic Importers

Synthetic importers can specify the displayable name by changing the `newfilename` member of `imFileAccessRec8`.

The first time this selector is sent, the `imGetPrefsRec.timelineData`, though non-null, contains garbage and should not be used.

It will only contain valid information once the user has put the clip into the timeline, and is double-clicking on it.

39.15.2 Custom Importers

Custom importers should return `imSetFile` after successfully creating a new file, storing the file access information in `imFileAccessRec8`.

Premiere will use this data to then ask the importer to open the file it created.

See Additional Details for more information on custom importers.

39.16 imOpenFile8

- param1 - *imFileRef**
- param2 - *imFileOpenRec8**

Open a file and give Premiere its handle.

This selector is sent only if `canOpen` was set to true during `imInit`; do so if you generate child files, you need to have read and write access during the Premiere session, or use a custom file system.

If you respond to this selector, you must also respond to `imQuietFile` and `imCloseFile`.

You may additionally need to respond to `imDeleteFile` and `imSaveFile`; see Additional Details.

Close any child files during `imCloseFile`.

Importers that open their own files should specify how many files they keep open between `imOpenFile8` and `imQuietFile` using the new Importer File Manager Suite, if the number is not equal to one.

Importers that don't open their own files, or importers that only open a single file should not use this suite.

Premiere's File Manager now keeps track of the number of files held open by importers, and limits the number open at a time by closing the least recently used files when too many are open.

On Windows, this helps memory usage, but on Mac OS this addresses a whole class of bugs that may occur when too many files are open.

39.17 imQuietFile

- param1 - *imFileRef**
- param2 - (void*) PrivateData**

Close the file in *imFileRef*, and release any hardware resources associated with it.

Respond to this selector only if *canOpen* was set to true during *imInit*.

A quieted file is closed (at the OS level), but associated *privateData* is maintained by Premiere.

Do not deallocate *privateData* in response to *imQuietFile*; do so during *imCloseFile*.

39.18 imSaveFile8

- param1 - *imSaveFileRec8**
- param2 - unused

Save the file specified in *imSaveFileRec8*.

Only sent if *canOpen* was set to true during *imInit*.

39.19 imDeleteFile

- param1 - *imDeleteFileRec**
- param2 - unused

Request this selector (by setting *canDelete* to true during *imInit*) only if you have child files or related files associated with your file.

If you have only a single file per clip you do not need to delete your own files.

Numbered still file importers do not need to respond to this selector; each file is handled individually.

39.20 imCalcSize8

- param1 - *imCalcSizeRec**
- param2 - *imFileAccessRec8**

Called before Premiere trims a clip, to get the disk size used by a clip.

This selector is called if the importer sets *imImportInfoRec.canCalcSizes* to non-zero.

An importer should support this call if it uses a tree of files represented as one top-level file to Premiere.

The importer should calculate either the trimmed or current size of the file and return it.

If the *trimIn* and *duration* are set to zero, Premiere is asking for the current size of the file.

If the `trimIn` and `duration` are valid values, Premiere is asking for the trimmed size.

39.21 `imCheckTrim8`

- `param1` - *`imCheckTrimRec*`*
- `param2` - *`imFileAccessRec8*`*

Called before Premiere trims a clip, to check if a clip can be trimmed at the specified boundaries.

`imCheckTrimRec` and `imFileAccessRec` are passed in.

The importer examines the proposed trimmed size of the file, and can change the requested in point and duration to new values if the file can only be trimmed at certain locations (for example, at GOP boundaries in MPEG files).

If the importer changes the in and duration, the new values must include all the material requested in the original trim request.

If an importer does not need to change the in and duration, it may either return `imUnsupported`, or `imNoErr` and simply not change the in/duration fields.

If the importer does not want the file trimmed (perhaps because the audio or video would be degraded if trimmed at all) it can return `imCantTrim` and the trim operation will fail and the file will be copied instead.

For a file with both audio and video, the selector will be sent several times.

The first time, `imCheckTrimRec` will have both `keepAudio` and `keepVideo` set to a non-zero value, and the trim boundaries will represent the entire file, and Premiere is asking if the file can be trimmed at all.

If the importer returns an error, it will not be called again.

The second time, `imCheckTrimRec` will have `keepAudio` set to a non-zero value, and the trim boundaries will represent the audio in and out points in the audio timebase, and Premiere is asking if the audio can be trimmed on these boundaries.

The third time, `imCheckTrimRec` will have `keepVideo` set to a non-zero value, and the trim boundaries will represent the video in and out points in the video timebase, and Premiere is asking if the video can be trimmed on these boundaries.

If either the video or audio boundaries extend further than the other boundaries, Premiere will trim the file at the furthest boundary.

39.22 `imTrimFile8`

- `param1` - *`imFileAccessRec8*`*
- `param2` - *`imTrimFileRec8*`*

Called when Premiere trims a clip.

`imFileAccessRec8` and `imTrimFileRec8` are passed in.

`imDiskFull` or `imDiskErr` may be returned if there is an error while trimming.

The current file, `inPoint`, and new duration are given and a destination file path.

If a file has video and audio, the trim time is in the video's timebase.

For audio only, the trim times are in the audio timebase.

A simple callback and `callbackID` is passed to `imTrimFile8` and `imSaveFile8` that allows plug-ins to query whether or not the user has cancelled the operation.

If non-zero (and they can be nil), the callback pointer should be called to check for cancellation.

The callback function will return `imProgressAbort` or `imProgressContinue`.

39.23 imCopyFile

- `param1` - *imCopyFileRec**
- `param2` - unused

`imCopyFile` is sent rather than `imSaveFile` to importers that have set `imImportInfoRec` can Copy when doing a copy operation using the Project Manager.

The importer should maintain data on the original file rather than the copy when it returns from the selector.

39.24 imRetargetAccelerator

- `param1` - *imAcceleratorRec**
- `param2` - unused

When the Project Manager copies media and its accelerator, this selector gives an opportunity to update the accelerator to refer to the copied media.

39.25 imQueryDestinationPath

- `param1` - *imQueryDestinationPathRec**
- `param2` - unused

New in CS5.

This allows the plug-in to modify the path that will be used for a trimmed clip, so the trimmed project is written with the correct path.

39.26 `imInitiateAsyncClosedCaptionScan`

- param1 - *imFileRef*
- param2 - *imInitiateAsyncClosedCaptionScanRec**

New in CC.

Gives a chance for the importer to allocate private data to be used during the scan for any closed captions embedded in the clip.

If there are no captions, return `imNoCaptions`.

39.27 `imGetNextClosedCaption`

- param1 - *imFileRef*
- param2 - *imGetNextClosedCaptionRec**

New in CC.

Called iteratively, each time asking the importer for a single closed caption embedded in the clip.

After returning the last caption, return `imNoCaptions` to signal the end of the scan.

39.28 `imCompleteAsyncClosedCaptionScan`

- param1 - *imFileRef*
- param2 - *imCompleteAsyncClosedCaptionScanRec**

New in CC.

Called to cleanup any temporary data used while getting closed captions embedded in the clip, and to see if the scan completed without error.

39.29 `imAnalysis`

- param1 - *imFileRef*
- param2 - *imAnalysisRec**

Provide information about the file in the `imAnalysisRec`; this is sent when the user views the Properties dialog for your file.

Premiere displays a dialog with information about the file, including the text you provide.

39.30 imDataRateAnalysis

- param1 - *imFileRef*
- param2 - *imDataRateAnalysisRec**

Give Premiere a data rate analysis of the file.

Sent when the user presses the Data Rate button in the Properties dialog, and is enabled only if `hasDataRate` was true in the `imFileInfoRec` returned during *imGetInfo*.

Premiere generates a data rate analysis graph from the data provided.

39.31 imGetTimeInfo8

- param1 - *imFileRef*
- param2 - *imTimeInfoRec8**

Read any embedded timecode data in the file.

Supercedes `imGetTimeInfo`.

39.32 imSetTimeInfo8

- param1 - *imFileRef*
- param2 - *imTimeInfoRec8**

Sent after a capture completes, where timecode was provided by the recorder or device controller.

Use this to write timecode data and timecode rate to your file.

See *Universals* for more information on time in Premiere.

Supercedes `imSetTimeInfo`.

Timecode rate is important for files that have timecode, but not an implicit frame rate, or where the sampling rate might differ from the timecode rate.

For example, audio captured from a tape uses the video's frame rate for timecode, although its sampling rate is not equal to the timecode rate.

Another example is capturing a still from tape, which could be stamped with timecode, yet not have a media frame rate.

39.33 imGetFileAttributes

- param1 - *imFileAttributesRec**

Optional.

Pass back the creation date stamp in *imFileAttributesRec*.

39.34 imGetMetaData

- param1 - *imFileRef*
- param2 - *imMetaDataRec**

Called to get a metadata chunk specified by a fourcc code.

If *imMetaDataRec->buffer* is null, the plug-in should set *buffersize* to the required buffer size and return *imNoErr*.

Premiere will then call again with the appropriate buffer already allocated.

39.35 imSetMetaData

- param1 - *imFileRef*
- param2 - *imMetaDataRec**

Called to add a metadata chunk specified by a fourcc code.

39.36 imDeferredProcessing

- param1 - *imDeferredProcessingRec**
- param2 - *unused*

Describe the current progress of the deferred processing on the clip.

39.37 imGetAudioChannelLayout

- param1 - *imFileRef*
- param2 - *imGetAudioChannelLayoutRec**

New in CC.

Called to get the audio channel layout in the file.

39.38 imGetPeakAudio

- param1 - *imFileRef*
- param2 - *imPeakAudioRec**

Optional selector allows Premiere to get audio peak data directly from the importer.

This is used for synthetic clips longer than five minutes.

Providing peak data can significantly improve waveform rendering performance when the user views audio waveform of the clip in the Source Monitor.

39.39 imQueryContentState

- param1 - *imQueryContentStateRec**
- param2 - unused

New in CS5.

This is used by streaming importers and folder based importers (P2, XDCAM, etc) that have multiple files that comprise the content.

If an importer doesn't support the selector then the host checks the last modification time for the main file.

39.40 imQueryStreamLabel

- param1 - *imQueryStreamLabelRec**
- param2 - unused

New in CS6.

This is used by stereoscopic importers to specify which stream IDs represent the left and right eyes.

39.41 imGetSubTypeNames

- param1 - (csSDK_int32) fileType
- param2 - *imSubTypeDescriptionRec**

New optional selector added for After Effects CS3.

As of CS4, this info still isn't used in Premiere Pro, but is used in After Effects to display the codec name in the Project Panel.

The importer should fill in the codec name for the specific subtype fourcc provided.

This selector will be sent repeatedly until names for all subtypes have been requested.

The *imSubTypeDescriptionRec* must be allocated by the importer, and will be released by the plug-in host.

39.42 imGetIndColorProfile

- param1 - (int) index
- param2 - *imIndColorProfileRec**

New in After Effects CS5.5; not used in Premiere Pro.

Only sent if the importer has set `imImageInfoRec.colorProfileSupport` to `imColorProfileSupport_Fixed`.

This selector is sent iteratively for the importer to provide a description of each color profile supported by the clip.

After all color profiles have been described, return a non-zero value.

39.43 imQueryInputFileList

- param1 - *imQueryInputFileListRec**
- param2 - unused

New for After Effects CS6; not used in Premiere Pro.

If an importer supports media that uses more than a single file (i.e.

a file structure with separate files for metadata, or separate video and audio files), this is the way the importer can specify all of its source files, in order to support Collect Files in After Effects.

In `imImportInfoRec`, a new member, `canProvideFileList`, specifies whether the importer can provide a list of all files for a copy operation.

If the importer does not implement this selector, the host will assume the media just uses a single file at the original imported media path.

CHAPTER 40

Return Codes

Return Code	Reason
<code>imNoErr</code>	Operation has completed without error.
<code>imTooWide</code>	File dimensions too large.
<code>imBadFile</code>	Bad file format. To defer an unsupported subtype to a lower priority importer, return this.
<code>imUnsupported</code>	Unsupported selector.
<code>imMemErr</code>	Memory error.
<code>imOtherErr</code>	Unknown error.
<code>imNoContent</code>	No audio or video.
<code>imBadRate</code>	Bad audio rate.
<code>imBadCompression</code>	Bad compression.
<code>imBadCodec</code>	Codec not found.
<code>imNotFlat</code>	Unflattened QuickTime movie.
<code>imBadSndComp</code>	Bad sound compression.
<code>imNoTimecode</code>	Timecode supported, but not found.
<code>imMissingComponent</code>	Missing component needed to open the file.
<code>imSaveErr</code>	Error saving file.
<code>imDeleteErr</code>	Error deleting file.
<code>imNotFoundErr</code>	The requested metadata chunk was not found.
<code>imSetFile</code>	Return this from <code>imGetPrefs8</code> only if you are a custom importer and you need Premiere to set the file.
<code>imIterateStreams</code>	Return from <code>imGetInfo8</code> to indicate that there are more streams to describe. Premiere will call <code>imGetInfo8</code> again.
<code>imBadStreamIndex</code>	Return from <code>imGetInfo8</code> after iterating through streams to indicate that there are no more streams.
<code>imCantTrim</code>	Return from <code>imCheckTrim</code> if the file cannot be trimmed by the importer.
<code>imDiskFull</code>	Return from <code>imTrimFile8</code> if there is not enough space to complete the trim operation.
<code>imDiskErr</code>	Return from <code>imTrimFile8</code> if there is a general disk or I/O error during the trim operation.
<code>imFileShareViolation</code>	Return from <code>imOpenFile8</code> if file cannot be opened due to another process having exclusive access.
<code>imIterateFrameSizes</code>	Return from <code>imGetPreferredFrameSize</code> , to be called again to describe more frame sizes.
<code>imMediaPending</code>	Return from <code>imGetSourceVideo</code> or <code>imCreateAsyncImporter</code> if the importer is still pending media.
<code>imDRMControlled</code>	Return from <code>imOpenFile8</code> if the file cannot be opened because it is under rights management.
<code>imActivationFailed</code>	Activation of a component failed (usually due to user cancellation). This is used by Premiere to indicate that a component failed to activate.

Table 1 – continued from previous page

Return Code	Reason
<code>imFrameNotFound</code>	New in CS4. Return if an importer could not find the requested frame (typically used with <code>imQueryContentState</code>)
<code>imBadHeader</code>	New in CS5. The file cannot be opened because of a header error
<code>imUnsupportedCompression</code>	New in CS5. The file has a compression type that the importer does not support
<code>imFileOpenFailed</code>	New in CS5. The importer was unable to open the file on disk
<code>imFileHasNoImportableStreams</code>	New in CS5. The file has no audio or video stream
<code>imFileReadFailed</code>	New in CS5. A read from an open file failed
<code>imUnsupportedAudioFormat</code>	New in CS5. The importer cannot import something in the audio format
<code>imUnsupportedVideoBitDepth</code>	New in CS5. The video bit depth of this file is unsupported by the importer
<code>imDecompressionError</code>	New in CS5. The importer hit an error decompressing the audio or video
<code>imInvalidPreferences</code>	New in CS5. Invalid prefs data was passed to the importer
<code>inFileNotAvailable</code>	New in CS5. Return from <code>imQueryContentState</code> if the file/stream is no longer available
<code>imRequiresProtectedContent</code>	New in CS5.5. Return from <code>imInit</code> if the importer depends on a library that has not been initialized
<code>imNoCaptions</code>	New in CC. Return from <code>imInitiateAsyncClosedCaptionScan</code> if the clip has no captions
<code>imCancel</code>	Return from <code>imGetPrefs8</code> if user cancels or the plug-in cannot open the file (custom/special)
<code>imBadFormatIndex</code>	Return this when given an out of range format index, and from <code>imGetIndFormat</code> when the format index is out of range
<code>imIsCacheable</code>	Return from <code>imInit</code> if a plug-in does not need to be called to initialize every time Premiere Pro opens a file

 Structure Descriptions

42.1 imAcceleratorRec

Selector: *imRetargetAccelerator*

Describes the path to the new media and new accelerator created when the Project Manager copies media and its accelerator.

```
typedef struct {
    const prUTF16Char *inOriginalPath;
    const prUTF16Char *inAcceleratorPath;
} imAcceleratorRec;
```

inOriginalPath	The unicode path and name of the copied media.
inAcceleratorPath	The unicode path and name of the copied accelerator.

42.2 imAnalysisRec

Selector: *imAnalysis*

Sending back analysis data is a two step process. First, set buffersize to the size of your character buffer and return imNoErr.

Premiere will immediately send imAnalysis again; populate the buffer with text. Previously-stored preferences and privateData are returned in this structure.

```
typedef struct {
    void *privatedata;
    void *prefs;
```

(continues on next page)

(continued from previous page)

```

csSDK_int32  buffersize;
char       *buffer;
csSDK_int32  *timecodeFormat;
} imAnalysisRec;

```

privatedata	Instance data from imGetInfo8 or imGetPrefs8.
prefs	Clip Source Settings data from imGetPrefs8 (setup dialog info).
buffersize	Set to the desired size and return imNoErr to Premiere, which will re-size and call the plug-in again with the imGetPrefs8 selector.
buffer	Text buffer. Terminate lines with line endings (CR and LF).
timecodeFormat	Preferred timecode format, sent by the host.

42.3 imAsyncImporterCreationRec

Selector: *imCreateAsyncImporter*

Create an asynchronous importer object using the data provided, and store it here.

```

typedef struct {
    void          *inPrivateData;
    void          *inPrefs;
    AsyncImporterEntry  outAsyncEntry;
    void          *outAsyncPrivateData;
}

```

inPrivateData	Instance data from imGetInfo8 or imGetPrefs8.
inPrefs	Clip Source Settings from imGetPrefs8 (setup dialog info).
outAsyncEntry	Provide the entry point for async selectors sent to the asynchronous importer object.
outAsyncPrivateData	PrivateData for the asynchronous importer object.

42.4 imAudioInfoRec7

Selector: *imGetInfo8* (member of *imFileInfoRec8*)

Audio data properties of the file (or of the data you will generate, if synthetic).

```

typedef struct {
    csSDK_int32      numChannels;
    float           sampleRate;
    PrAudioSampleType  sampleType;
}

```

numChannels	Number of audio channels in the audio stream. Either 1, 2, or 6.
sampleRate	Hertz.
sampleType	This is for informational use only, to disclose the format of the audio on disk, before it is converted to 32-bit float, uninterleaved, by the importer. The audio sample types are listed in <i>Universals</i> .

42.5 imCalcSizeRec

Selector: *imCalcSize8*

Asks the importer for an estimate of disk space used by the clip, given the provided trim boundaries.

```
typedef struct {
    void *privatedata;
    void *prefs;
    csSDK_int32 trimIn;
    csSDK_int32 duration;
    prInt64 sizeInBytes;
    csSDK_int32 scale;
    csSDK_int32 sampleSize;
} imCalcSizeRec;
```

privatedata	Instance data gathered from <i>imGetInfo8</i> or <i>imGetPrefs8</i> .
prefs	Clip Source Settings gathered from <i>imGetPrefs8</i> (setup dialog info).
trimIn	In point of the trimmed clip the importer should calculate the size for, in the timebase specified by scale over sampleSize.
duration	Duration of the trimmed clip the importer should calculate the size for. If 0, then the importer should calculate the size of the untrimmed clip.
sizeInBytes	Return the calculated size in bytes.
scale	The frame rate of the video clip, represented as scale over sampleSize.
sampleSize	

42.6 imCheckTrimRec

Selector: *imCheckTrim8*

Provides the requested trim boundaries to the importer, and allows adjusted trim boundaries to be passed back to Premiere.

```
typedef struct {
    void *privatedata;
    void *prefs;
    csSDK_int32 trimIn;
    csSDK_int32 duration;
    csSDK_int32 keepAudio;
```

(continues on next page)

(continued from previous page)

```

csSDK_int32  keepVideo;
csSDK_int32  newTrimIn;
csSDK_int32  newDuration;
csSDK_int32  scale;
csSDK_int32  sampleSize;
} imCheckTrimRec;

```

privatedata	Instance data gathered from <code>imGetInfo8</code> or <code>imGetPrefs8</code> .
prefs	Clip Source Settings gathered from <code>imGetPrefs8</code> (setup dialog info).
trimIn	Requested in point of the trimmed clip, in the timebase specified by <code>scale</code> over <code>sampleSize</code> .
duration	Requested duration. If 0, then the request is to leave the clip untrimmed, and at the current duration
keepAudio	If non-zero, the request is to keep the audio in the trimmed result.
keepVideo	If non-zero, the request is to keep the video in the trimmed result.
newTrimIn	Return the acceptable in point of the trimmed clip. It must be at or before the requested in point.
newDuration	Return the acceptable duration. <code>newTrimIn + newDuration</code> must be at or after the <code>trimIn + duration</code> .
scale	The frame rate of the video clip, represented as <code>scale</code> over <code>sampleSize</code> .
sampleSize	

42.7 imClipFrameDescriptorRec

Selector: *imSelectClipFrameDescriptor*

Based on the request in `inDesiredClipFrameDescriptor` and the importer's Source Settings, modify `outBestFrameDescriptor` as needed to describe what format the importer will provide.

```

typedef struct {
    void*          inPrivateData;
    void*          inPrefs;
    ClipFrameDescriptor  inDesiredClipFrameDescriptor;
    ClipFrameDescriptor  outBestFrameDescriptor;
} imClipFrameDescriptorRec;

```

inPrivatedata	Instance data gathered from <code>imGetInfo8</code> or <code>imGetPrefs8</code> .
inPrefs	Clip Source Settings gathered from <code>imGetPrefs8</code> (setup dialog info).
inDesiredClipFrameDescriptor	Requested frame properties, as described by the host. The <code>ClipFrameDescriptor</code> struct is defined in <code>PrSDKImporterShared.h</code> .
outBestFrameDescriptor	Frame properties to be produced, filled in with initial guesses

42.8 imCompleteAsyncClosedCaptionScanRec

Selector: *imCompleteAsyncClosedCaptionScan*

This structure is passed to provide one last chance to cleanup and dispose of `inAsyncCaptionScanPrivateData`, and to mark whether the closed caption scan completed without error.

```
typedef struct {
    void*      inPrivateData;
    const void* inPrefs;
    void*      inAsyncCaptionScanPrivateData;
    prBool     inScanCompletedWithoutError;
} imCompleteAsyncClosedCaptionScanRec;
```

<code>inPrivatedata</code>	Instance data gathered from <code>imGetInfo8</code> or <code>imGetPrefs8</code> .
<code>inPrefs</code>	Clip Source Settings gathered from <code>imGetPrefs8</code> (setup dialog info).
<code>inAsyncCaptionScanPrivateData</code>	Cleanup and dispose of any data here that was allocated in <code>imInitiateAsyncClosedCaptionScan</code> or <code>imGetNextClosedCaption</code> . This data should not be accessed after returning from this call.
<code>inScanCompletedWithoutError</code>	Set to true if no error.

42.9 imIndColorProfileRec

Selector: *imGetIndColorProfile*

Deprecated as of 13.0. Describes a color profile supported by a clip.

The first time `imGetIndColorProfile` is sent, `inDestinationBuffer` will be NULL, and `ioBufferSize` will be 0.

Set `ioBufferSize` to the required size for the buffer, and the host will allocate the memory and call the importer again, with a valid `inDestinationBuffer`, and `ioBufferSize` set to the value just provided by the importer.

```
typedef struct {
    void*      *inPrivateData;
    csSDK_int32 ioBufferSize;
    void*      *inDestinationBuffer;
    PrSDKString outName;
} imIndColorProfileRec;
```

42.10 imCopyFileRec

Selector: *imCopyFile*

Describes how to copy a clip. Also provides a callback to update the progress bar and check if the user has cancelled.

```
typedef struct {
    void*      *inPrivateData;
    csSDK_int32 *inPrefs;
    const prUTF16Char *inSourcePath;
    const prUTF16Char *inDestPath;
    importProgressFunc inProgressCallback;
```

(continues on next page)

(continued from previous page)

```

void *inProgressCallbackID;
} imTrimFileRec;

```

inPrivateData	Instance data gathered during <code>imGetInfo8</code> or <code>imGetPrefs8</code> .
inPrefs	Clip Source Settings gathered during <code>imGetPrefs8</code> (setup dialog).
inSourcePath	Full unicode path of the source file.
inDestPath	Full unicode path of the destination file.
inProgressCallbackID	ImportProgressFunc callback to call repeatedly to provide progress and to check for cancel by user. May be a NULL pointer, so make sure the function pointer is valid before calling.
inProgressCallbackID	Pass to ProgressCallback.

42.11 imDataRateAnalysisRec

Selector: *imDataRateAnalysis*

Specify the desired buffersize, return to Premiere with `imNoErr`; upon the next call fill buffer with `imDataSamples`, and specify a base data rate for audio (if any).

This structure is used like `imAnalysisRec`.

```

typedef struct {
void *privatedata;
void *prefs;
csSDK_int32 buffersize;
char *buffer;
csSDK_int32 baserate;
} imDataRateAnalysisRec;

```

privatedata	Instance data gathered from <code>imGetInfo8</code> or <code>imGetPrefs8</code> .
prefs	Clip Source Settings gathered from <code>imGetPrefs8</code> (setup dialog info).
buffersize	The size of the buffer you request from Premiere prior to passing data back data in buffer.
buffer	Pointer to the analysis buffer to be filled with <code>imDataSamples</code> (see structure below).
baserate	Audio data rate (bytes per second) of the file.

```

typedef struct {
csSDK_uint32 samplerdur;
csSDK_uint32 samplesize;
} imDataSample;

```

samplerdur	Duration of one sample in video timebase, in samplesize increments; set the high bit if this is a keyframe.
samplesize	Size of this sample in bytes.

42.12 imDeferredProcessingRec

Selector: *imDeferredProcessing*

Describes the current progress of the deferred processing on the clip referred to by inPrivateData.

```
typedef struct {
    void *inPrivateData;
    float outProgress;
    char outInvalidateFile;
    char outCallAgain;
} imDeferredProcessingRec;
```

inPrivateData	Instance data gathered from imGetInfo8 or imGetPrefs8.
outProgress	Set this to the current progress, from 0.0 to 1.0.
outInvalidateFile	The importer has updated information about the file.
outCallAgain	Set this to true to request that the importer be called again immediately.

42.13 imDeleteFileRec

Selector: *imDeleteFile*

Describes the file to be deleted.

```
typedef struct {
    csSDK_int32 filetype;
    const prUTF16Char deleteFile;
} imDeleteFileRec;
```

filetype	The file's unique four character code, defined in the IMPT resource
deleteFile	Specifies the name (and path) of the file to be deleted.

42.14 imFileAccessRec8

Selectors: *imGetInfo8* and *imGetPrefs8*

Describes the file being imported.

```
typedef struct {
    void *importID;
    csSDK_int32 filetype;
    const prUTF16Char *filepath;
    imFileRef fileref;
    PrMemoryPtr newfilename;
} imFileAccessRec;
```

importID	Unique ID provided by Premiere. Do not modify!
filetype	The file's unique four character code, defined in the IMPT resource.
filepath	The unicode file path and name.
fileRef	A Windows HANDLE. Premiere does not overload this value by using it internally, although setting it to the constant kBadFileRef may cause Premiere to think the file is closed. This value is always valid.
newfile	If the file is synthetic, the importer can specify the displayable name here as a prUTF16Char string during imGetPrefs8.

42.15 imFileAttributesRec

Selector: *imGetFileAttributes*

New in Premiere Pro 3.1. Provide the clip creation date.

```
typedef struct {
    prDateStamp    creationDateStamp;
    csSDK_int32    reserved[40];
} imFileAttributesRec;
```

creationDateStamp	Structure to store when the clip was created
-------------------	--

42.16 imFileInfoRec8

Selector: *imGetInfo8*

Describes the clip, or the stream with the ID streamIdx. Set the clip or stream attributes from the file header or data source. Create and store any privateData.

When a synthetic clip is created, and the user provides the desired resolution, frame rate, pixel aspect ratio, and audio sample rate in the New Synthetic dialog, these values will be pre-initialized by Premiere.

If importing stereoscopic footage, import the left-eye video channel for streamID 0, and the right-eye video channel for streamID 1.

```
typedef struct {
    char            hasVideo;
    char            hasAudio;
    imImageInfoRec vidInfo;
    csSDK_int32     vidScale;
    csSDK_int32     vidSampleSize;
    csSDK_int32     vidDuration;
    imAudioInfoRec7 audInfo;
    PrAudioSample   audDuration;
    csSDK_int32     accessModes;
    void            *privatedata;
    void            *prefs;
```

(continues on next page)

(continued from previous page)

```
char          hasDataRate;
csSDK_int32   streamIdx;
char          streamsAsComp;
prUTF16Char   streamName[256];
csSDK_int32   sessionPluginID;
char          alwaysUnquiet;
char          unused;
prUTF16Char   filePath[2048];
char          canProvidePeakData;
char          maybeGrowing;
} imFileInfoRec8;
```

hasVideo	If non-zero, the file contains video.
hasAudio	If non-zero, the file contains audio.
vidInfo	If there is video in the file, fill out the <code>imImageInfoRec</code> structure (e.g. height, width, alpha info, etc.).
vidScale	The frame rate of the video, represented as scale over <code>sampleSize</code> .
vidSampleSize	
vidDuration	The total number of frames of video, in the video time-base.
audInfo	If there is audio in the file, fill out the <code>imAudioInfoRec7</code> structure.
audDuration	The total number of audio sample frames.
accessModes	<p>The access mode of this file. Use one of the following constants:</p> <ul style="list-style-type: none"> <code>kRandomAccessImport</code> - This file can be read by random access (default) <code>kSequentialAudioOnly</code> - When accessing audio, only sequential reads allowed (for variable bit rate files) <code>kSequentialVideoOnly</code> - When accessing video, only sequential reads allowed <code>kSequentialOnly</code> - Both sequential audio and video <code>kSeparateSequentialAudio</code> - Both random access and sequential access. <p>This setting allows audio to be retrieved for scrubbing or playback even during audio conforming.</p>
privatedata	Private instance data. Allocate a handle using Premiere's memory functions and store it here. Premiere will return the handle with subsequent selectors.
prefs	Clip Source Settings data gathered from <code>imGetPrefs8</code> (setup dialog info). When a synthetic clip is created using File > New, <code>imGetPrefs8</code> is sent before <code>imGetInfo8</code> so this settings structure will already be valid.
hasDataRate	If set, the importer can read or generate data rate information for this file and will be sent <code>imDataRateAnalysis</code> .
streamIdx	The Premiere-specified stream index number. Only useful if clip uses multiple streams.
streamsAsComp	If multiple streams and this is stream zero, indicate whether to import as a composition or multiple clips.
streamName	<p>Optional. The unicode name of this stream if there are multiple streams.</p> <p>New in Premiere Pro 3.1, an importer may use this to set the clip name based on metadata rather than the file-name.</p> <p>The importer should set <code>imImportInfoRec.canSupplyMetadataClipName</code> to <code>true</code>, and fill out the name here.</p>
sessionPluginID	<p>This ID should be used in the <i>File Registration Suite</i> for registering external files (such as textures, logos, etc) that are used by an importer instance but do not appear as footage in the Project Window.</p> <p>Registered files will be taken into account when trimming or copying a project using the Project Manager.</p> <p>The <code>sessionPluginID</code> is valid only for the call that it is passed on.</p>
166	
alwaysUnquiet	Set to non-zero to tell Premiere if the clip should always

42.17 imFileOpenRec8

Selector: *imOpenFile8*

The file Premiere wants the importer to open.

```
typedef struct {
    imFileAccessRec8  fileinfo;
    void              *privatedata;
    csSDK_int32       reserved;
    PrFileOpenAccess  inReadWrite;
    csSDK_int32       inImporterID;
    csSDK_size_t      outExtraMemoryUsage;
    csSDK_int32       inStreamIdx;
} imFileOpenRec8;
```

fileinfo	imFileAccessRec8 describing the incoming file.
privatedata	Instance data gathered from <i>imGetInfo8</i> or <i>imGetPrefs8</i> .
reserved	Do not use.
inReadWrite	The file should be opened with the access mode specified: Either <code>kPrOpenFileAccess_ReadOnly</code> or <code>kPrOpenFileAccess_ReadWrite</code>
inImporterID	Can be used as the ID for calls in the <i>PPix Cache Suite</i> .
outExtraMemoryUsage	New in CS5. If the importer uses memory just by being open, which cannot otherwise be registered in the cache, put the size in bytes in this field.
inStreamIdx	New in CS6. If the clip has multiple streams (for stereoscopic video or otherwise), this ID differentiates between them.

42.18 imFileRef

Selectors:

- *imAnalysis*,
- *imDataRateAnalysis*,
- *imOpenFile8*,
- *imQuietFile*,
- *imCloseFile*,
- *imGetTimeInfo8*,
- *imSetTimeInfo8*,
- *imImportImage*,
- *imImportAudio7*

A file HANDLE on Windows, or a void* on MacOS.

imFileRef is also a member of imFileAccessRec.

Use OS-specific functions, rather than ANSI file functions, when manipulating imFileRef.

42.19 imFrameFormat

Selector: *imGetSourceVideo* (member of *imSourceVideoRec*)

Describes the frame dimensions and pixel format.

```
typedef struct {
    csSDK_int32    inFrameWidth;
    csSDK_int32    inFrameHeight;
    PrPixelFormat  inPixelFormat;
} imFrameFormat;
```

inFrameWidth	The frame dimensions requested.
inFrameHeight	
inPixelFormat	The pixel format of the frame requested.

42.20 imGetAudioChannelLayoutRec

Selector: *imGetAudioChannelLayout*

The importer should label each audio channel in the clip being imported.

If no labels are specified, the channel layout will be assumed to be discrete.

```
typedef struct {
    void*          inPrivateData;
    PrAudioChannelLabel  outChannelLabels[kMaxAudioChannelCount];
} imGetAudioChannelLayoutRec;
```

inPrivatedata	Instance data gathered from <i>imGetInfo8</i> or <i>imGetPrefs8</i> .
outChannelLabel	A valid audio channel label should be assigned for each channel in the clip. Labels are defined in the <i>Audio Suite</i> .

42.21 imGetNextClosedCaptionRec

Selector: *imGetNextClosedCaption*

This structure provides private data allocated in *imInitiateAsyncClosedCaptionScan*, and should be filled out to pass back a closed caption, it's time, format, size, and overall progress in the closed caption scan.

```
typedef struct {
    void*          inPrivateData;
    const void*   inPrefs;
    void*         inAsyncCaptionScanPrivateData;
    float         outProgress;
    csSDK_int64   outScale;
    csSDK_int64   outSampleSize;
    csSDK_int64   outPosition;
    PrClosedCaptionFormat outClosedCaptionFormat;
    PrMemoryPtr   outCaptionData;
    prUTF8Char    outTTMLData[kTTMLBufferSize];
    csSDK_size_t  ioCaptionDataSize;
} imGetNextClosedCaptionRec;
```

<code>inPrivatedata</code>	Instance data gathered from <code>imGetInfo8</code> or <code>imGetPrefs8</code> .
<code>inPrefs</code>	Clip Source Settings gathered from <code>imGetPrefs8</code> (setup dialog info).
<code>inAsyncCaptionScanPrivateData</code>	This provides any private data that was allocated in <code>imInitiateAsyncClosedCaptionScan</code> .
<code>outProgress</code>	Update this value to denote the current progress iterating through all the captions. Valid values are between 0.0 and 1.0.
<code>outScale</code>	The timebase of <code>outPosition</code> , represented as scale over <code>sampleSize</code> .
<code>outSampleSize</code>	
<code>outPosition</code>	The position of the closed caption.
<code>outClosedCaptionFormat</code>	<p>The format of the closed captions. One of the following:</p> <ul style="list-style-type: none"> <code>kPrClosedCaptionFormat_Undefined</code> <code>kPrClosedCaptionFormat_CEA608</code> - CEA-608 byte stream <code>kPrClosedCaptionFormat_CEA708</code> - CEA-708 byte stream (may contain 608 data wrapped in 708) <code>kPrClosedCaptionFormat_TTML</code> - W3C TTML string that conforms to the W3C Timed Text Markup Language (TTML) 1.0: http://www.w3.org/TR/ttaf1-dfxp or optionally conforming to SMPTE ST 2052-1:2010: http://store.smpete.org/, or optionally conforming to EBU Tech 3350 http://tech.ebu.ch/webdav/site/tech/shared/tech/. <p>If the TTML string contains tunneled data (e.g. CEA-608 data), then it is preferred that the plug-in provide that through the appropriate byte stream format (e.g. <code>kPrClosedCaptionFormat_CEA608</code>).</p>
<code>outCaptionData</code>	Memory location to where the plug-in should write the closed caption bytes, if providing CEA-608 or CEA-708.
<code>outTTMLData</code>	<p>UTF-8 String of valid W3C TTML data.</p> <p>The entire string may be split into substrings (e.g. line by line) and the host will concatenate and decode them (only used when <code>outCaptionData</code> is <code>kPrClosedCaptionFormat_TTML</code>).</p>
<code>ioCaptionDataSize</code>	Size of <code>outCaptionData</code> buffer (in bytes) allocated from the host. The importer should set this variable to the actual number of bytes that were written to <code>outCaptionData</code> , or the length of the string (characters, not bytes) pointed by <code>outTTMLData</code> .

