5.1 Installing scikit-criteria

The easiest way to install scikit-criteria is using pip:

```
pip install -U scikit-criteria
```

If you have not installed NumPy or SciPy yet, you can also install these using conda or pip. When using pip, please ensure that binary wheels are used, and NumPy and SciPy are not recompiled from source, which can happen when using particular configurations of operating system and hardware (such as Linux on a Raspberry Pi). Building numpy and scipy from source can be complex (especially on Windows) and requires careful configuration to ensure that they link against an optimized implementation of linear algebra routines. Instead, use a third-party distribution as described below.

5.1.1 Third-party Distributions

If you don’t already have a python installation with numpy and scipy, we recommend to install either via your package manager or via a python bundle. These come with numpy, scipy, matplotlib and many other helpful scientific and data processing libraries.

Available options are:

- **Canopy and Anaconda for all supported platforms**

  Canopy and Anaconda both ship a recent version of Python, in addition to a large set of scientific python library for Windows, Mac OSX and Linux.

5.2 Tutorial

This section contains a step-by-step by example tutorial of how to use scikit-criteria
5.2.1 Quick Start

This tutorial shows how to create a scikit-criteria Data structure, and how to feed them inside different multicriteria decisions algorithms.

Conceptual Overview

The multicriteria data are really complex thing; mostly because you need at least 2 totally disconnected vectors to describe your problem: A alternative matrix (mtx) and a vector that indicated the optimal sense of every criteria (criteria); also maybe you want to add weights to your criteria.

The skcriteria.Data object need at least the first two to be created and also accepts the weights, the names of the criteria and the names of alternatives as optional parameters.

Your First Data object

First we need to import the Data structure and the MIN, MAX contants from scikit-criteria:

```
In [2]: from skcriteria import Data, MIN, MAX
```

Then we need to create the mtx and criteria vectors.

The mtx must be a 2D array-like where every column is a criteria, and every row is an alternative.

```
In [3]: # 2 alternatives by 3 criteria
   mtx = [
   [1, 2, 3], # alternative 1
   [4, 5, 6], # alternative 2
]
mtx
```

```
Out[3]: [[1, 2, 3], [4, 5, 6]]
```

The criteria vector must be a 1D array-like whit the same number of elements than columns has the alternative matrix (mtx) where every component represent the optimal sense of every criteria.

```
In [4]: # let's says the first two alternatives are
   # for maximization and the last one for minimization
   criteria = [MAX, MAX, MIN]
criteria
```

```
Out[4]: [1, 1, -1]
```

As you see the MAX and MIN constants are only aliases for the numbers -1 (minimization) and 1 (maximization). As you can see the contantes usage makes the code more readable. Also you can use as aliases of minimization and maximization the built-in function min, max, the numpy function np.min, np.max, np.amin, np.amax, np.nanmin, np.nanmax and the strings min, minimization, max and maximization.

Now we can combine this two vectors in our scikit-criteria data.

```
In [5]: # we use the built-in function as aliases
   data = Data(mtx, [min, max, min])
data
```

```
Out[5]: ALT./CRIT. C0 (min) C1 (max) C2 (min)
------- -------- -------- --------
    A0       1        2        3
    A1       4        5        6
```
As you can see the output of the `Data` structure is much more friendly as the plain python lists.

To change the generic names of the alternatives (A0 and A1) and the criteria (C0, C1 and C2); let’s assume that our Data is about cars (car 0 and car 1) and their characteristics of evaluation are autonomy (MAX), confort (MAX) and price (MIN).

To feed this information to our `Data` structure we have the params: `anames` that accept the names of alternatives (must be the same number as row the `mtx` has), and `cnames` the criteria names (with the same number of elements as columns has the `mtx`).

```
In [6]: data = Data(mtx, criteria,
anames=['car 0', 'car 1'],
cnames=['autonomy', 'confort', 'price'])
```

```
data
Out[6]: ALT./CRIT. autonomy (max) confort (max) price (min)
          ------------ ---------------- --------------- -------------
    car 0 1 2 3
    car 1 4 5 6
```

In our final step let’s assume we know in our case, that the importance of the autonomy is the 50%, the confort only a 5% and the price is 45%. The param to feed this to the structure is called `weights` and must be a vector with the same elements as criterias has your alternative matrix (number of columns).

```
In [7]: data = Data(mtx, criteria,
weights=[.5, .05, .45],
anames=['car 0', 'car 1'],
cnames=['autonomy', 'confort', 'price'])
```

```
data
Out[7]: ALT./CRIT. autonomy (max) W.0.5 confort (max) W.0.05 price (min) W.0.45
          ------------ ------ ---------------- ------ ------------ ------
    car 0 1       2       3
    car 1 4       5       6
```

**Manipulating the Data**

The data object are immutable, if you want to modify it you need create a new one. All the numerical data (mtx, criteria, and weights) are stored as numpy arrays, and the alternative and criteria names as python tuples.

You can access to the different parts of your data, simply by typing `data.<your-parameter-name>` for example:

```
In [8]: data mtx
Out[8]: array([[1, 2, 3],
               [4, 5, 6]])
```

```
In [9]: data criteria
Out[9]: array([[1, 1, -1]])
```

```
In [10]: data weights
Out[10]: array([0.5, 0.05, 0.45])
```

```
In [11]: data anames, data cnames
Out[11]: (('car 0', 'car 1'), ('autonomy', 'confort', 'price'))
```

If you want (for example) change the names of the cars from car 0 and car 1; to VW and Ford you must copy from your original Data

```
In [12]: data = Data(data mtx, data criteria,
weights=data weights,
anames=['VW', 'Ford'],
```
data

cnames=data.cnames)

Out[12]:

<table>
<thead>
<tr>
<th></th>
<th>autonomy (max) W.0.5</th>
<th>confort (max) W.0.05</th>
<th>price (min) W.0.45</th>
</tr>
</thead>
<tbody>
<tr>
<td>VW</td>
<td>1</td>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>Ford</td>
<td>4</td>
<td>5</td>
<td>6</td>
</tr>
</tbody>
</table>

**Note:** A more flexible data manipulation API will released in future versions.

### Plotting

The Data structure suport some basic rutines for ploting. Actually 5 types of plots are supported:

- Radar Plot (radar).
- Histogram (hist).
- Violin Plot (violin).
- Box Plot (box).
- Scatter Matrix (scatter).

The default scikit criteria uses the Radar Plot to visualize all the data. Take in account that the radar plot by default convert all the minimization criteria to maximization and push all the values to be greater than 1 (obviously all this options can be overided).

