1.7 Changes .................................................. 45
Splash is a javascript rendering service. It’s a lightweight web browser with an HTTP API, implemented in Python using Twisted and QT. The (twisted) QT reactor is used to make the sever fully asynchronous allowing to take advantage of webkit concurrency via QT main loop. Some of Splash features:

- process multiple webpages in parallel;
- get HTML results and/or take screenshots;
- turn OFF images or use Adblock Plus rules to make rendering faster;
- execute custom JavaScript in page context;
- transparently plug into existing software using Proxy interface;
- get detailed rendering info in HAR format.
1.1 Installation

1.1.1 Linux + Docker

1. Install Docker.
2. Pull the image:
   
   ```
   $ sudo docker pull scrapinghub/splash
   ```
3. Start the container:
   
   ```
   $ sudo docker run -p 5023:5023 -p 8050:8050 -p 8051:8051 scrapinghub/splash
   ```
4. Splash is now available at 0.0.0.0 at ports 8050 (http), 8051 (https) and 5023 (telnet).

1.1.2 OS X + Docker

1. Install Docker (via Boot2Docker).
2. Pull the image:
   
   ```
   $ docker pull scrapinghub/splash
   ```
3. Start the container:
   
   ```
   $ docker run -p 5023:5023 -p 8050:8050 -p 8051:8051 scrapinghub/splash
   ```
4. Figure out the ip address of boot2docker:
   
   ```
   $ boot2docker ip
   ```
   The VM’s Host only interface IP address is: 192.168.59.103
5. Splash is available at the returned IP address at ports 8050 (http), 8051 (https) and 5023 (telnet).

1.1.3 Ubuntu 12.04 (manual way)

1. Install system dependencies:
$ sudo add-apt-repository -y ppa:pi-rho/security
$ sudo apt-get update
$ sudo apt-get install libre2-dev
$ sudo apt-get install netbase ca-certificates python \
    python-dev build-essential libicu48 \
    xvfb libqt4-webkit python-twisted python-qt4

2. TODO: install Python dependencies using pip, clone repo, chdir to it, start splash.

To run the server execute the following command:

```
python -m splash.server
```

Run `python -m splash.server --help` to see options available.

By default, Splash API endpoints listen to port 8050 on all available IPv4 addresses. To change the port use `--port` option:

```
python -m splash.server --port=5000
```

**Requirements**

```
# install PyQt4 (Splash is tested on PyQT 4.9.x and PyQT 4.11.x)
# and the following packages:
twisted
qt4reactor
psutil
adblockparser >= 0.4
-e git+https://github.com/axiak/pyre2.git#egg=re2
xvfbwrapper
Pillow

# for scripting support
lupa >= 1.1
funcparserlib >= 0.3.6

# the following libraries are only required by tests
pytest
pyOpenSSL
requests >= 1.0
jsonschema >= 2.0
strict-rfc3339
```

**1.1.4 Splash Versions**

docker pull scrapinghub/splash will give you the latest stable Splash release. To obtain the latest development version use docker pull scrapinghub/splash:master. Specific Splash versions are also available, e.g. docker pull scrapinghub/splash:1.2.1.

**1.1.5 Customizing Dockerized Splash**

**Passing Custom Options**

To run Splash with custom options pass them to `docker run`. For example, let’s increase log verbosity:
$ docker run -p 8050:8050 scrapinghub/splash -v3

To see all possible options pass --help. Not all options will work the same inside Docker: changing ports doesn’t make sense (use docker run options instead), and paths are paths in the container.

**Folders Sharing**

To set custom Request Filters use -v Docker option. First, create a folder with request filters on your local filesystem, then make it available to the container:

$ docker run -p 8050:8050 -v <my-filters-dir>:/etc/splash/filters scrapinghub/splash

Replace `<my-filters-dir>` with a path of your local folder with request filters.

Docker Data Volume Containers can also be used. Check https://docs.docker.com/userguide/dockervolumes/ for more info.