42.22 imGetPrefsRec

Selector: `imGetPrefs8`

Contains settings/prefs data gathered from (or defaults to populate) a setup dialog.

If you are creating media, you can may generate a video preview that includes the background frame from the timeline.

```
typedef struct {
    char *prefs;
    csSDK_int32 prefsLength;
    char firstTime;
    PrTimelineID timelineData;
    void *privatedata;
    TDB_TimeRecord tdbTimelineLocation;
    csSDK_int32 sessionPluginID;
    csSDK_int32 imageWidth;
    csSDK_int32 imageHeight;
    csSDK_uint32 pixelAspectNum;
    csSDK_uint32 pixelAspectDen;
    csSDK_int32 vidScale;
    csSDK_int32 vidSampleSize;
    float sampleRate;
} imGetPrefsRec;
```

prefs	A pointer to a private structure (which you allocate) for storing Clip Source Settings.
prefsLength	Point to storing anything in the prefs member, set prefsLength to the size of your structure and return imNoErr; Premiere will re-size and call the plug-in again with imGetPrefs8.
firstTime	If set, imGetPrefs8 is being sent for the first time. Instead, check to see if prefs has been allocated. If not, imGetPrefs8 is being sent for the first time. Set up default values for the prefsLength buffer and present any setup dialog.
timelineData	Can be passed to getPreviewFrameEx callback along with tdbTimelineLocation to get a frame from the timeline beneath the current clip or timeline location. This is useful for titler plug-ins.
privatedata	Private instance data. Allocate a handle using Premiere's memory functions and store it here, if not already allocated in imGetInfo8. Premiere will return the handle with subsequent selectors.
tdbTimelineLocation	Can be passed to getPreviewFrameEx callback along with timelineData to get a frame from the timeline beneath the current clip or timeline location. This is useful for titler plug-ins.
sessionPluginID	This ID should be used in the <i>File Registration Suite</i> for registering external files (such as textures, logos, etc) that are used by a importer instance but do not appear as footage in the Project Window. Registered files will be taken into account when trimming or copying a project using the Project Manager. The sessionPluginID is valid only for the call that it is passed on.
imageWidth	New in CS5. The native resolution of the video.
imageHeight	
pixelAspectNum	New in CS5. The pixel aspect ratio of the video.
pixelAspectDen	
vidScale	New in CS5. The frame rate of the video, represented as scale over sampleSize.
vidSampleSize	
sampleRate	New in CS5. Audio sample rate.

42.23 imImageInfoRec

Selector: *imGetInfo8* (member of *imFileInfoRec8*)

Describes the video to be imported.

```

typedef struct {
    csSDK_int32    imageWidth;
    csSDK_int32    imageHeight;
    csSDK_uint16   pixelAspectV1;
    csSDK_uint16   depth;
    csSDK_int32    subType;
    char           fieldType;
    char           fieldsStacked;
    char           reserved_1;
    char           reserved_2;
    char           alphaType;
    matteColRec    matteColor;
    char           alphaInverted;
    char           isVectors;
    char           drawsExternal;
    char           canForceInternalDraw;
    char           dontObscure;
    char           isStill;
    char           noDuration;
    char           reserved_3;
    csSDK_uint32   pixelAspectNum;
    csSDK_uint32   pixelAspectDen;
    char           isRollCrawl;
    char           reservedc[3];
    csSDK_int32    importerID;
    csSDK_int32    supportsAsyncIO;
    csSDK_int32    supportsGetSourceVideo;
    csSDK_int32    hasPulldown;
    csSDK_int32    pulldownCadence;
    csSDK_int32    posterFrame;
    csSDK_int32    canTransform;
    csSDK_int32    interpretationUncertain;
    csSDK_int32    colorProfileSupport;
    PrSDKString    codecDescription;
    csSDK_int32    colorSpaceSupport;
    csSDK_int32    reserved[15];
} imImageInfoRec;

```

42.23.1 Plug-in Info

importerID	Can be used as the ID for calls in the <i>PPix Cache Suite</i> .
supportsAsyncIO	Set this to true if the importer supports <code>imCreateAsyncImporter</code> and <code>ai*</code> selectors.
supportsGetSourceVideo	Set this to true if the importer supports the <code>imGetSourceVideo</code> selector.

42.23.2 Bounds Info

imageWidth	Frame width in pixels.
imageHeight	Frame height in pixels.
pixelAspectRatio	The pixel aspect ratio numerator and denominator. For synthetic importers, these are by default the PAR of the project. Only set this if you need a specific PAR for the geometry of the synthesized footage to be correct.
pixelAspectDen	

42.23.3 Time Info

isStill	If set, the file contains a single frame, so only one frame will be cached.
noDuration	One of the following: <ul style="list-style-type: none"> imNoDurationFalse imNoDurationNoDefault imNoDurationStillDefault - use the default duration for stills, as set by the user in the Preferences imNoDurationNoDefault - the importer will supply it's own duration This is primarily for synthetic clips, but can be used for importing non-sequential still images.
isRollCrawl	Set to non-zero value to specify this clip is a rolling or crawling title. This allows a player to optionally use the <i>RollCrawl Suite</i> to get sections of this title for real-time playback.
hasPulldown	Set this to true if the clip contains NTSC film footage with 3:2 pulldown.
pulldownCadence	Set this to the enumerated value that describes the pull-down of the clip: importer_PulldownPhase_NO_PULLDOWN 2:3 cadences: <ul style="list-style-type: none"> importer_PulldownPhase_WSSWW importer_PulldownPhase_SSWWW importer_PulldownPhase_SWWWS importer_PulldownPhase_WWWSS importer_PulldownPhase_WWSSW 24pa cadences: <ul style="list-style-type: none"> importer_PulldownPhase_WWWSW importer_PulldownPhase_WWSWW importer_PulldownPhase_WSWWW importer_PulldownPhase_SWWWW importer_PulldownPhase_WWWWS
posterFrame	New in Premiere Pro CS3. Poster frame number to be displayed. If not specified, the poster frame will be the first frame of the clip.

42.23.4 Format Info

depth	Bits per pixel. This currently has no effect and should be left unchanged.
subType	The four character code of the file's codec; associates files with MAL plug-ins. For uncompressed files, set to <code>imUncompressed</code> .
fieldType	One of the following: <ul style="list-style-type: none"> • <code>prFieldsNone</code> • <code>prFieldsUpperFirst</code> • <code>prFieldsLowerFirst</code> • <code>prFieldsUnknown</code>
fieldsStacked	Fields are present, and not interlaced.
alphaType	Used when depth is 32 or greater. One of the following: <ul style="list-style-type: none"> • <code>alphaNone</code> - no alpha channel (the default) • <code>alphaStraight</code> - straight alpha channel • <code>alphaBlackMatte</code> - premultiplied with black • <code>alphaWhiteMatte</code> - premultiplied with white • <code>alphaArbitrary</code> - premultiplied with the color specified in <code>matteColor</code> • <code>alphaOpaque</code> - for video with alpha channel prefilled to opaque. This gives Premiere the opportunity to make an optimization by skipping the fill to opaque that would otherwise be performed if <code>alphaNone</code> was set.
matteColor	Newly used in Premiere Pro CS3. Used to specify matte color if <code>alphaType</code> is set to <code>alphaArbitrary</code> .
alphaInverted	If non-zero, alpha is treated as inverted (e.g. black becomes transparent).
canTransform	Set to non-zero value to specify this importer handles resolution independent files and can apply a transform matrix. The matrix will be passed during the import request in <code>imImportImageRec.transform</code> . This code path is currently not called by Premiere Pro. After Effects uses this call to import Flash video.
interpretationUncertain	Use an 'or' operator to combine any of the following flags: <ul style="list-style-type: none"> • <code>imPixelAspectRatioUncertain</code> • <code>imFieldTypeUncertain</code> • <code>imAlphaInfoUncertain</code> • <code>imEmbeddedColorProfileUncertain</code>
colorProfileSupport	Deprecated as of 13.0. New in CS5.5. Set to <code>imColorProfileSupport_Fixed</code> to support color management. If the importer is uncertain, it should use <code>interpretationUncertain</code> above instead.
codecDescription	Text description of the codec in use.
ColorProfileRec	New in 13.0; describes the color profile being used by the importer, with this media.

42.23.5 Unused

pixelAspectV1	Obsolete. Maintained for backwards compatability. Plug-ins written for the Premiere 6.x or Premiere Pro API should use pixelAspectNum and pixelAspectDen.
isVectors	Use canTransform instead.
drawsExternal	
canForceInternalDraw	
dontObscure	

42.24 imImportAudioRec7

Selector: *imImportAudio7*

Describes the audio samples to be returned, and contains an allocated buffer for the importer to fill in.

Provide the audio in 32-bit float, uninterleaved audio format.

```
typedef struct {
    PrAudioSample position;
    csSDK_uint32 size;
    float **buffer;
    void *privatedata;
    void *prefs;
} imImportAudioRec7;
```

position	Import point, in audio sample frames. The importer should save the out point of the request in privatedata, because if position is less than zero, then the audio request is sequential, which means the importer should return contiguous samples from the last imImportAudio7 call.
size	The number of audio sample frames to import.
buffer	An array of buffers, one buffer for each channel, with length specified in size. These buffers are allocated by the host application, for the plug-in to fill in with audio data.
privatedata	Instance data gathered from imGetInfo8 or imGetPrefs8.
prefs	Clip Source Settings data gathered from imGetPrefs8 (setup dialog info).

42.25 imImportImageRec

Selector: *imImportImage*

Describes the frame to be returned.

```
typedef struct {
    csSDK_int32 onscreen;
    csSDK_int32 dstWidth;
    csSDK_int32 dstHeight;
```

(continues on next page)

(continued from previous page)

```

csSDK_int32    dstOriginX;
csSDK_int32    dstOriginY;
csSDK_int32    srcWidth;
csSDK_int32    srcHeight;
csSDK_int32    srcOriginX;
csSDK_int32    srcOriginY;
csSDK_int32    unused2;
csSDK_int32    unused3;
csSDK_int32    rowbytes;
char         *pix;
csSDK_int32    pixsize;
PrPixelFormat  pixformat;
csSDK_int32    flags;
prFieldType    fieldType;
csSDK_int32    scale;
csSDK_int32    sampleSize;
csSDK_int32    in;
csSDK_int32    out;
csSDK_int32    pos;
void         *privatedata;
void         *prefs;
prRect         alphaBounds;
csSDK_int32    applyTransform;
float        transform[3][3];
prRect         destClipRect;
} imImportImageRec;

```

42.25.1 Bounds Info

dstWidth	Width of the destination rectangle (in pixels).
dstHeight	Height of the destination rectangle (in pixels).
dstOriginX	Origin X point (0 indicates the frame is drawn offscreen).
dstOriginY	Origin Y point (0 indicates the frame is drawn offscreen).
srcWidth	The same number returned as dstWidth.
srcHeight	The same number returned as dstHeight.
srcOriginX	The same number returned as dstOriginX.
srcOriginY	The same number returned as dstOriginY.

42.25.2 Frame Info

rowbytes	The number of bytes in a single row of pixels.
pix	Pointer to a buffer into which the importer should draw. Allocated based on information from the imGetInfo8.
pixels	The number of pixels. rowbytes * height.
pixfmt	The pixel format Premiere requests.
flags	imDraftMode - Draw quickly if possible, using a faster and possibly less accurate algorithm. This may be passed when playing from the timeline. imSamplesAreFields - Most importers will ignore as Premiere already scales in/out/scale to account for fields, but if you need to know that this has occurred (because maybe you measure something in 'frames'), check this flag. Also, may we suggest considering measuring in seconds instead of frames?
fieldType	If the importer can swap fields, it should render the frame with the given field dominance: either imFieldsUpperFirst or imFieldsLowerFirst.
scale	The frame rate of the video, represented as scale over sampleSize.
sampleSize	
in	In point, based on the timebase defined by scale over sampleSize..
out	Out point, based on the timebase defined by scale over sampleSize..
pos	Import position, based on the above timebase. API bug: Synthetic and custom importers will always receive zero. Thus, adjusting the in point on the timeline will not offset the in point.
privateData	Instance data gathered during imGetInfo or imGetPrefs.
prefs	Clip Source Settings data gathered during imGetPrefs (setup dialog info).
alpha	This is the rect outside of which the alpha is always 0. Simply do not alter this field if the alpha bounds match the destination bounds. If set, the alpha bounds must be contained by the destination bounds. This is only currently used when a plug-in calls ppixGetAlphaBounds, and not currently used by any native plug-ins.
applyNewinAfter	New in After Effects CS3. Not currently provided by Premiere. If non-zero, the host is requesting that the importer apply the transform specified in transform and destClipRect before returning the resulting image in pix.
transform	New in After Effects CS3. Not currently provided by Premiere. The source to destination transform matrix.
destClipRect	New in After Effects CS3. Not currently provided by Premiere. Destination rect inside the bounds of the pix buffer.

42.26 imImportInfoRec

Selector: *imInit*

Describes the importer's capabilities to Premiere.

```
typedef struct {
    csSDK_uint32  importerType;
    csSDK_int32   canOpen;
    csSDK_int32   canSave;
    csSDK_int32   canDelete;
    csSDK_int32   canResize;
    csSDK_int32   canDoSubsize;
    csSDK_int32   canDoContinuousTime;
```

(continues on next page)

(continued from previous page)

```

csSDK_int32    noFile;
csSDK_int32    addToMenu;
csSDK_int32    hasSetup;
csSDK_int32    dontCache;
csSDK_int32    setupOnDblClk;
csSDK_int32    keepLoaded;
csSDK_int32    priority;
csSDK_int32    canAsync;
csSDK_int32    canCreate;
csSDK_int32    canCalcSizes;
csSDK_int32    canTrim;
csSDK_int32    avoidAudioConform;
prUTF16Char   *acceleratorFileExt;
csSDK_int32    canCopy;
csSDK_int32    canSupplyMetadataClipName;
csSDK_int32    private;
csSDK_int32    canProvidePeakAudio;
csSDK_int32    canProvideFileList;
csSDK_int32    canProvideClosedCaptions;
prPluginID    fileInfoVersion;
} imImportInfoRec;

```

42.26.1 Screen Info

noFile	If set, this is a synthetic importer. The file reference will be zero.
addToMenu	If set to imMenuNew, the importer will appear in the File > New menu.
canDoContinu	If set, the importer can render frames at arbitrary times and there is no set timecode. A color matte generator or a titler would set this flag.
canCreate	If set, Premiere will treat this synthetic importer as if it creates files on disk to be referenced for frames and audio. See Additional Details for more information on custom importers.

42.26.2 File Handling Flags

canOpen	If set, the importer handles open and close operations. Set if the plug-in needs to be called to handle imOpenFile, imQuietFile, and imCloseFile.
canSave	If set, the importer handles File > Save and File > Save As after a clip has been captured and must handle the imSaveFile selector.
canDelete	If set, the importer can delete its own files. The plug-in must handle the imDeleteFile selector.
canCalcSize	If set, the importer can calculate the disk space used by a clip during imCalcSize. An importer should support this call if it uses a tree of files represented as one top-level file to Premiere.
canTrim	If set, the importer can trim files during imTrimFile.
canCopy	Set this to true if the importer supports copying clips in the Project Manager.

42.26.3 Setup Flags

hasSetup	If set, the importer has a setup dialog. The dialog should be presented in response to <code>imGetPrefs</code> .
setupOnDoubleClick	If set, the setup dialog should be opened whenever the user double clicks on a file imported by the plug-in in the timeline or the project bin.

42.26.4 Memory Handling Flags

dontCache	Unused.
keepLoaded	If set, the importer plug-in should never be unloaded. Don't set this flag unless it's absolutely necessary (it usually isn't).

42.26.5 Other

priority	Determines priority levels for importers that handle the same filetype. Importers with higher numbers will override importers with lower numbers. For overriding importers that ship with Premiere, use a value of 100 or greater. Higher-priority importers can defer files to lower-priority importers by returning <code>imBadFile</code> during <code>imOpenFile8</code> or <code>imGetInfo8</code> .
importType	Type identifier for the import module assigned based on the plug-in's IMPT resource. Do not modify this field.
canProvideNewInPremiereProCC	New in Premiere Pro CC. Set this to true if the importer supports media with embedded closed captioning.
avoidAudioSearch	Set this to true if the importer supports fast audio retrieval and does not need the audio clips it imports to be conformed.
canProvideNewInPremiereProCS5.5	New in Premiere Pro CS5.5. Set this to true if your non-synthetic importer wants to provide peak audio data using <code>imGetPeakAudio</code> .
acceleratorFileExtensions	Fill this with UTF16Char array of size 256 with the file extensions of accelerator files that the importer creates and uses.
canSupplyMetadataBasedClipName	Allows file-based importer to set clip name from metadata. Set this in <code>imFileInfoRec8.streamName</code> .
canProvideNewInCS6	New in CS6. Set this to true if the importer will provide a list of all files for a copy operation in response to <code>imQueryInputFileList</code> .
fileInfoView	New in CC 2014. This is used by an optimization in an internal importer. Do not use.

42.26.6 Unused

canResize
canDoSubsize
canAsync

42.27 imIndFormatRec

Selector: *imGetIndFormat*

Describes the format(s) supported by the importer. Synthetic files can only have one format.

```
typedef struct {
    csSDK_int32 filetype;
    csSDK_int32 flags;
    csSDK_int32 canWriteTimecode;
    char FormatName[256];
    char FormatShortName[32];
    char PlatformExtension[256];
    prBool hasAlternateTypes;
    csSDK_int32 alternateTypes[kMaxAlternateTypes];
    csSDK_int32 canWriteMetaData;
} imIndFormatRec;
```

filetype	Unique four character code (fourcc) of the file.
flags	Legacy mechanism for describing the importer capabilities. Though the flags will still be honored for backward compatability, current and future importers should not use these flags. See table below for details.
canWriteTimecode	If set, timecode can be written for this filetype.
FormatName[256]	The descriptive importer name.
FormatShortName[32]	The short name for the plug-in, appears in the format menu.
PlatformExtension[256]	List of all the file extensions supported by this importer. If there's more than one, separate with null characters.
hasAlternateTypes	Unused
alternateTypes[kMaxAlternateTypes]	Unused
canWriteMetaData	New in 6.0. If set, imSetMetaData is supported for the filetype

The flags listed below are only for legacy plug-ins and should not be used.

Flag	Usage
xfIsMovie	Unused
xfCanReplace	Unused
xfCanOpen	Unused: Use <code>imImportInfoRec.canOpen</code> instead.
xfCanImport	Unused: The PiPL resource describes the file as an importer.
xfIsStill	Unused: Use <code>imFileInfoRec.imImageInfoRec.isStill</code> instead.
xfIsSound	Unused: Use <code>imFileInfoRec.hasAudio</code> instead.
xfCanWriteTimecode	If set, the importer can respond to <code>imGetTimecode</code> and <code>imSetTimecode</code> . Obsolete: use <code>imIndFormatRec.canWriteTimecode</code> instead.
xfCanWriteMeta	Writes (and reads) metadata, specific to the importer's four character code filetype. Obsolete: use <code>imIndFormatRec.canWriteMetaData</code> instead.
xfCantBatchPr	Unused

42.28 imIndPixelFormatRec

Selector: *imGetIndPixelFormat*

Describes the pixel format(s) supported by the importer.

```
typedef struct {
    void *privatedata;
    PrPixelFormat outPixelFormat;
    const void* prefs;
} imIndPixelFormatRec;
```

privatedata	Instance data from imGetInfo8 or imGetPrefs8.
outPixelFormat	One of the pixel formats supported by the importer
prefs	New in CC. Clip Source Settings data gathered during imGetPrefs8 (setup dialog).

42.29 imInitiateAsyncClosedCaptionScanRec

Selector: *imInitiateAsyncClosedCaptionScan*

Both *imGetNextClosedCaption* and *imCompleteAsyncClosedCaptionScan* may be called from a different thread from which *imInitiateAsyncClosedCaptionScan* was originally called.

To help facilitate this, *outAsyncCaptionScanPrivateData* can be allocated by the importer to be used for the upcoming closed caption scan calls, which should then be deallocated in *imCompleteAsyncClosedCaptionScan*.

The estimated duration of all the closed captions can also be filled in.

This is useful for certain cases where the embedded captions contain many frames of empty data.

```
typedef struct {
    void* privatedata;
    void* prefs;
    void* outAsyncCaptionScanPrivateData;
    csSDK_int64 outScale;
    csSDK_int64 outSampleSize;
    csSDK_int64 outEstimatedDuration;
} imInitiateAsyncClosedCaptionScanRec;
```

privatedata	Instance data gathered during imGetInfo8 or imGetPrefs8.
prefs	Clip Source Settings data gathered during imGetPrefs8 (setup dialog).
outAsyncCaptionScanPrivateData	The importer can allocate instance data for this closed caption scan, and pass it back here.
outScale	New in CC October 2013. The frame rate of the video clip, represented as scale over sampleSize.
outSampleSize	
outEstimatedDuration	New in CC October 2013. The estimated duration of all the captions, in the above timescale

42.30 imMetaDataRec

Selector: *imGetMetaData* and *imSetMetaData*

Describes the metadata specific to a given four character code.

```
typedef struct {
    void          *privatedata;
    void          *prefs;
    csSDK_int32   fourCC;
    csSDK_uint32  buffersize;
    char         *buffer;
} imMetaDataRec;
```

privatedata	Instance data gathered during <code>imGetInfo8</code> or <code>imGetPrefs8</code> .
prefs	Clip Source Settings data gathered during <code>imGetPrefs8</code> (setup dialog).
fourcc	Fourcc code of the metadata chunk.
buffersize	Size of the data in buffer.
buffer	The metadata.

42.31 imPeakAudioRec

Selector: `imGetPeakAudio`

Describes the peak values of the audio at the specified position.

```
typedef struct {
    void          *inPrivateData;
    void          *inPrefs;
    PrAudioSample inPosition;
    float         inSampleRate;
    csSDK_int32   inNumSampleFrames;
    float         **outMaxima;
    float         **outMinima;
} imPeakAudioRec;
```

inPrivateData	Instance data gathered during <code>imGetInfo8</code> or <code>imGetPrefs8</code> .
inPrefs	Instance data gathered during <code>imGetPrefs8</code> (setup dialog).
inPosition	The starting audio sample frame of the peak data.
inSampleRate	The sample rate at which to generate the peak data.
inNumSampleFrames	The number of sample frames in each buffer.
outMaxima	An array of arrays to be filled with the maximum sample values.
outMinima	An array of arrays to be filled with the minimum sample values.

42.32 imPreferredFrameSizeRec

Selector: `imGetPreferredFrameSize`

Describes a frame size preferred by the importer.

```
typedef struct {
    void *inPrivateData;
    void *inPrefs;
    PrPixelFormat inPixelFormat;
    csSDK_int32 inIndex;
    csSDK_int32 outWidth;
    csSDK_int32 outHeight;
} imPreferredFrameSizeRec;
```

inPrivateData	Instance data gathered during <code>imGetInfo8</code> or <code>imGetPrefs8</code> .
inPrefs	Clip Source Settings data gathered during <code>imGetPrefs8</code> (setup dialog).
inPixelFormat	The pixel format for this preferred frame size.
inIndex	The index of this preferred frame size.
outWidth	The dimensions of this preferred frame size.
outHeight	

42.33 imQueryContentStateRec

Selector: *imQueryContentState*

Fill in the `outContentStateID`, which should be a GUID calculated based on the content state of the clip at `inSourcePath`.

If the state hasn't changed since the last call, the GUID returned should be the same.

```
typedef struct {
    const prUTF16Char* inSourcePath;
    prPluginID outContentStateID;
} imQueryContentStateRec;
```

42.34 imQueryDestinationPathRec

Selector: *imQueryDestinationPath*

Fill in the desired `outActualDestinationPath`, based on the `inSourcePath` and `inSuggestedDestinationPath`.

```
typedef struct {
    void *inPrivateData;
    void *inPrefs;
    const prUTF16Char *inSourcePath;
    const prUTF16Char *inSuggestedDestinationPath;
    prUTF16Char *outActualDestinationPath;
} imQueryDestinationPathRec;
```

inPrivateData	Instance data gathered during imGetInfo8 or imGetPrefs8.
inPrefs	Clip Source Settings data gathered during imGetPrefs8 (setup dialog).
inSourcePath	The path of the source file to be trimmed
inSuggestedDestinationPath	The path suggested by Premiere where the destination file should be created.
outActualDestinationPath	The path where the importer wants the destination file to be created.

42.35 imQueryInputFileListRec

Selector: *imQueryInputFileList*

Fill in the outContentStateID, which should be a GUID calculated based on the content state of the clip at inSourcePath.

If the state hasn't changed since the last call, the GUID returned should be the same.

```
typedef struct {
    void*      inPrivateData;
    void*      inPrefs;
    PrSDKString inBasePath;
    csSDK_int32 outNumFilePaths;
    PrSDKString *outFilePaths;
} imQueryInputFileListRec;
```

inPrivateData	Instance data gathered from imGetInfo8 or imGetPrefs8.
inPrefs	Clip Source Settings data gathered from imGetPrefs8 (setup dialog info).
inBasePath	Path of main file that was passed earlier in imOpenFile.
outNumFilePaths	The first time imQueryInputFileList is sent, fill in the number of files that the media uses.
outFilePaths	The second time imQueryInputFileList is sent, this will be preallocated as an array of NULL strings. Use the <i>String Suite</i> to fill the array with PrSDKStrings with the actual paths.

42.36 imQueryStreamLabelRec

Selector: *imQueryStreamLabel*

New in CS6. Based on the stream ID passed in, allocate and pass back a label for the stream.

For stereoscopic importers, use the predefined labels in PrSDKStreamLabel.h.

```
typedef struct {
    void *inPrivateData;
    csSDK_int32 *inPrefs;
    csSDK_int32 inStreamIdx;
    PrSDKString* outStreamLabel;
} imQueryStreamLabelRec;
```

privatedata	Instance data gathered from <code>imGetInfo8</code> or <code>imGetPrefs8</code> .
prefs	Clip Source Settings data gathered from <code>imGetPrefs8</code> (setup dialog info).
inStreamIdx	The ID of the stream that needs to be labeled.
outStreamLabel	The stream label, allocated using the <i>String Suite</i> .

42.37 imSaveFileRec8

Selector: *imSaveFile8*

Describes the file to be saved.

```
typedef struct {
    void *privatedata;
    csSDK_int32 *prefs;
    const prUTF16Char* sourcePath;
    const prUTF16Char* destPath;
    char move;
    importProgressFunc progressCallback;
    void *progressCallbackID;
} imSaveFileRec8;
```

privatedata	Instance data gathered from <code>imGetInfo8</code> or <code>imGetPrefs8</code> .
prefs	Clip Source Settings data gathered from <code>imGetPrefs8</code> (setup dialog info).
sourcePath	Full path of the file to be saved.
destPath	Full path the file should be saved to.
move	If non-zero, this is a move operation and the original file (the <code>sourcePath</code>) can be deleted after copying is complete.
progressCallbackID	Function to call repeatedly to provide progress and to check for cancel by user. May be a NULL pointer, so make sure the function pointer is valid before calling.
progressCallback	Pass to <code>progressCallback</code> .

42.38 imSourceVideoRec

Selector: *imGetSourceVideo*, *aiInitiateAsyncRead*, *aiGetFrame*

Describes the requested frame, to be passed back in `outFrame`.

```
typedef struct {
    void *inPrivateData;
    csSDK_int32 currentStreamIdx;
    PrTime inFrameTime;
    imFrameFormat *inFrameFormats;
    csSDK_int32 inNumFrameFormats;
    bool removePulldown;
    PPixHand *outFrame;
    void *prefs;
```

(continues on next page)

(continued from previous page)

```

csSDK_int32      prefsSize;
PrSDKString      selectedColorProfileName;
PrRenderQuality  inQuality;
} imSourceVideoRec;

```

inPrivateData	Instance data gathered during <code>imGetInfo8</code> or <code>imGetPrefs8</code> .
currentStreamIdx	New in CS6. If the clip has multiple streams (for stereoscopic video or otherwise), this ID differentiates between them.
inFrameTime	Time of frame requested.
inFrameFormats	An array of requested frame formats, in order of preference. If NULL, then any format is acceptable.
inNumFrameFormats	The number of frame formats in the <code>inFrameFormats</code> .
removePullDown	If true, pulldown should be removed if the pixel format supports it.
outFrame	Allocate memory to hold the requested frame, and pass it back here.
prefs	New in Premiere Pro 4.1. prefs data from <code>imGetPrefs8</code>
prefsSize	New in Premiere Pro 4.1. Size of prefs data.
selectedColorProfileName	New in Premiere Pro CS5.5. A string that specifies the color profile of the imported frame.
inQuality	New in Premiere Pro CC 2014.

42.39 imSubTypeDescriptionRec

Selector: `imGetSubTypeNames`

Added in Premiere Pro CS3. Describes the codec name associated with a given fourcc.

```

typedef struct {
    csSDK_int32  subType;
    prUTF16Char  subTypeName[256];
} imSubTypeDescriptionRec;

```

42.40 imTimeInfoRec8

Selector: `imGetTimeInfo8` and `imSetTimeInfo8`

Describes the timecode and timecode rate associated with a clip.

```

typedef struct {
    void      *privatedata;
    void      *prefs;
    char      orgtime[18];
    csSDK_int32  orgScale;
    csSDK_int32  orgSampleSize;
    char      alttime[18];
    csSDK_int32  altScale;
    csSDK_int32  altSampleSize;
}

```

(continues on next page)

(continued from previous page)

```

char      orgreel[40];
char      altreel[40];
char      logcomment[256];
csSDK_int32  dataType;
} imTimeInfoRec;

```

privatedata	Instance data gathered during imGetInfo8 or imGetPrefs8.
prefs	Clip Source Settings data gathered during imGetPrefs8 (setup dialog).
orgtime	The original time in hours;minutes;seconds;frames, as captured from the source reel. The use of semi-colons indicates (to Premiere) drop-frame timecode, e.g. "00:00:00:00". Use colons for non-drop-frame timecode, e.g. "00:00:00:00".
orgScale	Timebase of the timecode in orgtime, represented as scale over sampleSize.
orgSampleSize	
alttime	An alternative timecode (may differ from the source timecode), formatted as described above.
altScale	Timebase of the timecode in alttime.
altSampleSize	
orgreel	Original reel name.
altreel	Alternate reel name.
logcomment	Comment string.
dataType	Currently always set to 1, denoting SMPTE timecode. More values may be added in the future.

42.41 imTrimFileRec8

Selector: imGetIndColorSpace

Describes how to trim a clip, based on information returned by the importer during imCheckTrim8.

Also provides a callback to update the progress bar and check if the user has cancelled.

```

typedef struct {
    void      *privatedata;
    void      *prefs;
    csSDK_int32  trimIn;
    csSDK_int32  duration;
    csSDK_int32  keepAudio;
    csSDK_int32  keepVideo;
    const prUTF16Char  *destFilePath;
    csSDK_int32  scale;
    csSDK_int32  sampleSize;
    importProgressFunc  progressCallback;
    void      *progressCallbackID;
} imTrimFileRec8;

```

privatedata	Instance data gathered during <code>imGetInfo8</code> or <code>imGetPrefs8</code> .
prefs	Clip settings data gathered during <code>imGetPrefs8</code> (setup dialog).
trimIn	In point of the trimmed clip, in the timebase specified by <code>scale</code> and <code>sampleSize</code> .
duration	Duration of the trimmed clip. If 0, then the request is to leave the clip untrimmed, and at the current duration
keepAudio	If non-zero, the request is to keep the audio in the trimmed result.
keepVideo	If non-zero, the request is to keep the video in the trimmed result.
destFilePath	The unicode path and name of the file to create.
scale	The frame rate of the video, represented as scale over <code>sampleSize</code> .
sampleSize	
progressCallback	ImportProgressFunc callback to call repeatedly to provide progress and to check for cancel by user. May be a NULL pointer, so make sure the function pointer is valid before calling.
progressCallbackID	Pass to IDProgressCallback.

42.42 ColorSpaceRec

Selector: `imGetIndColorSpace`

Describes the colorspace in use with the media.

```
typedef struct {
    void *privatedata;
    PrSDKColorSpaceType outColorSpaceType;
    RawColorProfileRec ioProfileRec;
    prSEIColorCodesRec outSEICodesRec;
} ColorSpaceRec;
```

privatedata	Private.
outColorSpaceType	One of the following: <ul style="list-style-type: none"> • <code>kPrSDKColorSpaceType_Undefined</code> • <code>kPrSDKColorSpaceType_ICC</code> • <code>kPrSDKColorSpaceType_LUT</code> • <code>kPrSDKColorSpaceType_SEITags</code> • <code>kPrSDKColorSpaceType_MXFTags</code>
ioProfileRec	A structure describing the color profile. <pre>csSDK_int32 ioBufferSize; void* inDestinationBuffer; PrSDKString outName;</pre>
outSEICodesRec	A structure describing the color profile; used with H.265, HEVC, AVC and ProRes media. <pre>csSDK_int32 colorPrimariesCode; csSDK_int32 transferCharacteristicCode; csSDK_int32 matrixEquationsCode; csSDK_int32 bitDepth; prBool isFullRange; prBool isRGB;</pre>

43.1 Suites

For information on how to acquire and manage suites, see *SweetPea Suites*.

43.1.1 Async File Reader Suite

New in Premiere Pro CS5. A cross-platform file handling suite.

43.1.2 Deferred Processing Suite

Allows an importer to schedule processing time when importing asynchronously, and to notify the user that the media item is pending additional processing.

In the Project panel, the name of the item will be italicized, and its thumbnail will show as Pending.

Recorders

Recorders interface directly with capture hardware, and capture video and/or audio to any file format. The recorder is responsible for displaying any video preview in the Capture panel, playing any audio preview to the system sound or hardware output, driving the meters in the Audio Master Meters panel, providing any settings in a custom dialog, and digitizing the video and audio to a file (or multiple files) on disk. A recorder can optionally provide source timecode information to Premiere, and notify Premiere when the video format changes so that the capture preview area can be resized. The recorder does not communicate anything about the audio to Premiere. When recording is complete, Premiere imports the file using any available importers that support that filetype.

A recorder can only capture to a single filetype. To capture to several filetypes, provide several recorders.

If you've never developed a recorder before, you can skip *Whats New*, and go directly to *Getting Started*.