In [13]: data.plot();
You can accessing the different plot by passing as first parameter the name of the plot

```python
In [14]: data.plot("box");
```

or by using the name as method call inside the `plot` attribute

```python
In [15]: data.plot.violin();
```
Every plot has their own set of parameters, but at last every one can receive:

- **`ax`**: The plot axis.
- **`cmap`**: The color map (More info).
- **`mnorm`**: The normalization method for the alternative matrix as string (Default: "none").
- **`wnorm`**: The normalization method for the criteria array as string (Default: "none").
- **`weighted`**: If you want to weight the criteria (Default: True).
- **`show_criteria`**: Show or not the criteria in the plot (Default: True in all except radar).
- **`min2max`**: Convert the minimization criteria into maximization one (Default: False in all except radar).
- **`push_negatives`**: If a criteria has values lesser than 0, add the minimum value to all the criteria (Default: False in all except radar).
- **`addepsto0`**: If a criteria has values equal to 0, add an $\epsilon$ value to all the criteria (Default: False in all except radar).

Let’s change the colors of the radar plot and show their criteria optimization sense:

```python
In [16]: data.plot.radar(cmap="inferno", show_criteria=False);
```
Using this data to feed some MCDA methods

Let’s rank our toy data by Weighted Sum Model, Weighted Product Model and TOPSIS

In [17]: from skcriteria.madm import closeness, simple

First you need to create the decision maker.

Most of methods accepts as hyper parameters (parameters of the to configure the method), the method of normalization of the alternative matrix (divided by the sum in Weighted Sum and Weighted Product, and the vector normalization on TOPSIS) and the method to normalize the weight array (normally sum); But complex methods has more.

**Weighted Sum Model:**

In [18]: # first create the decision maker
   # (with the default hiper parameters)
   dm = simple.WeightedSum()
   dm

Out[18]: <WeightedSum (mnorm=sum, wnorm=sum)>

In [19]: # Now lets decide the ranking
   dec = dm.decide(data)
   dec

Out[19]: WeightedSum (mnorm=sum, wnorm=sum) - Solution:
   ALT./CRIT. autonomy (max) W.0.5 confort (max) W.0.05 price (min) W.0.45 Rank
   ----------------- ---------------------- ---------------------- -------
The result says that the **VW** is better than the **FORD**, lets make the maths:

**Note**: The last criteria is for minimization and because the WeightedSumModel only accepts maximization criteria by default, scikit-criteria invert all the values to convert the criteria to maximization

```
In [20]: print("VW:", 0.5 * 1/5. + 0.05 * 2/7. + 0.45 * 1 / (3/9.))
   print("FORD:", 0.5 * 4/5. + 0.05 * 5/7. + 0.45 * 1 / (6/9.))
VW: 1.4642857142857144
   FORD: 1.1107142857142858
```

If you want to acces this points, the Decision object stores all the particular information of every method in a attribute called `e_`

```
In [21]: print(dec.e_)
   dec.e_.points
Extra(points)
Out[21]: array([1.46428571, 1.11071429])
```

Also you can acces the type of the solution

```
In [22]: print("Generate a ranking of alternatives?", dec.alpha_solution_)
   print("Generate a kernel of best alternatives?", dec.beta_solution_)
   print("Choose the best alternative?", dec.gamma_solution_)
Generate a ranking of alternatives? True
   Generate a kernel of best alternatives? False
   Choose the best alternative? True
```

The rank as numpy array (if this decision is a $\alpha$-solution)

```
In [23]: dec.rank_
Out[23]: array([1, 2])
```

The index of the row of the best alternative (if this decision is a $\gamma$-solution)

```
In [24]: dec.best_alternative_, data.anames[dec.best_alternative_]
Out[24]: (0, 'VW')
```

And the kernel of the non supered alternatives (if this decision is a $\beta$-solution)

```
In [25]: # this return None because this
   # decision is not a beta-solution
   print(dec.kernel_)
None
```

**Weighted Product Model**

```
In [26]: dm = simple.WeightedProduct()
   dm
Out[26]: <WeightedProduct (mnorm=sum, wnorm=sum)>
In [27]: dec = dm.decide(data)
   dec
```
As before let’s do the math (remember the weights are now exponents)

```python
In [28]: print("VW:", ((1/5.) ** 0.5) * ((2/7.) ** 0.05) + ((1 / (3/9.)) ** 0.45))
print("FORD:", ((4/5.) ** 0.5) * ((5/7.) ** 0.05) + ((1 / (6/9.)) ** 0.45))
```

VW: 2.059343755676466
FORD: 2.07967086650222

As we expected the **Ford** are little better than the **VW**. Now let’s check the `e_` object

```python
In [29]: print(dec.e_)
    dec.e_.points
```

Extra(points)

Out[29]: array([-0.16198384,  0.02347965])

As you note the points are different, this is because internally to avoid underflows Scikit-Criteria uses a sum of logarithms instead products. So let’s check

```python
In [30]: import numpy as np
print("VW:", 0.5 * np.log10(1/5.) + 0.05 * np.log10(2/7.) + 0.45 * np.log10(1 / (3/9.)))
print("FORD:", 0.5 * np.log10(4/5.) + 0.05 * np.log10(5/7.) + 0.45 * np.log10(1 / (6/9.)))
```

VW: -0.16198383976167505
FORD: 0.02347965828711646

**TOPSIS**

```python
In [31]: dm = closeness.TOPSIS()
    dm
```

Out[31]: <TOPSIS (mnorm=vector, wnorm=sum)>

```python
In [32]: dec = dm.decide(data)
    dec
```

Out[32]: TOPSIS (mnorm=vector, wnorm=sum) - Solution:

<table>
<thead>
<tr>
<th>ALT./CRIT.</th>
<th>autonomy (max) W.0.5</th>
<th>confort (max) W.0.05</th>
<th>price (min) W.0.45</th>
<th>Rank</th>
</tr>
</thead>
<tbody>
<tr>
<td>VW</td>
<td>1</td>
<td>2</td>
<td>3</td>
<td>2</td>
</tr>
<tr>
<td>Ford</td>
<td>4</td>
<td>5</td>
<td>6</td>
<td>1</td>
</tr>
</tbody>
</table>

The TOPSIS add more information into the decision object.

```python
In [33]: print(dec.e_)
    print("Ideal:", dec.e_.ideal)
    print("Anti-Ideal:", dec.e_.anti_ideal)
    print("Closeness:", dec.e_.closeness)
```

Extra(ideal, anti_ideal, closeness)

Ideal: [0.48507125 0.04642383 0.20124612]
Anti-Ideal: [0.12126781 0.01856953 0.40249224]
Closeness: [0.35548671 0.64451329]

Where the **ideal** and **anti_ideal** are the normalized synthetic better and worst alternatives created by TOPSIS, and the **closeness** is how far from the **anti-ideal** and how closer to the **ideal** are the real alternatives
Finally we can change the normalization criteria of the alternative matrix to \texttt{sum} (divide every value by the sum of their criteria) and check the result:

```
In [34]: dm = closeness.TOPSIS(mnorm="sum")
   ...: dm
```

```
Out[34]: <TOPSIS (mnorm=sum, wnorm=sum)>
```

```
In [35]: dm.decide(data)
```

```
Out[35]: TOPSIS (mnorm=sum, wnorm=sum) - Solution:
   ALT./CRIT.    autonomy (max) W.0.5 confort (max) W.0.05 price (min) W.0.45 Rank
-------------------------- ---------------------- -------------------- ---------------------- ------
    VW              1                   2                   3                   4.5    2
    Ford            4                   5                   6                   7.5    1
```