*Proxy Profiles* and *Javascript Profiles* can be added in a similar way:

$ docker run -p 8050:8050 -v <my-proxy-profiles-dir>:/etc/splash/proxy-profiles -v <my-js-profiles-dir>:/etc/splash/js-profiles scrapinghub/splash

To setup Custom Lua Modules mount a folder to /etc/splash/lua_modules. If you use a Lua sandbox (default) don’t forget to list safe modules using --lua-sandbox-allowed-modules option:

$ docker run -p 8050:8050 -v <my-lua-modules-dir>:/etc/splash/lua_modules --lua-sandbox-allowed-modules 'module1;module2' scrapinghub/splash

**Warning:** Folder sharing (-v option) doesn’t work on OS X and Windows (see https://github.com/docker/docker/issues/4023). It should be fixed in future Docker & Boot2Docker releases. For now use one of the workarounds mentioned in issue comments or clone Splash repo and customize its Dockerfile.

**Splash in Production**

In production you may want to daemonize Splash, start it on boot and restart on failures. Since Docker 1.2 an easy way to do this is to use --restart and -d options together; another way to do that is to use standard tools like upstart, systemd or supervisor.

**Note:** --restart option won’t work without -d.

Please also take into account the memory usage: Splash uses an unbound in-memory cache and so it will eventually consume all RAM. A workaround is to restart the process when it uses too much memory; there is Splash --maxrss option for that. You can also add Docker --memory option to the mix.

In production it is a good idea to pin Splash version - instead of scrapinghub/splash it is usually better to use something like scrapinghub/splash:1.4.

The final command for starting a long-running Splash server which uses up to 4GB RAM and daemonizes & restarts itself could look like this:

1.1. Installation
Building Local Docker Images

To build your own Docker image, checkout Splash source code using git, then execute the following command from Splash source root:

```
$ docker build -t my-local-splash .
```

To build Splash-Jupyter Docker image use this command:

```
$ docker build -t my-local-splash-jupyter -f dockerfiles/splash-jupyter/Dockerfile .
```

You may have to change FROM line in `dockerfiles/splash-jupyter/Dockerfile` if you want it to be based on your local Splash Docker container.

1.2 Splash HTTP API

Consult with Installation to get Splash up and running.

Splash is controlled via HTTP API. For all endpoints below parameters may be sent either as GET arguments or encoded to JSON and POSTed with `Content-Type: application/json` header.

The most versatile endpoint that provides all Splash features is `execute` (WARNING: it is still experimental). Other endpoints may be easier to use in specific cases - for example, `render.png` returns a screenshot in PNG format that can be used as `img src` without any further processing, and `render.json` is convenient if you don’t need to interact with a page.

The following endpoints are supported:

1.2.1 render.html

Return the HTML of the javascript-rendered page.

Arguments:

- **url** [string][required] The url to render (required)
- **baseurl** [string][optional] The base url to render the page with.
  
  If given, base HTML content will be fetched from the URL given in the url argument, and render using this as the base url.
- **timeout** [float][optional] A timeout (in seconds) for the render (defaults to 30).
  
  By default, maximum allowed value for the timeout is 60 seconds. To override it start Splash with `--max-timeout` command line option. For example, here Splash is configured to allow timeouts up to 2 minutes:

  ```
  $ python -m splash.server --max-timeout 120
  ```
- **wait** [float][optional] Time (in seconds) to wait for updates after page is loaded (defaults to 0). Increase this value if you expect pages to contain setInterval/setTimeout javascript calls, because with wait=0 callbacks of setInterval/setTimeout won’t be executed. Non-zero wait is also required for PNG rendering when doing full-page rendering (see `render_all`). Maximum allowed value for wait is 10 seconds.
- **proxy** [string][optional] Proxy profile name. See Proxy Profiles.
js  [string][optional] Javascript profile name. See Javascript Profiles.

js_source  [string][optional] JavaScript code to be executed in page context. See Executing custom Javascript code within page context.

filters  [string][optional] Comma-separated list of request filter names. See Request Filters

allowed_domains  [string][optional] Comma-separated list of allowed domain names. If present, Splash won’t load anything neither from domains not in this list nor from subdomains of domains not in this list.

viewport  [string][optional] View width and height (in pixels) of the browser viewport to render the web page. Format is “<width>x<height>”, e.g. 800x600. Default value is 1024x768.

‘viewport’ parameter is more important for PNG rendering; it is supported for all rendering endpoints because javascript code execution can depend on viewport size.