45.1 What's New in Premiere Pro CC 2014?

A new return code was added, `rmRequiresRoyaltyContent`. Return this from `recmod_Startup8` or `recmod_StartRecord`, if the codec used is unlicensed.

45.2 What's New in Premiere Pro CS6?

The parent window handle is now properly passed in, during `recmod_ShowOptions` when a recorder should display its modal setup dialog.

45.3 What's New in Premiere Pro CS5?

Recorders can now display audio meters in the Audio Master Meters panel while previewing and capturing. Just use the new `AudioPeakDataFunc` callback passed in `recOpenParms` with `recmod_Open`.

45.4 What's New in Premiere Pro CS4?

Audio settings in the Capture Settings window are no longer supported. Any audio settings should be in the custom dialog shown by the recorder during `recmod_ShowOptions`. Recorders should no longer set the `acceptsAudioSettings` flag in `recInfoRec8`.

45.4.1 No More Project Presets

Since Premiere Pro CS4 support sequence-specific settings, project presets have been replaced by sequence presets. The difference from project presets are that sequence presets do not contain information to initialize capture settings. This means that users will have to initialize capture settings manually the first time they use a recorder with custom settings.

When the Capture Panel is invoked, if the capture settings are invalid or uninitialized, the Capture Settings dialog is invoked. In the Capture Settings dialog: If the recorder requires private data, the user cannot continue past the Capture Settings dialog until they have opened the current recorder's settings dialog.

45.5 What's New in Premiere Pro CS3?

A new function, `GetDeviceTimecodeFunc`, can be used to ask the device controller for its current timecode.

A new return value, `rmRequiresCustomPrefsError`, should be returned on `recmod_SetActive` if there are no valid capture prefs.

46.1 Selector Calling Sequence

The best ways to get familiar with the recorder API is to observe the messages sent between Premiere and the recorder plug-in.

`recmod_Startup8` is sent once when Premiere launches. When Project Settings > Capture Settings is opened, `recmod_Open` is sent to create a new recorder instance and open the capture driver. `recmod_GetSetupInfo8` is then sent, so the recorder can specify which settings buttons (if any) should be enabled in the Capture Settings window when the recorder is selected.

If one or more settings buttons are enabled and then clicked by the user, `recmod_ShowOptions` is sent so the recorder can display a dialog (and save any user choices). When the Capture Settings window is closed, `recmod_Close` is sent to end the capture instance.

Whenever the Capture panel is open, the recorder will receive `recmod_SetActive` calls, with a parameter telling it to become active or inactive (based on user activity). `recmod_SetDisp` provides the plug-in the dimensions of the preview area in the Capture panel. `recmod_Idle` is repeatedly sent until the Record button is pushed, to give the recorder time to update the preview area and play audio coming from the capture hardware.

When the user clicks Record, or starts an In/Out or Batch capture, `recmod_PrepRecord8` is sent. The recorder prepares to capture, and if a start timecode is provided, tells the device controller to get the device into position using `preRollFunc`. The `preRollFunc` will block until the device is exactly in the right position, and when it returns, the recorder should immediately return back to Premiere, open which `recmod_StartRecord` is then sent to the recorder, which should immediately start capturing.

When the recorder starts capturing and returns from `recmod_StartRecord`, Premiere will repeatedly call `recmod_ServiceRecord` to give the recorder processor time. During recording, report status to Premiere with `StatusDispFunc`.

The capture may be stopped in several ways:

- The user could click the Stop button,
- the capture may reach the predetermined out point of an In/Out or Batch capture,
- or the recorder might return an error from `recmod_ServiceRecord`.

In all cases, `recmod_StopRecord` will be sent to stop the capture, possibly followed by `recmod_CloseRecord` if there are no more items in the batch.

Finally, `recmod_Close` is sent when the Capture panel is closed to destroy the recorder instance. `recmod_Shutdown` is sent when Premiere terminates.

46.2 Try the Sample Recorder Plug-in

Now that you've read the overview of the selector calling sequence above, build the sample recorder plug-in included with this SDK, and give it a whirl. To properly simulate a capture, you'll also need to create an `.sdk` media file and place it in the proper location.

1. Build the recorder, importer, and exporter into the plug-ins directory
2. Launch Premiere Pro and use the exporter to transcode any media file into the `.sdk` file format.
3. Place the newly created media file at "C:\premiere.sdk" on Windows, or "premiere.sdk" on the Desktop on Mac OS.

Now when you "capture" a file, it will use this file, and automatically import it using the importer.

46.3 Metadata

Pixel aspect ratio and timecode are provided by the recorder by filling out `recCapturedFileInfo`. Starting in CS4, after a clip has been captured, if Premiere has an XMP handler that supports the clip's filetype, the XMP handler will open the captured file and inject the information. If no such XMP handler is provided, the recorder is responsible for embedding any pixel aspect ratio information to the file, but Premiere will send `imSetTimeInfo8` to the importer to stamp the file with timecode.

46.4 Save Captured File Dialog

After a single clip is captured, the Save Captured File dialog allows the user to rename the filename of the clip just captured. The recorder is not involved in this process. Instead, the importer is called to open the newly captured clip, and it is sent `imSaveFile8` with the move flag set to true to move the file. This is handled by the importer, since `imSaveFile8` is usually already implemented to support the Project Manager.

46.5 Switching Preview Area Between Different Frame Sizes

`FormatChangedFunc` enables recorders to tell Premiere when the pixel aspect ratio has changed so the Capture Panel preview area can be resized. It can be called during preview, and even during capture.

46.6 Scene Detection

A recorder can optionally implement one or both of two features based on scene detection: Scene Capture and Scene Searching. What determines a scene break is up to the discretion of the recorder. The built-in DV recorder determines scene breaks by time/date breaks in the DV stream. But a recorder could analyze the video for breaks, or use any method it chooses to implement.

46.6.1 Scene Capture

Scene Capture enables a recorder to capture a continuous stream to multiple files divided up by scenes.

To support scene capture, the recorder must set `recInfoRec8.canCaptureScenes = kPrTrue` during `recmod_Startup8`. When the user captures with Scene Detect on, `recCapParmsRec8.captureScenes` will be non-zero during `recmod_PrepRecord8`. The recorder should begin capture, and when it detects the end of a scene, call `SceneCapturedFunc8`, to notify Premiere that a scene has been captured. Premiere passes back the `recFileSpec8` to

give the recorder the filepath to which the next scene should be captured. Premiere also reserves memory for and passes back `recCapturedFileInfo` for the next capture.

46.6.2 Scene Searching

Scene Searching enables a recorder to fast forward or rewind to different scenes. The user can hit the Next Scene or Previous Scene buttons several times to seek several scenes away. Of course, this feature is only possible with the help of a device controller as well.

To support scene capture, the recorder must set `recInfoRec8.canSearchScenes = kPrTrue` during `recmod_Startup8`. When the user chooses Next Scene or Previous Scene, the recorder is sent `recmod_StartSceneSearch`. The scene searching algorithm happens in two passes.

The first pass is a play fast forward or backward in the initial direction. In this mode, when the recorder passes the scene boundary, it should call `ReportSceneFunc` to tell Premiere the approximate range where the scene boundary is and return `rmEndOfScene`. Premiere will call `recmod_StopSceneSearch`, followed by `recmod_StartSceneSearch`, to start a new slow scan scene search in the opposite direction, passing back the approximate range reported by `ReportSceneFunc`. When the recorder reaches the scene boundary again, it should once again call `ReportSceneFunc` and return `rmEndOfScene`.

46.7 Entry Point

Below is the entry point function prototype for all recorder plug-ins. Premiere calls this entry point function to drive the recorder based on user input.

```
int RecEntry (
    csSDK_int32 selector,
    rmStdParms *stdParms,
    void *param1,
    void *param2)
```

The *selector* is the action Premiere wants the recorder to perform. It tells the recorder the reason for the call.

`stdParms` provides the recorder with callback functions to access additional information from Premiere or to have Premiere perform tasks.

Parameters 1 and 2 contain state information and vary with the selector; they may contain a specific value or a pointer to a structure.

Return `rmNoErr` if successful, or an appropriate return code.

46.8 Standard Parameters

This structure is sent from Premiere to the plug-in with every selector.

```
typedef struct {
    int          rmInterfaceVer;
    recCallbackFuncs *funcs;
    piSuitesPtr  piSuites;
} rmStdParms;
```

Member	Description
<code>rmInterfaceVer</code>	Recorder API version <ul style="list-style-type: none"> • Premiere Pro CS6 - <code>RECMOD_VERSION_12</code> • Premiere Pro CS5.5 - <code>RECMOD_VERSION_11</code> • Premiere Pro CS5 - <code>RECMOD_VERSION_10</code> • Premiere Pro CS4 - <code>RECMOD_VERSION_9</code> • Premiere Elements 3 - <code>RECMOD_VERSION_8</code> • Premiere Pro CS3 - <code>RECMOD_VERSION_7</code>
<code>funcs</code>	Pointers to callbacks for recorders
<code>piSuites</code>	Pointer to universal callback suites

46.9 Recorder-Specific Callbacks

Recorders have access to ClassData Functions and Memory Functions through the `recCallbackFuncs`, which is a member of `rmStdParms`.

`StatusDispFunc`, `PrerollFunc`, `ReportSceneFunc`, and `SceneCapturedFunc8` are accessible through `recCapParmsRec8`, which is sent with `recmod_PrepRecord8`.

```
typedef struct {
    ClassDataFuncsPtr  classFuncs;
    PlugMemoryFuncsPtr memoryFuncs;
} recCallbackFuncs;

int (*StatusDispFunc) (
    void *callbackID,
    char *stattext,
    int framenum);

csSDK_int32 (*PrerollFunc) ( void *callbackID);

void (*ReportSceneFunc) (
```

(continues on next page)

(continued from previous page)

```
void          *callbackID,
csSDK_uint32  inSceneEdgeTimecode,
csSDK_uint32  inEarliestSceneEdgeTimecode,
csSDK_uint32  inGreatestSceneEdgeTimecode);

void (*SceneCapturedFunc8) (
    void          *callbackID,
    prUTF16Char   *inFileCaptured,
    recFileSpec8  *outNextSceneFilename,
    recCapturedFileInfo **outFileInfo);

void (*SceneCapturedFunc) (
    void          *callbackID,
    char          *inFileCaptured,
    recFileSpec   *outNextSceneFilename,
    recCapturedFileInfo **outFileInfo);

void (*FormatChangedFunc) (
    void          *callbackID,
    unsigned int  inPixelAspectRatioNum,
    unsigned int  inPixelAspectRatioDen,
    unsigned int  inMaxFrameWidth,
    unsigned int  inMaxFrameHeight,
    TDB_TimeRecord inFramerate,
    int           isDropFrame);

void (*GetDeviceTimecodeFunc) (
    void          *callbackID,
    csSDK_uint32  *outTimecode,
    TDB_TimeRecord *outFrameRate,
    int           *outIsDropFrame);

void (*AudioPeakDataFunc) (
    void          *callbackID,
    recAudioPeakData *inAudioPeakData)
```

Function	Description
<code>classFuncs</code>	See <code>ClassData</code> functions
<code>memoryFuncs</code>	Legacy memory-related callbacks. These are the same ones passed in through <i>piSuites</i> .
<code>StatusDispFunc</code>	Available in <code>recCapParmsRec8</code> during <code>recmod_PrepRecord8</code> . Callback function pointer for use during capture to call into Premiere and update status information in the Capture Window. <ul style="list-style-type: none"> <code>callbackID</code> is the recording session instance passed in <code>recCapParmsRec</code>. <code>stattext</code> is text Premiere will display at the top of the Capture Window. <code>framenum</code> is the frame number being captured, represented in the absolute number of frames. For example, 00;00;04;03 in NTSC drop-frame timecode would be represented as 123.
<code>PrerollFunc</code>	Available in <code>recCapParmsRec8</code> during <code>recmod_PrepRecord8</code> , only if the user has initiated a device controlled capture (Capture In/Out or Batch Capture). Callback function pointer to initiate device control preroll, by sending a <code>dsExecute/cmdLocate</code> message to the device controller. Callback returns when the deck is playing at the proper frame. <code>callbackID</code> is the recording session instance passed in <code>recCapParmsRec</code> . Host returns a <code>prDevicemodError</code> to inform why the preroll failed.
<code>ReportSceneFunc</code>	Although this callback is obsolete for Scene Capture (superseded by <code>SceneCapturedFunc8</code>), it is still used for Scene Search to return the scene detected by the recorder. Available in <code>recSceneDetectionParmsRec</code> during <code>recmod_StartSceneSearch</code> . The <code>inSceneEdgeTimecode</code> parameter marks the timecode of the scene edge, if it can be determined exactly. If it cannot, it marks the approximated timecode of the edge, and the <code>inEarliestSceneEdgeTimecode</code> and <code>inGreatestSceneEdgeTimecode</code> parameters mark the earliest and latest possible timecodes that the scene would fall in between. If the scene break can be determined exactly, all three return parameters should be set to the same value.
<code>SceneCapturedFunc8</code>	New in Premiere Pro 2.0. Available in <code>recCapParmsRec8</code> during <code>recmod_PrepRecord8</code> . Callback to notify Premiere that a scene has been captured. Premiere returns the <code>recFileSpec8</code> to designate a filename for the next scene to capture and reserves memory for and returns <code>recCapturedFileInfo</code> for the next capture.
<code>SceneCapturedFunc</code>	Obsolete. Use <code>SceneCapturedFunc8</code> . Chapter 46. Getting Started
<code>FormatChangedFunc</code>	Available in <code>recOpenParms</code> during <code>recmod_Open</code> . Use this when the pixel aspect ratio has changed so the Capture Panel can be resized.

CHAPTER 47

Selector Table

This table summarizes the various selector commands a recorder can receive.

Selector	param1	param2
<i>recmod_Startup8</i>	<i>recInfoRec8</i>	unused
<i>recmod_Shutdown</i>	unused	unused
<i>recmod_GetSetupInfo8</i>	PrivateData	<i>recCapSetups8</i>
<i>recmod_ShowOptions</i>	PrivateData	<i>recSetupParms</i>
<i>recmod_Open</i>	PrivateData	<i>recOpenParms</i>
<i>recmod_Close</i>	PrivateData	unused
<i>recmod_SetActive</i>	PrivateData	(csSDK_int32) boolean toggle
<i>recmod_SetDisp</i>	PrivateData	<i>recDisplayPos</i>
<i>recmod_Idle</i>	PrivateData	<i>recGetTimecodeRec</i>
<i>recmod_PrepRecord8</i>	PrivateData	<i>recCapParmsRec8</i>
<i>recmod_StartRecord</i>	PrivateData	<i>recCapturedFileInfo</i>
<i>recmod_ServiceRecord</i>	PrivateData	unused
<i>recmod_StopRecord</i>	PrivateData	unused
<i>recmod_CloseRecord</i>	PrivateData	unused
<i>recmod_QueryInfo</i>	PrivateData	<i>recCapInfoRec</i>
recmod_StartSceneSearch		<i>recSceneDetectionParmsRec</i>
recmod_StopSceneSearch		unused
recmod_ServiceSceneSearch		unused
Obsolete: <ul style="list-style-type: none"> • <i>recmod_Startup</i> • <i>recmod_GetSetupInfo</i> • <i>recmod_PrepRecord</i> 		
Currently unused in CS4: <ul style="list-style-type: none"> • <i>recmod_QueryInfo</i> • <i>recmod_AudioIndFormat</i> • <i>recmod_GetAudioIndFormat7</i> • <i>recmod_StepRecord</i> • <i>recmod_StillRecord</i> 		

Selector Descriptions

This section provides a brief overview of each selector and highlights implementation issues.

48.1 `recmod_Startup8`

- `param1` - *recInfoRec8*
- `param2` - unused

Sent once when Premiere launches so the plug-in can initialize and return its attributes to Premiere.

The module should connect to any required capture hardware or drivers and fill in the `recInfoRec8`.

48.2 `recmod_Shutdown`

- `param1` - unused
- `param2` - unused

Sent when Premiere terminates. Deallocate any memory and release the capture hardware or driver.

48.3 `recmod_GetSetupInfo8`

- `param1` - `PrivateData`
- `param2` - `recCapSetups8`

Sent when the Capture Settings dialog is first displayed to obtain custom settings information.

`recCapSetups8` provides text label fields button titles and enabling.

48.4 `recmod_ShowOptions`

- `param1` - `PrivateData`
- `param2` - `recSetupParms`

Sent when the user presses a settings button (one of four available) in the Capture Settings dialog.

Request settings buttons during `recmod_GetSetupInfo8`.

`recSetupParms` indicates which button was pushed.

If the `char*` passed in `recSetupParms` isn't `NULL`, it points to memory containing private data; otherwise, no previous settings are available.

All the setup dialogs share the same memory; only one record is preserved.

If there are several different setup records, they should all fit within one flattened memory allocation.

48.5 `recmod_Open`

- `param1` - `PrivateData`
- `param2` - `recOpenParms`

Sent when Premiere's New Project Settings > Capture Settings dialog or the Movie Capture window is displayed.

Initialize hardware, create a private data structure for instance data, and pass a pointer to it back in `param1`.

It will be sent back to you with subsequent selectors. `recOpenParms` contains information about the capture window and `callbackID`; store this information in private instance data.

48.6 `recmod_Close`

- `param1` - `PrivateData`
- `param2` - `unused`

Capture is complete and the capture window is closed. Disconnect from the hardware and deallocate the private instance data.

48.7 recmod_SetActive

- param1 - `PrivateData`
- param2 - `boolean toggle`

param2 indicates whether the plug-in should activate. When a capture window is opened or receives the focus, it will be activated.

48.8 recmod_SetDisp

- param1 - `PrivateData`
- param2 - `recDisplayPos`

Sent when the capture window is resized or moved. Update a proxy or overlay in the capture window during capture. `recDisplayPos` specifies the new bounds.

If they are unacceptable, modify them; the selector will be sent again with the new position.

Set `mustresize` in `recDisplayPos` to resize the preview frame with the specified bounds.

The plug-in is not allowed to resize the capture window, just the preview frame.

If `mustresize` is set but the plug-in can't resize the frame, display something (black, grey, a graphic of your choice) for a preview.

`mustresize` will be set when the Capture Settings dialog is being displayed.

48.9 recmod_Idle

- param1 - `PrivateData`
- param2 - `recGetTimecodeRec`

Sent to give the plug-in processing time.

48.10 recmod_PrepRecord8

- param1 - `PrivateData`
- param2 - `recCapParmsRec8`

Set up for recording, based on the data in `recInfoRec8`. If the `prerollFunc` callback function pointer is valid, call it to tell the device controller to get the device ready.

Recording commences with the next selector, `recmod_StartRecord`.

If pressing the record button results in a recorder error before the `recmod_PrepRecord8` selector is even sent, make sure that the `fileType` four character code set in `recInfoRec8` is supported by an installed importer.

48.11 recmod_StartRecord

- param1 - `PrivateData`
- param2 - `recCapturedFileInfo`

Sent after `recmod_PrepRecord`. Start capturing immediately.

The pointer to `recCapturedFileInfo` is valid until the recording finishes.

48.12 recmod_ServiceRecord

- param1 - `PrivateData`
- param2 - `unused`

Sent repeatedly to give the plug-in processor time while recording.

48.13 recmod_StopRecord

- param1 - `PrivateData`
- param2 - `unused`

Stop recording and release record buffers.

48.14 recmod_CloseRecord

- param1 - `PrivateData`
- param2 - `unused`

Sent after `recmod_StopRecord`.

During batch capturing, `recmod_StopRecord` will be called after every clip, but `recmod_CloseRecord` will not be called until after the last clip has been captured, to finalize the record process.

48.15 recmod_QueryInfo

- param1 - `PrivateData`
- param2 - `recCapInfoRec`

Sent when the user hits the Log Clip button in the Capture panel.

The recorder should provide the dimensions, pixel aspect ratio, and other attributes to be assigned to the offline clip.

If the dimensions are not provided, the `maxWidth/maxHeight` values set in `recInfoRec8` will be used, which may be incorrect if the recorder supports multiple video resolutions.

CHAPTER 49

Return Codes

Return Code	Reason
rmNoErr	Operation has completed without error.
rmUnsupported	Unsupported command selector.
rmAudioRecordError	Audio recording error.
rmVideoRecordError	Video recording error.
rmVideoDataError	Data rate too high to record (return this if too many frames get dropped).
rmDriverError	Driver error.
rmMemoryError	Memory error.
rmDiskFullError	Disk full.
rmDriverNotFound	Can't connect to the capture driver.
rmStatusCaptureDone	Return from <code>recmod_StartRecord</code> when capture is complete.
rmCaptureLimitReached	Return from <code>recmod_ServiceRecord</code> when the (self-imposed) record limit time is reached.
rmBadFormatIndex	Invalid format index - stops <code>recmod_GetAudioIndFormat</code> queries from Premiere.
rmFormatAccept	The output format is valid.
rmFormatDecline	Cannot capture to this format.
rmErrorPrerollAbort	Preroll function aborted.
rmUserAbort	Return from <code>recmod_StartRecord</code> if user aborts.
rmErrFileSizeLimitErr	Return from <code>recmod_ServiceRecord</code> if file size limit was reached.
rmFramesDropped	Return value to use for dropped frames.
rmDeviceRemoved	The device was removed during capture. Premiere assumes all material captured before this.
rmDeviceNotFound	The capture device was not found.
rmCapturedNoFrames	No frames were captured.
rmEndOfScene	If detecting scenes and recorder senses end of scene
rmNoFrameTimeout	Haven't seen any frames in a while, maybe the tape stopped or hit blank part of tape
rmCantDetectScenesError	If the recorder can't find the info it needs to properly judge scene bounds
rmCantFindRecordInPoint	If capturing in to out and the recorder can't find the in point timecode
rmLastErrorSet	The recorder set the last error string using the <i>Error Suite</i>
rmLastWarningSet	The recorder set the last warning string using the <i>Error Suite</i>
rmLastInfoSet	The recorder set the last info string using the <i>Error Suite</i>

Table 1 – continued from previous page

Return Code	Reason
<code>rmIllegalAudioFormatChange</code>	Return when two different audio formats are recorded on a tape and the user tries to capture
<code>rmRequiresCustomPrefsError</code>	New for Premiere Pro CS3. Return when no valid capture prefs are found during <code>recmod_</code>
<code>rmErrBadFile</code>	Problem with output file.
<code>rmIsCacheable</code>	Return from <code>recmod_Startup8</code> if the plug-in is cacheable, <code>rmNoError</code> if not cacheabl
<code>rmRequiresRoyaltyContent</code>	New for Premiere Pro CC 2014. Return from <code>recmod_Startup8</code> or <code>recmod_StartRe</code>

CHAPTER 50

Structures

Structure	Sent with selector
<i>recInfoRec8</i>	<i>recmod_Startup8</i>
<i>recCapSetups8</i>	<i>recmod_GetSetupInfo8</i>
<i>recDisplayPos</i>	<i>recmod_SetDisp</i> , <i>recmod_Open</i> (member of <i>recOpenParms</i>)
<i>recOpenParms</i>	<i>recmod_Open</i>
<i>recCapturedFileInfo</i>	<i>recmod_StartRecord</i>

<i>recCapInfoRec</i>	<i>recmod_QueryInfo</i>
<i>recSceneDetectionParmsRec</i>	<i>recmod_StartSceneSearch</i>
Obsolete: <ul style="list-style-type: none">• <i>recInfoRec</i>• <i>recCapSetups</i>• <i>recFileSpec</i>• <i>recCapParmsRec</i>	

Structure Descriptions

51.1 recInfoRec8

Selector: *recmod_Startup8*

Describes the recorder's capabilities to Premiere.

```
typedef struct {
    csSDK_int32    recmodID;
    csSDK_int32    fileType;
    csSDK_int32    classID;
    int           canVideoCap;
    int           canAudioCap;
    int           canStepCap;
    int           canStillCap;
    int           canRecordLimit;
    int           acceptsTimebase;
    int           acceptsBounds;
    int           multipleFiles;
    int           canSeparateVidAud;
    int           canPreview;
    int           wantsEvents;
    int           wantsMenuInactivate;
    int           acceptsAudioSettings;
    int           canCountFrames;
    int           canAbortDropped;
    int           requestedAPIVersion;
    int           canGetTimecode;
    int           reserved[16];
    csSDK_int32    prefTimescale;
    csSDK_int32    prefSampleSize;
    csSDK_int32    minWidth;
    csSDK_int32    minHeight;
    csSDK_int32    maxWidth;
}
```

(continues on next page)

(continued from previous page)

```

csSDK_int32    maxHeight;
int          prefAspect;
csSDK_int32    prefPreviewWidth;
csSDK_int32    prefPreviewHeight;
prUTF16Char    recmodName[256];
csSDK_int32    audioOnlyFileType;
int          canSearchScenes;
int          canCaptureScenes;
prPluginID     outRecorderID;
} recInfoRec, *recInfoPtr;

```

recmodID	Premiere's internal identifier for the plug-in. Never change this value.
fileType	Four character code for the captured file (for example 'AVIV' for Video for Windows .AVI files, and 'MOOV' for QuickTime .MOV files). Invent a unique code for proprietary formats as necessary, but make sure an importer is installed that supports the fourcc. If no such importer is installed, pressing the record button will result in a recorder error before the <code>recmod_PrepRecord</code> selector is even sent.
classID	Class identifier, used to differentiate between plug-ins that support the same fileType. ClassID is the identifying characteristic of plug-ins which form a media abstraction layer.
canVideoCap	If set, the recorder can capture video.
canAudioCap	If set, the recorder can capture audio
canStepCap	Unused
canStillCap	Unused
canRecordLimit	If set, the recorder can accept recording time limits. The recorder will receive the user-specified record limit in <code>recCapParmsRec.recordLimit</code> . The plug-in must enforce the time limit during capture.
acceptsTimebase	If set, the recorder can capture to an arbitrary timebase.
acceptsBounds	If set, the recorder can capture to an arbitrary frame size.
multipleFiles	Unused
canSeparateVidAud	Unused
canPreview	Unused
wantsEvents	Unused
wantsMenuInactivate	Unused
acceptsAudioSettings	Unused, do not set
canCountFrames	If set, the recorder is expected to count frames and quit when the count is reached.
canAbortDropped	If set, the recorder can abort when frames are dropped
requestedAPIVersion	Unused
canGetTimecode	Can provide timecode from the capture stream (like DV).
reserved[16]	Do not use.
activeDuringSetup	If set, that the recorder shouldn't be deactivated before a <code>recmod_GetSetupInfo8</code> selector is issued

Continued on next page

Table 1 – continued from previous page

<code>prefTimescale</code>	Frames per second, in scale over <code>sampleSize</code> .
<code>prefSampleSize</code>	
<code>minWidth</code>	Define the minimum and maximum frame sizes the plug-in can capture. If the plug-in can only capture to a single fixed size, then set them to the same value.
<code>minHeight</code>	
<code>minWidth</code>	
<code>minHeight</code>	
<code>prefAspect</code>	Preferred frame aspect ratio for the captured frames. Shift the width into the high order word and the height into the low order word. For example, store 640x480 (a 4:3 aspect ratio) as: <code>prefAspect = (640 << 16) + 480;</code>
<code>prefPreviewWidth</code>	Unused
<code>prefPreviewHeight</code>	Unused
<code>recmodName [256]</code>	The recorder's name (appears in the Capture Format pulldown menu).
<code>audioOnlyFileType</code>	File type for audio-only captures. If 0, the video file type will be used.
<code>canSearchScenes</code>	If true, the recorder can detect a scene boundary for searching purposes
<code>canCaptureScenes</code>	If true, the recorder can identify when it has reached the end of a scene
<code>outRecorderID</code>	New in Premiere Pro 2.0. A GUID identifier is now required for all recorders. Editing Mode XMLs use these GUIDs to refer to recorders.

51.2 recCapSetups8

Selector: `recmod_GetSetupInfo8`

Enumerate custom setup buttons for the Capture Settings dialog, and pull-down menu items in the Capture panel.

```
typedef struct {
    int          customSetups;
    csSDK_int32  enableFlags;
    recSetupItem8 setups[4];
} recCapSetups8;
```

<code>customSetups</code>	Number of setup buttons (up to 4).
<code>enableFlags</code>	Bitstring where bits 0 to 3 correspond with setups 1 to 4. Set the appropriate bits to indicate to Premiere which setups should be enabled
<code>setups [4]</code>	Four <code>recSetupItem8</code> s used to label the setup buttons. A <code>recSetupItem8</code> is just a <code>prUTF16Char [256]</code> .

51.3 recDisplayPos

Selector: *recmod_SetDisp*, *recmod_Open* (member of *recOpenParms*)

Describes the display position for preview frames.

```
typedef struct {
    prWnd  wind;
    int    originTop;
    int    originLeft;
    int    dispWidth;
    int    dispHeight;
    int    mustresize;
} recDisplayPos;
```

wind	The window.
originTop	originTop and originLeft identify the offset in pixels from the top left of the window in which to display.
originLeft	
dispWidth	Display area dimensions.
dispHeight	
mustresize	If set, the video must be resized to fit within these bounds (see <i>recmod_SetDisp</i>).

51.4 recOpenParms

Selector: *recmod_Open*

Provides capture session information; save this information in private instance data.

```
typedef struct {
    recDisplayPos  disp;
    void          *callbackID;
    char          *setup;
    FormatChangedFunc  formatFunc;
    AudioPeakDataFunc  audioPeakDataFunc;
} recOpenParms;
```

disp	Preview display area
callbackID	Premiere's instance identifier for this recording session. Save this value for use with callback routines.
setup	If not null, points to settings saved from a previous recording session.
formatFunc	Use to inform Premiere of a new aspect ratio so the Capture panel can be updated
audioPeakDataFunc	New in CS5. Callback function to send audio metering data to be displayed by Premiere in the Audio Master Meters panel.

51.5 recCapturedFileInfo

Selector: *recmod_StartRecord*

Provide pixel aspect ratio and starting timecode of the captured clip.

```
typedef struct {
    unsigned int pixelAspectRatioNum;
    unsigned int pixelAspectRatioDen;
    char timeCode[31];
    TDB_TimeRecord tdb;
    char date[31];
} recCapturedFileInfo;
```

pixelAspectRatioNum	Fill in the clip's pixel aspect ratio.
pixelAspectRatioDen	
timeCode	Provide the text representation of the starting timecode, as known by the recorder. If the recorder can provide it, and it is non-zero then fill this in. Don't fill this in if the timecode is zero. As of CS5.5, that will result in odd starting timecodes, such as "08;06;40;11".
tdb	Timebase of the captured file.
date	New in Premiere Elements 7. The date of the the captured file, formatted in one of the following ways: "d/m/y" or "d/m/y h:m" or "d/m/y h:m:s"

51.6 recFileSpec8

Selector: *recmod_PrepRecord8* (member of *recCapParmsRec8*)

Used to describe the capture destination file.

```
typedef struct {
    short volID;
    csSDK_int32 parID;
    prUTF16Char name[kPrMaxPath];
} recFileSpec8;
```

volID	Unused
parID	Unused
name	Full file path.

51.7 recSetupParms

Selector: *recmod_ShowOptions*

Indicates which settings dialog should be displayed, and provides any previously saved settings.

```
typedef struct {
    uintptr_t parentwind;
    int setupnum;
    char *setup;
} recSetupParms;
```

parentwind	Parent window owner.
setupnum	Which setup button (1-4) was selected by the user.
setup	If not null, points to saved settings from previous sessions.

51.8 recCapParmsRec8

Selector: *recmod_PrepRecord8*

Specifies capture settings.

```
typedef struct {
    void *callbackID;
    int stepcapture;
    int capVideo;
    int capAudio;
    int width;
    int height;
    csSDK_int32 timescale;
    csSDK_int32 samplesize;
    csSDK_int32 audSubtype;
    csSDK_uint32 audrate;
    int audsamplesize;
    int stereo;
    char *setup;
    int abortondrops;
    int recordlimit;
    recFileSpec8 thefile;
    StatusDispFunc statFunc;
    PrerollFunc prerollFunc;
    csSDK_int32 frameCount;
    char reportDrops;
    short currate;
    short timeFormat;
    csSDK_int32 timeCode;
    csSDK_int32 inHandleAmount;
    ReportSceneFunc reportSceneFunc;
    int captureScenes;
    SceneCapturedFunc8 sceneCapturedFunc;
    bool recordImmediate;
    GetDeviceTimecodeFunc getDeviceTimecodeFunc;
} recCapParmsRec8;
```

callbackID	Premiere's instance identifier for this recording session. Save this value for use with callback routines.
stepcapture	Unused
capVideo	If set, capture video.
capAudio	If set, capture audio.
width	Dimensions of the video frames to capture. These are only sent if <code>acceptsBounds</code> was set in the <code>recInfoRec8</code> . If the plug-in doesn't accept bounds, capture to the preferred dimensions we previously set in <code>recInfoRec8</code> .
height	
timescale	Recording timebase. Only sent if <code>acceptsTimebase</code> was set in the <code>recInfoRec8</code> . Otherwise, capture using the timebase we previously set in <code>recInfoRec8</code> . This supercedes <code>currate</code> below.
samplesize	
audSubtype	Unused
audrate	Unused
audsamples	Unused
stereo	Unused
setup	Pointer to private instance data allocated in response to <code>recmod_GetSetupInfo8</code> .
abortondrop	If set, stop capture if frames are dropped.
recordlimit	Recording time limit, in seconds, only valid if <code>canRecordLimit</code> was set in <code>recInfoRec8</code> . Value passed in by Premiere. The plug-in must enforce the limit during capture.
thefile	Structure of type <code>recFileSpec8</code> describing the capture destination file, only valid during <code>recmod_PrepRecord8</code> .
statFunc	Callback function pointer for use during capture to call into Premiere and update status information in the Capture Panel. See <code>StatusDispFunc</code> for more information.
preroll	Callback function pointer to initiate device control pre-roll. This callback is only initialized if it will be needed, meaning only if doing an in/out capture or batch capture. Otherwise, this function pointer to be set to NULL. See <code>PrerollFunc</code> for more information.
frameCount	If <code>canCountFrames</code> was set in <code>recInfoRec8</code> , the number of frames to capture. No device polling will be done.
reportDrop	If non-zero, report dropped frames when they occur (by returning <code>rmErrVidDataErr</code>).
currate	Frames per second to capture at (23, 24, 25, 30, 59). This is superceded by <code>timescale / samplesize</code> above.
timeFormat	0 = non-drop frame, 1 = drop frame timecode.
timeCode	Timecode for in-point of capture (-1 means ignore).
inHandleAmount	Number of frames of handle (buffered lead-in), previous to the user-specified capture in point, the record module requires.
reportScene	Obsolete. Use <code>sceneCapturedFunc8</code> instead.
captureScene	True if user has initiated scene capture
sceneCaptured	Use this callback during scene capture to report the end of a scene
recordImmediate	If non-zero, begin recording immediately after device control returns from seek for pre-roll; don't wait for a timecode.
getDeviceTimecode	New for Premiere Pro CS3. Use this callback to ask the device controller for its current timecode.

51.9 recGetTimecodeRec

Selector: *recmod_Idle*

Allows the recorder to supply timecode information.

```
typedef struct {
    csSDK_int32  status;
    short        currate;
    short        timeFormat;
    csSDK_int32  timeCode;
    short        autoDetectDropness;
} recGetTimecodeRec;
```

status	0 indicates valid timecode, 1 indicates it's unknown or stale.
currate	30 for NTSC timecode, 25 for PAL.
timeFormat	0 for non-drop, 1 for drop-frame timecode.
timeCode	Timecode as an integer, represented in the absolute number of frames. For example, 00;00;04;03 in NTSC drop-frame timecode would be represented as 123.
autoDetectDropness	Non-zero if the device controller has set DeviceRec.autoDetectDropness to true. This means that the device controller is relying on the recorder to determining whether the timecode is drop-frame or non-drop-frame. The recorder must call FormatChangedFunc if there is any change.