The ranking has changed, so we can compare the two normalization by plotting:

```
In [36]: import matplotlib.pyplot as plt
   ...: f, (ax1, ax2) = plt.subplots(1, 2, sharey=True)
   ...: ax1.set_title("Sum Norm")
   ...: data.plot.violin(mnorm="sum", ax=ax1);
   ...: ax2.set_title("Vector Norm")
   ...: data.plot.violin(mnorm="vector", ax=ax2);
   ...: f.set_figwidth(15)
```

```
In [37]: import datetime as dt
   ...: import skcriteria
   ...: print("Scikit-Criteria version:", skcriteria.VERSION)
   ...: print("Running datetime:", dt.datetime.now())
```

```
Scikit-Criteria version: 0.2.10
Running datetime: 2018-06-22 00:59:20.974570
```

### 5.2.2 The SIMUS tutorial

**SIMUS** (**Sequential Interactive Model for Urban Systems**) is a tool to aid decision-making problems with multiple objectives. The method solves successive scenarios formulated as linear programs. For each scenario, the decision-maker must choose the criterion to be considered objective while the remaining restrictions constitute the constraints system that the projects are subject to. In each case, if there is a feasible solution that is optimum, it is recorded in a matrix of efficient results. Then, from this matrix two rankings allow the decision maker to compare results obtained by different procedures. The first ranking is obtained through a linear weighting of each column by a factor - equivalent of establishing a weight - and that measures the participation.
of the corresponding project. In the second ranking, the method uses dominance and subordinate relationships between projects, concepts from the French school of MCDM.

The Case: Land rehabilitation

An important port city has been affected by the change in the modality of maritime transport, since the start of containers transport in the mid-20th century. The city was left with 39 hectares of empty docks, warehouses and a railway terminal.

Three projects was developed to decide what to do with this places

- **Project 1**: Corporate towers - Hotels - Navy Base - Small park
- **Project 2**: Habitacional towers - Comercial Center in the old Railway terminal.
- **Project 3**: Convention center - Big park and recreational area.

The criteria for the analysis of proposals are:

1. New jobs positions (jobs).
2. Green spaces (green)
3. Financial feasibility (fin)
4. Environmental impact (env)

Only for the 2nd criteria a maximum limit of 500 are provided. El Decisor considera a los cuatro criterios como objetivos, por lo que se deberán resolver cuatro programas lineales con tres restricciones cada uno. The data are provided in the next table:

<table>
<thead>
<tr>
<th>Criteria</th>
<th>Project 1</th>
<th>Project 2</th>
<th>Project 3</th>
<th>Optimal Sense</th>
</tr>
</thead>
<tbody>
<tr>
<td>jobs</td>
<td>250</td>
<td>130</td>
<td>350</td>
<td>Maximize</td>
</tr>
<tr>
<td>green</td>
<td>120</td>
<td>200</td>
<td>340</td>
<td>Maximize</td>
</tr>
<tr>
<td>fin</td>
<td>20</td>
<td>40</td>
<td>15</td>
<td>Maximize</td>
</tr>
<tr>
<td>env</td>
<td>800</td>
<td>1000</td>
<td>600</td>
<td>Maximize</td>
</tr>
</tbody>
</table>

Data input

We can create a `skcriteria.Data` object with all this information (except the limits):

```
In [1]: # first lets import the DATA class
from skcriteria import Data

data = Data(
    # the alternative matrix
    mtx=[[250, 120, 20, 800],
         [130, 200, 40, 1000],
         [250, 120, 20, 800],
         [130, 200, 40, 1000],
    ...
)
```

Note: SIMUS uses the alternatives as columns and the criteria as rows; but in scikit-criteria is the opposite, so expect to see the previous table transposed.
# optimal sense
criteria=[max, max, min, max],

# names of alternatives and criteria
anames=['Prj 1', 'Prj 2', 'Prj 3'],
cnames=['jobs', 'green', 'fin', 'env'])

# show the data object
data

Out[1]:

<table>
<thead>
<tr>
<th>ALT./CRIT.</th>
<th>jobs (max)</th>
<th>green (max)</th>
<th>fin (min)</th>
<th>env (max)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Prj 1</td>
<td>250</td>
<td>120</td>
<td>20</td>
<td>800</td>
</tr>
<tr>
<td>Prj 2</td>
<td>130</td>
<td>200</td>
<td>40</td>
<td>1000</td>
</tr>
<tr>
<td>Prj 3</td>
<td>350</td>
<td>340</td>
<td>15</td>
<td>600</td>
</tr>
</tbody>
</table>

Create the model

In [2]: # import the class
   from skcriteria.madm.simus import SIMUS

   # create the new simus and
dm = SIMUS()

By default the call SIMUS() create a solver that internally uses the PuLP solver to solve the linear programs. Other available solvers are:

- SUMUS(solver='glpk') for the GNU Linear programming toolkit
- SUMUS(solver='gurobi') to use Gurobi Optimizer
- SUMUS(solver='cplex') for IBM ILOG CPLEX Optimization Studio

Note: The check the full list of available optimizers are stored in skcriteria.utils.lp.SOLVERS.

Also the njobs parameter determines how many cores the user want to use to run the linear programs. For example SIMUS(njobs=2) uses up to two cores. (By default all CPUs are used).

Also the last (and most important) parameter is rank_by (default is 1): determines which of the two ranks methods executed by SIMUS is the one that determines the final ranking. If the experiment is consistent, the two methods must determines the same ranking (Please check the paper for more details).

Solve the problem

This is achived by calling the method decide() of the decision maker object (dm)

In [3]: # store the decision inside the dec variable
dec = dm.decide(data, b=[None, 500, None, None])
   # let's see the decision
dec

Out[3]: SIMUS (mnorm=none, wnorm=none) - Solution:

<table>
<thead>
<tr>
<th>ALT./CRIT.</th>
<th>jobs (max)</th>
<th>green (max)</th>
<th>fin (min)</th>
<th>env (max)</th>
<th>Rank</th>
</tr>
</thead>
</table>

22 Chapter 5. Contents
If you check the last column the ranking is:

1. Project 3
   • Project 2
   • Project 1

Analysis

Most of the “intermediate” data of the SIMUS method are stored in the e_ field of the decision object dec.

In [4]: dec.e_
Out[4]: Extra(rank_by, solver, stages, stage_results, points1, points2, tita_j_p, tita_j_d, doms, dom_by_crit)

for example the attribute stages stores all the Linear programs executed by SIMUS:

In [5]: dec._e.stages
Out[5]: [no-name:

If you’re new to Python, you might want to start by getting an idea of what the language is like. Scikit-criteria is 100% Python, so if you’ve got minimal comfort with Python you’ll probably get a lot more out of our project.

If you’re new to programming entirely, you might want to start with this list of Python resources for non-programmers.

If you already know a few other languages and want to get up to speed with Python quickly, we recommend Dive Into Python. If that’s not quite your style, there are many other books about Python.

At last if you already know Python but check the Scipy Lecture Notes.

5.3 API

Scikit-Criteria is a collection of algorithms, methods and techniques for multiple-criteria decision analysis.

5.3.1 skcriteria.base module

Module containing the basic functionality for the data representation used inside Scikit-Criteria.

class skcriteria.base.Data(*, mtx, criteria, weights=None, anames=None, cnames=None, meta=None)

Bases: object

Multi-Criteria data representation.

This make easy to manipulate:
• The matrix of alternatives. \( \texttt{mtx} \)
• The array with the sense of optimality of every criteria \( \texttt{criteria} \).
• Optional weights of the criteria \( \texttt{weights} \)
• Optional names of the alternatives \( \texttt{anames} \) and the criteria \( \texttt{cnames} \)
• Optional metadata \( \texttt{meta} \)

Attributes

<table>
<thead>
<tr>
<th><strong>anames</strong></th>
<th>Names of the alternatives as tuple of string.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>cnames</strong></td>
<td>Names of the criteria as tuple of string.</td>
</tr>
<tr>
<td><strong>criteria</strong></td>
<td>Sense of optimality of every criteria</td>
</tr>
<tr>
<td><strong>meta</strong></td>
<td>Dict-like metadata</td>
</tr>
<tr>
<td><strong>mtx</strong></td>
<td>Alternative matrix as 2d \texttt{numpy.ndarray}</td>
</tr>
<tr>
<td><strong>weights</strong></td>
<td>Relative importance of the criteria or None if all the same</td>
</tr>
</tbody>
</table>

Methods

<table>
<thead>
<tr>
<th><strong>plot</strong></th>
<th>alias of \texttt{skcriteria.plot.DataPlotMethods}</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>raw()</strong></td>
<td>Return a ( \texttt{mtx}, \texttt{criteria}, \texttt{weights}, \texttt{anames}, \texttt{cnames} ) tuple</td>
</tr>
<tr>
<td><strong>to_str(<strong>params</strong>)</strong></td>
<td>String representation of the Data object.</td>
</tr>
</tbody>
</table>

**anames**
Names of the alternatives as tuple of string.

**cnames**
Names of the criteria as tuple of string.

**criteria**
Sense of optimality of every criteria

**meta**
Dict-like metadata

**mtx**
Alternative matrix as 2d \texttt{numpy.ndarray}.

**plot**
alias of \texttt{skcriteria.plot.DataPlotMethods}

**raw()**
Return a \( \texttt{mtx}, \texttt{criteria}, \texttt{weights}, \texttt{anames}, \texttt{cnames} \) tuple

**to_str(**params**)**
String representation of the Data object.

Parameters **kwargs**:
Parameters to configure \texttt{tabulate}
weights
Relative importance of the criteria or None if all the same

5.3.2 skcriteria.validate module

This module core functionalities for validate the data used inside scikit criteria.

• Constants that represent minimization and maximization criteria.
• Scikit-Criteria Criteria ndarray creation.
• Scikit-Criteria Data validation.

\[ \text{skcriteria.validate.MIN} = -1 \]
Int: Minimization criteria

\[ \text{skcriteria.validate.MAX} = 1 \]
Int: Maximization criteria

exception skcriteria.validate.DataValidationError
Bases: exceptions.ValueError
Raised when some part of the multicriteria data (alternative matrix, criteria array or weights array) are not compatible with another part.

skcriteria.validate.criteriarr(criteria)
Validate if the iterable only contains MIN (or any alias) and MAX (or any alias) values. And also always returns an ndarray representation of the iterable.

Parameters criteria: Array-like
Iterable containing all the values to be validated by the function.

Returns numpy.ndarray:
Criteria array.

Raises DataValidationError:
if some value of the criteria array are not MIN (-1) or MAX (1)

skcriteria.validate.validate_data(mtx, criteria, weights=None)
Validate if the main components of the Data in scikit-criteria are compatible.

The function tests:
• The matrix (mtx) must be 2-dimensional.
• The criteria array must be a criteria array (criteriarr function).
• The number of criteria must be the same number of columns in mtx.
• The weight array must be None or an iterable with the same length of the criteria.

Parameters mtx: 2D array-like
2D alternative matrix, where every column (axis 0) are a criteria, and every row (axis 1) is an alternative.

criteria: Array-like
The sense of optimality of every criteria. Must has only MIN (-1) and MAX (1) values.
Must has the same elements as columns has mtx

weights: array like or None
The importance of every criteria. Must has the same elements as columns has \( \text{mtx} \) or None.

**Returns** \( \text{mtx} \): numpy.ndarray

\( \text{mtx} \) representations as 2d numpy.ndarray.

\( \text{criteria} \): numpy.ndarray

A criteria as numpy.ndarray.

\( \text{weights} \): numpy.ndarray or None

A weights as numpy.ndarray or None (if weights is None).

**Raises** DataValidationError:

If the data are incompatible.

### 5.3.3 `skcriteria.plot` package

Plotting utilities

```python
class skcriteria.plot.DataPlotMethods(data)
    Bases: object

    Data plotting accessor and method
```

#### Examples

```python
>>> data.plot()
>>> data.plot.hist()
>>> data.plot.scatter('x', 'y')
>>> data.plot.radar()
```

These plotting methods can also be accessed by calling the accessor as a method with the `kind` argument:

`data.plot(kind='violin')` is equivalent to `data.plot.violin()`

#### Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>__call__()</code></td>
<td>Make plots of Data using matplotlib / pylab.</td>
</tr>
<tr>
<td><code>bars(**kwargs)</code></td>
<td></td>
</tr>
<tr>
<td><code>box(**kwargs)</code></td>
<td></td>
</tr>
<tr>
<td><code>hist(**kwargs)</code></td>
<td></td>
</tr>
<tr>
<td><code>plot(func[, mnorm, wnorm, anames, cnames, ...])</code></td>
<td>Preprocess the data and send to the plot function <code>func</code>.</td>
</tr>
<tr>
<td><code>preprocess(data, mnorm, wnorm, anames, ...)</code></td>
<td>Preprocess the data to be plotted.</td>
</tr>
<tr>
<td><code>radar(**kwargs)</code></td>
<td>Creates a radar chart, also known as a spider or star chart [R25].</td>
</tr>
<tr>
<td><code>scatter(**kwargs)</code></td>
<td></td>
</tr>
<tr>
<td><code>to_str()</code></td>
<td></td>
</tr>
<tr>
<td><code>violin(**kwargs)</code></td>
<td></td>
</tr>
</tbody>
</table>
The function that make the plot. The return value of func are the return value of this method.