51.10 recCapInfoRec

Selector: *recmod_QueryInfo*

Allows the recorder to supply the resolution and pixel aspect ratio of the clip being logged.

```
typedef struct {
    csSDK_int32  version;
    int          timeScale;
    int          sampleSize;
    csSDK_int32  vidSubType;
    int          width;
    int          height;
    int          depth;
    int          fieldType;
    int          quality;
    csSDK_int32  pixelAspectRatio;
    csSDK_int32  audSubType;
    int          audRate;
    int          audSampleSize;
    int          audStereo;
    int          reserved[10];
    char        *setup;
} recCapInfoRec;
```

version	The version of this structure. kRecCapInfoRecVersion
timeScale	Unused. A logged clip gets it's frame rate from the device controller in cmdStatus.
sampleSize	
vidSubType	Unused.
width	Video resolution
height	
depth	Unused.
fieldType	
quality	
pixelAspect	Pixel aspect ratio. This uses a representation where the numerator is bit-shifted 16 to the left, and OR'd with the denominator. For example NTSC DV 0.9091 PAR is (10 << 16) \ 11.
audSubType	Unused.
audRate	
audSampleSize	
audStereo	

51.11 recSceneDetectionParamsRec

Selectors: recmod_StartSceneSearch

Used for scene searching. searchingForward is provided as a hint as the state of the device, and the reportSceneFunc should be used to notify Premiere of a scene boundary.

```
typedef struct {
    void          *callbackID;
    ReportSceneFunc reportSceneFunc;
    int           searchingForward;
    int           searchMode;
    short         isDropFrame;
    csSDK_int32   earliestTimecode;
    csSDK_int32   greatestTimecode;
} recSceneDetectionParamsRec;
```

callbackID	Required for reportSceneFunc
reportSceneFunc	Use this to report the scenes
searchingForward	True if the tape is playing forward
searchMode	Either sceneSearch_FastScan or sceneSearch_SlowScan
isDropFrame	True if drop-frame, false otherwise
earliestTimecode	Only set for sceneSearch_SlowScan: in point for range to report scene edge
greatestTimecode	Only set for sceneSearch_SlowScan: out point for range to report scene edge

Export Controllers

Starting in Premiere Pro 5.0.2, an export controller can drive any exporter to generate a file in any format and perform custom post-processing operations. Developers wanting to integrate Premiere Pro with an asset management system will want to use this API instead.

An export controller adds its own custom menu item to the File > Export submenu. When the user chooses the menu item, the plug-in is called with a TimelineID, which represents the current sequence. Although details on the current sequence are not passed in, the export controller can use the *Sequence Info Suite* to query for various properties. The export controller can then optionally display any custom modal UI to allow the user to set any parameters for the export.

This UI will need to be provided by the export controller.

The export controller should then call `ExportFile` in the Export Controller Suite, which takes the TimelineID, a path to an exporter preset, and a path for the output. This will tell Premiere Pro to handle the export, displaying progress. The call will return either a success value, an error, or that the user canceled. During the export, the UI will be blocked, just as when doing a standard export that doesn't use the Adobe Media Encoder Render Queue.

Once Premiere Pro completes the export, the call will return to the export controller. The plug-in can then perform any post-processing operations, such as transferring the newly exported file over the network, or registering the file in an asset management system.

Exporters

Exporters are used to export video, audio, and markers in any format. Exporters get individual video frames in a requested pixel format (generally, uncompressed video) and uncompressed audio. The exporter is responsible for any compression of the video and audio data, and wrapping the output in a file format. To reuse an existing exporter, you may provide an export controller.

Exporters can be used from within Premiere Pro, or from Adobe Media Encoder. From within Premiere Pro, go to the File > Export > Media dialog. From there, the Export Settings dialog appears. The format chosen in the Format drop-down determines the exporter used, and the exporter provides the parameter settings and summary displayed in the Export Settings dialog.

Exporters can optionally provide hardware acceleration by coordinating with a renderer plug-in to render timeline segments. Legacy editing modes are formed by the combination of an exporter and a player; the exporter generates preview files and the player manages the cutlist.

If you've never developed an exporter before, you can skip *Whats New*, and go directly to *Getting Started*.

54.1 What's New in CC

A new Captions tab has been added to the Export Settings, for Closed Captioning export. For all formats, a sidecar file containing the captions can be exported.

To learn how exporters can optionally embed Closed Captioning directly in the output file, see *Closed Captioning*.

Two new selectors have been added to GetExportSourceInfo in the *Export Info Suite*. You can use kExportInfo_UsePreviewFiles to check if the user has checked “Use Previews” in the Export Settings dialog. If so, if possible, reuse any preview files already rendered. You can use kExportInfo_NumAudioChannels to get the number of audio channels in a given source.

This can be used to automatically initialize the audio channel parameter in the Audio tab of the Export Settings to match the source.

In the *Export Param Suite*, a new function, MoveParam(), can be used to move an existing parameter to a new location.

54.2 What's New in CS6

Exporters can now use the *Exporter Utility Suite* for “push” model compression. The exporter host can simply push frames to a thread-safe exporter-specified callback. This will cut down on the code previously required for render loop management. It should also yield substantial performance increases for exporters that haven't finely tuned their multithreaded rendering. The “pull” model is still supported, and required for Encore and legacy versions of Premiere Pro and Media Encoder.

The new *Export Standard Param Suite* provides the standard parameters used in many built-in exporters. This can greatly reduce the amount of code needed to manage standard parameters for a typical exporter, and guarantee consistency with built-in exporters.

Stereoscopic video is now supported when exporting directly from Premiere Pro. In other words, when exports are queued to run in Adobe Media Encoder, they can not get stereoscopic video. Note that currently stereoscopic exporters must use the “pull” model and the new

`MakeVideoRendererForTimelineWithStreamLabel()` to get rendered frames from multiple video streams.

Export Param Suite now adds `SetParamDescription()`, to set tooltip strings for parameters. For the three line Export Summary description in the Export Settings dialog, we’ve swapped the 2nd and 3rd lines so that the bitrate summary comes after the audio summary. We’ve renamed the structure to make developers aware of this during a recompile.

Adobe Media Encoder now includes a Preset Browser that provides more organization for presets. Make sure your presets take advantage of this organization, and are shown in your desired proper location in the Preset Browser.

Exporters can now set events (error, warning, or info) for a specific encode in progress in the Adobe Media Encoder render queue. The existing call in the *Error Suite* is not sufficient for AME to relate the event to a specific encode. So the new *Exporter Utility Suite* provides a way for exporters running either in Premiere Pro or Adobe Media Encoder to log events. These events are displayed in the application UI, and are also added to the AME encoding log.

Multiple exporters are now supported in a single plug-in. To support this, `exExporterInfoRec` is now set to exporters on `exShutdown`.

`exQueryOutputSettingsRec` has a new member, `outUseMaximumRenderPrecision`, moving knowledge of this render parameter to the exporter.

54.3 What’s New in CS5.5

A new call, `RenderVideoFrameAndConformToPixelFormat`, has been added to the *Sequence Render Suite*. This allows an exporter to request a rendered frame and then conform it to a specific pixel format.

A new return value, `exportReturn_ParamButtonCancel`, has been added to signify that an exporter is returning from `exSelParamButton` without modifying anything.

54.3.1 Export Controller API

We have opened up a new export controller API that can drive any exporter to generate a file in any format and perform custom post-processing operations. Developers wanting to integrate Premiere Pro with an asset management system will want to use this API instead.

54.4 What’s New in CS5

`exQueryOutputFileListAfterExportRec` is now `exQueryOutputFileListRec`, with a slight change to the structure order.

We’ve also fixed a few bugs, such as bug 1925419, where all sliders would be given a checkbox to disable the control, as if `exParamFlag_optional` had been set.

We’ve made a couple new attributes available to exporters via the `GetExportSourceInfo()` call - the video poster frame time, and the source timecode.

3rd-party exporters can now be used to transcode assets to MPEG-2 or Blu-ray compliant files. Please refer to the Guidelines for Exporters in Encore for instructions on how to set up your exporter so that Encore can use it for transcoding.

54.5 Porting From the Compiler API

The export API replaces the old compiler API from CS3 and earlier versions. The export API combines the processing speed and quality of the old compiler API, with the UI flexibility of Media Encoder. Although the selectors and structures have been renamed and reorganized, much of the code that deals with rendering and writing frames is mostly the same.

The parameter UI is what has changed the most. Rather than having a standard set of parameters as standard compilers had, or having a completely custom UI as custom compilers had, in

the new exporter API, all parameters must be explicitly added using the *Export Param Suite*. First register the parameters during `exSelGenerateDefaultParams`, and then provide the localized strings and constrained parameter values during `exSelPostProcessParams`. When the exporter is sent `exSelExport` to export, get the parameter values, again using the *Export Param Suite*.

Start your plug-in by modifying the SDK sample. Step through the code in your debugger to learn the order of events.

55.1 Media Encoder as a Test Harness

It may be faster to developing exporters using Media Encoder, since it is a lighter-weight application. However, you will want to test your exporter in Premiere Pro, to make sure the behavior is the same as when running in Media Encoder.

55.2 Adding Parameters

Starting in CS6, the *Export Standard Param Suite* provides a way to add several basic sets of parameters, whether for video, audio, still sequences, etc. Beyond the standard parameters, custom defined parameters can be added using the *Export Param Suite*.

First register the parameters during `exSelGenerateDefaultParams`. Then provide the localized strings and min/max parameter values during `exSelPostProcessParams`. When the exporter is sent `exSelExport` to export, get the user-specified parameter values using the *Export Param Suite*.

55.3 Updating Parameters Dynamically

Parameters can be updated dynamically based on user interaction with any related parameter. The time to update is during the `exSelValidateParamChanged` selector. Use `ChangeParam` in the *Export Param Suite* to make the

change. Then, set `exParamChangedRec.rebuildAllParams` to `true` before returning. If you don't set that flag, parameters may appear out of order after a change.

55.4 Supporting “Match Source”

The exporter must set `exExporterInfoRec.canMatchSource` to `true`. This will add the Match Source button to the Video tab in the Export Settings.

Next, if the Match Source button is pressed in the Export Settings, `exPostProcessParamsRec.doConformToMatchParams` will be `true`. The exporter should respond by updating any parameter values it can to match the source settings.

55.5 Get Video Frames and Audio Samples

Starting in CS6, exporters can use the new push model, or the legacy pull model for obtaining frames. The new push model is supported starting in CS6, and the pull model is still supported. Developing for Encore and previous versions of Premiere Pro and Media Encoder requires using the pull model.

55.5.1 Push Model

Using the push model, the exporter host can simply push frames to a thread-safe exporter-specified callback. Use `DoMultiPassExportLoop` in the *Exporter Utility Suite* to register the callback.

Compared with the pull model, this will cut down on the code previously required for render loop management. It should also yield substantial performance increases for exporters that haven't finely tuned their multithreaded rendering.

55.5.2 Pull Model

Using the pull model to get video and audio data involves making calls to the host to ask for this data. Use the *Sequence Render Suite* to get individual video frames, and the *Sequence Audio Suite* to get buffers of audio samples.

Video frames can be requested synchronously or asynchronously. The asynchronous method can yield better performance, but it is up to the exporter to provide its asynchronous render loop.

55.6 Handling a Pause or Cancel by the User (Pull Model only)

Push model export does not require any special code to handle pause or cancel by the user. For pull model export, the way to check if the user has paused or cancelled the export is to call `UpdateProgressPercent` in the *Export Progress Suite*, and check the return value. If the return value is `suiteError_ExporterSuspended`, the user has hit the pause button, which is only available in the Media Encoder UI. If the return value is `exportReturn_Abort`, then the export has been cancelled by the user.

If `UpdateProgressPercent` returns `suiteError_ExporterSuspended`, then the exporter should next call `WaitForResume`, which will block until the user has unpaused the export.

If `UpdateProgressPercent` returns `exportReturn_Abort`, the exporter should take steps to abort the export and clean up. Note that the exporter can still continue to ask for video frames and audio samples after a cancel has been received, which is useful in certain circumstances, such as if an exporter needs a few more frames to complete an MPEG GOP, or if it wants to include the audio for the video exported up to the point of cancel. This allows the exporter to generate well-formed output files, even in the case of a cancel.

55.7 Creating Presets

Create your own presets using the Export Settings UI, either from within Premiere Pro, or Media Encoder. Just modify the parameters the way you want, and hit the Save icon to save the preset to disk. The presets are saved with the extension '.epr'.

Starting in CS5, all the presets are saved to the same location, regardless of whether saved from Premiere Pro or Media Encoder:

On Windows 7, presets are saved here: `[User folder]\AppData\Roaming\Adobe\Common\AME\[version]\Presets\`

On Mac OS: `~/Library/Preferences/Adobe/Common/AME/[version]/Presets/`

In CS4, where the files are saved depends on whether you've opened the Export Settings UI in Premiere Pro or Media Encoder:

55.7.1 Media Encoder presets

On Windows Vista, presets are saved here: `[User folder]\AppData\Roaming\Adobe\Adobe Media Encoder\[version]\Presets\`

On Windows XP: `[Documents and Settings folder]\[user name]\Application Data\Adobe\Adobe Media Encoder\[version]\Presets\`

On Mac OS: `~/Library/Preferences/Adobe/Adobe Media Encoder/[version]/ Presets/`

55.7.2 Premiere Pro presets

On Windows Vista, presets are saved here: `[User folder]\AppData\Roaming\Adobe\Premiere Pro\[version]\ Presets\`

On Windows XP: `[Documents and Settings folder]\[user name]\Application Data\Adobe\Premiere Pro\[version]\Presets\`

On Mac OS: `~/Library/Preferences/Adobe/Adobe Premiere Pro/[version]/Presets/`

AME Preset Browser

Starting in CS6, Adobe Media Encoder has a Preset Browser with provides a structured organization of presets. Third-party presets can be added to any folder or subfolder within the main categories. Once you have created a preset, it will default to the Other folder. You can set the desired folder location in the `<FolderDisplayPath>` tag in the preset XML.

For example, if you set it to: `<FolderDisplayPath>System Presets/Image Sequence/PNG</FolderDisplayPath>` then AME will display the preset in the System Presets > Image Sequence > PNG folder.

It is essential to use: “System Presets/xxx/” where the xxx must be any of the existing main categories (use the English name for this). Only one level below can you create a custom-named folder. If the folder doesn’t already exist, it will be created.

The Preset Browser data is cached in a file at: [User Folder] \AppData \Roaming \Adobe \Common \AME \ [version] \PresetTree.xml

If you want to force a refresh of the Preset Browser data, just quit AME, delete this file, and re-launch AME.

55.7.3 Installation in CS4

For better performance, in CS4, we recommend you install any presets for your exporter in the application folder for Premiere Pro and Media Encoder.

For both Windows and Mac OS: [App installation path] \MediaIO \systempresets \ [exporter subfolder]

The subfolder must be named based on the hexadecimal fourCCs of the ClassID and filetype of the exporter. For example, the SDK exporter has a ClassID of ‘DTEK’ or 0x4454454B, and a filetype of SDK or 0x53444B5F. So the subfolder must be named ‘4454454B_53444B5F’. For convenience, you can find the ClassID and filetype fourCCs in the preset file itself, in a decimal representation.

55.8 Parameter Caching

During development, when you modify parameters in your exporter and reload the plug-in into the host, the Settings UI may continue to show stale parameter data. New parameters that you have added may not appear, or old ones may continue to appear. Or if you have changed the UI for an existing parameter, it may not take effect.

At a minimum, any old presets must be deleted. This includes Media Encoder presets and Premiere Pro presets. After deleting the old presets, there are two options, depending on whether the an older version of the exporter has already been distributed and is in use.

55.8.1 Increment the Parameter Version

If an older version of the exporter is already being used by customers, you’ll need to use parameter versioning. During `exSelGenerateDefaultParams`, you should call `SetParamsVersion()` in the *Export Param Suite* and increment the version number.

After that, create new presets and sequence encoder presets (if needed) using the new set of parameters. Make sure your installer removes the old presets, and installs the new ones.

55.8.2 Flush the Parameter Cache

If you don’t increment the parameter version, you can manually flush the parameter cache in a few steps. After you’ve deleted the old presets, do the following:

1. Delete hidden presets that were created by the hosts for the most recently used parameter settings. Look for a file called Placeholder Preset.epr in both the folders above the Media Encoder presets and the Premiere Pro presets.
2. Delete batch.xml, used by Media Encoder. This is also in the folder above the Media Encoder presets. Deleting this is equivalent to deleting the items out of the Media Encoder render queue.

3. Delete Premiere Pro sequence encoder presets that use the exporter, if any
 4. Even after deleting all the old presets, Media Encoder may initially show old cached parameter UI. In the Settings UI, just switch to a different format and then back to yours.
-

55.9 Multichannel Audio Layouts

To support multichannel audio layouts, `kPrAudioChannelType_MaxChannel` should be the type requested in `MakeAudioRenderer()`.

The audio buffers you use for `GetAudio()` should likewise be an array of `kPrAudioChannelType_MaxChannel` channels, and yes, this means you may be allocating more space than actually used.

In the exporter's Audio tab UI, you can provide a parameter to choose between various multi-channel audio layouts. You can compare your settings to what we have with the built-in formats, QuickTime and MXF (such as MXF OP1a and DNxHD). From the user selection in your audio export settings (e.g., 2x stereo, etc), you will know how many of those channels passed back in `GetAudio()` should actually be written to the file.

Here's a helpful video on audio track mapping: <http://www.video2brain.com/en/lessons/changes-in-audio-tracks-and-merged-clip-audio>

55.10 Closed Captioning

Starting in CC, the Export Settings includes a new Captions tab, for Closed Captioning export. For all formats, a sidecar file containing the captions can be exported. Additionally, exporters can optionally embed Closed Captioning directly in the output file. First, the exporter must set `exExporterInfoRec.canEmbedCaptions` to true. This will add the option to embed the captions in the output file, from the Export Options drop-down in the Captions tab. If this option is selected during export, `exDoExportRec.embedCaptions` will be true. The exporter should retrieve the captions using the *Captioning Suite*.

55.11 Multiple File Formats

To support more than one file format in a single exporter, describe one format at a time during `exSelStartup`. After describing the first one, return `exportReturn_IterateExporter` from `exSelStartup`, and the exporter will be called again to describe the second format, and so on. After describing the last format, return `exportReturn_IterateExporter`, and the exporter will be called yet again. This time, return `exportReturn_IterateExporterDone`.

Use a unique `fileType` for each format. When you are later sent `exSelGenerateDefaultParams`, `exSelPostProcessParams`, etc, you'll want to pay attention to the `fileType`, and respond according to the format.

55.12 Exporters Used for Editing Modes

An exporter that is used in an editing mode must have a codec parameter, and that parameter ID must be `ADBEVideoCodec`. If Premiere Pro cannot find this parameter, it will not be able to reopen projects in the custom editing mode, and will revert the project to Desktop mode.

55.12.1 Sequence Encoder Presets

Sequence preview presets are now required for editing modes. These contain the exporter parameters to generate preview files. This makes preview file formats much easier to define, by using the Media Encoder or Premiere Pro UI to create presets, rather than directly editing XML.

To create a sequence encoder preset:

1. Create a preset. The name that you give it will be the name that will be used in the Sequence Settings > General > Preview File Format drop-down.
2. Make sure this preset is installed in the application folder for Premiere Pro, along with the other sequence presets:

On Windows, they should be installed here: [App installation path]\Settings\EncoderPresets\SequencePreview mode GUID]*.epr

On MacOS, it is basically the same (inside the application package): [App installation path]/[Premiere Pro package]/Contents/Settings/EncoderPresets/ SequencePreview/[editing mode GUID]*.epr

As you can see by the installation paths above, Premiere Pro associates the sequence preview presets with the editing mode they go with, by using the presets in the folder that matches the GUID of the editing mode. The editing mode GUID is defined in the editing mode XML file, using the <EditingMode.ID> tag.

55.12.2 Adding new Preview File Formats to Existing Editing Modes

You can not only provide sequence preview presets for your own editing mode, but you could even add additional sequence preview presets for one of the built-in editing modes. Editing mode GUIDs for built-in editing modes can be found in the Adobe Editing Modes.xml file. For example, the Desktop editing mode on Windows has the GUID 9678AF98A7B7-4bdb-B477-7AC9C8DF4A4E. On Mac OS it is 795454D9-D3C2-429d-9474- 923AB13B7018.

You can additionally restrict the list and specify which one is chosen by default, by editing the <PresetComments> tag in the preset file.

If the value of the tag starts with “IsConstrained,”, then a comma delimited list of 4ccs follows that dictates which codecs are available, and the first one is chosen by default.

For example, QuickTime DV NTSC.epr for the Mac DV NTSC editing mode has this:
<PresetComments>IsConstrained,dvc </PresetComments>

Which restricts the codec selection of the exporter to be only the single codec choice.

55.13 Stereoscopic Video

Note that currently stereoscopic exporters must use the old “pull” model, and only receive stereoscopic video when exporting directly from Premiere Pro. In other words, when exports are queued to run in Adobe Media Encoder, they will not get stereoscopic video.

To get rendered frames for both left and right eye, use the *Video Segment Suite* to request the left and right cutlists, and render frames from both. An exporter can tell if segments in both of them are identical (implying that they have nothing stereoscopic about them) by looking at the segment hashes, and you can tell if two frames are identical (by looking at the request identifiers).

55.14 Timeline Segments in Exporters

The timeline segments available to exporters do not always fully describe the sequence being exported. To consistently get timeline segments that fully describe the sequence, an exporter needs to work along with a renderer plug-in.

During a sequence export, Premiere Pro makes a copy of the project file and passes it to Media Encoder. Media Encoder takes that project and uses the PProHeadless process to generate rendered frames. So when an exporter, which is running in Media Encoder, parses the sequence, it only has a very high-level view. It sees the entire sequence as a single clip, and sees any optional cropping or filters as applied effects. So when parsing that simple, high-level sequence, if there are no effects, an exporter can just use the `MediaNode`'s `ClipID` with the *Clip Render Suite* to get frames directly from the PProHeadless process. In the PProHeadless process, a renderer plug-in can step in, parse the real sequence in all its glory, and optionally provide frames in a custom pixel format.

When rendering preview files, Premiere Pro does the rendering without Media Encoder, so an exporter can get the individual segments for each clip, similar to before.

55.15 Smart Rendering

Under very specific circumstances, an exporter can request compressed frames, avoiding unnecessary de/recompression.

This would be done by providing both exporter and renderer plug-ins that parse timeline segments.

If the source can be copied over to the destination, the compressed frames can be passed in a custom pixel format.

These compressed frames are not guaranteed, however, so the exporter should be prepared to handle uncompressed frames.

55.16 Entry Point

```
DllExport PREMPLUGENTRY xSDKExport (
    csSDK_int32      selector,
    exportStdParams* stdParamsP,
    void*           param1,
    void*           param2)
```

selector is the action the host wants the exporter to perform.

stdParams provides callbacks to obtain additional information from the host or to have the host perform tasks.

Parameters 1 and 2 vary with the selector; they may contain a specific value or a pointer to a structure.

Return `exportReturn_ErrNone` if successful, or an appropriate return code.

55.17 Standard Parameters

A pointer to this structure is sent from the host to the plug-in with every selector.

```
typedef struct {
    csSDK_int32          interfaceVer;
    plugGetSPBasicSuiteFunc* getSPBasicSuite;
} exportStdParms;
```

Member	Description
interfaceVer	<p>Exporter API version</p> <ul style="list-style-type: none"> • Premiere Pro CC - prExportVersion400 • Premiere Pro CS6 - prExportVersion300 • Premiere Pro CS5.5 - prExportVersion250 • Premiere Pro CS5 - prExportVersion200 • Premiere Pro 4.0.1 through 4.2.1 - prExportVersion101 • Premiere Pro CS4 - prExportVersion100
getSPBasicSuite	<p>This very important call returns the SweetPea suite that allows plug-ins to acquire and release all other <i>SweetPea Suites</i>.</p> <pre>SPBasicSuite* getSPBasicSuite();</pre>

Selector Table

This table summarizes the various selector commands an exporter can receive.

Selector	param1	param2
<i>exSelStartup</i>	<i>exExporterInfoRec*</i>	unused
<i>exSelBeginInstance</i>	<i>exExporterInstanceRec*</i>	unused
<i>exSelGenerateDefaultParams</i>	<i>exGenerateDefaultParamRec*</i>	unused
<i>exSelPostProcessParams</i>	<i>exPostProcessParamsRec*</i>	unused
<i>exSelValidateParamChanged</i>	<i>exParamChangedRec*</i>	unused
<i>exSelGetParamSummary</i>	<i>exParamSummaryRec*</i>	unused
<i>exSelParamButton</i>	<i>exParamButtonRec*</i>	unused
<i>exSelExport</i>	<i>exDoExportRec*</i>	unused
<i>exSelQueryExportFileExtension</i>	<i>exQueryExportFileExtensionRec*</i>	unused
<i>exSelQueryOutputFileList</i>	<i>exQueryOutputFileListRec*</i>	unused
<i>exSelQueryStillSequence</i>	<i>exQueryStillSequenceRec*</i>	unused
<i>exSelQueryOutputSettings</i>	<i>exQueryOutputSettingsRec*</i>	unused
<i>exSelValidateOutputSettings</i>	<i>exValidateOutputSettingsRec*</i>	unused
<i>exSelEndInstance</i>	<i>exExporterInstanceRec*</i>	unused
<i>exSelShutdown</i>	<i>exExporterInfoRec*</i>	unused

Selector Descriptions

This section provides a brief overview of each selector and highlights implementation issues. Additional implementation details are at the end of the chapter.

57.1 exSelStartup

- param1 - *exExporterInfoRec**
- param2 - unused

Sent during application launch, unless the exporter has been cached.

A single exporter can support multiple codecs and file extensions.

`exExporterInfoRec` describes the exporter's attributes, such as the format display name.

57.2 exSelBeginInstance

- param1 - *exExporterInstanceRec**
- param2 - unused

Allocate any private data.

57.3 exSelGenerateDefaultParams

- param1 - *exGenerateDefaultParamRec**
- param2 - unused

Set the exporter's default parameters using the *Export Param Suite*.

57.4 exSelPostProcessParams

- param1 - *exPostProcessParamsRec**
- param2 - unused

Post process parameters. This is where the localized strings for the parameter UI must be provided.

57.5 exSelValidateParamChanged

- param1 - *exParamChangedRec**
- param2 - unused

Validate any parameters that have changed. Based on a change to a parameter value, the exporter may update other parameter values, or show/hide certain parameter controls, using the *Export Param Suite*.

To notify the host that the plug-in is changing other parameters, set `exParamChangedRec.rebuildAllParams` to a non-zero value.

57.6 exSelGetParamSummary

- param1 - *exParamSummaryRec**
- param2 - unused

Provide a text summary of the current parameter settings, which will be displayed in the summary area of the Export Settings dialog.

57.7 exSelParamButton

- param1 - *exParamButtonRec**
- param2 - unused

Sent if exporter has one or more buttons in its parameter UI, and the user clicks one of the buttons in the Export Settings.

The ID of the button pressed is passed in `exParamButtonRec.buttonParamIdentifier`.

Display any dialog using platform-specific UI, collect any user input, and save any changes back to `privateData`.

If the user cancels the dialog, return `exportReturn_ParamButtonCancel` to signify that nothing in the `privateData` has changed.

57.8 exSelExport

- param1 - *exDoExportRec**
- param2 - unused

Do the export! Sent when the user starts an export to the format supported by the exporter, or if the exporter is used in an Editing Mode and the user renders the work area.

Single file exporters are sent this selector only once per export (e.g. AVI, QuickTime). To create a single file, setup a loop where you request each frame in the `startTime` to `endTime` range using one of the render calls in the *Sequence Render Suite* and `GetAudio` in the *Sequence Audio Suite*. For better performance, you can use the asynchronous calls in the *Sequence Render Suite* to have the host render multiple frames on multiple threads.

Still frame exporters are sent `exSelExport` for each frame in the sequence (e.g. numbered TIFFs). The host will name the files appropriately.

Save render time by checking to see if frames are repeated. Inspect the `SequenceRender_GetFrameReturnRec.repeatCount` returned from a render call, which holds a frame repeat count.

57.9 exSelQueryExportFileExtension

- param1 - *exQueryExportFileExtensionRec**
- param2 - unused

For exporters that support more than one file extension, specify an extension given the file type.

If this selector is not supported by the exporter, the extension is specified by the exporter in `exExporterInfoRec.fileTypeDefaultExtension`.

57.10 exSelQueryOutputFileList

- param1 - *exQueryOutputFileListRec**
- param2 - unused

For exporters that export to more than one file. This is called before an export for the host to find out which files would need to be overwritten.

It is called after an export so the host will know about all the files created, for any post encoding tasks, such as FTP. If this selector is not supported by the exporter, the host application will only know about the original path.

This selector will be called three times. On the first call, the plug-in fills out numOutputFiles. The host will then make numOutputFiles count of outputFileRecs, but empty.

On the second call, the plug-in fills out the path length (incl trailing null) for each exOutputFileRec element in outputFileRecs. The host will then allocate all paths in each outputFileRec.

On the third call, the plug-in fills in the path members of the outputFileRecs.

57.11 exSelQueryStillSequence

- param1 - *exQueryStillSequenceRec**
- param2 - unused

The host application asks a still-only exporter if it wants to export as a sequence, and at what frame rate.

57.12 exSelQueryOutputSettings

- param1 - *exQueryOutputSettingsRec**
- param2 - unused

The host application asks the exporter for general details about the current settings. This is a required selector.

57.13 exSelValidateOutputSettings

- param1 - *exValidateOutputSettingsRec**
- param2 - unused

The host application asks the exporter if it can export with the current settings.

The exporter should return `exportReturn_ErrLastErrorSet` if not, and the error string should be set to a description of the failure.

57.14 exSelEndInstance

- param1 - *exExporterInstanceRec**
- param2 - unused

Deallocate any private data.

57.15 exSelShutdown

- param1 - unused
- param2 - unused

Sent immediately before shutdown. Free all remaining memory and close any open file handles.

CHAPTER 58

Return Codes

Return Code	Reason
exportReturn_ErrNone	Operation has completed without error.
exportReturn_Abort	User aborted the export.
exportReturn_Done	Export finished normally.
exportReturn_InternalError	Return this if none of the other errors apply.
exportReturn_OutOfDiskSpace	Out of disk space error.
exportReturn_BufferFull	The offset into the buffer would overflow it.
exportReturn_ErrOther	The vaguer the better, right?
exportReturn_ErrMemory	Out of memory.
exportReturn_ErrFileNotFound	File not found.
exportReturn_ErrTooManyOpenFiles	Too many open files.
exportReturn_ErrPermErr	Permission violation.
exportReturn_ErrOpenErr	Unable to open the file.
exportReturn_ErrInvalidDrive	Invalid drive.
exportReturn_ErrDupFile	Duplicate filename.
exportReturn_ErrIo	File I/O error.
exportReturn_ErrInUse	File is in use.
exportReturn_IterateExporter	Return value from <code>exSelStartup</code> to request exporter iteration.
exportReturn_IterateExporterDone	Return value from <code>exSelStartup</code> to indicate there are no more exports.
exportReturn_InternalErrorSilent	Return error code from <code>exSelExport</code> to put a custom error message.
exportReturn_ErrCodecBadInput	A video codec refused the input format.
exportReturn_ErrLastErrorSet	The exporter is returning an error using the <i>Error Suite</i> .
exportReturn_ErrLastWarningSet	The exporter is returning a warning using the <i>Error Suite</i> .
exportReturn_ErrLastInfoSet	The exporter is returning information using the <i>Error Suite</i> .
exportReturn_ErrExceedsMaxFormatDuration	The exporter (or the host) has deemed the duration of the export to be too long.
exportReturn_VideoCodecNeedsActivation	The current video codec is not activated and cannot be used.
exportReturn_AudioCodecNeedsActivation	The current audio codec is not activated and cannot be used.
exportReturn_IncompatibleAudioChannelType	The requested audio channels are not compatible with the source audio.
exportReturn_IncompatibleVideoCodec	New in CS5. User tried to load a preset with an invalid video codec.

Table 1 – continued from previous page

Return Code	Reason
<code>exportReturn_IncompatibleAudioCodec</code>	New in CS5. User tried to load a preset with an invalid audio codec
<code>exportReturn_ParamButtonCancel</code>	New in CS5.5. Return this from <code>exSelParamButton</code> if the user c
<code>exportReturn_Unsupported</code>	Unsupported selector.

Structure	Sent with selector
<i>exDoExportRec</i>	<i>exSelExport</i>
<i>exExporterInfoRec</i>	<i>exSelStartup</i>
<i>exExporterInstanceRec</i>	<i>exSelBeginInstance</i> and <i>exSelEndInstance</i>
<i>exGenerateDefaultParamRec</i>	<i>exSelGenerateDefaultParams</i>
<i>exParamButtonRec</i>	<i>exSelParamButton</i>
<i>exParamChangedRec</i>	<i>exSelValidateParamChanged</i>
<i>exParamSummaryRec</i>	<i>exSelGetParamSummary</i>
<i>exPostProcessParamsRec</i>	<i>exSelPostProcessParams</i>
<i>exQueryExportFileExtensionRec</i>	<i>exSelQueryExportFileExtension</i>
<i>exQueryOutputFileListRec</i>	<i>exSelQueryOutputFileList</i>
<i>exQueryOutputSettingsRec</i>	<i>exSelQueryOutputSettings</i>
<i>exQueryStillSequenceRec</i>	<i>exSelQueryStillSequence</i>
<i>exValidateOutputSettingsRec</i>	<i>exSelValidateOutputSettings</i>

60.1 exDoExportRec

Selector: *exSelExport*

Provides general export settings. The exporter should retrieve the parameter settings from the *Export Param Suite*.

```
typedef struct {
    csSDK_uint32  exporterPluginID;
    void*        privateData;
    csSDK_uint32  fileType;
    csSDK_int32  exportAudio;
    csSDK_int32  exportVideo;
    PrTime       startTime;
    PrTime       endTime;
    csSDK_uint32  fileObject;
    PrTimelineID timelineData;
    csSDK_int32  reserveMetaDataSpace;
    csSDK_int32  maximumRenderQuality;
    csSDK_int32  embedCaptions
} exDoExportRec;
```

exporterPlugFileID	The host's internal identifier for this exporter, used for various suite calls, such as in the <i>Sequence Render Suite</i> and <i>Sequence Audio Suite</i> .
privateData	Data allocated and managed by the exporter.
fileType	The file format four character code set by the exporter during <i>exSelStartup</i> . Indicates which format the exporter should write, since exporters can support multiple formats.
exportAudio	If non-zero, export audio.
exportVideo	If non-zero, export video.
startTime	The start time of the sequence to export.
endTime	The end time of the sequence to export. If <code>startTime</code> is 0, also the total duration to export. Range specified is <code>[startTime, endTime)</code> , meaning the <code>endTime</code> is not actually included in the range.
fileObject	For use with the <i>Export File Suite</i> , to get and manipulate the file specified by the user.
timelineData	Handle used for the Timeline Functions.
reserveMetadata	Amount to reserve in a file for metadata storage.
maximumRenderQuality	If non-zero, the exporter should set <code>SequenceRender_ParamsRec.inRenderQuality</code> and <code>inDeinterlaceQuality</code> to <code>kPrRenderQuality_Max</code> .
embedCaptions	New in CC. If non-zero, the exporter should embed captions obtained from the <i>Captioning Suite</i> .

60.2 exExporterInfoRec

Selector: *exSelStartup* and *exSelShutdown* (starting in CS6)

Describe the exporter's capabilities by filling out this structure during *exSelStartup*.

For each filetype, populate `exExporterInfoRec` and return `exportReturnIterateExporter`.

exSelStartup will then be resent. Repeat the process until there are no more file formats to describe, then return `exportReturn_IterateExporterDone`.

The `fileType` indicates which format the exporter should currently work with in subsequent calls.

```
typedef struct {
    csSDK_uint32    unused;
    csSDK_uint32    fileType;
    prUTF16Char    fileTypeNames[256];
    prUTF16Char    fileTypeDefaultExtension[256];
    csSDK_uint32    classID;
    csSDK_int32     exportReqIndex;
    csSDK_int32     wantsNoProgressBar;
    csSDK_int32     hideInUI;
    csSDK_int32     doesNotSupportAudioOnly;
    csSDK_int32     canExportVideo;
    csSDK_int32     canExportAudio;
    csSDK_int32     singleFrameOnly;
    csSDK_int32     maxAudiences;
    csSDK_int32     interfaceVersion;
    csSDK_uint32    isCacheable;
    csSDK_uint32    canConformToMatchParams;
    csSDK_uint32    canEmbedCaptions;
} exExporterInfoRec;
```

fileType	The file format four character code (e.g. 'AVIV' = Video for Windows, 'MooV' = QuickTime).
fileTypeName	The localized display name for the filetype.
fileTypeDefaultExtension	The default extension for the filetype. An exporter can support multiple extensions per filetype, by implementing <code>exSelQueryExportFileExtension</code> .
classID	Class identifier for the module, differentiates between exporters that support the same filetype and creates associations between different Media Abstraction Layer plug-ins.
exportReqIndex	If an exporter supports multiple filetypes, this index will be incremented by the host for each call, as the exporter is requested to describe its capabilities for each filetype. Initially zero, incremented by the host each time the exporter returns <code>exportReturn_IterateExporter</code> .
wantsNoProgressDialog	If non-zero, the default exporter progress dialog will be turned off, allowing the exporter to display its own progress dialog. The exporter also will not get <code>exportReturn_Abort</code> errors from the host during callbacks – it must detect an abort on its own, and return <code>exportReturn_Abort</code> from <code>exSelExport</code> if the user aborts the export.
hideInUI	Set this to non-zero if this filetype should only be used for making preview files, and should not be visible as a general export choice.
doesNotSupportAudioOnly	Set this to non-zero for filetypes that do not support audio-only exports.
canExportVideo	Set this to non-zero if the exporter can output video.
canExportAudio	Set this to non-zero if the exporter can output audio.
singleFrameOnly	Set this to non-zero if the exporter makes single frames (used by still image exporters).
maxAudiences	
interfaceVersion	Exporter API version that the plug-in supports.
isCacheable	New in CS5. Set this non-zero to have Premiere Pro cache this exporter.
canConform	New in CC. Set this to non-zero if the exporter wants to support the Match Source button.
canEmbedClosedCaptioning	New in CC. Set this to non-zero if the exporter can embed Closed Captioning directly in the file.

60.3 exExporterInstanceRec

Selector: `exSelBeginInstance` and `exSelEndInstance`

Provides access to the `privateData` for the indicated filetype, so that the exporter can allocate `privateData` and pass it to the host, or deallocate it.

```
typedef struct {
    csSDK_uint32  exporterPluginID;
    csSDK_uint32  fileType;
    void*         privateData;
} exExporterInstanceRec;
```

exporterPluginID	The host's internal identifier for this exporter. Do not modify.
fileType	The file format four character code set by the exporter during <code>exSelStartup</code> .
privateData	Data allocated and managed by the exporter.

60.4 exGenerateDefaultParamRec

Selector: *exSelGenerateDefaultParams*

Provides access to the `privateData` for the indicated filetype, so that the exporter can generate the default parameter set.

```
typedef struct {
    csSDK_uint32  exporterPluginID;
    void*        privateData;
    csSDK_uint32  fileType;
} exExporterInstanceRec;
```

<code>exporterPluginID</code>	The host's internal identifier for this exporter. Do not modify.
<code>privateData</code>	Data allocated and managed by the exporter.
<code>fileType</code>	The file format four character code set by the exporter during <i>exSelStartup</i> .

60.5 exParamButtonRec

Selector: *exSelParamButton*

Provides access to the `privateData` for the indicated filetype, and discloses the specific button hit by the user, since there can be multiple button parameters.

```
typedef struct {
    csSDK_uint32  exporterPluginID;
    void*        privateData;
    csSDK_uint32  fileType;
    csSDK_int32   exportAudio;
    csSDK_int32   exportVideo;
    csSDK_int32   multiGroupIndex;
    exParamIdentifier  buttonParamIdentifier;
} exParamButtonRec;
```

<code>exporterPluginID</code>	The host's internal identifier for this exporter. Do not modify.
<code>privateData</code>	Data allocated and managed by the exporter.
<code>fileType</code>	The file format four character code set by the exporter during <i>exSelStartup</i> .
<code>exportAudio</code>	If non-zero, the current settings are set to export audio.
<code>exportVideo</code>	If non-zero, the current settings are set to export video.
<code>multiGroupIndex</code>	Discloses the index of the multi-group, containing the button hit by the user.
<code>buttonParamIdentifier</code>	Discloses the parameter ID of the button hit by the user.

60.6 exParamChangedRec

Selector: *exSelValidateParamChanged*

Provides access to the `privateData` for the indicated filetype, and discloses the specific parameter changed by the user.

To notify the host that the plug-in is changing other parameters, set `rebuildAllParams` to a non-zero value.

```
typedef struct {
    csSDK_uint32    exporterPluginID;
    void*          privateData;
    csSDK_uint32    fileType;
    csSDK_int32     exportAudio;
    csSDK_int32     exportVideo;
    csSDK_int32     multiGroupIndex;
    exParamIdentifier changedParamIdentifier;
    csSDK_int32     rebuildAllParams;
} exParamChangedRec;
```

<code>exporterPluginID</code>	The host's internal identifier for this exporter. Do not modify.
<code>privateData</code>	Data allocated and managed by the exporter.
<code>fileType</code>	The file format four character code set by the exporter during <i>exSelStartup</i> .
<code>exportAudio</code>	If non-zero, the current settings are set to export audio.
<code>exportVideo</code>	If non-zero, the current settings are set to export video.
<code>multiGroupIndex</code>	Discloses the index of the multi-group, containing the parameter changed by the user.
<code>changedParamIdentifier</code>	Discloses the parameter ID of the parameter changed by the user. May be empty if the changed item was <code>exportAudio</code> , <code>exportVideo</code> or the current <code>multiGroupIndex</code> .
<code>rebuildAllParams</code>	Set this to non-zero to tell the host to refresh ALL parameters using the latest provided information. This can solve various problems when dynamically updating parameter visibility, valid ranges, etc.

60.7 exParamSummaryRec

Selector: *exSelGetParamSummary*

Provides access to the `privateData` for the indicated filetype, and provides buffers for the exporter to fill in with a localized summary of the parameters.

```
typedef struct {
    csSDK_uint32    exporterPluginID;
    void*          privateData;
    csSDK_int32     exportAudio;
    csSDK_int32     exportVideo;
    prUTF16Char     videoSummary[256];
    prUTF16Char     audioSummary[256];
    prUTF16Char     bitrateSummary[256];
} exParamSummaryRec;
```

<code>exporterPluginID</code>	The host's internal identifier for this exporter. Do not modify.
<code>privateData</code>	Data allocated and managed by the exporter.
<code>exportAudio</code>	If non-zero, the current settings are set to export audio.
<code>exportVideo</code>	If non-zero, the current settings are set to export video.
<code>videoSummary</code>	Fill these in with a line of a localized summary of the parameters.
<code>audioSummary</code>	
<code>bitrateSummary</code>	

60.8 exPostProcessParamsRec

Selector: *exSelPostProcessParams*

Provides access to the `privateData` for the indicated filetype.

```
typedef struct {
    csSDK_uint32  exporterPluginID;
    void*        privateData;
    csSDK_uint32  fileType;
    csSDK_int32   exportAudio;
    csSDK_int32   exportVideo;
    csSDK_int32   doConformToMatchParams;
} exPostProcessParamsRec;
```

<code>exporterPluginID</code>	The host's internal identifier for this exporter. Do not modify.
<code>privateData</code>	Data allocated and managed by the exporter.
<code>fileType</code>	The file format four character code set by the exporter during <i>exSelStartup</i> .
<code>exportAudio</code>	If non-zero, the current settings are set to export audio.
<code>exportVideo</code>	If non-zero, the current settings are set to export video.
<code>doConformToMatchParams</code>	New in CC.

60.9 exQueryExportFileExtensionRec

Selector: *exSelQueryExportFileExtension*

Provides access to the `privateData` for the indicated filetype, and provides a buffer for the exporter to fill in with the file extension.

```
typedef struct {
    csSDK_uint32  exporterPluginID;
    void*        privateData;
    csSDK_uint32  fileType;
    prUTF16Char  outFileExtension[256];
} exQueryExportFileExtensionRec;
```

<code>exporterPluginID</code>	The host's internal identifier for this exporter. Do not modify.
<code>privateData</code>	Data allocated and managed by the exporter.
<code>fileType</code>	The file format four character code set by the exporter during <i>exSelStartup</i> .
<code>outFileExtension</code>	Provide the file extension here, given the current parameter settings.

60.10 exQueryOutputFileListRec

Selector: *exSelQueryOutputFileList*

Provides access to the `privateData` for the indicated filetype, and provides a pointer to a array of `exOutputFileRecs` for the exporter to fill in with the file paths.

```
typedef struct {
    csSDK_uint32    exporterPluginID;
    void*          privateData;
    csSDK_uint32    fileType;
    csSDK_uint32    numOutputFiles;
    PrSDKString     path;
    exOutputFileRec *outputFileRecs;
} exQueryOutputFileListRec;
```

exporterPluginID	The host's internal identifier for this exporter. Do not modify.
privateData	Data allocated and managed by the exporter.
fileType	The file format four character code set by the exporter during <i>exSelStartup</i> .
numOutputFiles	On the first call to <i>exSelQueryOutputFileList</i> , provide the number of file paths here.
path	New in CS5. Contains the primary intended destination path provided by the host.
outputFileRecs	An array of <code>exOutputFileRecs</code> . On the second call to <i>exSelQueryOutputFileList</i> , the path length (including trailing null) for each path. On the third call, fill in the path of each <code>exOutputFileRec</code> . <pre>typedef struct { int pathLength; prUTF16Char* path; } exOutputFileRec;</pre>

60.11 exQueryOutputSettingsRec

Selector: *exSelQueryOutputSettings*

Provides access to the `privateData` for the indicated filetype, and provides a set of members for the exporter to fill in with the current export settings.

```
typedef struct {
    csSDK_uint32    exporterPluginID;
    void*          privateData;
    csSDK_uint32    fileType;
    csSDK_int32     inMultiGroupIndex;
    csSDK_int32     inExportVideo;
    csSDK_int32     inExportAudio;
```

(continues on next page)

(continued from previous page)

```

csSDK_int32      outVideoWidth;
csSDK_int32      outVideoHeight;
PrTime          outVideoFrameRate;
csSDK_int32      outVideoAspectNum;
csSDK_int32      outVideoAspectDen;
csSDK_int32      outVideoFieldType;
double         outAudioSampleRate;
PrAudioSampleType outAudioSampleType;
PrAudioChannelType outAudioChannelType;
csSDK_uint32     outBitratePerSecond;
csSDK_int32      outUseMaximumRenderPrecision;
} exQueryOutputSettingsRec;

```

exporterPluginID	The host's internal identifier for this exporter. Do not modify.
privateData	Data allocated and managed by the exporter.
fileType	The file format four character code set by the exporter during <i>exSelStartup</i> .
inMultiGroupIndex	Return the parameter settings of the multi-group with this index.
inExportVideo	If non-zero, the current settings are set to export video.
inExportAudio	If non-zero, the current settings are set to export audio.
outVideoWidth	Return each parameter setting, by getting the current value of the parameter using the <i>Export Param Suite</i> .
outVideoHeight	Some settings, such as <code>outVideoFieldType</code> , may be implicit, for example if the format only supports progressive frames.
outUseMaximumRenderPrecision	New in CS6. If non-zero, renders will always be made at maximum bit-depth.

60.12 exQueryStillSequenceRec

Selector: *exSelQueryStillSequence*

Provides access to the `privateData` for the indicated filetype, and provides a set of members for the exporter to provide information on how it would export the sequence of stills.

```

typedef struct {
csSDK_uint32  exporterPluginID;
void*       privateData;
csSDK_uint32  fileType;
csSDK_int32   exportAsStillSequence;
PrTime        exportFrameRate;
} exQueryStillSequenceRec;

```

exporterPluginID	The host's internal identifier for this exporter. Do not modify.
privateData	Data allocated and managed by the exporter.
fileType	The file format four character code set by the exporter during <i>exSelStartup</i> .
exportAsStillSequence	Set this to non-zero to tell the host that the exporter can export the stills as a sequence.
exportFrameRate	Set this to the frame rate of the still sequence.

60.13 exValidateOutputSettingsRec

Selector: *exSelValidateOutputSettings*

Provides access to the `privateData` for the indicated filetype, so that the exporter can validate the current parameter settings.

```
typedef struct {
    csSDK_uint32  exporterPluginID;
    void*         privateData;
    csSDK_uint32  fileType;
} exExporterInstanceRec;
```

exporterPluginID	The host's internal identifier for this exporter. Do not modify.
privateData	Data allocated and managed by the exporter.
fileType	The file format four character code set by the exporter during <i>exSelStartup</i> .

For information on how to acquire and manage suites, see *SweetPea Suites*.

61.1 Export File Suite

A cross-platform suite for writing to files on disk. Also provides a call to get the file path, given the file object.

Version 2 resolves a mismatch in seek modes in version 1, where `fileSeekMode_End` was handled as `fileSeekMode_Current` and visa versa.

See `PrSDKExportFileSuite.h`.

61.2 Export Info Suite

61.2.1 GetExportSourceInfo

Get information on the source currently being exported.

```
prSuiteError (*GetExportSourceInfo) (  
    csSDK_uint32          inExporterPluginID,  
    PrExportSourceInfoSelector inSelector,  
    PrParam              *outSourceInfo);
```

Value	Type	Description
kExportInfo_VInt32W	Int32	Width of source video
kExportInfo_VInt32H	Int32	Height of source video
kExportInfo_VPrFrmRate	PrFrmRate	Frame rate
kExportInfo_VInt32F	Int32	One of the prFieldType values
kExportInfo_VInt64A	Int64	Audio ARTime value
kExportInfo_PInt32A	Int32	Pixel aspect ratio (PAR) numerator
kExportInfo_PInt32D	Int32	Pixel aspect ratio denominator
kExportInfo_AInt64A	Int64	Audio ARTime value
kExportInfo_AInt32C	Int32	One of the TypeAudioChannelType values. Returns 0 (which is undefined) if there's no audio.
kExportInfo_AFloatS	Float	SampleRate
kExportInfo_SBoolNZ	Bool	Non-Zero if source has audio
kExportInfo_SBoolNV	Bool	Non-Zero if source has video
kExportInfo_RBoolRN	Bool	Returns a non-zero value if currently rendering preview files.
kExportInfo_SGUIDA	GUID	AudioEBIDuginID, which is a unique GUID for the sequence.
kExportInfo_SPMemA	PMemA	PreFFFHChar array. The exporter should release the pointer using the <i>Memory Manager Suite</i> .
kExportInfo_VInt64P	Int64	New in CS5. Audio ARTime value.
kExportInfo_SPrMcnA	PrMcnA	New in CS5.0.2. The timecode of the source clip or sequence. The sequence timecode is set by the Start Time of a sequence using the sequence wing-menu. A pointer to a ExporterTimecodeRec structure. The exporter should release the pointer using the <i>Memory Manager Suite</i> .
kExportInfo_UBoolN	Bool	New in CCs Use this to check if the user has checked "Use Previews" in the Export Settings dialog. If so, if possible, reuse any preview files already rendered, which can be retrieved using <code>AcquireVideoSegmentsWithPreviewsID</code> in the <i>Video Segment Suite</i> .
kExportInfo_NInt32A	Int32	New in CCs Get the number of audio channels in a given source. This can be used to automatically initialize the audio channel parameter in the Audio tab of the Export Settings to match the source.

```
typedef struct {
    csSDK_int64  mTimecodeTicks;
    csSDK_int64  mTicksPerFrame;
    bool        mTimecodeStartPrefersDropFrame;
} ExporterTimecodeRec;
```

61.3 Export Param Suite

Specify all parameters for your exporter UI. See `PrSDKExportParamSuite.h`.

Also, see the SDK Export sample for a demonstration of how to use this suite.

To provide either a set of radio buttons or a drop-down list of choices, use `AddConstrainedValuePair()`.

Adding two choices will result in a pair of radio buttons side-by-side.

Three or more choices will be displayed as a drop-down box.

Adding only one value will result in a hard-coded string.

In CS5, and later fixed in 5.0.2, there is an issue where width and height ranges aren't correctly set.

You may notice this when adjusting the width and height in the Export Settings UI.

By unclicking the chain that constrains width and height ratio, you will be able to modify the width and height.

As a side-effect of this bug, if the exporter is used to render preview files in an Editing Mode, the user will be able to choose any preview frame size between 24x24 and 10240x8192.

CS6 adds SetParamDescription(), to set tooltip strings for parameters.

CC adds MoveParam(), to move an existing parameter to a new location. This can be used for both standard parameters and group parameters.

61.4 Export Progress Suite

For pull-model exporters. Report progress during the export. Also, handle the case where the user pauses or cancels an export. See PrSDKExportProgressSuite.h.

61.5 Export Standard Param Suite

New in CS6. A suite for registering one of several common parameter sets, reducing parameter management code on the plug-in side.

61.5.1 AddStandardParams

Register a set of standard parameters to be used by the exporter.

Call during exSelGenerateDefaultParams.

```
prSuiteError (*AddStandardParams) (
    csSDK_uint32      inExporterID,
    PrSDKStdParamType inSDKStdParamType);
```

Parameter	Description
inExporterID	Pass in exporterPluginID from exDoExportRec.
inSDKStdParamType	Use one of the following: <pre>enum PrSDKStdParamType { SDKStdParams_Video, SDKStdParams_Audio, SDKStdParams_Still, SDKStdParams_VideoBitrateGroup, SDKStdParams_Video_NoRenderMax, SDKStdParams_Video_AddRenderMax, SDKStdParams_AudioTabOnly, SDKStdParams_AudioBitrateGroup, SDKStdParams_VideoWithSizePopup };</pre>

61.5.2 PostProcessParamNames

Call during `exSelPostProcessParams`.

```
prSuiteError (*PostProcessParamNames) (
    csSDK_uint32      inExporterID,
    PrAudioChannelType inSourceAudioChannelType);
```

Parameter	Description
<code>inExporterID</code>	Pass in <code>exporterPluginID</code> from <code>exDoExportRec</code> .
<code>inSourceAudioChannelType</code>	Pass in the source audio channel type, which can be queried from <code>GetExportSourceInfo</code> in the <i>Export Info Suite</i> .

61.5.3 QueryOutputSettings

Call during `exSelQueryOutputSettings`.

```
prSuiteError (*QueryOutputSettings) (
    csSDK_uint32      inExporterID,
    exQueryOutputSettingsRec* outOutputSettings);
```

Parameter	Description
<code>inExporterID</code>	Pass in <code>exporterPluginID</code> from <code>exDoExportRec</code> .
<code>outOutputSettings</code>	This structure will be filled out based on the standard parameter settings.

61.5.4 MakeParamSummary

Call during `exSelGetParamSummary`.

```
prSuiteError (*MakeParamSummary) (
    csSDK_uint32 inExporterID,
    csSDK_int32  inDoVideo,
    csSDK_int32  inDoAudio,
    prUTF16Char* outVideoDescription,
    prUTF16Char* outAudioDescription);
```

Parameter	Description
<code>inExporterID</code>	Pass in <code>exporterPluginID</code> from <code>exDoExportRec</code> .
<code>inDoVideo</code>	Pass in <code>exParamSummaryRec.exportVideo/exportAudio</code> so that the summary will be set based on whether video / audio are being exported.
<code>inDoAudio</code>	
<code>outVideoDescription</code>	This will be filled out based on the standard parameter settings.
<code>outAudioDescription</code>	

61.6 Exporter Utility Suite

New in CS6. Provides functions for push-model exporters, and also provides a way to register an export event (error, warning, or info) to be displayed by the host and written to the log.

61.6.1 DoMultiPassExportLoop

Register the callback to be made to push video frames to the exporter. This function assumes that your exporter supports `exSelQueryOutputSettings`, which will be called.

```
prSuiteError (*DoMultiPassExportLoop) (
    csSDK_uint32                                inExporterID,
    const ExportLoopRenderParams*              inRenderParams,
    csSDK_uint32                                inNumberOfPasses,
    PrSDKMultipassExportLoopFrameCompletionFunction inCompletionFunction,
    void*                                       inCompletionParam);
```

Parameter	Description
<code>inExporterID</code>	Pass in <code>exporterPluginID</code> from <code>exDoExportRec</code> .
<code>inRenderParams</code>	<p>Pass in the parameters that will be used for the render loop that will push rendered frames via the provided callback <code>inCompletionFunction</code>. <code>inReservedProgressPreRender</code> and <code>inReservedProgressPostRender</code> should be set to the amount of progress to be shown in any progress bar before starting the render loop, and how much is remaining after finishing the render loop. These values default to zero.</p> <pre>typedef struct { csSDK_int32 inRenderParamsSize; csSDK_int32 inRenderParamsVersion; PrPixelFormat inFinalPixelFormat; PrTime inStartTime; PrTime inEndTime; float inReservedProgressPreRender; float inReservedProgressPostRender; } ExportLoopRenderParams;</pre>
<code>inNumberOfPasses</code>	Set to 1, unless you need multipass encoding such as two-pass or three-pass encoding.
<code>inCompletionFunction</code>	<p>Provide your own callback here, which will be called when the host pushes rendered frames. Use the following function signature:</p> <pre>typedef prSuiteError_ ↳ (*PrSDKMultipassExportLoop_ ↳ FrameCompletionFunction) (csSDK_uint32 inWhichPass, csSDK_uint32 inFrameNumber, csSDK_uint32 inFrameRepeatCount, PPixHand inRenderedFrame, void* inCallbackData);</pre> <p>Currently, there is no simple way to ensure that pushed frames survive longer than the life of the function call. If you are interested in this capability, please contact us and explain your need.</p>
<code>inCompletionParam</code>	Pass in a void * to the data you wish to send to your <code>inCompletionFunction</code> above in <code>inCallbackData</code> .

61.6.2 ReportIntermediateProgressForRepeatedVideoFrame

Register the callback to be made to push video frames to the exporter.

This function assumes that your exporter supports `exSelQueryOutputSettings`, which will be called.

```
prSuiteError (*ReportIntermediateProgressForRepeatedVideoFrame) (
    csSDK_uint32  inExporterID,
```

(continues on next page)

(continued from previous page)

```
csSDK_uint32 inRepetitionsProcessedSinceLastUpdate);
```

Parameter	Description
inExporterID	Pass in exporterPluginID from exDoExportRec.
inRepetitionsProcessedSinceLastUpdate	Pass in the number of repeated frames processed since the last call was made, if any.

61.6.3 ReportEvent

Report an event to the host, for a specific encode in progress in the Adobe Media Encoder render queue or Premiere Pro.

These events are displayed in the application UI, and are also added to the AME encoding log.

```
prSuiteError (*ReportEvent) (
    csSDK_uint32      inExporterID,
    csSDK_uint32      inEventType,
    const prUTF16Char* inEventTitle,
    const prUTF16Char* inEventDescription);
```

Parameter	Description
inExporterID	Pass in exporterPluginID from exDoExportRec.
inEventType	Use one of the types from the <i>Error Suite</i> : <ul style="list-style-type: none"> • kEventTypeInformational, • kEventTypeWarning, or • kEventTypeError
inEventTitle	Provide information about the event for the user.
inEventDescription	

61.7 Palette Suite

A seldom-used suite for palettizing an image, for example, for GIFs. See PrSDKPaletteSuite.h.

61.8 Sequence Audio Suite

Get audio from the host.

61.8.1 MakeAudioRenderer

Create an audio renderer, in preparation to get rendered audio from the host.

```

prSuiteError (*MakeAudioRenderer) (
    csSDK_uint32      inPluginID,
    PrTime           inStartTime,
    PrAudioChannelType inChannelType,
    PrAudioSampleType inSampleType,
    float            inSampleRate,
    csSDK_uint32*    outAudioRenderID);

```

Parameter	Description
inPluginID	Pass in exporterPluginID from exDoExportRec.
inStartTime	Start time for the audio requests.
inChannelType	PrAudioChannelType enum value for the channel type needed.
inSampleType	This should always be kPrAudioSampleType_32BitFloat. Other types are unsupported.
inSampleRate	Samples per second.
outAudioRenderID	This ID passed back is needed for subsequent calls to this suite.

61.8.2 ReleaseAudioRenderer

Release the audio renderer when the exporter is done requesting audio.

```

prSuiteError (*ReleaseAudioRenderer) (
    csSDK_uint32 inPluginID,
    csSDK_uint32 inAudioRenderID);

```

Parameter	Description
inPluginID	Pass in exporterPluginID from exDoExportRec.
inAudioRenderID	The call will release the audio renderer with this ID.

61.8.3 GetAudio

Returns from the host the next contiguous requested number of audio sample frames, specified in inFrameCount, in inBuffer as arrays of uninterleaved floating point values.

Returns suiteError_NoError if no error.

The plug-in must manage the memory allocation of inBuffer, which must point to n buffers of floating point values of length inFrameCount, where n is the number of channels.

When inClipAudio is non-zero, this parameter makes GetAudio clip the audio samples at +/- 1.0.

```

prSuiteError (*GetAudio) (
    csSDK_uint32 inAudioRenderID,
    csSDK_uint32 inFrameCount,
    float**      inBuffer,
    char         inClipAudio);

```

Parameter	Description
inAudioRenderID	Pass in the outAudioRenderID returned from MakeAudioRenderer(). This gives the host the context of the audio render.
inFrameCount	The number of audio frames to return in inBuffer. The next contiguous audio frames will always be returned, unless ResetAudioToBeginning has just been called.
inBuffer	An array of float arrays, allocated by the exporter. The host returns the samples for each audio channel in a separate array.
inClipAudio	When true, GetAudio will return audio clipped at +/- 1.0. Otherwise, it will return unclipped audio.

61.8.4 ResetAudioToBeginning

This call will reset the position on the audio generation to time zero. This can be used for multipass encoding.

```
prSuiteError (*ResetAudioToBeginning) (
    csSDK_uint32  inAudioRenderID);
```

61.8.5 GetMaxBlip

Returns the maximum number of audio sample frames that can be requested from one call to GetAudio in maxBlipSize.

```
prSuiteError (*GetMaxBlip) (
    csSDK_uint32  inAudioRenderID,
    PrTime       inTicksPerFrame,
    csSDK_uint32* maxBlipSize);
```

61.9 Sequence Render Suite

Get rendered video from one of the renderers available to the host. This may use one of the host's built-in renderers, or a plug-in renderer, if available. For best performance, use the asynchronous render requests with the source media prefetching calls, although synchronous rendering is available too.

Version 4, new in CS5.5, adds RenderVideoFrameAndConformToPixelFormat().

61.9.1 MakeVideoRenderer()

Create a video renderer, in preparation to get rendered video.

```
prSuiteError (*MakeVideoRenderer) (
    csSDK_uint32  pluginID,
    csSDK_uint32* outVideoRenderID
    PrTime       inFrameRate);
```

Parameter	Description
pluginID	Pass in exporterPluginID from exDoExportRec.
outVideoRenderID	This ID passed back is needed for subsequent calls to this suite.
inFrameRate	Frame rate, in ticks.

61.9.2 ReleaseVideoRenderer()

Release the video renderer when the exporter is done requesting video.

```
prSuiteError (*ReleaseVideoRenderer) (
    csSDK_uint32  pluginID,
    csSDK_uint32  inVideoRenderID);
```

Parameter	Description
pluginID	Pass in exporterPluginID from exDoExportRec.
inVideoRenderID	The call will release the video renderer with this ID.

61.9.3 struct SequenceRender_ParamsRec

Fill this structure in before calling `RenderVideoFrame()`, `QueueAsyncVideoFrameRender()`, or `PrefetchMediaWithRenderParameters()`.

Note that if the frame aspect ratio of the request does not match that of the sequence, the frame will be letterboxed or pillarboxed, rather than stretched to fit the frame.

```
typedef struct {
    const PrPixelFormat*  inRequestedPixelFormatArray;
    csSDK_int32          inRequestedPixelFormatArrayCount;
    csSDK_int32          inWidth;
    csSDK_int32          inHeight;
    csSDK_int32          inPixelAspectRatioNumerator;
    csSDK_int32          inPixelAspectRatioDenominator;
    PrRenderQuality      inRenderQuality;
    prFieldType          inFieldType;
    csSDK_int32          inDeinterlace;
    PrRenderQuality      inDeinterlaceQuality;
    csSDK_int32          inCompositeOnBlack;
} SequenceRender_ParamsRec;
```

Member	Description
inRequestedPixelFormat	An array of PrPixelFormat that list your format preferences in order.
inRequestedPixelFormatCount	Size of the pixel format array.
inWidth	Width to render at.
inHeight	Height to render at.
inPixelAspectRatio	Numerator of the pixel aspect ratio.
inPixelAspectRatioDenominator	Denominator of the pixel aspect ratio.
inRenderQuality	Use one of the PrRenderQuality enumerated values.
inFieldType	Use one of the prFieldType constants.
inDeinterlace	Set to non-zero, to force an explicit deinterlace. Otherwise, the renderer will use the output field setting to determine whether to automatically deinterlace any interlaced sources.
inDeinterlaceQuality	Use one of the PrRenderQuality enumerated values.
inCompositeOnBlack	Set to non-zero, to composite the render on black.

61.9.4 struct SequenceRender_GetFrameReturnRec

Returned from RenderVideoFrame () and passed by PrSDKSequenceAsyncRenderCompletionProc ().

```
typedef struct {
    void*          asyncCompletionData;
    csSDK_int32   returnVal;
    csSDK_int32   repeatCount;
    csSDK_int32   onMarker;
    PPixHand      outFrame;
} SequenceRender_GetFrameReturnRec;
```

Member	Description
asyncCompletionData	Passed data to PrSDKSequenceAsyncRenderCompletionProc () from QueueAsyncVideoFrameRender (). Not used by RenderVideoFrame ().
returnVal	ErrNone, Abort, Done, or an error code.
repeatCount	The number of repeated frames from this frame forward. In the output file, this could be writing NULL frames, changing the current frame's duration, or whatever is appropriate according to the codec.
onMarker	If non-zero, there is a marker on this frame.
outFrame	Returned from RenderVideoFrame (). Not returned from PrSDKSequenceAsyncRenderCompletionProc ()

61.9.5 RenderVideoFrame()

The basic, synchronous call to get a rendered frame from the host.

Returns:

- suiteError_NoError if you can continue exporting,
- exportReturn_Abort if the user aborted the export,
- exportReturn_Done if the export has finished, or
- an error code.

```
prSuiteError (*RenderVideoFrame) (
    csSDK_uint32                inVideoRenderID,
    PrTime                      inTime,
    SequenceRender_ParamsRec*   inRenderParams,
    PrRenderCacheType           inCacheFlags,
    SequenceRender_GetFrameReturnRec* getFrameReturn);
```

Parameter	Description
inVideoRenderID	Pass in the outVideoRenderID returned from MakeVideoRenderer(). This gives the host the context of the video render.
inTime	The frame time requested.
inRenderParams	The details of the render.
inCacheFlags	One or more cache flags.
getFrameReturn	Passes back a structure that contains info about the frame returned, and the rendered frame itself.

61.9.6 GetFrameInfo()

Gets information about a given frame.

Currently, SequenceRender_FrameInfoRec only contains repeatCount, which is the number of repeated frames from this frame forward.

```
prSuiteError (*GetFrameInfo) (
    csSDK_uint32                inVideoRenderID,
    PrTime                      inTime,
    SequenceRender_FrameInfoRec* outFrameInfo);
```

61.9.7 SetAsyncRenderCompletionProc()

Register a notification callback for getting asynchronously rendered frames when the render completes.

asyncGetFrameCallback should have the signature described in PrSDKSequenceAsyncRenderCompletionProc below.

```
prSuiteError (*SetAsyncRenderCompletionProc) (
    csSDK_uint32                inVideoRenderID,
    PrSDKSequenceAsyncRenderCompletionProc asyncGetFrameCallback,
    long                        callbackRef);
```

Parameter	Description
inVideoRenderID	Pass in the outVideoRenderID returned from MakeVideoRenderer(). This will be passed to PrSDKSequenceAsyncRenderCompletionProc.
asyncGetFrameCallback	The notification callback.
inCallbackRef	A pointer holding data private to the exporter. This could be, for example, a pointer to an exporter instance. This will also be passed to PrSDKSequenceAsyncRenderCompletionProc.

61.9.8 PrSDKSequenceAsyncRenderCompletionProc()

Use this function signature for your callback used for async frame notification, passed to `SetAsyncRenderCompletionProc`.

Error status (error or abort) is returned in `inGetFrameReturn`.

```
void (*PrSDKSequenceAsyncRenderCompletionProc) (
    csSDK_uint32          inVideoRenderID,
    void*                 inCallbackRef,
    PrTime                inTime,
    PPixHand              inRenderedFrame,
    SequenceRender_GetFrameReturnRec *inGetFrameReturn);
```

Parameter	Description
<code>inVideoRenderID</code>	The <code>outVideoRenderID</code> that the exporter passed to <code>SetAsyncRenderCompletionProc</code> earlier.
<code>inCallbackRef</code>	A pointer that the exporter sets using <code>SetAsyncRenderCompletionProc()</code> . This could be, for example, a pointer to an exporter instance.
<code>inTime</code>	The frame time requested.
<code>inRenderedFrame</code>	The rendered frame. The exporter is responsible for disposing of this <code>PPixHand</code> using the <code>Dispose()</code> call in the <i>PPix Suite</i> .
<code>inGetFrameReturn</code>	A structure that contains info about the frame returned, and it includes the <code>inAsyncCompletionData</code> originally passed to <code>QueueAsyncVideoFrameRender()</code> .

61.9.9 QueueAsyncVideoFrameRender()

Use this call rather than `RenderVideoFrame()` to queue up a request to render a specific frame asynchronously.

The rendering can happen on a separate thread or processor.

When the render is completed, the `PrSDKSequenceAsyncRenderCompletionProc` that was set using `SetAsyncRenderCompletionProc` will be called.

```
prSuiteError (*QueueAsyncVideoFrameRender) (
    csSDK_uint32          inVideoRenderID,
    PrTime                inTime,
    csSDK_uint32*        outRequestID,
    SequenceRender_ParamsRec* inRenderParams,
    PrRenderCacheType    inCacheFlags,
    void*                 inAsyncCompletionData);
```

Parameter	Description
<code>inVideoRenderID</code>	Pass in the <code>outVideoRenderID</code> returned from <code>MakeVideoRenderer()</code> . This gives the host the context of the video render.
<code>inTime</code>	The frame time requested.
<code>outRequestID</code>	Passes back a request ID, which... doesn't seem to have any use.
<code>inRenderParams</code>	The details of the render.
<code>inCacheFlags</code>	One or more cache flags.
<code>inAsyncCompletionData</code>	This data will be passed to the <code>PrSDKSequenceAsyncRenderCompletionProc</code> in <code>inGetFrameReturn.asyncCompletionData</code> .

61.9.10 PrefetchMedia()

Prefetch the media needed to render this frame. This is a hint to the importers to begin reading media needed to render this video frame.

```
prSuiteError (*PrefetchMedia)(
    csSDK_uint32  inVideoRenderID,
    PrTime       inFrame);
```

61.9.11 PrefetchMediaWithRenderParameters()

Prefetch the media needed to render this frame, using all of the parameters used to render the frame.