**mnorm**: string, callable, optional (default="none")
Normalization method for the alternative matrix.

**wnorm**: string, callable, optional (default="none")
Normalization method for the weights array.

**anames**: list of str or None, optional (default=None)
The list of alternative names to be render in the plot. If is None then the alternative names of data are used.

**cnames**: list of str or None, optional (default=None)
The list of criteria names to be render in the plot. If is None then the criteria names of data are used.

**cmap**: string or None, optional (default=None)
Name of the color map to be used [R20]

**weighted**: bool, optional (default=True)
If the data must be weighted before redering.

**show_criteria**: bool, optional (default=True)
I the sense of optimality must be rendered in the plot.

**min2max**: bool, optional (default=False)
If true all the data of the minimization criteria are inverted before render.

**push_negatives**: bool, optional (default=False)
If True all the criterias with some value < 0 are incremented to be at least 0 in the minimun value.

**addepsto0**: bool, optional (default=False)
If true add an small value to all the zeros inside the data.

**kwargs** :
Arguments to send to *func*

**Returns**
The return value of *func*.

**Notes**
All the plot methods of Scikit-Criteria returns a matplotlib axis.
References

[R20]

**preprocess** (data, mnorm, wnorm, anames, cnames, cmap, weighted, show_criteria, min2max, push_negatives, addepsto0)

Preprocess the data to be plotted.

- **Parameters**
  - **data** : skcritria.core.Data
    - The data to be preprocessed.
  - **mnorm** : string, callable
    - Normalization method for the alternative matrix.
  - **wnorm** : string, callable
    - Normalization method for the weights array.
  - **anames** : list of str or None
    - The list of alternative names to be render in the plot. If is None then the alternative names of data are used.
  - **cnames** : list of str or None
    - The list of criteria names to be render in the plot. If is None then the criteria names of data are used.
  - **cmap** : string or None
    - Name of the color map to be used [R21]
  - **weighted** : bool
    - If the data must be weighted before redering.
  - **show_criteria** : bool
    - If the sense of optimality must be rendered in the plot.
  - **min2max** : bool
    - If true all the data of the minimization criteria are inverted before render.
  - **push_negatives** : bool
    - If True all the criterias with some value < 0 are incremented to be at least 0 in the minimun value.
  - **addepsto0** : bool
    - If true add an small value to all the zeros inside the data.

- **Returns**
  - **preprocessed_data** : dict
    - All the data ready to be sended to a plot function

References

[R21]
**radar(**kwargs

Creates a radar chart, also known as a spider or star chart [R22].

A radar chart is a graphical method of displaying multivariate data in the form of a two-dimensional chart of three or more quantitative variables represented on axes starting from the same point. The relative position and angle of the axes is typically uninformative.

**Parameters**

frame : {"polygon", "circle"}
Shape of frame surrounding axes.

ax : None or PolarAxes, optional (default=None)
Axis where the radar must be rendered. Is is None a new axis are created.

legendcol : int, optional (default=5)
How many columns must has the legend.

subplots_kwargs : dict or None, optional (default=None)
Argument to send to matplotlib.pyplot.subplots if axis is None. If axis is not None, subplots_kwargs are ignored.

**Returns**

ax : matplotlib.projections.polar.PolarAxes
Axis where the radar are rendered

See also:

DataPlotMethods.plot To check all the available parameters

**Notes**

All the parameters in plot() are supported; but by default this method override some default values:

- show_criteria=False
- min2max=True
- push_negatives=True
- addepsto0=True

**References**

[R22]

**5.3.4 skcriteria.madm package**

This package contains several implementations of Multi criteria decision analyses methods (MADM) methods.

Conflicting criteria are typical in evaluating options: cost or price is usually one of the main criteria, and some measure of quality is typically another criterion, easily in conflict with the cost. In purchasing a car, cost, comfort, safety, and fuel economy may be some of the main criteria we consider – it is unusual that the cheapest car is the most comfortable and the safest one. In portfolio management, we are interested in getting high returns but at the same time reducing our risks, but the stocks that have the potential of bringing high returns typically also carry high risks of losing money. In a service industry, customer satisfaction and the cost of providing service are fundamental conflicting criteria.

**Modules:**
skcriteria.madm.simple module

Simplest method of multi-criteria

```python
class skcriteria.madm.simple.WeightedSum(mnorm='sum', wnorm='sum')
```

Bases: skcriteria.madm._dmaker.DecisionMaker

The weighted sum model (WSM) is the best known and simplest multi-criteria decision analysis for evaluating a number of alternatives in terms of a number of decision criteria. It is very important to state here that it is applicable only when all the data are expressed in exactly the same unit. If this is not the case, then the final result is equivalent to “adding apples and oranges.” To avoid this problem a previous normalization step is necessary.

In general, suppose that a given MCDA problem is defined on \( m \) alternatives and \( n \) decision criteria. Furthermore, let us assume that all the criteria are benefit criteria, that is, the higher the values are, the better it is. Next suppose that \( w_j \) denotes the relative weight of importance of the criterion \( C_j \) and \( a_{ij} \) is the performance value of alternative \( A_i \) when it is evaluated in terms of criterion \( C_j \). Then, the total (i.e., when all the criteria are considered simultaneously) importance of alternative \( A_i \), denoted as \( A_i^{WSM-score} \), is defined as follows:

\[
A_i^{WSM-score} = \sum_{j=1}^{n} w_j a_{ij}, \text{ for } i = 1, 2, 3, ..., m
\]

For the maximization case, the best alternative is the one that yields the maximum total performance value.

**Parameters**

- **mnorm**: string, callable, optional (default="sum")
  - Normalization method for the alternative matrix.

- **wnorm**: string, callable, optional (default="sum")
  - Normalization method for the weights array.

**Returns**

- **Decision**: skcriteria.madm.Decision
  - With values:
    - **kernel**: None
    - **rank**: A ranking (start at 1) where the i-nth element represent the position of the i-nth alternative.
    - **best_alternative**: The index of the best alternative.
    - **alpha_solution**: True
    - **beta_solution**: False
    - **gamma_solution**: True
    - **e**: Particular data created by this method.
      - **e_points**: Array where the i-nth element represent the importance of the i-nth alternative.

**Notes**

If some criteria is for minimization, this implementation calculates the inverse.

**References**

[R12], [R13], [R14]
Attributes

- mnorm: Normalization function for the alternative matrix.
- wnorm: Normalization function for the weights vector.