This is a hint to the importers to begin reading media needed to render this video frame.

```
prSuiteError (*PrefetchMediaWithRenderParameters)(
    csSDK_uint32          inVideoRenderID,
    PrTime               inTime,
    SequenceRender_ParamsRec* inRenderParams);
```

61.9.12 CancelAllOutstandingMediaPrefetches()

Cancel all media prefetches that are still outstanding.

```
prSuiteError (*PrefetchMedia)(
    csSDK_uint32  inVideoRenderID);
```

61.9.13 IsPrefetchedMediaReady()

Check on the status of a prefetch request.

```
prSuiteError (*IsPrefetchedMediaReady)(
    csSDK_uint32  inVideoRenderID,
    PrTime       inTime,
    prBool*      outMediaReady);
```

61.9.14 MakeVideoRendererForTimeline()

Similar to MakeVideoRenderer, but for use by renderer plug-ins.

Creates a video renderer, in preparation to get rendered video from the host.

The TimelineID in question must refer to a top-level sequence.

```
prSuiteError (*MakeVideoRendererForTimeline)(
    PrTimelineID  inTimeline,
    csSDK_uint32* outVideoRenderID);
```

61.9.15 MakeVideoRendererForTimelineWithFrameRate()

Similar to MakeVideoRendererForTimeline, with an additional frame rate parameter.

This is useful for the case of a nested multicam sequence.

```
prSuiteError (*MakeVideoRendererForTimelineWithFrameRate) (
    PrTimelineID    inTimeline,
    PrTime          inFrameRate,
    csSDK_uint32*   outVideoRendererID);
```

61.9.16 ReleaseVideoRendererForTimeline()

Similar to ReleaseVideoRenderer, but for use by renderer plug-ins. Release the video renderer when the renderer plug-in is done requesting video.

```
prSuiteError (*ReleaseVideoRendererForTimeline) (
    csSDK_uint32   inVideoRendererID);
```

61.9.17 RenderVideoFrameAndConformToPixelFormat()

New in CS5.5. Similar to RenderVideoFrame., but conforms the resulting frame to a specific pixel format.

Allows an exporter to request a frame in a specific pixel format.

```
prSuiteError (*RenderVideoFrameAndConformToPixelFormat) (
    csSDK_uint32                inVideoRenderID,
    PrTime                      inTime,
    SequenceRender_ParamsRec*   inRenderParams,
    PrRenderCacheType          inCacheFlags,
    PrPixelFormat                inConformToFormat,
    SequenceRender_GetFrameReturnRec* getFrameReturn);
```

61.9.18 MakeVideoRendererForTimelineWithStreamLabel()

New in CS6. Similar to MakeVideoRenderer, but is stream label-aware.

Allows an exporter to request rendered frames from multiple video streams.

```
prSuiteError (*MakeVideoRendererForTimelineWithStreamLabel) (
    PrTimelineID    inTimeline,
    PrSDKStreamLabel inStreamLabel,
    csSDK_uint32*   outVideoRendererID);
```

62.1 Multiplexer Tab Ordering

If your exporter provides a Multiplexer tab like some of the built-in exporters do, you may find that it appears after the Video and Audio tab, rather than before those tabs as in the case of our exporters. The key is to use the following define as the parameter identifier for the multiplexer tab group:

```
#define ADBEMultiplexerTabGroup "ADBEAudienceTabGroup"
```

62.2 Creating a Non-Editable String in the Parameter UI

During `exSelGenerateDefaultParams`, add a parameter with `exNewParamInfo.flags = exParamFlag_none`.

Then during `exSelPostProcessParams`, call `AddConstrainedValuePair()` in the *Export Param Suite*.

If you only add one value pair, then the parameter will be a non-editable string.

In the case of the SDK Exporter sample, it adds two, which appear as a pair of radio buttons side-by-side.

62.3 Guidelines for Exporters in Encore

Starting in CS5, third-party exporters can now be used to transcode assets to MPEG-2 or Blu-ray compliant files. Currently, the option to choose a third-party exporter is only available on a per-clip basis, not on a project-wide basis. The user will need to right-click on an asset in the Project panel, choose Transcode Settings, and choose the third-party preset from the Quality Preset drop-down.

Prior to CS6, Encore was a 32-bit application. So if you are developing plug-ins for Encore CS5, use the CS5 headers to create 32-bit plug-ins. We have left the 32-bit configurations in the

sample projects to facilitate this. Install the exporter in the Encore application folder at Plug-ins/ Common/. Note that on Mac OS, this subfolder is in within the application package.

62.3.1 Naming Your Exporter

Encore only uses the MPEG2-DVD and MPEG2 Blu-ray formats for transcoding to MPEG2-DVD and MPEG2 Blu-ray formats, respectively. Currently it looks for the substrings “MPEG2-DVD”, “MPEG2 Blu-ray” and “H.264 Blu-ray” in the exporter name to identify the video format of the exporter, and to enable it within the Encore UI. So the format name returned from exporter plug-in should contain one of these as a substring, in order for it to be usable within Encore.

For example “My MPEG2 Blu-ray”, “Accelerated MPEG2-DVD”, etc. Please avoid using the exact same names as the built-in formats to avoid conflict.

62.3.2 Naming Your Output

Encore uses the exporters to create elementary video and audio streams (muxing is switched to off during transcoding). The output file extensions should be standard ones: .m2v for MPEG2-DVD, MPEG2 Blu-ray video formats, .m4v for H.264 Blu-ray; .ac3 for Dolby audio, .wav for PCM, .mpa for MPEG-1 Layer 2.

62.3.3 Parameters

Please refer to the built-in MPEG2-DVD and MPEG2 Blu-ray formats present in Encore to get familiar with the typical exporter user interface in Encore. Having UI properties similar to the built-in formats in Encore will make it easier to integrate a third-party exporter.

The audio formats available in an exporter should correspond to the same choices as available in Encore for a DVD or Blu-ray project. In an MPEG-2 DVD exporter, the audio formats should be either Dolby Digital 2.0 (stereo), MPEG-1 Layer 2 audio in stereo or PCM audio (48kHz). For an MPEG2 Blu-ray exporter, only the Dolby and the PCM formats should be available. For more details regarding audio formats supported in Encore, please refer to the Encore help documentation. Allowing audio formats other than these for encoding will not work in Encore due to the constraints of the DVD/Blu-ray disc specifications.

Encore will need to access many of the exporter’s encoding parameters. It may even modify some of the encoding parameters during the transcoding to MPEG-2 DVD and Blu-ray formats, so that the encoding stays within the bit-budget constraints of the project. So a third-party exporter must use specific property identifiers and property types. If these parameters are not used, then there

is little guarantee of the correctness of the encoded file and the size of the final disc, since Encore will not be able to control the settings of the exporter to apply the size constraints to the output files.

Below is a list of the properties with their identifiers and types that an exporter plugin must support:

Property Identifier	Required	Property type	Description
ADBEVideoWidth	Yes	exParamType_int	Frame width
ADBEVideoHeight	Yes	exParamType_int	Frame height
ADBEVideoVBR	No	exParamType_int Constrained value list	Type of encoding (constant/variable bitrate, 1 / 2 passes) <ul style="list-style-type: none"> • 0 = CBR • 1 = VBR, 1 Pass • 2 = VBR, 2 Pass
<ul style="list-style-type: none"> • ADBEVideoBitRate • ADBEVideoMaxBitRate • ADBEVideoAvgBitRate • ADBEVideoMinBitRate 	No	exParamType_float	Video bitrate(s) (Mbps) For CBR encoding use the first parameter. For VBR encoding use parameters 2-4
ADBEVideoFPS	Yes	exParamType_ticksPerFrame	Frame rate
ADBE MPEGCodecBroadcastStandard	Yes	exParamType_int Constrained value list	<ul style="list-style-type: none"> • 0 = NTSC • 1 = PAL • 2 = SECAM
ADBEVideoAspect	No	exParamType_int Constrained value list	Frame aspect ratio <ul style="list-style-type: none"> • 1 = Square 1:1 • 2 = Standard 4:3 • 3 = Widescreen 16:9
ADBEVMCMux_Type	No	exParamType_int Constrained value list	Encore needs a way to switch off muxing as it creates only elementary streams <ul style="list-style-type: none"> • 0 = MPEG-1 • 1 = VCD • 2 = MPEG-2 • 3 = SVCD • 4 = DVD • 5 = TS • 6 = None
ADBEVideoFieldType	No	exParamType_int Constrained value list	<ul style="list-style-type: none"> • 0 = Progressive • 1 = Upper field first • 2 = Lower field first
ADBEAudioCodec	Yes	exParamType_int Constrained value list	Use these 4CCs for values - 'dlby' – Dolby - 'PCMA' – PCM - 'mpa' – MPEG-1 Layer 2
ADBEAudio_Endianness	Optional	exParamType_int Constrained value list	If using Dolby audio; Encore will set to big endian for AC3 files <ul style="list-style-type: none"> • 0 = little endian • 1 = big endian
62.3. Guidelines for Exporters in Encore			277
ADBEAudioBitrate	Yes, for Dolby and MPEG-2 audio codecs	exParamType_int	Audio codec bitrate (kpbs)

62.4 Guidelines for Exporters in Premiere Elements

First, make sure you are building the exporter using the right SDK. Premiere Elements 8 requires the Premiere Pro CS4 SDK. The next version of Premiere Elements will likely use the CS5 SDK.

62.4.1 Exporter Preset

For an exporter to show up in the Premiere Elements UI, you'll need to create and install a preset in a specific location:

1. Create a folder named "OTHERS" in [App installation folder]/sharingcenter/Presets/pc/
2. Create a sub-folder with your name (e.g. MyCompany) under OTHERS and place the preset file (.epr) in it. The final path of the preset file should be something like [App installation folder]/ sharingcenter/Presets/pc/OTHERS/MyCompany/MyPreset.epr
3. Relaunch Premiere Elements.
 1. Add a clip to the timeline
 2. Goto the "Share" tab
 3. Under that choose "Personal Computer"
 4. You should see the "Others – 3rd Party Plug-ins" in the list of formats. Select this.
 5. Your preset should be seen in the drop-down.

62.4.2 Return Values

Premiere Elements 8 uses a slightly different definition of the return values. Use the following definition instead:

```
enum {
    exportReturn_ErrNone = 0,
    exportReturn_Abort,
    exportReturn_Done,
    exportReturn_InternalError,
    exportReturn_OutputFormatAccept,
    exportReturn_OutputFormatDecline,
    exportReturn_OutOfDiskSpace,
    exportReturn_BufferFull,
    exportReturn_ErrOther,
    exportReturn_ErrMemory,
    exportReturn_ErrFileNotFound,
    exportReturn_ErrTooManyOpenFiles,
    exportReturn_ErrPermErr,
    exportReturn_ErrOpenErr,
    exportReturn_ErrInvalidDrive,
    exportReturn_ErrDupFile,
    exportReturn_ErrIo,
    exportReturn_ErrInUse,
    exportReturn_IterateExporter,
    exportReturn_IterateExporterDone,
    exportReturn_InternalErrorSilent,
```

(continues on next page)

(continued from previous page)

```
exportReturn_ErrCodecBadInput,  
exportReturn_ErrLastErrorSet,  
exportReturn_ErrLastWarningSet,  
exportReturn_ErrLastInfoSet,  
exportReturn_ErrExceedsMaxFormatDuration,  
exportReturn_VideoCodecNeedsActivation,  
exportReturn_AudioCodecNeedsActivation,  
exportReturn_IncompatibleAudioChannelType,  
exportReturn_Unsupported = -100  
};
```

The red values are unique to Premiere Elements 8, and shifted the subsequent return values 2 values higher than their definition in the Premiere Pro SDK.

Starting in CS6, the Transmit API is the preferred mean

This new API provides support for pushing video, audio, and closed captions to external hardware. Transmitters can be specified by the user in Preferences > Playback. Other plug-ins such as importers and effects with settings preview dialogs can send video out to the active transmitter, opening up new possibilities for hardware monitoring. Transmit plug-ins are supported in Premiere Pro, After Effects (starting in CC 2014), SpeedGrade, Encore, and Prelude (note that since Prelude CS6 Windows is a 32-bit application, it uses 32-bit transmitter plug-ins).

When a new transmitter instance is created, it is asked to describe the format(s) it wishes to receive the rendered video in. A transmitter plug-in can request different formats depending on the source clip or timeline format. The host application will handle all the conversions to the desired video format. As an example, a transmitter instance may specify that it can only handle a fixed width and height, but any pixel format. Besides video conversions, the host handles scheduling for prefetching the media and asynchronous rendering.

A transmitter may leave the audio to be played by the host, through the system's sound drivers (ASIO or CoreAudio). Or, if a transmitter wants to handle the audio itself to send it to the external hardware, it can request audio using `GetNextAudioBuffer` in the *Playmod Audio Suite*.

On playback, the host provides the transmitter with a clock callback, which the transmitter must call to update the host with the new time every frame. This allows the transmitter to orchestrate the audio/video sync.

Transmitters can use the *Captioning Suite* to get any closed captions for the sequence.

Transmitters do not need to call the Playmod Device Controller suite to handle Export to Tape. This is handled at the player level.

63.1 What's New in Premiere Pro CS6.0.2?

A transmitter can now provide strings to label its audio channels, in `tmAudioMode.outOutputAudioNames`. These strings will be used for the Audio Output Mapping preferences, rather than the default strings.

64.1 Basic Organization

A transmitter module can define multiple plug-ins. Each plug-in can appear in the Playback Preferences as an option for video playback and/or audio playback. Only one transmitter can be used for audio, since the transmitter used for audio drives the clock. Multiple transmitters may be selected for video simultaneously.

When active, multiple instances of a single plug-in can be created. An instance is created to display a clip or sequence. Hardware access is regulated through `ActivateDeactivate`. Only an active instance should access the hardware.

64.2 Video Formats

Specify which video format(s) you wish to receive during `QueryVideoMode`. To simplify your plug-in, be as specific as possible, and allow the host to perform the conversion asynchronously ahead of time. Packed and compressed formats are also supported. If multiple formats are specified, the closest will be selected at render time. If your transmitter would benefit from on-GPU frames, please let us know.

When sent `QueryVideoMode`, the transmitter is informed about the clip/sequence video attributes by being passed a `tmInstance` pointer. So, for example, if the transmitter instance is constructed to support a 1920x1080 timeline, it can report that same size back to the host application, so that it will not have to handle any scaling. If, for example, it does handle scaling, and it is constructed to handle a 1440x1080 timeline, it can report 1440x1080 and handle the scaling itself. In this way you can choose a single fixed size depending on the timeline.

When video frames are pushed to the transmitter, properties like pixel format may change on a segment-by-segment basis depending on the source footage. Other properties like size may change based on the current fractional resolution, which may differ between scrubbing and stopped.

64.3 Fractional Resolution

In the Premiere Pro Source and Program Monitors, the user can choose independent resolutions for rendering during playback and paused modes. For example, it is common to have the playback resolution set to half, and paused resolution set to full.

If an output card has a hardware scaler, the transmit plug-in can declare support for fractional resolutions. For example, for a 1920x1080 instance, it could declare support for not only

1920x1080, but also 960x540, 480x270, etc. This will allow the renderer to skip the step of rescaling back up to full resolution after rendering at a fractional resolution. If however, the plug-in only declares support for full resolution, the renderer will scale the video back up before pushing it to the transmitter.

64.4 Audio Format

During `QueryAudioMode`, a transmitter will be told how many channels the instance has. The transmitter should change that value based on what it can support and then make sure the buffers it provides match that. Although Premiere Pro can support 32 channels of audio, transmitters can only support up to 16 channels of audio.

As of CS6, sequences will currently always report audio available in `CreateInstance`, even if empty. An example of somewhere that a transmitter will be called with no audio is for video output from the RED settings dialog, which is video only.

A transmitter should call `GetNextAudioBuffer` only when `inAudioActive` is passed as true to `ActivateDeactivate`.

64.5 Frame Rate

For framerate, video will be pushed to you at the rate of the timeline. This was chosen because of the wide variety in conversion policies, including pulldown, frame duplication, etc.

64.6 Dropped Frames

If the host cannot keep up rendering, it will send duplicate frames with `PushVideo`. If you receive a frame that cannot be sent out to hardware on time, notify the host using `inDroppedFrame` Callback in `tmPlaybackClock`. In Premiere Pro, the user can turn on the Dropped Frame Indicator to see the total number of frames that were dropped either because the host couldn't keep up, or the hardware couldn't keep up.

64.7 Sync Between Application UI and Hardware Output

Naturally there is some latency between the time the host sends frames to be displayed on the output, and the time it can actually be displayed. Use `tmVideoMode.outLatency` to specify the latency. For example, if a transmitter specifies 5 frames of latency, when the user starts playback, the host will send 5 frames of video to the transmitter before sending `StartPlaybackClock`. This allows time for the transmitter to send frames to the hardware output in advance, so that the hardware output will be in sync with the monitor in the host application UI.

When the user is scrubbing in the timeline, send the video frames as fast as possible to the output. The host application UI will not wait for the hardware output to catch up, and currently as of

6.0.1 there may be a noticeable latency. To reduce the scrubbing latency as much as possible, when scrubbing or stopped the transmitter should cancel any frames it has pending to immediately display the new one.

64.8 Dog Ears

Turn on dog ears to view statistics about the frames being sent to the transmitter. This is useful to view information such as pixel formats and much more. Note that this mode may result it duplicate `PushVideo` calls made for a single frame.

64.9 Closed Captioning

This captioning data is attached to a sequence by the user via menu items in the Sequence menu. In the Program Monitor, the Closed Captioning Display options in the fly-out menu give the user control over the display. The hardware should always transmit any Closed Captioning data, and the user can go through the hardware monitor's on-screen display menu to choose which caption track to view. The closed captioning data is accessible using the new *Captioning Suite*. Use this data for the hardware output.

64.10 Driving Transmitters from Other Plug-ins

Transmitters can be driven by many areas of the Premiere Pro interface. Currently, they are called to show frames from the Program Monitor and Source Monitor. But other types of plug-ins can use the *Transmit Invocation Suite* to push frames to transmitters. For example, an effect or titler with a modal setup dialog could push frames to the output.

64.11 Entry Point

This entry point function will be called once on load, and once on unload.

```
tmResult (*tmEntryFunc) (
    csSDK_int32    inInterfaceVersion,
    prBool        inLoadModule,
    piSuitesPtr   piSuites,
    tmModule*     outModule)
```

A tmModule is a structure of function pointers, which the transmitter implements.

CHAPTER 65

tmModule Functions

Fill in 0 for any unsupported calls. Thread safety is defined per-module, only a single thread will enter a module at a time.

Member	Description
Startup	<p>Initialize a transmitter, fill in basic plug-in info, allocate memory to hold user settings and other data.</p> <pre>tmResult (*Startup)(tmStdParms* ioStdParms, tmPluginInfo* outPluginInfo);</pre> <p>tmResult_ContinueIterate may be returned to support multiple transmit plug-ins within the same module.</p> <p>ioPrivatePluginData, ioSerializedPluginData & ioSerializedPluginDataSize may be written from Startup.</p>
Shutdown	<p>Terminate a transmitter.</p> <pre>tmResult (*Shutdown)(tmStdParms* ioStdParms);</pre> <p>Dispose of ioPrivatePluginData if previously allocated in Startup.</p>
QueryAudioMode	<p>Describe the audio modes supported by the transmitter, one at a time.</p> <pre>tmResult (*QueryAudioMode)(const tmStdParms* inStdParms, const tmInstance* inInstance, csSDK_int32 ↪inQueryIterationIndex, tmAudioMode* outAudioMode);</pre> <p>Note that currently one audio mode is currently supported. You can convert between audio formats using the Audio Suite.</p>
QueryVideoMode	<p>Describe the video modes supported by the transmitter, one at a time.</p> <pre>tmResult (*QueryVideoMode)(const tmStdParms* inStdParms, const tmInstance* inInstance, csSDK_int32 ↪inQueryIterationIndex, tmVideoMode* outVideoMode);</pre> <p>The video sent later in PushVideo will be one of the formats specified here.</p>
SetupDialog	<p>Display your own modal settings dialog.</p> <pre>tmResult (*SetupDialog)(tmStdParms* ioStdParms, prParentWnd inParent);</pre> <p>Will only be called if the plugin returned outHasSetup.</p> <p>Save any settings to ioSerializedPluginData and if needed update ioSerializedPluginDataSize.</p> <p>NeedsReset will be invoked after this call, to allow your transmitter a chance to reset all open plug-ins and startup with the new settings.</p>
NeedsReset	<p>Will be called regularly on the first plug-in of a module to allow rebuilding on state changes.</p>

```
tmResult (*NeedsReset)(
    const tmStdParms* inStdParms,
    prBool*           outResetModule);
```

If the passed in settings differ enough from the created settings, or if the settings on the hardware itself

tmModule Structures

66.1 tmStdParms

This is passed to all calls. Most of it is allocated and filled in by the transmitter on Startup, and may be modified during SetupDialog.

```
typedef struct {
    csSDK_int32    inPluginIndex;
    PrMemoryPtr   ioSerializedPluginData;
    csSDK_size_t  ioSerializedPluginDataSize;
    void*         ioPrivatePluginData;
    piSuitesPtr   piSuites;
} tmStdParms;
```

inPluginIndex	If the plug-in has defined multiple transmitters in the same module, this index value tells them apart.
ioSerializedPluginData	This data should contain user-selectable settings for the transmitter, that would be shown in the transmitter settings dialog, and need to persist so they can be saved and restored from one session to another. When allocating this for the first time during Startup, this must be allocated using <code>NewPtr</code> so it can be disposed by the host on shutdown. This must be flat memory that can be serialized by the host and will be already filled in when Startup is called if previously available.
ioSerializedPluginDataSize	Size of the data above. Set this during Startup, if not already set.
ioPrivatePluginData	This data should contain any memory needed for use across calls to the transmitter, except the settings data stored in <code>ioSerializedPluginData</code> . Allocate this during Startup. Unlike <code>ioSerializedPluginData</code> , it does not need to be flat, and must be disposed of by the plug-in on Shutdown.

66.2 tmPluginInfo

This is to be filled in by the transmitter on Startup.

```
typedef struct {
    prPluginID      outIdentifier;
    unsigned int    outPriority;
    prBool          outAudioAvailable;
    prBool          outAudioDefaultEnabled;
    prBool          outClockAvailable;
    prBool          outVideoAvailable;
    prBool          outVideoDefaultEnabled;
    prUTF16Char    outDisplayName[256];
    prBool          outHideInUI;
    prBool          outHasSetup;
    csSDK_int32     outInterfaceVersion;
} tmPluginInfo;
```

outIdentifier	Persistent plugin identifier.
outPriority	0 is default, higher priority wins.
outAudioAvailable	Set this to kPrTrue if the transmitter supports audio.
outAudioDefaultEnabled	Set this to kPrTrue if you want to be turned on to handle audio by default.
outClockAvailable	Set this to kPrTrue if providing plug-in based audio. Currently, even if using host-based audio, a transmitter must provide a clock - please let us know if you would like to use host-based audio only, and we will log a bug on this.
outVideoAvailable	Set this to kPrTrue if the transmitter supports video.
outVideoDefaultEnabled	Set this to kPrTrue if you want to be turned on to handle video by default.
outDisplayName	Set the display name of the transmitter, up 256 UTF-16 characters, including NULL terminator.
outHideInUI	Set this to kPrTrue if you don't want this to show up as a user-selectable option in the transmitter choices.
outHasSetup	Set this to kPrTrue if providing a setup dialog.
outInterfaceVersion	Set this to the tmInterfaceVersion that the transmitter is being compiled for.

66.3 tmInstance

This structure contains information for the transmitter to use for initializing an instance.

```
typedef struct {
    csSDK_int32      inInstanceID;
    PrTimelineID    inTimelineID;
    PrPlayID        inPlayID;
    prBool          inHasAudio;
    csSDK_uint32    inNumChannels;
    PrAudioChannelLabel inChannelLabels[16];
    PrAudioSampleType inAudioSampleType;
    float           inAudioSampleRate;
    prBool          inHasVideo;
    csSDK_int32     inVideoWidth;
    csSDK_int32     inVideoHeight;
    csSDK_int32     inVideoPARNum;
```

(continues on next page)

(continued from previous page)

csSDK_int32	inVideoPARDen;
PrTime	inVideoFrameRate;
prFieldType	inVideoFieldType;
void*	ioPrivateInstanceData;
} tmInstance;	

inInstanceID	Instance identifier.
inTimelineID	TimelineID, for use with various suite functions. May be 0.
inPlayID	PlayID, for use with various suite functions. May be 0.
inHasAudio	True if the instance is handling a sequence with audio.
inNumChannels	The number of audio channels.
inChannelLabels	The identifiers for each audio channel.
inAudioSampleType	The format of the audio data.
inAudioSampleRate	The sample rate of the audio data.
inHasVideo	True if the instance is handling a sequence with video.
inVideoWidth	The video resolution.
inVideoHeight	
inVideoPARNum	The numerator and denominator of the video pixel aspect ratio.
inVideoPARDen	
inVideoFrameRate	The frame rate of the video.
inVideoFieldType	The field dominance of the video.
ioPrivateInstanceData	May be written by plug-in in CreateInstance, and disposed of by DisposeInstance. Need not be serializable by the host.

66.4 tmAudioMode

A full description of an audio mode that the transmitter will support.

The transmitter should fill in this information during QueryAudioMode.

```
typedef struct {
    float          outAudioSampleRate;
    csSDK_uint32  outMaxBufferSize;
    csSDK_uint32  outNumChannels;
    PrAudioChannelLabel outChannelLabels[16];
    PrTime        outLatency;
    PrSDKString   outAudioOutputNames[16]
} tmAudioMode;
```

outAudioRate	The preferred audio sample rate.
outMaxBufSize	The maximum audio buffer size needed if the transmitter uses plug-in-based audio to request audio buffers using the <i>Playmod Audio Suite</i> .
outNumChannels	The maximum number of audio channels supported.
outChannelMap	See the audio channel configuration for the output hardware using the appropriate identifiers for each audio channel.
outLatency	This value is only used for playback, not when scrubbing. It specifies how early to send frames in advance when audio-only playback starts, and how many frames that will be sent prior to a <code>StartPlaybackClock</code> call. Use this value to get playback in sync between the Source/Program Monitors and external hardware output. All modes must have the same latency. Take care to not set this value any higher than necessary, since playback start will be delayed by this amount. A value equivalent to 5 video frames or less is recommended.
outAudioOutputNames	Now in CS6.0.2. These must be displayable names of physical audio outputs like “XYZ HD Speaker 1” The audio output names in <code>tmAudioMode</code> should be allocated by the plug-in using the <i>String Suite</i> and NOT disposed by the plugin. The host will take care of disposing these strings.

66.5 tmVideoMode

A full description of a video mode that the transmitter will support.

Transmitter should fill in this information during `QueryVideoMode`.

```
typedef struct {
    csSDK_int32    outWidth;
    csSDK_int32    outHeight;
    csSDK_int32    outPARNum;
    csSDK_int32    outPARDen;
    prFieldType    outFieldType;
    PrPixelFormat    outPixelFormat;
    PrSDKString    outStreamLabel;
    PrTime          outLatency;
} tmVideoMode;
```

outWidth	The preferred video resolution. Set to 0 if any resolution is supported.
outHeight	
outPAR	The preferred video pixel aspect ratio. Set to 0 if any pixel aspect ratio is supported.
outPARDen	
outFields	The supported video field type. Set to prFieldsAny if any field dominance is supported.
outPixelFormat	The preferred video pixel format. Set to PrPixelFormat_Any if any format is acceptable. If your transmitter would benefit from on-GPU frames, please let us know.
outStreamLabels	Leave this as 0 for now. Stream labels are not yet supported by transmitters (bug group BG127571)
outLatency	This value is only used for playback, not when scrubbing. It specifies how early to send frames in advance when playback starts, and how many frames that will be sent prior to a StartPlaybackClock call. Use this value to get playback in sync between the Source/Program Monitors and external hardware output. All modes must have the same latency. Take care to not set this value any higher than necessary, since playback start will delayed by this amount. A value equivalent to 5 frames or less is recommended.

66.6 tmPlaybackClock

This structure is filled out by the host and sent to the transmitter to describe the playback clock to be managed by the transmitter.

The transmitter uses the callback here to update the host at regular intervals.

```
typedef struct {
    tmClockCallback      inClockCallback;
    void*                inCallbackContext;
    PrTime               inStartTime;
    pmPlayMode           inPlayMode;
    float                inSpeed;
    PrTime               inInTime;
    PrTime               inOutTime;
    prBool               inLoop;
    tmDroppedFrameCallback inDroppedFrameCallback;
} tmPlaybackClock;
```

tmClockCallback	<p>A pointer to a call with the following signature:</p> <pre>void (*tmClockCallback) (void* inContext, PrTime inRelativeTimeAdjustment);</pre> <p>Call this function when the time changes with a non-speed adjusted amount to increment the clock by. This can be called once per frame in response to PushVideo.</p> <p>Using a negative time should only be used to wait for device, not to achieve sync.</p> <p>The transmitter will not receive any frames while using a negative time.</p> <p>After the first positive valued clock callback, the time will be $\text{StartTime} + \text{inRelativeTimeAdjustment} * \text{inSpeed}$.</p>
inCallbackContext	Pass this into the clock callback above.
inStartTime	Start the clock at this time.
inPlayMode	Specifies whether the StartPlaybackClock was set for playback or scrubbing.
inSpeed	1.0 is normal speed, -2.0 is double speed backwards. Informational only. This is useful for the built-in DV transmitter, which only writes DV captions if playing at regular speed.
inInTime	Informational only and will be handled by the host.
inOutTime	
inLoop	
inDroppedFrameCallback	<p>A pointer to a call with the following signature:</p> <pre>void (*tmDroppedFrameCallback) (void* inContext, csSDK_int64 inNewDroppedFrames);</pre> <p>Use this call to report frames pushed to the transmit plug-in on PushVideo but not delivered to the device. If every frame pushed to the transmitter is sent out to hardware on time, then this should never need to be called as the host will count frames not pushed to the plug-in.</p> <p><code>inNewDroppedFrames</code> should be the number of additional dropped frames since the last time <code>tmDroppedFrameCall</code> back was called.</p>

66.7 tmPushVideo

Describes a frame of video to be transmitted.

```
typedef struct {
    PrTime           inTime;
    pmPlayMode      inPlayMode;
    PrRenderQuality inQuality;
```

(continues on next page)

(continued from previous page)

```

const tmLabeledFrame*  inFrames;
csSDK_size_t           inFrameCount;
} tmPushVideo;

```

inTime	Describes which frame of the video is being passed in. A negative value means the frame should be displayed immediately. Use this value to determine the corresponding timecode for the frame being pushed.
inPlayMode	Pass this into the clock callback above.
inQuality	The quality of the render.
inFrames	The frame or set of frames to transmit. As of CS6, this will always be a single frame. tmLabeledFrame is defined as: <pre> typedef struct { PPixHand inFrame; PrSDKStreamLabel inStreamLabel; } tmLabeledFrame; </pre> The frame(s) must be disposed of by the transmitter when done.
inFrameCount	The number of frames in inFrames.

For information on how to acquire and manage suites, as well as information on more suites that are available to other plug-in types beyond just transmitters, see *SweetPea Suites*.

67.1 Playmod Audio Suite

This suite is used to play audio during playback. There are many more functions that were used by players, still documented in the players chapter. Here we will only consider the single call in the suite that is relevant to transmitters.

67.1.1 Host-Based, or Plug-in Based Audio?

A transmitter has two choices for playing audio: it can ask the host to play the audio through the audio device selected by the user, or it can get audio buffers from the host and handle its own playback of audio.

67.1.2 GetNextAudioBuffer

Retrieves from the host the next contiguous requested number of audio sample frames, specified in `inNumSampleFrames`, in `inInBuffers` as arrays of uninterleaved floats.

The plug-in must manage the memory allocation of `inInBuffers`, which must point to `n` buffers of floating point values of length `inNumSampleFrames`, where `n` is the number of channels. This call is only available if `InitPluginAudio` was used.

Returns:

- `suiteError_NoError`,
- `suiteError_PlayModuleAudioNotInitialized`, or
- `suiteError_PlayModuleAudioNotStarted`

```

prSuiteError (*GetNextAudioBuffer) (
    csSDK_int32    inPlayID,
    float**       inInBuffers,
    float**       outOutBuffers,
    unsigned int   inNumSampleFrames);

```

Parameter	Description
inInBuffers	Currently unused in CS6. A pointer to an array of buffers holding <code>inNumSampleFrames</code> input audio in each buffer, corresponding to the total number of available input channels.
outOutBuffers	A pointer to an array of buffers <code>inNumSampleFrames</code> long into which the host will write the output audio. There must be N buffers, where N is the number of output channels for the output channel type specified in <code>InitPluginAudio</code> .
inNumSampleFrames	The size of each of the buffers in the array in both <code>inInBuffers</code> and <code>outOutBuffers</code> .

67.2 Transmit Invocation Suite

This suite can be used by other types of plug-ins to push frames to transmitters.

For example, an effect or titler with a modal setup dialog could push frames to the output.

We strongly recommend using the **After Effects SDK** to develop effects plug-ins.

Almost all of the effects included in Premiere Pro are After Effects plug-ins, and future development will be based on the After Effects API.

Video filters process a video frame into a destination frame. Filter parameters can vary with time.

Premiere provides basic user interface in the Effect Controls panel, drawing sliders, color pickers, angle dials, and checkboxes based on the parameter definitions in the PiPL resource. Video filters can have their own custom modal setup dialog for additional settings.

If you've never developed a video filter before, you can skip *Whats New*, and go directly to *Getting Started*.

69.1 What's New in Premiere Pro CS5?

In the Effects panel, video filters now appear with badges to advertise if they support YUV, 32-bit, and accelerated rendering.

The user can filter the list of effects to show only the effects that support those rendering modes. Video filters will automatically receive YUV and 32-bit badges if they advertise support using the existing `fsGetPixelFormatSupported`.

Custom badges can also be created. See [Effect Badging](#) for more information.

69.2 What's New in Premiere Pro CS3?

Checkbox controls are now supported directly in the Effect Controls panel.

Filters can specify whether or not they want a setup button in the Effect Controls panel during `fsHasSetupDialog`, by returning `fsHasNoSetupDialog` or `fsNoErr`.

Previously, this was set in the PiPL resource.

CHAPTER 70

Getting Started

Begin with one of the two video filter sample projects, progressively replacing its functionality with your own.

70.1 Resources

Filter plug-ins can use PiPL resources to define their behaviors and supported properties.

To provide any parameters in the Effect Controls panel, they must be defined in the PiPL in ANIM_ParamAtom sections, as demonstrated in the example below.

The 'no UI' UI type is for non-keyframeable parameters. After making changes to the PiPL, rebuild the plug-in each time, so that the PiPL will be recompiled.

70.1.1 A Filter PiPL Example

```
#include "PrSDKPiPLVer.h"
#ifdef PRWIN_ENV
#include "PrSDKPiPL.r"
#endif

// The following two strings should be localized
#define plugInName "Cool Video Filter"
#define plugInCategory "SDK Filters"

// This name should not be localized or updated
#define plugInMatchName "SDK Cool Filter"

resource 'PiPL' (16000) {
    {
        // The plug-in type
```

(continues on next page)

(continued from previous page)

```

Kind {PrEffect},

// The plug-in name as it will appear to the user
Name {plugInName},

// The internal name of this plug-in
AE_Effect_Match_Name {plugInMatchName},

// The folder containing the plug-in in the Effects Panel
Category {plugInCategory},

// The version of the PiPL resource definition
AE_PiPL_Version {PiPLVerMajor, PiPLVerMinor},

// The ANIM properties describe the filter parameters, and also how the data is
↳stored in the project file. There is one ANIM_FilterInfo property followed by n
↳ANIM_ParamAtoms
    ANIM_FilterInfo {
        0,
        #ifdef PiPLVer2p3

        // Non-square pixel aspect ratio supported
        notUnityPixelAspectRatio,
        anyPixelAspectRatio,
        reserved4False,
        reserved3False,
        reserved2False,

        #endif
    },

},  
}  
};
```

70.2 Entry Point

```
short xFilter (  
    short selector,  
    VideoHandle theData)
```

selector is the action Premiere wants the video filter to perform.