Methods

- as_dict(): Create a simply dict representation of the object.
- decide(data[, criteria, weights]): Execute the Solver over the given data.
- make_result(data, kernel, rank, extra): Create a new skcriteria.madm.Decision
- preprocess(data): Normalize the alternative matrix and weight vector.
- solve(**kwargs): Execute the multi-criteria method.

```python
class skcriteria.madm.simple.WeightedProduct(mnorm=u'sum', wnorm=u'sum')
```

The weighted product model (WPM) is a popular multi-criteria decision analysis method. It is similar to the weighted sum model. The main difference is that instead of addition in the main mathematical operation now there is multiplication.

In general, suppose that a given MCDA problem is defined on \( m \) alternatives and \( n \) decision criteria. Furthermore, let us assume that all the criteria are benefit criteria, that is, the higher the values are, the better it is. Next suppose that \( w_j \) denotes the relative weight of importance of the criterion \( C_j \) and \( a_{ij} \) is the performance value of alternative \( A_i \) when it is evaluated in terms of criterion \( C_j \). Then, the total (i.e., when all the criteria are considered simultaneously) importance of alternative \( A_i \), denoted as \( A_i^{WPM-score} \), is defined as follows:

\[
A_i^{WPM-score} = \prod_{j=1}^{n} a_{ij}^{w_j}, \text{ for } i = 1, 2, 3, \ldots, m
\]

To avoid underflow, instead the multiplication of the values we add the logarithms of the values; so \( A_i^{WPM-score} \), is finally defined as:

\[
A_i^{WPM-score} = \sum_{j=1}^{n} w_j \log(a_{ij}), \text{ for } i = 1, 2, 3, \ldots, m
\]

For the maximization case, the best alternative is the one that yields the maximum total performance value.

- Parameters mnorm: string, callable, optional (default="sum")
  - Normalization method for the alternative matrix.
- wnorm: string, callable, optional (default="sum")
  - Normalization method for the weights array.
- Returns Decision: skcriteria.madm.Decision
With values:

- **kernel**: None
- **rank**: A ranking (start at 1) where the i-nth element represents the position of the i-nth alternative.
- **best_alternative**: The index of the best alternative.
- **alpha_solution**: True
- **beta_solution**: False
- **gamma_solution**: True
- **e**: Particular data created by this method.
  - **e_points**: Array where the i-nth element represents the importance of the i-nth alternative.

**Notes**

The implementation works as follows:

- If we have some values of any criteria < 0 in the alternative-matrix we add the minimimun value of this criteria to all the criteria.
- If we have some 0 in some criteria all the criteria is incremented by 1.
- If some criteria is for minimization, this implementation calculates the inverse.
- Instead the multiplication of the values we add the logarithms of the values to avoid underflow.

</tbody>
</table>

**preprocess(**kwargs)**

Normalizes the alternative matrix and weight vector.

Creates a new instance of data by applying the normalization function to the alternative matrix and the weights vector contained inside the given data.
Parameters  **data**: skcriteria.Data

A data to be Preprocessed

Returns  skcriteria.Data

A new instance of data with the **mtx** attributes normalized with **mnorm** and **weights** normalized with **wnorm**. **anames** and **cnames** are preserved

**solve(****kwargs**)**

Execute the multi-criteria method.

Parameters  **data**: skcriteria.Data

Preprocessed Data.

Returns  object

object or tuple of objects with the raw result data.

**skcriteria.madm.closeness module**

Methods based on an aggregating function representing “closeness to the ideal”.

**class**  skcriteria.madm.closeness.TOPSIS(**mnorm=u'vector', wnorm=u'sum'**)

**Bases**: skcriteria.madm._dmaker.DecisionMaker

TOPSIS is based on the concept that the chosen alternative should have the shortest geometric distance from the ideal solution and the longest euclidean distance from the worst solution.

An assumption of TOPSIS is that the criteria are monotonically increasing or decreasing, and also allow trade-offs between criteria, where a poor result in one criterion can be negated by a good result in another criterion.

Parameters  **mnorm**: string, callable, optional (default="vector")

Normalization method for the alternative matrix.

**wnorm**: string, callable, optional (default="sum")

Normalization method for the weights array.

Returns  Decision  : skcriteria.madm.Decision

With values:

- **kernel**: None
- **rank**: A ranking (start at 1) where the i-th element represent the position of the i-th alternative.
- **best_alternative**: The index of the best alternative.
- **alpha_solution**: True
- **beta_solution**: False
- **gamma_solution**: True
- **e**: Particular data created by this method.
  - **e_closeness**: Array where the i-th element represent the closeness of the i-th alternative to ideal and worst solution.
**References**

[R1], [R2], [R3]

**Attributes**

- `mnorm`: Normalization function for the alternative matrix.
- `wnorm`: Normalization function for the weights vector.

**Methods**

- `as_dict()`: Create a simply dict representation of the object.
- `decide(data[, criteria, weights])`: Execute the Solver over the given data.
- `make_result(data, kernel, rank, extra)`: Create a new `skcriteria.madm.Decision`.
- `preprocess(data)`: Normalize the alternative matrix and weight vector.
- `solve(**kwargs)`: Execute the multi-criteria method.

```python
solve(**kwargs)
```

Execute the multi-criteria method.

**Parameters**

- `data`: `skcriteria.Data`
  Preprocessed Data.

**Returns**

- `object` or tuple of objects with the raw result data.

---

**skcriteria.madm.moora module**

Implementation of a family of Multi-objective optimization based on ratio analysis (MOORA) methods.

**class** `skcriteria.madm.moora.RatioMOORA (wnorm='sum')`

**Bases:** `skcriteria.madm._dmaker.DecisionMaker`

The method refers to a matrix of responses of alternatives to objectives, to which ratios are applied.

In MOORA the set of ratios (by default) has the square roots of the sum of squared responses as denominators.

\[
\bar{X}_{ij} = \frac{X_{ij}}{\sqrt{\sum_{j=1}^{m} X_{ij}^2}}
\]

These ratios, as dimensionless, seem to be the best choice among different ratios. These dimensionless ratios, situated between zero and one, are added in the case of maximization or subtracted in case of minimization:

\[
N_{yi} = \sum_{i=1}^{g} N_{x_{ij}} - \sum_{i=1}^{g+1} N_{x_{ij}}
\]

with: \(i = 1, 2, ..., g\) for the objectives to be maximized, \(i = g+1, g+2, ..., n\) for the objectives to be minimized.

Finally, all alternatives are ranked, according to the obtained ratios.

**Parameters**

- `wnorm`: string, callable, optional (default="sum")
Normalization method for the weights array.

**Returns** Decision: `skcriteria.madm.Decision`

With values:

- **kernel**: None
- **rank**: A ranking (start at 1) where the i-nth element represent the position of the i-nth alternative.
- **best_alternative**: The index of the best alternative.
- **alpha_solution**: True
- **beta_solution**: False
- **gamma_solution**: True
- **e**: Particular data created by this method.
  - **e.points**: Array where the i-nth element represent the importance of the i-nth alternative.

**References**

[R7]

**Attributes**

- **mnorm**: Normalization function for the alternative matrix.
- **wnorm**: Normalization function for the weights vector.

**Methods**

- **as_dict(**kwargs)**: Create a simply dict representation of the object.
- **decide(data[, criteria, weights])**: Execute the Solver over the given data.
- **make_result(data, kernel, rank, extra)**: Create a new `skcriteria.madm.Decision`
- **preprocess(data)**: Normalize the alternative matrix and weight vector.
- **solve(**kwargs)**: Execute the multi-criteria method.

**Notes**

```python
tax.as_dict != dict(x)
solve(**kwargs)
```

Execute the multi-criteria method.

**Parameters** data: `skcriteria.Data`

Preprocessed Data.
Returns `object`

object or tuple of objects with the raw result data.

class skcriteria.madm.moora.RefPointMOORA (wnorm='sum')
Bases: skcriteria.madm._dmaker.DecisionMaker

Rank the alternatives from a reference point selected with the Min-Max Metric of Tchebycheff.

\[
\min_j \left\{ \max_i |r_i - x_{ij}^*| \right\}
\]

This reference point theory starts from the already normalized ratios as defined in the MOORA method, namely formula:

\[
X_{ij} = \frac{X_{ij}}{\sqrt{\sum_{j=1}^{m} X_{ij}^2}}
\]

Preference is given to a reference point possessing as co-ordinates the dominating co-ordinates per attribute of the candidate alternatives and which is designated as the **Maximal Objective Reference Point**. This approach is called realistic and non-subjective as the co-ordinates, which are selected for the reference point, are realized in one of the candidate alternatives.

**Parameters**

- **wnorm** : string, callable, optional (default="sum")
  
  Normalization method for the weights array.

**Returns**

- **Decision** : skcriteria.madm.Decision
  
  With values:
  
  - **kernel** : None
  - **rank** : A ranking (start at 1) where the i-th element represent the position of the i-th alternative.
  - **best_alternative** : The index of the best alternative.
  - **alpha_solution** : True
  - **beta_solution** : False
  - **gamma_solution** : True
  - **e** : Particular data created by this method.
    - **e.points** : array where the i-th element represent the closenees of the i-th alternative to a reference point based on the **Min-Max Metric of Tchebycheff**.

Methods

- **as_dict(**kwargs)**: Create a simply **dict** representation of the object.
- **decide(data[, criteria, weights])**: Execute the Solver over the given data.
- **make_result(data, kernel, rank, extra)**: Create a new skcriteria.madm.Decision.
- **preprocess(data)**: Normalize the alternative matrix and weight vector.
- **solve(**kwargs)**: Execute the multi-criteria method.

**as_dict(**kwargs)**
Create a simply **dict** representation of the object.

**Notes**

```
x.as_dict != dict(x)
```

**solve(**kwargs)**
Execute the multi-criteria method.

**Parameters**

data: skcriteria.Data
Preprocessed Data.

**Returns**

object or tuple of objects with the raw result data.

class skcriteria.madm.moora.FMFMOORA(wnorm=u'sum')
Bases: skcriteria.madm._dmaker.DecisionMaker

Full Multiplicative Form, a method that is non-linear, non-additive, does not use weights and does not require normalization.

To combine a minimization and maximization of different criteria in the same problem all the method uses the formula:

\[ U'_j = \prod_{g=1}^{i} x_{gi} \prod_{k=i+1}^{n} x_{kj} \]

Where \( j \) = the number of alternatives; \( i \) = the number of objectives to be maximized; \( ni \) = the number of objectives to be minimize; and \( U'_j \): the utility of alternative \( j \) with objectives to be maximized and objectives to be minimized.

To avoid underflow, instead the multiplication of the values we add the logarithms of the values; so \( U'_j \): is finally defined as:

\[ U'_j = \sum_{g=1}^{i} \log(x_{gi}) - \sum_{k=i+1}^{n} \log(x_{kj}) \]

**Parameters**

wnorm: string, callable, optional (default="sum")
Normalization method for the weights array.

**Returns**

Decision: skcriteria.madm.Decision
With values:

- **kernel**: None
• **rank**: A ranking (start at 1) where the i-nth element represent the position of the i-nth alternative.

• **best_alternative**: The index of the best alternative.

• **alpha_solution**: True

• **beta_solution**: False

• **gamma_solution**: True

• **e**: Particular data created by this method.
  – **e_points**: Array where the i-nth element represent the importance of the i-nth alternative.

**Notes**

The implementation works as follow:

• Before determine $U_j$ the values are normalized by the ratio sugested by MOORA.

$$X_{ij} = \frac{X_{ij}}{\sqrt{\sum_{j=1}^{m} X_{ij}^2}}$$

• If we have some values of any criteria < 0 in the alternative-matrix we add the minimum value of this criteria to all the criteria.

• If we have some 0 in some criteria all the criteria is incremented by 1.

• If some criteria is for minimization, this implementation calculates the inverse.

• Instead the multiplication of the values we add the logarithms of the values to avoid underflow.

as_dict(**kwargs)
Create a simply dict representation of the object.

Notes

x.as_dict != dict(x)

preprocess(**kwargs)
Normalize the alternative matrix and weight vector.

Creates a new instance of data by applying the normalization function to the alternative matrix and the
weights vector contained inside the given data.

Parameters data: skcriteria.Data
A data to be Preprocessed

Returns skcriteria.Data
A new instance of data with the mtx attributes normalized with mnorm and weights
normalized with wnorm. anames and cnames are preserved

solve(**kwargs)
Execute the multi-criteria method.

Parameters data: skcriteria.Data
Preprocessed Data.

Returns object
object or tuple of objects with the raw result data.

class skcriteria.madm.moora.MultiMOORA
Bases: skcriteria.madm._dmaker.DecisionMaker
MULTIMOORA is compose the ranking resulting of applying the methods, RatioMOORA, RefPointMOORA
and FMFMOORA.

These three methods represent all possible methods with dimensionless measures in multi-objective optimization
and one can not argue that one method is better than or is of more importance than the others; so for determining
the final ranking the implementation maximizes how many times an alternative i dominates and alternative j.

Returns Decision: skcriteria.madm.Decision
With values:
• kernel: None
• rank: A ranking (start at 1) where the i-nth element represent the position of the
  i-nth alternative.
• best_alternative: The index of the best alternative.
• alpha_solution_: True
• beta_solution_: False
• gamma_solution_: True
• e: Particular data created by this method.
  – e_rank_mtx: 2x3 Array where the first column is the RatioMOORA ranking, the
    second one the RefPointMOORA ranking and the last the FMFMOORA ranking.
Notes

The implementation works as follow:

- Before determine \( U_j \) the values are normalized by the ratio suggested by MOORA.

  \[
  X_{ij} = \frac{X_{ij}}{\sqrt{\sum_{j=1}^{m} X_{ij}^2}}
  \]

- If we have some values of any criteria < 0 in the alternative-matrix we add the minimum value of this criteria to all the criteria.
- If we have some 0 in some criteria all the criteria is incremented by 1.
- If some criteria is for minimization, this implementation calculates the inverse.
- Instead the multiplication of the values we add the logarithms of the values to avoid underflow.
- For determining the final ranking the implementation maximizes how many times an alternative \( i \) dominates and alternative \( j \).