EffectHandle provides source and destination buffers, and other useful information.

Return *fsNoErr* if successful, or an appropriate return code.

CHAPTER 71

Selector Table

This table summarizes the various selector commands a video filter can receive.

Selector	Optional?	Description
<i>fsInitSpec</i>	Yes	Allocate and initialize your parameters with default values without popping a modal setup dialog.
<i>fsHasSetupDialog</i>	Yes	New for Premiere Pro CS3. Specify whether or not the filter has a setup dialog.
<i>fsSetup</i>	Yes	Allocate memory for your parameters if necessary. Display your modal setup dialog with default parameter values or previously stored values. Save the new values to <code>specsHandle</code> .
<i>fsExecute</i>	No	Filter the video using the stored parameters from <code>specsHandle</code> . Be aware of interlaced video, and don't overlook the alpha channel!
<i>fsDisposeData</i>	Yes	Dispose of any instance data created during <code>fsExecute</code> .
<i>fsCanHandlePAR</i>	Yes	Tell Premiere how your effect handles pixel aspect ratio.
<i>fsGetPixelFormatsSupported</i>	Yes	Gets pixel formats supported. Called iteratively until all formats have been given.
<i>fsCacheOnLoad</i>	Yes	Return <code>fsDoNotCacheOnLoad</code> to disable plug-in caching for this filter.

Selector Descriptions

72.1 fsInitSpec

Responding to this selector is optional. This selector is sent when the filter is applied to a clip and the plug-in is called for the first time. This call can be used to initialize the plug-in parameters with default values in order to achieve an initial “silent setup”, in which `fsSetup` is skipped when the filter is applied to a clip, to avoid popping the modal dialog that may be needed in `fsSetup`.

Allocate and pass back a handle to a structure containing the parameter values in `specsHandle`. The filter is given the total duration (in samples), and number of the first sample in the source buffer.

72.2 fsHasSetupDialog

New for Premiere Pro CS3. Optional. Specify whether or not the filter has a setup dialog, by returning `fsHasNoSetupDialog` or `fsNoErr`.

72.3 fsSetup

Optional. Sent when the filter is applied, if `fsInitSpec` doesn't allocate a valid `specsHandle`. Also sent when the user clicks on the setup link in the Effect Controls Panel. The filter can optionally display a (platform-dependent) modal dialog to get new parameter values from the user. First, check `VideoHandle.specsHandle`. If NULL, the plug-in is being called for the first time.

Initialize the parameters to their default values. If non-NULL, load the parameter values from `specsHandle`. Now use the parameter values to display a modal setup dialog to get new values. Return a handle to a structure containing the parameter values in `specsHandle`.

In order to properly store parameter values between calls to the plug-in, describe the structure of your `specsHandle` data in your PiPL's ANIM properties. Premiere interpolates animatable parameter values as appropriate before sending `fsExecute`.

The filter is given the total duration in samples and the sample number of the first sample in the source buffer.

During `fsSetup`, the frames passed to `VideoRecord.source` will almost always be 320x240. The exception is if the plug-in is receiving the `fsSetup` selector when the effect is initially applied, in which case it will receive a full height frame, with the width adjusted to make the frame square pixel aspect ratio. For example, a filter applied in a 1440x1080 HDV sequence will receive a full 1920x1080 buffer. The frame is the layer the filter is applied to at the current time indicator. If the CTI is not on the clip the filter is applied to, the frame is transparent black.

If the filter has a setup dialog, the `VFilterCallbackProcPtr` should be used to get source frames for previews. `getPreviewFrameEx` can be used to get rendered frames, although if this call is used, the video filter should be ready to be called reentrantly with `fsExecute`.

72.4 fsExecute

This is really the only required selector for a video filter, and it's where the rendering happens. Take the input frame in `VideoHandle.source`, render the effect and return the frame to Premiere in `VideoHandle.destination`. The `specsHandle` contains your parameter settings (already interpolated if animatable). You can store a handle to any additional non-parameter data in `VideoHandle.InstanceData`. If you do so, deallocate the handle in response to `fsDisposeData`, or your plug-in will leak memory.

The video your filter receives may be interlaced, in the field order determined by the project settings. If interlaced, your plug-in will be called twice for each frame of video, and each PPix will be half the frame height.

72.5 fsDisposeData

Optional. Called when the project closes. Dispose of any instance data created during `fsExecute`. See `VideoHandle->InstanceData`.

72.6 fsCanHandlePAR

Optional. Indicate how your filter wants to handle pixel aspect ratio by returning a combination of the following flags.

This selector is only sent if several conditions are met.

The pixel aspect ratio of the clip to which the filter is applied must be known, and not be square (1.0).

The clip must not be a solid color.

The PiPL bits `anyPixelAspectRatio` and `unityPixelAspectRatio` must not be set.

Flag	Description
<code>prEffectCanHandlePAR</code>	Premiere should not make any adjustment to the source image to compensate for PAR
<code>prEffectUnityPARSetup</code>	Premiere should render the source image to square pixels during <code>fsSetup</code>
<code>prEffectUnityPARExecute</code>	Premiere should render the source image to square pixels during <code>fsExecute</code>

72.7 fsGetPixelFormatSupported

Optional.

Gets pixel formats supported.

Called iteratively until all formats have been given.

Set (**theData*) -> `pixelFormatSupported` to a supported pixel format, and return `fsNoErr`.

When all formats have been described, return `fsBadFormatIndex`.

See the field-aware video filter sample for an example.

72.8 fsCacheOnLoad

Optional. Return `fsDoNotCacheOnLoad` to disable plug-in caching for this filter.

CHAPTER 73

Return Codes

Return Code	Reason
fsNoErr	Operation has completed without error.
fsBadFormatIndex	Return from <code>fsGetPixelFormatFormatsSupported</code> when all pixel formats have been enumerated.
fsDoNotCacheOnLoad	Return from <code>fsCacheOnLoad</code> to disable plug-in caching for this filter.
fsHasNoSetupDialog	Return from <code>fsHasSetupDialog</code> to disable setup button in Effect Controls panel
fsUnsupported	The selector is not recognized, or unsupported.

A video filter is passed a handle to a VideoRecord with almost every selector.

```
typedef struct {
    PrMemoryHandle          specsHandle;
    PPixHand                source;
    PPixHand                destination;
    csSDK_int32             part;
    csSDK_int32             total;
    char                    previewing;
    void*                   privateData;
    VFilterCallBackProcPtr callBack;
    BottleRec*              bottleNecks;
    short                   version;
    short                   sizeFlags;
    csSDK_int32             flags;
    TDB_TimeRecord*         tdb;
    PrMemoryHandle          instanceData;
    piSuitesPtr             piSuites;
    PrTimelineID            timelineData;
    char                    altName[MAX_FXALIAS];
    PrPixelFormat            pixelFormatSupported;
    csSDK_int32             pixelFormatIndex;
    csSDK_uint32            instanceID;
    TDB_TimeRecord          tdbTimelineLocation;
    csSDK_int32             sessionPluginID;
} VideoRecord, **VideoHandle;
```

specsHandle	Instance settings, persistent across Premiere sessions. Create this handle during <code>fsInitSpec</code> or <code>fsSetup</code> . Populated by Premiere if the filter's parameters can be manipulated in the Effect Controls Panel. Use Premiere's memory allocation callbacks to allocate memory for the <code>specsHandle</code> .
source	PPixHand for the source video frame.
destination	PPixHand for the destination video frame, always the same size as source. Store the output frame here during <code>fsExecute</code> .
part	How far into the effect you are. <code>part</code> varies from 0 to total, inclusive.
total	Total length of the video filter. Divide <code>part</code> by <code>total</code> to calculate the percentage of the time-variant filter for a given <code>fsExecute</code> . This value doesn't necessarily correspond to frames or fields.
previewing	Unsupported
privateData	Data private to Premiere. Pass to the frame-retrieval callback when requesting a frame.
callBack	Pointer to <code>VFilterCallbackProcPtr</code> , used for retrieving frames (or fields, for interlaced video) from source clips.
bottleNecks	Pointer to Premiere's <code>bottleRec</code> functions.
version	Version of this structure (<code>kVideoFilterVersion</code>). <ul style="list-style-type: none"> Premiere Pro CS5 = <code>VIDEO_FILTER_VERSION_11</code> Premiere Pro CS3 = <code>VIDEO_FILTER_VERSION_10</code>
sizeFlags	Field-rendering information.
flags	If doing a lower-quality render, Premiere will pass in <code>kEffectFlags_DraftQuality</code> during <code>fsExecute</code> . The filter can then optionally render a faster, lower-quality image for previewing.
tdb	Pointer to a time database record describing the sequence timebase.
instanceData	Handle to private instance data that persists across invocations. Allocate the memory for this during <code>fsExecute</code> and deallocate during <code>fsDisposeData</code> . Do not use this field during <code>fsSetup</code> .
piSuites	Pointer to callback <i>piSuites</i> .
timelineData	Only available during <code>fsInitSpec</code> and <code>fsSetup</code> . This opaque handle to the timeline database is required by <code>timelineFuncs</code> callbacks available in <i>piSuites</i> . This handle is useful in order to have a preview in a modal setup dialog during <code>fsSetup</code> .
altName	Unused.
pixelFormatSupported	Only valid during <code>fsGetPixelFormatsSupported</code> . Return pixel type supported.
pixelFormatIndex	Only valid during <code>fsGetPixelFormatsSupported</code> . Index of four CC of pixel type supported.
instanceID	The runtime instance ID uniquely identifies filters during a session. This is the same ID that is passed to players in <code>prtFilterRec</code> .

74.1 VFilterCallbackProcPtr

Pointer to a callback for retrieving frames (or fields, for interlaced video) from the source clip.

Do not expect real-time performance from this callback.

```
typedef short (CALLBACK *VFilterCallbackProcPtr) (
    csSDK_int32  frame;
    PPixHand    thePort;
    RECT*       theBox;
    Handle      privateData);
```

Parameter	Description
frame	Frame requested. The frame value passed in should be frame * samplesize. The callback will always return the current field (upper or lower) during field rendering.
thePort	PPixHand where Premiere will store the frame
theBox	Bounds of the frame you want Premiere to retrieve.
privateData	Handle provided by Premiere in VideoRecord.privateData

74.2 sizeFlags

For sizeFlags, the following bit flags are of interest:

Flag	Description
gvFieldsEven	The video filter should render upper-field dominance
gvFieldsOdd	The video filter should render lower-field dominance
gvFieldsFirst	The video filter is currently rendering the dominant field

75.1 Fields and Field Processing

In an interlaced project, Premiere calls your video filter once per field.

This allows video filters to have interlaced motion. `(*theData)->total` will be twice as large, each frame will be half-height, and rowbytes will double.

Respect the value of rowbytes when traversing data or the output will be incorrect.

75.2 Frame Caching

The rendered output of video filters is stored in the host media cache. For example, when the user scrubs over a frame with a filter on it, the filter will be called to render its effect on the frame and return the buffer to Premiere. Premiere caches the returned frame, so when the user scrubs over the same frame, Premiere will return the cached frame without having to call the filter again. If the user has modified the filter settings, the clip settings, the preview quality, etc, Premiere will call the filter to render with the new settings, but will keep the previously cache frame for a while. So if the changes are reversed, Premiere may still have the cached frame to return when appropriate.

If the filter should generate random, non-deterministic output, or if it changes over time without keyframes, the randomness bit must be set in the `ANIM_FilterInfo` section in the PiPL (.r file).

If you set the bit to `noRandomness`, Premiere will only render one frame of a still image.

75.3 Creating Effect Presets

Effect presets appear in the Presets bin in the Effects panel, and can be applied just like Effects with specific parameter settings and keyframes. Effect presets can be created as follows:

1. Apply a filter to a clip
2. Set the parameters of the filter, adding keyframes if desired
3. Right-click on the filter name in the Effect Controls panel, and select “Save Preset...”
4. Create preset bins if desired by right-clicking in the Effects panel and choosing “New Presets Bin”
5. Organize the presets in the preset folders
6. Select the bins and/or presets you wish to export, right-click, and choose “Export Preset”

On Windows, newly created presets are saved in the hidden Application Data folder of the user’s Documents and Settings (e.g. C:\Documents and Settings[user]\Application Data\Adobe\Premiere Pro[version]\Effect Presets and Custom Items.prfpset). On Mac OS, they are in the user folder, at ~/Library/Application Support/Adobe/Premiere Pro/[version]/Effect Presets and Custom Items.prfpset.

Effect Presets should be installed as described in the section, “Plug-in Installation”. Once they are installed in that folder, they will be read-only, and the user will not be able to move them to a different folder or change their names. User-created presets will be modifiable.

75.4 Effect Badging

Starting in CS5, video filters now appear with badges in the Effects panel to advertise if they support YUV, 32-bit, and/or accelerated rendering. The user can filter the list of effects to show only the effects that support those rendering modes. Video filters will automatically receive YUV and 32-bit badges if they advertise support using the existing *fsGetPixelFormatSupported*. Custom badges can also be created.

To add your own effect badge, go to the following folder:

On Windows: [App installation path]\Settings\BadgeIcons\

On Mac OS: Adobe Premiere Pro CS5.app/Contents/Settings/BadgeIcons/

In that folder are the PNG graphics that are loaded at runtime for various badges, and an additional set of 'Sample-*.png' and 'Sample.xml' files.

1. Make copies of the Sample-.png files, replacing the “Sample” prefix with the prefix that matches whatever you want to call the new badge (like ‘NewBadge-.png’). Edit the PNG as you’d like, but don’t change the image dimensions.
2. Copy the Sample.xml file to a new name that matches whatever you want to call the new badge (like ‘NewBadge.xml’). Edit the list of match names that you want to be decorated with your badge. Change the <Name> tag to the name you chose in step 1 (like ‘NewBadge’). You can also add your tooltip text as the <Description-Item> tags. These tags act as a localization map with the langid as the key. If a language isn’t found, ‘en_US’ is used by default. Provide your own GUID in the <Guid> tag.
3. Relaunch the application. You’ll get a badge filter icon next to the others and a badge icons next to each effect that was listed in the XML file.

Note: ‘Sample’ is a special case that is intentionally excluded. Any other set of .xml/.png files will be used.

75.5 Premiere Elements and Effect Thumbnail Previews

Premiere Elements (but not Premiere Pro) displays visual icons for each effect. You will need to provide icons for your effects, or else an empty black icon will be shown for your effects, or even worse behavior in Premiere Elements 8. The icons are 60x45 PNG files, and are placed here:

[Program Files]Adobe\Adobe Premiere Elements [version]\Plug-ins\CommonEffectPreviews\

The filename should be the match name of the effect, which you specify in the PiPL, prefixed with “PR.” So if the match name was “MatchName”, then the filename should be “PR.MatchName.png”

GPU Effects & Transitions

This chapter describes the additional capabilities available to effects and transitions for GPU interoperability with Premiere Pro. The GPU extensions allow these plug-ins to have full access to GPU-resident frames without readback to system memory, when using the Mercury Playback Engine in a GPU-accelerated mode. Effects and transitions can also optionally tell the host that they support real-time processing, so that they will not be flagged as non-realtime.

The GPU extensions work on top of effects and transitions built using the After Effects SDK. The extensions are designed to supplement a regular software effect or transition, which defines the software rendering path, parameters, custom UI drawing, and other standard interaction. The GPU effect exists as a new entry point for rendering using the GPU if possible. The software render path will be used otherwise.

76.1 System Requirements

The system requirements for developing GPU effects & transitions are higher than developing other plug-ins. You'll need a video card that supports Mercury Playback Engine GPU-

acceleration. Make sure your video card supports the type of video acceleration you are developing, on the platform you are developing on. See this page for the latest supported video cards: <https://helpx.adobe.com/premiere-pro/system-requirements.html>

The CUDA SDK is also needed for CUDA rendering development.

CHAPTER 77

CUDA, OpenCL, Metal, or OpenGL?

The GPU architecture of Premiere Pro is entirely CUDA/OpenCL/Metal, and this is what is exposed through the GPU extensions to the effect/transition APIs. A GPU-accelerated effect may use any combination of CUDA, OpenCL, and Metal.

If you want, you have the ability to transfer frames from CUDA/OpenCL to OpenGL (though not always efficiently). Read more about that [here](#).

What's New in Premiere Pro 12.0?

GPU effects and transitions built using this SDK can now be compatible with After Effects 15.0 and later. The sample GPU effect projects have been updated so that they load in both Premiere Pro and After Effects.

The newly provided PrGPU SDK macros and device functions allow you to write kernels that will compile on multiple GPU compute languages - OpenCL, CUDA, and Metal.

CHAPTER 79

What's New in Premiere Pro CC 2015.4?

GPU-accelerated rendering using Metal is now supported for third-party effects and transitions. `PrGPUDeviceFramework_Metal` has been added as one of the enum values in `PrGPUDeviceFramework`.

CHAPTER 80

What's New in Premiere Pro CC 2014?

OpenCL rendering now also uses the half-precision 16-bit floating point pixel format for rendering. GPU effects and transitions that support OpenCL should implement both 16f and 32f rendering.

81.1 Setting up the Sample Projects

If you are developing an effect, begin with one of the two GPU effect sample projects, progressively replacing its functionality with your own. Refer to *Introduction* for general instructions on how to build the SDK projects.

In addition to those general instructions, the sample project is also dependent on the After Effects plug-in SDK. Download it here. On Windows, create an environment variable pointing to it named `AE_SDK_BASE_PATH`, so that the compiler will find the AE headers that the project includes. On macOS, in *Xcode > Preferences > Locations > Source Trees*, specify `AE_SDK_BASE_PATH` to be the root folder of the AE plug-in SDK you have downloaded and unzipped.

The samples also use Boost, which may be downloaded at boost.org. Download that, and create a variable named `BOOST_BASE_PATH` just as you did with `AE_SDK_BASE_PATH` above.

Finally, install Python, if you do not have it already. It may be downloaded at python.org. The sample projects use this as part of the custom build steps.

Depending on whether your effect will use OpenCL or CUDA or both, you'll need to download the CUDA SDK. On Windows, create an environment variable pointing to it named `CUDA_SDK_BASE_PATH`, so that the linker will find the right libraries.

81.2 Querying for Parameters and other Attributes of a Effect or Transition

You'll notice that `PrGPUFilterRenderParams` has some attributes about an effect or transition, but many things, such as the parameters or duration of the clip to which the plug-in is applied, are not found in that structure. These attributes will need to be queried using the `GetParam()` and `GetProperty()` helper functions in `PrGPUFilterModule.h`. For example:

```
GetProperty(kVideoSegmentProperty_Effect_EffectDuration, duration);
```

```
GetProperty(kVideoSegmentProperty_Transition_TransitionDuration, duration);
```

81.3 Lifetime of a GPU Effect / Transition

A new GPU effect instance is created when an effect/transition is applied in the timeline, or when an effect parameter is changed. When rendering a series of frames it won't needlessly be recreated. The *Opaque Effect Data Suite* should be used to share unflattened sequence data between instances of the same effect on a track item.

81.4 Fallback to Software Rendering

When a new GPU effect instance is created, the instance has the option of opting-in or out of providing GPU rendering. The GPU effect should be reasonably sure it has sufficient resources to complete the render if it opts-in, because there is no API support to fall back to software rendering in the middle of a render.

Calling `GetDeviceInfo()` in the *GPU Device Suite*, and checking `outDeviceInfo.outMeetsMinimumRequirementsForAcceleration`, you can see if supports the minimum system requirements for acceleration. Do not proceed with

`AcquireExclusiveDeviceAccess()`, if the minimum requirements are not met.

In emergency situations, when there is not enough GPU memory available to complete a render, an effect may call `PurgeDeviceMemory` in the *GPU Device Suite* to free up memory not initially available. This will impact performance, and should be used only if absolutely necessary.

81.5 OpenGL Interoperability

If you want, you have the ability to transfer frames from CUDA/OpenCL to OpenGL (though not always efficiently).

In Premiere Pro, OpenCL contexts are created with OpenGL interoperability. We expose info about it through `PrGPUDeviceInfo` available through `PrSDKGPUDeviceSuite.h`:

```
void* outOffscreenOpenGLContextHandle; // CGLContextObj or HGLRC
void* outOffscreenOpenGLDeviceHandle; // HDC
```

For CUDA interoperability with OpenGL:

CUDA -> OpenGL: Create an OpenGL buffer, map it into CUDA with `cuGraphicsMapResources`, get the mapped address with `cuGraphicsResourceGetMappedPointer`, copy from the CUDA address to the mapped address with `cuMemcpyDtoDAsync`, unmap with `cuGraphicsUnmapResources`.

OpenGL -> CUDA: Map the OpenGL buffer into CUDA with `cuGraphicsMapResources`, get the mapped address with `cuGraphicsResourceGetMappedPointer`, copy from the mapped address to CUDA with `cuMemcpyDtoDAsync`, unmap with `cuGraphicsUnmapResources`.

Note that on the Mac there is no real OpenGL/CUDA interoperability, and these calls will go through system memory.

81.6 Entry Point

The GPU entry point function will only be called if the current project is using GPU acceleration. Otherwise, the normal entry point function will be called as described in the After Effects SDK, or *GPU Effects & Transitions* or *Video Filters* in this SDK Guide.

Make sure GPU acceleration is activated in File > Project Settings > General > Video Rendering and Playback > Renderer. If a GPU option is not available, then you will need to install a suitable video card in your system.

```
prSuiteError xGPUFilterEntry (  
    csSDK_uint32      inHostInterfaceVersion,  
    csSDK_int32*     ioIndex,  
    prBool           inStartup,  
    piSuitesPtr      piSuites,  
    PrGPUFilter*     outFilter,  
    PrGPUFilterInfo* outFilterInfo)
```

If `inStartup` is non-zero, the effect/transition should startup and initialize the functions needed to implement `PrGPUFilter`, as well as the info in `PrGPUFilterInfo`.

If `inStartup` is false, then the effect/transition should shutdown, unloading any resources it loaded on startup.

As of CC, `inHostInterfaceVersion` is `PrSDKGPUFilterInterfaceVersion1 == 1`.

If a single plug-in supports multiple effects, increment `ioIndex` to the next value before returning, in order to be called again to describe the next effect.

PrGPUFilter Function Table

PrGPUFilter is a structure consisting of the following functions that a effect/transition can implement.

Selector	Op- tional	Description
<i>CreateInstance</i>	No	Allocate and initialize any GPU resources.
<i>DisposeInstance</i>	No	Release GPU resources.
<i>GetFrameDepen- dencies</i>	Yes	If the rendered result of the effect/transition depends on frames other than the input frame, specify these here.
<i>PreCompute</i>	Yes	Precompute.
<i>Render</i>	No	Render.

Function Descriptions

83.1 CreateInstance

```
prSuiteError (*CreateInstance)(  
    PrGPUFilterInstance* ioInstanceData);
```

Creates a GPU filter instance representing an effect or transition on a track item.

Returning an error from CreateInstance will cause this node to be rendered in software for the current set of parameters.

Unlike software instances of effects and transitions, GPU instances are created and disposed whenever an effect parameter changes.

This allows an effect have more flexibility about opting-in for GPU rendering, depending on the parameters. Separate instances may be called concurrently.

83.2 DisposeInstance

```
prSuiteError (*DisposeInstance)(  
    PrGPUFilterInstance* ioInstanceData);
```

Cleanup any resources allocated during CreateInstance.

83.3 GetFrameDependencies

```
prSuiteError (*GetFrameDependencies) (
    PrGPUFilterInstance*      inInstanceData,
    const PrGPUFilterRenderParams* inRenderParams,
    csSDK_int32*              ioQueryIndex,
    PrGPUFilterFrameDependency* outFrameDependencies);
```

Return dependency information about a render, or nothing if only the current frame is required.

Increment `ioQueryIndex` for additional dependencies.

83.4 PreCompute

```
prSuiteError (*Precompute) (
    PrGPUFilterInstance*      inInstanceData,
    const PrGPUFilterRenderParams* inRenderParams,
    csSDK_int32              inIndex,
    PPixHand                  inFrame);
```

Precompute a result into preallocated uninitialized host (pinned) memory.

Will only be called if `PrGPUDependency_Precompute` was returned from `GetFrameDependencies`.

Precomputation may be called ahead of render time.

Results will be uploaded to the GPU by the host.

If `outPrecomputePixelFormat` is not custom, frames will be converted to the GPU pixel format.

83.5 Render

```
prSuiteError (*Render) (
    PrGPUFilterInstance*      inInstanceData,
    const PrGPUFilterRenderParams* inRenderParams,
    const PPixHand*          inFrames,
    csSDK_size_t              inFrameCount,
    PPixHand*                 outFrame);
```

Render into an allocated `outFrame` allocated with `PrSDKGPUDeviceSuite` or operate in place.

Result must be in the same pixel format as the input. If the effect grows or shrinks the output area (e.g. rendering a drop shadow), it is allowable for the effect to allocate and return a different sized `outFrame`.

For effects, `inFrames[0]` will always be the frame at the current time, other input frames will be in the same order as returned from `GetFrameDependencies`. For transitions `inFrames[0]` will be the incoming frame and `inFrames[1]` the outgoing frame. Transitions may not have other frame dependencies.

Use the utility function `GetParam` to retrieve the parameter values at the current time.

CHAPTER 84

Return Codes

Return Code	Reason
malNoError	No error.
malUnknownError	Error.

Structure Descriptions

85.1 PrGPUFilterInfo

This structure contains some basic info about a GPU filter. It provides access to various suites, and access to private data where the instance can allocate memory and store data which will be passed to subsequent functions.

```
typedef struct {
    csSDK_uint32  outInterfaceVersion;
    PrSDKString  outMatchName;
} PrGPUFilterInfo;
```

Member	Description
outInterfaceVersion	Set to the GPU API version corresponding to the version defined in the SDK you are using.
outMatchName	outMatchName must be equal to a registered software filter, if NULL will default to the module's PiPL.

85.2 PrGPUFilterInstance

This structure contains some basic info about a GPU filter. It provides access to various suites, and access to private data where the instance can allocate memory and store data which will be passed to subsequent functions.

```
typedef struct {
    piSuitesPtr  piSuites;
    csSDK_uint32  inDeviceIndex;
    PrTimelineID  inTimelineID;
    csSDK_int32   inNodeID;
    void*        ioPrivatePluginData;
```

(continues on next page)

(continued from previous page)

```

    prBool        outIsRealtime;
} PrGPUFilterInstance;

```

Member	Description
piSuites	Standard suites.
inDeviceIndex	For use with PrSDKGPUDeviceSuite.
inTimelineID	For use with PrSDKVideoSegmentSuite.
inNodeID	For use with PrSDKVideoSegmentSuite.
ioPrivatePluginData	Used by a plug-in to store instance data, never touched by the host.
outIsRealtime	Specify if the plug-in is likely to play in real-time, used to determine whether the segment is red, yellow, or unmarked in the timeline.

85.3 PrGPUFilterRenderParams

This structure describes the current render request.

```

typedef struct {
    PrTime    inClipTime;
    PrTime    inSequenceTime;

    // Render properties
    PrRenderQuality    inQuality;
    float              inDownsampleFactorX;
    float              inDownsampleFactorY;

    // Frame properties
    csSDK_uint32       inRenderWidth;
    csSDK_uint32       inRenderHeight;
    csSDK_uint32       inRenderPARNum;
    csSDK_uint32       inRenderPARDen;
    prFieldType        inRenderFieldType;
    PrTime             inRenderTicksPerFrame;
    pmFieldDisplay     inRenderField;
} PrGPUFilterRenderParams;

```

Member	Description
inClipTime	The time of the current render, relative to clip start
inSequenceTime	The time of the current render, relative to sequence start
inQuality	Render quality; one of the PrRenderQuality enum values
inDownsampleHorizontal	Horizontal downsample factor
inDownsampleVertical	Vertical downsample factor
inRenderWidth	Video resolution
inRenderHeight	
inRenderPARNum	Video pixel aspect ratio, described as a fractional number with separate values for numerator and denominator.
inRenderPARDen	
inRenderField	Render field type
inRenderTick	Video frame rate
inRenderField	GPU rendering is always done on full-height progressive frames unless PrGPUFilterFrameDependency.outNeedsFieldSeparation is false. inRenderField indicates which field is being rendered.

85.4 PrGPUFilterFrameDependency

This structure describes any dependencies for a rendered frame.

```
typedef struct {
    PrGPUFilterFrameDependencyType  outDependencyType;

    // Dependence on other frame times
    csSDK_int32  outTrackID;
    PrTime      outSequenceTime;

    // Dependence on precomputation phase
    PrPixelFormat  outPrecomputePixelFormat;
    csSDK_uint32  outPrecomputeFrameWidth;
    csSDK_uint32  outPrecomputeFrameHeight;
    csSDK_uint32  outPrecomputeFramePARNumerator;
    csSDK_uint32  outPrecomputeFramePARDenominator;
    prFieldType   outPrecomputeFrameFieldType;
    csSDK_size_t  outPrecomputeCustomDataSize;
    prBool        outNeedsFieldSeparation;
} PrGPUFilterFrameDependency;
```

Member	Description
outDependencyType	The dependency type. Could be either: <ul style="list-style-type: none"> • PrGPUDependency_InputFrame, • PrGPUDependency_Precompute, • PrGPUDependency_FieldSeparation
outTrackID	Specify which track is a dependency. Set to 0 for the current track
outSequenceTime	Set the sequence time which is a dependency.
outPrecomputePixelFormat	Dependence on precomputation phase
outPrecomputeFrameWidth	
outPrecomputeFrameHeight	
outPrecomputeFramePARNumerator	
outPrecomputeFramePARDenominator	
outPrecomputeFrameFieldType	
outPrecomputeCustomDataSize	Only needed if outPrecomputePixelFormat is custom
outNeedsFieldSeparation	Indicates if the plug-in may operate on both fields simultaneously (eg non-spatial and non-time varying)

PrGPU SDK Macros

The PrGPU SDK macros and device functions allow you to write kernels that will compile on multiple GPU compute languages - CUDA, OpenCL, and Metal. These languages have an enormous overlap - a C98 language subset, and by using the porting macros and functions to abstract out the differences, you can write portable code. You can still access API specific features not covered by the porting set but you'll need to include an alternate code path for the other APIs.

Currently the SDK does not provide host side code to compile or launch arbitrary kernels, but there are SDK examples that show how to do this for the different APIs.

The macros are not part of the plug-in API - they are provided as a utility if you would like to use them. This gives you broad latitude to fork them and make any changes you see fit without breaking plug-in compatibility. On the Adobe end, we may expand and modify the SDK kernel porting set in future releases to cover other compute APIs or other enhancements.

86.1 External Dependencies

The macros do add one external source dependency - Boost (boost.org). We use the Boost preprocessor package to manipulate kernel definitions.

Depending on how you choose to compile and deploy your kernels, we also provide a small python script that may be useful (See "Preprocessing as a Separate Step")

86.2 Include Paths

You need to add some include paths to your kernel compilation environment:

- the path to PrGPU/KernelSupport/ (found in the SDK at Examples/Projects/GPUVideoFilter/ Utils/)

- the path to the Boost library
-

86.3 Defines

You will also need to define a symbol to tell the header file what API to process when compiling the kernel:

- Metal: `-DGF_DEVICE_TARGET_METAL=1`
- OpenCL: `- DGF_DEVICE_TARGET_OPENCL=1 - DGF_OPENCL_SUPPORTS_16F=1` or 0, depending on whether you will support half (16-bit float) access for this device. Some older cards are quite slow at half support, or just don't support it.
- CUDA: the `KernelCore.h` header will automatically sense the cuda compiler and will `#define GF_DEVICE_TARGET_CUDA 1` for you.

Only one device target flag will be active in any given compilation. The header the define the device target macros to 0 for the inactive APIs. Feel free to use these macros in your code for any API specializations. Outside of the header, we don't need to do this much.

86.4 Header Files

- `KernelCore.h` - basic header macros. You'll certainly want these
- `KernelMemory.h` - global device memory access abstractions for float and half
- `FloatingPoint.h` - common floating point routines. These mostly hide naming differences across APIs.

You'll want to include them like this in your kernel:

```
#include "PrGPU/KernelSupport/KernelCore.h"
```

The folder contains additional files used by the above files.

One thing to watch out for is whether your projects are tracking header dependencies properly. If not, you'll need to manually recompile kernels when include files change. This is true whether or not you use the SDK porting set, so you've likely already sorted this out.

86.5 Top Level Kernel Files

You can organize your code and projects as you like, but we find it convenient to have separate top level kernel files for each API (`.cl`, `.cu`, and `.metal`) that just include shared code and are otherwise nearly empty. This makes build rules much easier.

86.6 Preprocessing as a Separate Step

If you compile the kernel source on the customer machine, you may wish to preprocess the kernel at plug-in compile time, and store the kernel source in your plug-in. A python script is provided that will convert preprocessed source to a character array. The script is in Examples/Projects/GPUVideoFilter/Utils/CreateCString.py. See the ProcAmp example for usage.

You can also compile kernels (which is always the case for CUDA) at plug-in compile time, in which case you don't need the python script, or a separate preprocessing run. You will need to package the compiled kernel in your plug-in if you go this route.

The ProcAmp plug-in example uses a preprocessing step for OpenCL and Metal.

86.7 Declaring Kernels

Metal kernels require syntax that is quite different than OpenCL or CUDA, and the PrGPU macros use the Boost preprocessing package to express parameters. This is by far the most complicated part of the package, so grab a fresh cup of coffee and sit back for a read.

The GF_KERNEL_FUNCTION macro is used to pass values as parameters (OpenCL/CUDA) or in a struct (metal). The macro will create an API-specific kernel entry point which will call a

function that it defines, leaving you to fill in the body. The macro uses Boost preprocessor sequences to express a type/name pair:

```
(float) (inValue)
```

These pairs are then nested into a sequence of parameters:

```
((float) (inAge)) ((int) (inMarbles))
```

There are different categories of parameters, such as buffers, values, and kernel position. Each category sequence is a separate macro parameter. Example usage:

```
GF_KERNEL_FUNCTION(RemoveFlicker,
//kernel name, then comma, ((GF_PTR(float4)) (inSrc))
//all buffers and textures go after the first comma
((GF_PTR(float4)) (outDest)),
((int) (inDestPitch))
//After the second comma, all values to be passed_
↔ ((DevicePixelFormat) (inDeviceFormat))
((int) (inWidth))
((int) (inHeight)),
((uint2) (inXY) (KERNEL_XY))
//After the third comma, the position arguments.
((uint2) (inBlockID) (BLOCK_ID))
{
    <do something interesting here>
}
```

In the example above, the host does not pass the position values when invoking the kernel.

Position values are filled in automatically by the unmarshalling code generated by the `GF_KERNEL_FUNCTION` macro. The code you write will actually end up in a device function that the unmarshalling code will call. See the ProcAmp example plug-in for usage.

Kernels that use statically sized shared memory use a different macro, `GF_KERNEL_FUNCTION_SHARED`. Please see the header for details.

86.8 Declaring Device Functions

By comparison, device functions are a snap to write:

```
GF_DEVICE_FUNCTION float Average(float a, float b) {...
```

86.9 Other Macros and Functions

There's a variety of other macros and functions in the KernelSupport headers. Please see the Headers and examples for details.

For information on how to acquire and manage suites, see *SweetPea Suites*.

87.1 GPU Device Suite

This suite provides info on any GPU devices available. For example, `GetDeviceInfo()` allows an effect/transition to see if the device supports OpenCL or CUDA.

Use this suite to get exclusive access to a device using `AcquireExclusiveDeviceAccess` and `ReleaseExclusiveDeviceAccess`. If needed, you can reconcile devices using the `outDeviceHandle` passed back from `GetDeviceInfo()`.

Device memory should ideally be allocated through this suite. In some cases you may find it more efficient to use a texture / image object as the source. With CUDA, you can bind a texture reference to an existing linear buffer. With OpenCL, you can create an image object from an existing 2D buffer object using `image_2d_from_buffer`. Temporary allocations are also fine but may be rather slow.

87.2 Opaque Effect Data Suite

This suite provides effects a way to share unflattened sequence data between instances of the same effect on a track item. The data is opaque to the host and effects are responsible for maintaining thread safety of the shared data. The host provides reference-counting that the effect can use to manage the lifetime of the shared data. Here's an overview of how this suite should be used:

When the effect is applied, in `PF_Cmd_SEQUENCE_SETUP`, the effect plug-in allocates and initializes the sequence data in `PF_OutData->out_data`. Then it calls

`AcquireOpaqueEffectData()`. The opaque effect data does not yet exist, so the plug-in allocates it, and calls `RegisterOpaqueEffectData`, and then copies over the data from the sequence data. So both sequence data and opaque effect data are allocated.

Then `PF_Cmd_SEQUENCE_RESETUP` is called (multiple times) for clones of the effect used for rendering. The effect instance knows it's a clone because the `PF_InData->sequence_data` is `NULL` (there is a special case if the effect has Opaque Effect Data – in that case, its render clones will receive `PF_Cmd_SEQUENCE_RESETUP` with a `NULL` `sequence_data` pointer). It then calls `AcquireOpaqueEffectData()`. As a render clone, it relies on this opaque effect data, rather than sequence data, and does not try to copy the sequence data to opaque effect data.

When, on the other hand, `SEQUENCE_RESETUP` is called with valid `sequence_data` in `PF_InData`, this is not a render clone. The plug-in unflattens this sequence data. It then calls `AcquireOpaqueEffectData()`, and if the opaque effect data does not yet exist (i.e. when reopening a saved project), the plug-in allocates it, and calls `RegisterOpaqueEffectData`. It then copies the sequence data to opaque effect data.

On `SEQUENCE_FLATTEN`, the plug-in takes the unflattened data, flattens it, and disposes of the un-flat data.

When `SEQUENCE_SETDOWN` is called (it may be called multiple times to dispose of render clones), `ReleaseOpaqueEffectData()` is called.

87.2.1 instanceID

The *Opaque Effect Data Suite* functions need the `instanceID` of the effect. For the software entry point, you can obtain this using `GetFilterInstanceID()` in `PF_UtilitySuite`, defined in `PrSDKAESupport.h`. For the GPU Render entry point, you can use the following code: `csSDK_uint32 instanceID;`

```
GetProperty( kVideoSegmentProperty_Effect_RuntimeInstanceID, instanceID);
```

... where `GetProperty()` is defined in `PrGPUFilterModule.h`, and the `kVideoSegmentProperty_ IDs` are defined in `PrSDKVideoSegmentProperties.h`.

AE Transition Extensions

This chapter describes how to build native transitions in Premiere Pro based on the After Effects API. From a user-perspective, plug-ins built this way can show their parameters directly in the Effect Controls panel, even providing custom parameter UI in that panel or in the Sequence Monitor. Such plug-ins can run not only in Premiere Pro, but also in After Effects, although they will appear as effects rather than transitions.

The transition extensions work on top of effects built using the After Effects SDK. Since AE effects only have a single input, the second input is a layer parameter defined by the plug-in.

PF_TransitionSuite

In `PrSDKAESupport.h`, we've added `PF_TransitionSuite::RegisterTransitionInputParam()`.

This call must be made before the `PF_ADD_PARAM()` call during `PF_Cmd_PARAM_SETUP`.

Pass in the param to be used as the input layer for the other side of the transition.

This enables you effect to be applied between two clips in the timeline just like our native transitions, but it will show up in the Effect Controls panel with full keyframable parameters similar to existing AE effects.

90.1 Setting up the Sample Project

If you are developing an transition, begin with the sample project, named `SDK_CrossDissolve`, progressively replacing its functionality with your own. Refer to *Introduction* for general instructions on how to build the SDK projects.

In addition to those general instructions, the sample project is also dependent on the After Effects SDK. Download it here. On Windows, create an environment variable pointing to it named “`AE_SDK_BASE_PATH`”, so that the compiler will find the AE headers that the project includes. On

MacOS, in XCode > Preferences > Locations > Source Trees, specify `AE_SDK_BASE_PATH` to be the root folder of the AE SDK you have downloaded and unzipped.

Depending on whether your transition will use OpenCL or CUDA or both, you’ll need to download the CUDA SDK. On Windows, create an environment variable pointing to it named “`CUDA_SDK_BASE_PATH`”, so that the linker will find the right libraries.

90.2 Compatibility Considerations

For compatibility with plug-in hosts that doesn’t support the AE Transition Extensions, a plug-in should check first for the existence of the suite. If it isn’t available, the plug-in should act as a normal effect. This is demonstrated in the `SDK_CrossDissolve` sample project.

Device Controllers

Device controllers drive hardware devices, such as cameras and tape decks, enabling timecode-accurate, hardware-assisted video capture and output to tape. Device controllers are used when working in the Capture and Edit to Tape panels. A device controller can implement one or more communication protocols, and should gracefully handle differences across various hardware that support the same protocol.

Device controllers are usually called by Premiere when the user is in the Capture panel or Edit to Tape panel, for example, when using the VTR transport controls in either panel to navigate through video on a VTR. But device controllers can also be driven by recorder plug-ins during

capture. Especially when capturing video, the device controller's operation becomes deeply intertwined with the recorder. Device controllers work along with recorders to update Premiere with timecode information from the hardware.

If you've never developed a device controller before, you can skip *Whats New*, and go directly to *Getting Started*.

92.1 What's New in CC October 2013

The new command *cmdSetDeviceHandler* was added. This command tells the device controller which panel is using the device controller – either the Capture panel, or Export to Tape panel.

92.2 What's New in CC July 2013?

In the July 2013 release of CC, the new capability flag *fCanPrintToTape* was added for a device controller supporting Edit to Tape using the new panel to specify whether or not it supports Print to Tape mode. *fCanDelayMovieStart* was added for a device controller to optionally specify that it wants to handle Delay Movie Start on its own. If the flag is set, the value as set by

the user will be passed in *DeviceRec.delayFrames* during an Edit to Tape. The *DeviceRec.* version has been incremented to *kDeviceControlAPIVersion13* for plug-ins to distinguish which version they are running in.

92.3 What's New in CC?

In CC, the new Edit to Tape panel provides an integrated UI with settings and controls for exporting a clip or sequence to tape. The device controller can optionally support various common settings in the Edit to Tape panel. Three types of record modes are now natively supported: Print to Tape, Insert, and Assemble modes. Although a device controller can still provide a custom setup dialog for any additional settings, the panel eliminates much of the need for custom UI. It also allows for integrated device presets, and some bonus capabilities like adding Bars and Tone / Black Video / Universal Counting Leader to the start of the edit to tape. To update your device controller to use the new panel, set *fCanInsertNoUI* along with any other flags during *dsExecute/ cmdGetFeatures*. Then take your *cmdInsertEdit* implementation and integrate your logic to respond to the new record modes sent in *cmdNewMode*.

92.4 What's New in CS6.0.1?

In CS6.0.1, `DroppedFrameProc` was added to give device controllers a way to get the number of frames dropped during an insert edit. A device controller can use this to provide the feature to abort an Export to Tape if frames are dropped. This method is already superceded by the new Edit to Tape panel functionality in CC.

You'll need a thorough understanding of the device(s) you hope to control before developing a device control plug-in. Begin with the sample project, progressively replacing its functions with your own.

Will your device controller be used for the capture process, or for output to tape, or both? Below are notes describing how to support these in your plug-in.

93.1 Resources

Device controllers use a basic PiPL to specify their name and the match name that Premiere uses to identify them. When making changes to the PiPL resource, rebuild the plug-in each time, so that the PiPL will be recompiled.

93.2 Entry Point

```
short xDevice (  
    short selector,  
    DeviceHand theData)
```

selector is the action Premiere wants the device controller to perform. *DeviceHand* is a handle to *DeviceRec*, which provides all pertinent information.

Return `dmNoError` if successful, or an appropriate return code.

94.1 Timecode

Since the device controller and recorder sample plug-ins both only simulate hardware, they will return different timecode values to the app. You can set the Capture panel to only display device controller timecode by going to Preferences > Capture, and check “Use device control timecode”. On the other hand, leaving this box unchecked and observing the different timecodes returned is a good way to get a feel for when the device controller timecode is used, and when the recorder timecode is used.

94.2 Preroll Time

The Preroll Time value is set in the Capture panel, in the Settings tab. The value defaults to zero seconds, but it may be set to any positive value chosen by the user. Adjusting the Preroll Time setting will have an effect on the DeviceRec.preroll value sent during *dsExecute/cmdLocate*. The value will be converted from seconds into frames for the device controller.

94.3 Timecode Offset

The Timecode Offset value is set in the Capture panel, in the Settings tab. The value defaults to zero frames, but it may be set to any value chosen by the user when they calibrate their VTR to account for any latencies. So when using the same tape in two separate VTRs, to capture the same timecode span, the Timecode Offset may be used to account for any differences in the way the VTRs report timecode back to Premiere. Using the Timecode Offset, the in point sent to the device controller can be shifted earlier or later, while the timecode embedded in the clip after the capture will remain the same.

Adjusting the Timecode Offset setting will be transparent to the device controller, but will have an effect on the DeviceRec.timecode value sent during *dsExecute/cmdLocate*. Starting in

CS5.5, a negative Timecode Offset value is acceptable. Note that for In/Out capture, the earliest allowable time for the in point is 2 seconds. If the provided in point is earlier than that, it will be automatically adjusted to start at 2 seconds.

95.1 Audio Channels

The device controller should specify how many audio channels are supported by the connected device, so that the Edit to Tape panel will only enable valid audio channel controls. During `cmdGetFeatures`, the device controller should set the bits corresponding to the audio channels available on the device in `DeviceRec.exportAudioChannels`.

Then later if performing an Insert Edit, during `modeRecordInsert`, if the device supports audio channel selection, the bits in `exportAudioChannels` will be set by the host corresponding to audio channels to export: A1 == bit 0, A2 == bit 1, etc.

95.2 Record

Starting in CC, the Edit to Tape panel provides three types of export modes: Insert, Assemble, and Print to Tape. The device controller should specify if it supports Assemble mode by setting `fCanAssembleEdit` along with any other flags during `dsExecute/cmdGetFeatures`.

When the user presses the Record button in the Edit to Tape Panel, Premiere will send `dsExecute / cmdNewMode` with either `modeRecord`, `modeRecordInsert`, or `modeRecordAssemble`, depending on the Export Type set in the Edit to Tape panel.

Hitting the Record button with Export Type set to Print to Tape sends `modeRecord`. This record mode is a simple crash record that has no preroll before the in point and causes noticeable breaks in the video signal. Setting Assemble sends `modeRecordAssemble`. This mode uses a preroll before the in point for a smooth transition at the in point, but the out point ends the recording abruptly which will leave a noticeable break if there is any subsequent video.

Setting Insert sends `modeRecordInsert`. This mode uses a preroll before the in point and also ends the recording at the outpoint without any breaks in the video signal. This is also the only mode that allows for selective replacement of specific video/audio channels.

DeviceRec.exportFlags will denote whether video and/or closed captioning should be exported or not, and DeviceRec.exportAudioChannels will denote which audio channels to export. DeviceRec.timecode provides the in point of the edit to tape operation, and DeviceRec.preroll provides the user-specified preroll.

Premiere will play the video output in the Edit to Tape panel. When the record is complete, the device controller should return from `dsExecute / cmdNewMode`.

95.3 Preview Edits

Starting in CC, the device controller should specify if it supports previewing edits by setting `fCanPreviewEdit` along with any other flags during `dsExecute/cmdGetFeatures`. If Preview is supported, the button will be activated in the Edit to Tape panel, and when pressed, the device controller will receive the same messaging as described above when pressing Record, except that `previewEdit` will be set in `DeviceRec.exportFlags`.

95.4 Abort on Dropped Frames

New in CC, when using the Edit to Tape panel, this is handled transparently to the device controller. If a transmit plugin or renderer reports dropped frames, Premiere will stop playback and send `dsExecute/modeStop` to the device controller.

In Premiere Pro CS6.0.1, or in CC if the device controller doesn't support the Edit to Tape panel, use the `Dropped-FrameProc` callback to query the current number of frames dropped during an insert edit. A device controller can use this to provide the feature to abort an Export to Tape if frames are dropped. It can make the call regularly during Export to Tape, and if the value returned is non-zero, return `dmExportToTapeFinished` to abort playback.

95.5 Closed Captioning

When using the Edit to Tape panel, the device controller should specify if it supports Closed Captioning export by setting `fCanUseCC` along with any other flags during `dsExecute / cmdGetFeatures`.

If the user checks the Insert Closed Captioning checkbox and chooses Record or Preview, the device controller should use the *Captioning Suite* to get the captions and send them out with the export.

Selector Table

This table summarizes the various selector commands a device controller can receive.

Selector	Description
<i>dsInit</i>	Create private instance data, and initialize hardware connection.
<i>dsRestart</i>	Restart device controller – used at startup to reconnect to a device.
<i>ds-Setup</i>	Display a modal dialog with any user settings and info the device controller wishes to show the user.
<i>dsExecute</i>	Execute a specified device control command. Once a device controller has been initialized, most of the various user-driven interactions will be sent as dsExecute selectors with a subcommand.
<i>dsCleanup</i>	Dispose of any allocated data structures.
<i>dsQuiet</i>	Disconnect from the device, but don't dispose of allocated structures.
<i>dsHasOptions</i>	Return dmHasNoOptions to disable the device controller options button.

Selector Descriptions

97.1 dsInit

This will be sent when the device controller is selected in the UI for the first time, because no device controller private data is stored in the application preferences. When there is already existing private data in the preferences, *dsRestart* will be sent instead. To delete the preferences, hold down Ctrl-Alt-Shift on Win and Ctrl-Opt-Shift on MacOS when launching the app.

Allocate a memory handle to private data, and store the handle in `DeviceRec.deviceData`.

Initialize the hardware connection, and choose a default operating mode if more than one is available.

A dialog can be presented to prompt the user for settings.

If the connection fails, return `dmDeviceNotFound`.

Keep in mind, though, that the host will still send messages to the device controller, in case the hardware comes on-line later.

97.2 dsRestart

Reestablish connections to hardware devices.

This selector is similar to `dsInit`, but the private instance data, `deviceData`, is already populated.

If you have just modified the definition of the private data structure, you can run into problems unless you provide some version checking here.

`dsInit` can fall into the `dsRestart` case.

97.3 dsSetup

This selector is sent when the user hits the Device Settings button in the Edit to Tape panel, the Options button in the Device Control area of the Capture panel, or the Options button in the Device Control area of the Preferences.

Display a modal dialog with any user settings and info the device controller wishes to show the user. If your device controller doesn't require user input, this selector can be safely ignored, but should return `dmNoErr`. To specify that the Setup button in the device control options should not be shown, respond to *dsHasOptions*.

97.4 dsExecute

Perform a device control operation based on the command in the DeviceRec. See *Commands* for detailed descriptions.

97.5 dsCleanup

Disconnect from hardware and dispose of the plug-in's private instance data (stored in `deviceData`).

97.6 dsQuiet

Like `dsCleanup`; disconnect from the device, but don't dispose of private instance data.

`dsRestart` will be sent to reconnect the device.

97.7 dsHasOptions

Return `dmHasNoOptions` to disable the device controller options button.

Return Codes

Return Code	Reason
dmNoErr	Operation has completed without error.
dmDeviceNotFound	The device is not available.
dmTimecodeNotFound	The device cannot read the timecode from the media, or there is none to be read.
dmBadTimecode	The device has timecode but it doesn't trust it.
dmCantRecord	The device is unable to record to the media.
dmUserAborted	The operation has stopped because the user cancelled.
dmLastErrorSet	The device controller set the last error string using the <i>Error Suite</i> .
dmExportToTapeFinished	The device controller is signaling the end of the export to tape operation.
dmTapeWriteProtected	Return value during Export To Tape if tape is write protected.
dmNoTape	Return value during Export To Tape if there is no tape in the deck.
dmLastInfoSet	The device controller set the last info string using the <i>Error Suite</i> .
dmLastWarningSet	The device controller set the last warning string using the <i>Error Suite</i> .
dmHasNoOptions	Return during dsHasOptions to disable the device controller options button..
dmUnknownError	The device controller set the last error string using the <i>Error Suite</i> .
dmUnsupported	The selector is not recognized, or unsupported.
dmGeneralError	Unspecified error.

DeviceRec

A device controller is passed a handle to a DeviceRec with every selector.

Yes, we know, it's a monster.

```
typedef struct {
    PrMemoryHandle      deviceData;
    short               command;
    short               mode;
    csSDK_int32         timecode;
    short               timeformat;
    short               timerate;
    csSDK_int32         features;
    short               error;
    short               preroll;
    CallbackPtr        callback;
    PauseProcPtr       PauseProc;
    ResumeProcPtr      ResumeProc;
    long                xtimecode;
    long                keycode;
    short               editmode;
    short               exteditmode;
    Print2TapeProcPtr  PrintProc;
    HWND                parentWindow;
    piSuitesPtr        piSuites;
    char*               displayName;
    TimecodeUpdatePtr  TimecodeUpdateProc;
    void*               classID;
    long                version;
    short               videoStreamIsDrop;
    short               autoDetectDropness;
    char*               currentDeviceIDStr;
    long                preferredScale;
    unsigned long       preferredSampleSize;
    DroppedFrameCountPtr DroppedFrameProc;
    csSDK_uint32        exportAudioChannels;
}
```

(continues on next page)

(continued from previous page)

```

csSDK_uint16      exportFlags;
csSDK_int32      delayFrames;
} DeviceRec, *DevicePtr, **DeviceHand;

```

deviceData	Handle to private data allocated during <i>dsInit</i> or <i>dsRestart</i> . Saved in the application preferences, and restored when the app is restarted.
command	The command to be performed when you receive <i>dsExecute</i> .
mode	Used in three ways. For <i>dsExecute/cmdNewMode</i> , mode contains your device's new mode. For <i>dsExecute/cmdStatus</i> , mode is where you indicate the device's current mode (the last mode reported will still be there). For <i>dsExecute/cmdShuttle</i> , mode contains the shuttle rate (-100 to 100).
timecode	Used three ways. For <i>dsExecute/cmdGoto</i> and <i>dsExecute/cmdLocate</i> , the timecode field indicates the timecode to which you should move. For <i>dsExecute/cmdStatus</i> , return the deck's current timecode position via the timecode field, where: <ul style="list-style-type: none"> • <i>kInvalidTimecode</i> will display "N/A" (not available), • -2 will blank the timecode display, and • -3 will display "Searching...". For <i>dsExecute/cmdJogTo</i> , timecode specifies the location to which you should jog.
timeformat	Reports the format of timecode for a <i>dsExecute/cmdStatus</i> ; 0 for non-drop frame, 1 for drop-frame.
timerate	Reports the frame rate of timecode for a <i>dsExecute/cmdStatus</i> call. Set to 24, 25, 30, or 60. Note, for 23.976 fps footage, set timerate to 24, and timeformat to 1. 24 fps timecode will be used, as expected. Of course, there is no such thing as 24 fps drop-frame timecode, but this was the way 23.976 fps support was added within the constraints of the existing API.
features	Reports the device's features in response to a <i>dsExecute/cmdGetFeatures</i> call.
error	Set this field to an appropriate error code and return a non-zero value from your device controller.
preroll	Used by <i>dsExecute/cmdLocate</i> . Preroll is how far before (smaller timecode) the seek time specified in timecode you should seek. The preroll value is the product of a calibration sequence the user performs.

Table 1 – continued from previous page

callback	<p>Pointer to a callback to use during <i>dsExecute/cmdLocate</i> to determine if the user is attempting to abort.</p> <pre>typedef csSDK_int32 (*CallBackPtr) ↳ (void);</pre> <p>If the return value is non-zero, the user has attempted to abort.</p>
PauseProc	<p>Pointer to a callback that you can use to temporarily pause any sequence grabber operations in a device-controlled window.</p> <p>It is defined as follows:</p> <pre>typedef void (*PauseProcPtr) (void);</pre>
ResumeProc	<p>A pointer to a routine to call to resume sequence capture after calling <i>PauseProc</i>.</p> <p>Every call to <i>PauseProc</i> must be matched by a call to <i>ResumeProc</i>.</p> <pre>typedef void (*ResumeProcPtr) (void);</pre> <p>Call these routines before putting up an error alert, for instance:</p> <pre>(* (*theData) -> PauseProc) (); // your error handler here (* (*theData) -> ResumeProc) ();</pre> <p>If <i>PauseProc</i> isn't called before putting up an alert (or any other dialog), video will be played over it</p>
xtimecode	Duration of the movie being exported (used for the Export to Tape).
keycode	Unused.
editmode	<p>Can be any combination of the following flags to enable user actions:</p> <ul style="list-style-type: none"> • insertVideo, • insertAudio1, • insertAudio2, • insertTimeCode, • insertAssemble, • insertPreview
exteditmode	Unused.
PrintProc	<p>New in CC, this callback is no longer needed as the host drives the Edit to Tape rather than the device controller. A pointer to a plug-in function Premiere calls to print to tape.</p> <pre>csSDK_int32 (*Print2TapeProcPtr) (PrMemoryHandle deviceHand, long selector);</pre> <p><i>deviceHand</i> is passed to the plug-in in <i>DeviceRec</i>. <i>selector</i> can be <i>setupWaitProc</i>, <i>idle</i>, or <i>complete</i>. See <i>cmdInsertEdit</i>.</p>
piSuites	Pointer to universal callback suites.
displayName	A 255 character string to display the name of the device the plug-in is currently controlling.

Continued on next page

Table 1 – continued from previous page

TimecodeUpdateProc	During <code>cmdLocate</code> , use this to report timecode. <pre>void (*TimecodeUpdatePtr) (csSDK_int32 outTimecode, void* outClassID);</pre>
classID	Used for <code>TimecodeUpdateProc</code>
version	Premiere informs the device controller of the API version, so the plug-in can modify its behavior to support multiple versions, if desired. <ul style="list-style-type: none"> • Premiere Pro CC, October 2013 update - <code>kDeviceControlAPIVersion14</code> • Premiere Pro CC, July 2013 update - <code>kDeviceControlAPIVersion13</code> • Premiere Pro CC - <code>kDeviceControlAPIVersion12</code> • Premiere Pro CS6.0.1 - <code>kDeviceControlAPIVersion11</code> • Premiere Pro CS5.5 - <code>kDeviceControlAPIVersion105</code> • Premiere Pro CS5 - <code>kDeviceControlAPIVersion10</code> • Premiere Pro CS3 and CS4 - <code>kDeviceControlAPIVersion9</code>
videoStreamIsDrop	If <code>autoDetectDropness</code> was set earlier, and the recorder called <code>FormatChangedFunc</code> to provide the drop-frame attribute of the timecode, 0Premiere will call <code>cmdSetDropness</code> and use this to tell the device controller if the video stream is drop-frame.
autoDetectDropness	Set this to true if you want Premiere to notify the device controller whether or not the video stream uses drop-frame timecode. Premiere will get this timecode information from the active recorder. The result will be sent during <code>cmdSetDropness</code> in <code>videoStreamIsDrop</code> .
currentDeviceIDStr	For internal use only.
preferredScale	The current timebase. Use this rather than calling <code>piSuites->utilFuncs->getSettings(kSettingsProjectS</code>
preferredSampleSize	New in Premiere Pro CS3. The current timebase. Use this rather than calling <code>piSuites->utilFuncs->getSettings(kSetting sProjectSampleSize)</code> .
DroppedFrameProc	New in CC, if the Edit to Tape panel is supported, this callback is no longer needed as Abort on Dropped Frames is handled transparently to the device controller. In Premiere Pro CS6.0.1, use this callback to query the current number of frames dropped during an insert edit. A device controller can use this to provide the feature to abort an Edit to Tape if frames are dropped. <pre>csSDK_int32 (*DroppedFrameProc) (void* inClassID);</pre>

Table 1 – continued from previous page

exportAudioChannels	<p>New in CC. During cmdGetFeatures, the device controller should set the bits corresponding to the audio channels available on the device.</p> <p>Then later during the record commands, if the device supports audio channel selection, the bits will be set by the host corresponding to audio channels to export: A1 == bit 0, A2 == bit 1, etc.</p>
exportFlags	<p>New in CC. During the record commands, one or more of the following may be set:</p> <ul style="list-style-type: none"> • exportVideo - set if user has checked the Video checkbox in the Edit to Tape panel • processCCData - set if user has checked the Insert Closed Caption Data checkbox in the Edit to Tape panel • previewEdit - set if user has pressed the Preview button in the Edit to Tape panel
delayFrames	<p>New in CC July 2013. If fCanDelayMovieStart was set, during an Edit to Tape, this will be the value as set by the user (in frames) in the Edit to Tape panel, and Premiere Pro will let the device controller handle the Delay Movie Start.</p>

CHAPTER 100

Commands

When the plug-in receives `dsExecute`, `DeviceRec.command` indicates the behavior requested.

Command	Description
<i>cmdGetFeatures</i>	Fill in the features field with the device's features.
<i>cmdStatus</i>	Return the deck mode and current timecode position.
<i>cmdNewMode</i>	Change the deck's mode.
<i>cmdGoto</i>	Move asynchronously to a particular time and return in pause mode.
<i>cmdLocate</i>	Move synchronously to a particular time and return in play mode.
<i>cmdShuttle</i>	Shuttle the deck at a specified rate.
<code>cmdEject</code>	Eject media.
<i>cmdInsertEdit</i>	No longer needed in CC and later, if the Edit to Tape panel is supported. In previous versions this was sent for Export To Tape. This has been left in for backwards-compatibility.
<i>cmdGetDeviceDisplayName</i>	Provide the device display name for display in the Capture Panel.
<i>cmdSetDropness</i>	Tells the device controller whether the current timecode is drop-frame or non-drop-frame.
<code>cmdGetCurrentDevice</code>	For internal use only.
<i>cmdSetDeviceHandler</i>	New in CC October 2013. Optional. Tells the plug-in which panel is using the device controller – either the Capture panel, or Export to Tape panel.

100.1 cmdGetFeatures

Populate `DeviceRec.features` with the features of your device controller, using the following flags OR'd together in a bit-field:

Flag	Description
fExportDialog	The device controller has an export dialog and wishes to control the edit.
fCanInsertEdit	No longer needed in CC. In previous versions, this flag would tell Premiere that Insert Edit mode was supported.
fDrvrQuiet	Quiet mode is supported.
fHasJogMode	Jog is supported.
fCanEject	Media ejection is supported.
fStepFwd	Stepping the device forward one frame is supported.
fStepBack	Stepping the device backward one frame is supported.
fRecord	Your device can record.
fPositionInfo	Your device can retrieve position information.
fGoto	Your device can seek to a particular frame. You must also set fPositionInfo, and respond to <i>cmdGoto</i> .
f1_5	Your device can play at one-fifth speed.
fBasic	Your device supports the basic five deck control operations: stop, play, pause, fast-forward, and rewind.
fReverse	Your device can play in reverse.
fCanLocate	Your device can accurately locate a particular timecode and supports <i>cmdLocate</i> . Please do so; <i>cmdLocate</i> is more accurate than <i>cmdGoto</i> .
fCanShuttle	Your device is capable of variable-speed shuttle operations, forward and backward.
fNoTransport	Device supports no transport modes (play, stop, etc).
fCanAssemble	New in CC. Set if the device controller supports <i>modeRecordAssemble</i> .
fCanPreviewRecord	New in CC. Set if <i>modePreviewRecord</i> is supported for the Edit to Tape panel.
fCanInsertEdit	New in CC. Set if new Edit to Tape panel is supported. Otherwise, legacy device controllers can continue to function as previously built for CS6 and earlier.
fCanUseCC	New in CC. Set if Closed Captioning is supported. This will enable the Insert Closed Captioning Data checkbox in the Edit to Tape panel.
fCanPrintToTape	New in CC July 2013. Set to tell Premiere Pro that the device controller supports the “Print to Tape” option in the Export Type popup of the Edit to Tape panel.
fCanDelayMovieStart	New in CC July 2013. Set this flag to specify that the device controller wants to handle Delay Movie Start on its own. If the flag is set, the value as set by the user (in frames) in the Edit to Tape panel will be passed in <i>DeviceRec.delayFrames</i> , and Premiere Pro will let the device controller handle the delay.

100.2 cmdStatus

Premiere sends *cmdStatus* to obtain the deck’s current mode (play, pause, etc.) and the current timecode position. Store the device’s current mode in *mode*, and the current timecode value in *timecode*. Be sure to set *timerate* and *timeformat* as described in *DeviceRec*.

The values of *mode* and *timecode* persist. If you only know one of the two pieces of information, store it, and ignore the other. If your device controller makes two calls to determine these values, alternately request one and return the other.

100.3 cmdNewMode

Puts the device into a new operating mode, specified in *mode*.

Mode	Description
<code>modeStop</code>	Stop.
<code>modePlay</code>	Play.
<code>modePlay1_5</code>	Play at 1/5 speed.
<code>modePlay1_10</code>	Play at 1/10 speed.
<code>modePause</code>	Pause.
<code>modeFastFwd</code>	Fast forward.
<code>modeRewind</code>	Rewind.
<code>modeRecord</code>	Record. This is the original record mode for Print to Tape.
<code>modeGoto</code>	Go to time specified in <code>DeviceRec.timecode</code> .
<code>modeStepFwd</code>	Step one frame forward.
<code>modeStepBack</code>	Step one frame backward.
<code>modePlayRev</code>	Play backward at full speed.
<code>modePlayRev1_5</code>	Play backward at 1/5 speed.
<code>modePlayRev1_10</code>	Play backward at 1/10 speed.
<code>modeTapeOut</code>	No tape is in device.
<code>modeLocal</code>	Device is unavailable.
<code>modeRecordPause</code>	Pause in record mode.
<code>modeRecordPlayFastFwd</code>	Fast forward in play mode.
<code>modeRecordPlayRewind</code>	Rewind in play mode.
<code>modeRecordAssemble</code>	New in CC. This is selected by the user in the Edit to Tape panel, in the Export Type drop-down.
<code>modeRecordInsert</code>	New in CC. This is selected by the user in the Edit to Tape panel, in the Export Type drop-down.

100.4 cmdGoto

This is sent, for example, when typing in a new timecode value into the current timecode hot-text control in the lower left hand corner of the Capture panel. It can also be sent when the user chooses Capture In/Out, if the device controller does not support `cmdLocate`.

Begin seeking to the timecode specified by `timecode`. Set up an asynchronous seek, save off the desired timecode in private data, and return immediately with mode set to `modeGoto`.

Premiere will then send `cmdStatus` repeatedly, so that you can continue to query the timecode of the device as it moves toward the desired timecode. In `modeGoto`, Premiere will put “Searching...” in the status panel. Later, when the device arrives at the desired timecode, place

the device in `modePause` (if you were able to complete the seek) or `modeStop` (if there was an error).

100.5 cmdLocate

This is sent, for example, when the user chooses Capture In/Out, if the device controller has set `fCanLocate` during `cmdGetFeatures`.

Seek to an exact frame specified in `DeviceRec.timecode`, minus any amount specified by the Preroll Time, and return immediately with the device in `modePlay`. Unlike `cmdGoto`, which is asynchronous, this is a synchronous operation. Do not return until the operation is complete or an error occurs.

100.6 cmdShuttle

Sent when the user moves the shuttle control; mode is the shuttle speed:

Use intermediate speeds if the device supports them. If it doesn't implement shuttling but does support multiple play speeds, Premiere will simulate shuttling by playing at different rates, based on the shuttle control position. Better results can be obtained by directly supporting shuttling with the *cmdShuttle* command.

100.7 cmdInsertEdit

No longer needed starting in CC, if the Edit to Tape panel is supported. Otherwise, this was sent if the device controller supports insert mode and wants to control the edit (set *fExportDialog* and *fCanInsertEdit* during *cmdGetFeatures* to do so).

When the user invokes Export To Tape, Premiere prepares to play the chosen clip and sets the following in the Device-Hand:

```
command = *cmdInsertEdit*
mode = modeRecord
xTimecode = duration of the movie
```

Premiere then enters a loop, calling the device controller with the above DeviceHand. When the device controller returns, Premiere sends the PrintProc specified in *DeviceHand.setupWaitProc*. Premiere will have already performed the preroll; everything is ready to play.

When the device controller returns, Premiere plays the clip, sending idle to PrintProc once per frame. Premiere again calls the plug-in's entry point with the DeviceHand, allowing the device controller to perform any cue operations. Premiere calls PrintProc with complete when finished. If *cmdInsertEdit* is proceeding correctly PrintProc should always return 0.

100.8 cmdGetDeviceDisplayName

Sent so the device controller can provide the device display name for display in the Capture Panel. The device controller fills in *DeviceRec.displayName*.

100.9 cmdSetDropness

Sent only if *DeviceRec.autoDetectDropness* is set to true. This selector tells the device controller whether the current timecode is drop-frame or non-drop-frame, as determined by the active recorder. The timecode information is passed in *videoStreamIsDrop* in *DeviceRec*. Sent when recorder determines drop-frame attribute and calls *FormatChangedFunc*.

100.10 cmdSetDeviceHandler

New in CC October 2013. Optional. Tells the plug-in which panel is using the device controller – either the Capture panel, or Export to Tape panel. DeviceRec.mode will contain either handlerCapture or handlerEditToTape.

CHAPTER 101

Control Surfaces

Starting in Premiere Pro CC 2014, a control surface plug-in can interface with a hardware control surface. This is the API that provides built-in support for EUCON and Mackie devices to control audio mixing and basic transport controls. The API supports two-way communication with Premiere Pro, so that hardware faders, VU meters, etc are in sync with the application.

Compile the sample plug-in into a subfolder of the main application folder: `Plug-ins\ControlSurface\`

You should see the plug-in in the PPro UI in Preferences > Control Surface, when you hit the Add button, as one of the options in the Device Class drop-down next to Mackie and EUCON (currently shows as “SDK Control Surface Sample”).

You’ll want to implement handlers for any relevant functions defined in the plugin suites here:
`adobesdk\controlsurface\plugin`

And to do that, you can use any APIs to call into the host defined in the host suites here:
`adobesdk\controlsurface\host`

101.1 Calling Sequence

When the application is launched, the control surface plug-ins are loaded, and the entry point is called. The host ID and API version is passed in, and the plug-in passes back `ADOBESDK_ControlSurfacePluginFuncs`, an array of function pointers.

Next, the `Startup()` function is called, where the plug-in registers a suite of functions as defined in `ControlSurface-PluginSuite.h`. For each base class it will inherit from (defined in `adobesdkcontrolsurfacepluginwrapper`), it calls `RegisterSuite()`. These suites are the way for the host application to call the control surface plug-in later on. There are separate base classes for the transport controls, audio mixer, Lumetri Color controls, and more.

Then, `CreatePluginInstance()` is called. When a project is opened, `Connect()` is called. Here the plug-in instantiates a `ControlSurface` object, which inherits from any of the previously men-

tioned base classes. It acquire any host suites it needs, and then it passes back a reference to the `ControlSurface` object.

101.2 Getting Started

Please write us if you would like further guidance.