Notes

preprocess(**kwargs)

Normalize the alternative matrix and weight vector.

Creates a new instance of data by applying the normalization function to the alternative matrix and the weights vector contained inside the given data.
Parameters data: skcriteria.Data
A data to be Preprocessed

Returns skcriteria.Data
A new instance of data with the mtx attributes normalized with mnorm and weights normalized with wnorm. anames and cnames are preseved

solve(**kwargs)
Execute the multi-criteria method.

Parameters data: skcriteria.Data
Preprocessed Data.

Returns object
object or tuple of objects with the raw result data.

skcriteria.madm.electre.py module

ELECTRE is a family of multi-criteria decision analysis methods that originated in Europe in the mid-1960s. The acronym ELECTRE stands for: ELimination Et Choix Traduisant la REalité (ELimination and Choice Expressing REality).

Usually the Electre Methods are used to discard some alternatives to the problem, which are unacceptable. After that we can use another MCDA to select the best one. The Advantage of using the Electre Methods before is that we can apply another MCDA with a restricted set of alternatives saving much time.

class skcriteria.madm.electre.ELECTRE1 (p=0.65, q=0.35, mnorm=u'sum', wnorm=u'sum', njobs=None)
Bases: skcriteria.madm._dmaker.DecisionMaker

The ELECTRE I model find the kernel solution in a situation where true criteria and restricted outranking relations are given.

That is, ELECTRE I cannot derive the ranking of alternatives but the kernel set. In ELECTRE I, two indices called the concordance index and the discordance index are used to measure the relations between objects.

Parameters p : float, optional (default=0.65)
Concordance threshold. Threshold of how much one alternative is at least as good as another to be significative.

q : float, optional (default=0.35)
Discordance threshold. Threshold of how much the degree one alternative is strictly preferred to another to be significative.

mnorm : string, callable, optional (default="sum")
Normalization method for the alternative matrix.

wnorm : string, callable, optional (default="sum")
Normalization method for the weights array.

njobs : int, default=None
How many cores to use to solve the linear programs and the second method. By default all the availables cores are used.

Returns Decision: skcriteria.madm.Decision
With values:

- **kernel_**: Array with the indexes of the alternatives in the kernel.
- **rank_**: None
- **best_alternative_**: None
- **alpha_solution_**: False
- **beta_solution_**: True
- **gamma_solution_**: False
- **e_**: Particular data created by this method.
  - **e_.closeness**: Array where the i-th element represents the closeness of the i-th alternative to ideal and worst solution.
  - **e_.outrank**: numpy.ndarray of bool. The outranking matrix of superation. If the element[i][j] is True, the alternative i outranks the alternative j.
  - **e_.mtx_concordance**: numpy.ndarray. The concordance indexes matrix where the element[i][j] measures how much the alternative i is at least as good as j.
  - **e_.mtx_discordance**: numpy.ndarray. The discordance indexes matrix where the element[i][j] measures the degree to which the alternative i is strictly preferred to j.
  - **e_.p**: float. Concordance index threshold.
  - **e_.q**: float. Discordance index threshold.

Create a simply dict representation of the object.
```
Notes

\[ x \text{.as_dict} \neq \text{dict}(x) \]

**njobs**
How many cores to use to solve the linear programs and the second method. By default all the available cores are used.

**P**
Concordance threshold. Threshold of how much one alternative is at least as good as another to be significative.

**q**
Discordance threshold. Threshold of how much the degree one alternative is strictly preferred to another to be significative.

**solve**(**kwargs**)
Execute the multi-criteria method.

**Parameters data**: skcriteria.Data
Preprocessed Data.

**Returns object**
object or tuple of objects with the raw result data.

**skcriteria.madm.simus module**

SIMUS (Sequential Interactive Model for Urban Systems) Method

**class skcriteria.madm.simus.SIMUS**(**mnorm=“none”, wnorm=“none”, rank_by=1, solver=“pulp”, njobs=None**)

**Bases**: skcriteria.madm._dmaker.DecisionMaker

SIMUS (Sequential Interactive Model for Urban Systems) developed by Nolberto Munier (2011) is a tool to aid decision-making problems with multiple objectives. The method solves successive scenarios formulated as linear programs. For each scenario, the decision-maker must choose the criterion to be considered objective while the remaining restrictions constitute the constrains system that the projects are subject to. In each case, if there is a feasible solution that is optimum, it is recorded in a matrix of efficient results. Then, from this matrix two rankings allow the decision maker to compare results obtained by different procedures. The first ranking is obtained through a linear weighting of each column by a factor - equivalent of establishing a weight - and that measures the participation of the corresponding project. In the second ranking, the method uses dominance and subordinate relationships between projects, concepts from the French school of MCDM.

**Parameters mnorm**: string, callable, optional (default=“none”)
Normalization method for the alternative matrix.

**wnorm**: string, callable, optional (default=“none”)
Normalization method for the weights array.

**rank_by**: 1 or 2 (default=1)
Wich of the two methods are used to calculate the ranking. The two methods are executed always.

**solver**: str, default=“pulp”
Which solver to use to solve the underlying linear programs. The full list are available in skcriteria.utils.lp.SOLVERS
**njobs**: int, default=None

How many cores to use to solve the linear programs and the second method. By default all the available cores are used.

**Returns** **Decision**: `skcriteria.madm.Decision`

With values:

- **kernel**: None
- **rank**: A ranking (start at 1) where the i-nth element represent the position of the i-nth alternative.
- **best_alternative**: The index of the best alternative.
- **alpha_solution**: True
- **beta_solution**: False
- **gamma_solution**: True
- **e**: Particular data created by this method.
  - **rank_by**: 1 or 2. Which of the two methods are used to calculate the ranking. Essentialy if the rank is calculated with \( e_.points1 \) or \( e_points2 \)
  - **solver**: With solver was used for the underlying linear problems.
  - **stages**: The underlying linear problems.
  - **stage_results**: The values of the variables of the linear problems as a n-dimensional array. When th n-th row represent the result values of the variables for the n-th stage.
  - **points1**: The points of every alternative obtained by the first method.
  - **points2**: The points of every alternative obtained by the first method.
  - **tita_j_p**: 2nd. method domination.
  - **tita_j_d**: 2nd. method subordination.
  - **doms**: Total dominance matrix of the 2nd. method.
  - **dom_by_crit**: Dominance by criteria of the 2nd method.