For backward compatibility reasons, it also accepts ‘full’ as value; viewport=full is semantically equivalent to render_all=1 (see render_all).

images  [integer][optional] Whether to download images. Possible values are 1 (download images) and 0 (don’t download images). Default is 1.

Note that cached images may be displayed even if this parameter is 0. You can also use Request Filters to strip unwanted contents based on URL.

headers  [JSON array or object][optional] HTTP headers to set for the first outgoing request.

This option is only supported for application/json POST requests. Value could be either a JSON array with (header_name, header_value) pairs or a JSON object with header names as keys and header values as values.

“User-Agent” header is special: is is used for all outgoing requests, unlike other headers.

Examples

Curl example:

The result is always encoded to utf-8. Always decode HTML data returned by render.html endpoint from utf-8 even if there are tags like

<meta http-equiv="Content-Type" content="text/html; charset=iso-8859-1">

in the result.

1.2.2 render.png

Return a image (in PNG format) of the javascript-rendered page.

Arguments:

Same as render.html plus the following ones:

width  [integer][optional] Resize the rendered image to the given width (in pixels) keeping the aspect ratio.

height  [integer][optional] Crop the rendered image to the given height (in pixels). Often used in conjunction with the width argument to generate fixed-size thumbnails.
render_all  [int][optional] Possible values are 1 and 0. When render_all=1, extend the viewport to include the whole webpage (possibly very tall) before rendering. Default is render_all=0.

Note: render_all=1 requires non-zero wait parameter. This is an unfortunate restriction, but it seems that this is the only way to make rendering work reliably with render_all=1.

scale_method  [string][optional] Possible values are raster (default) and vector. If scale_method=raster, rescaling operation performed via width parameter is pixel-wise. If scale_method=vector, rescaling is done element-wise during rendering.

Note: Vector-based rescaling is more performant and results in crisper fonts and sharper element boundaries, however there may be rendering issues, so use it with caution.

Examples

Curl examples:

# render with timeout

# 320x240 thumbnail

1.2.3 render.har

Return information about Splash interaction with a website in HAR format. It includes information about requests made, responses received, timings, headers, etc.

You can use online HAR viewer to visualize information returned from this endpoint; it will be very similar to “Network” tabs in Firefox and Chrome developer tools.

Currently this endpoint doesn’t expose raw request and response contents; only meta-information like headers and timings is available.

Arguments for this endpoint are the same as for render.html.

1.2.4 render.json

Return a json-encoded dictionary with information about javascript-rendered webpage. It can include HTML, PNG and other information, based on arguments passed.

Arguments:

Same as render.png plus the following ones:

html  [integer][optional] Whether to include HTML in output. Possible values are 1 (include) and 0 (exclude). Default is 0.

png  [integer][optional] Whether to include PNG in output. Possible values are 1 (include) and 0 (exclude). Default is 0.

iframes  [integer][optional] Whether to include information about child frames in output. Possible values are 1 (include) and 0 (exclude). Default is 0.
script [integer][optional] Whether to include the result of the executed javascript final statement in output (see *Executing custom Javascript code within page context*). Possible values are 1 (include) and 0 (exclude). Default is 0.

console [integer][optional] Whether to include the executed javascript console messages in output. Possible values are 1 (include) and 0 (exclude). Default is 0.

history [integer][optional] Whether to include the history of requests/responses for webpage main frame. Possible values are 1 (include) and 0 (exclude). Default is 0.

Use it to get HTTP status codes and headers. Only information about “main” requests/responses is returned (i.e. information about related resources like images and AJAX queries is not returned). To get information about all requests and responses use ‘har’ argument.

har [integer][optional] Whether to include HAR in output. Possible values are 1 (include) and 0 (exclude). Default is 0. If this option is ON the result will contain the same data as render.har provides under ‘har’ key.

Examples

By default, URL, requested URL, page title and frame geometry is returned:

```
{
  "url": "http://crawlera.com/",
  "geometry": [0, 0, 640, 480],
  "requestedUrl": "http://crawlera.com/",
  "title": "Crawlera"
}
```

Add ‘html=1’ to request to add HTML to the result:

```
{
  "url": "http://crawlera.com/",
  "geometry": [0, 0, 640, 480],
  "requestedUrl": "http://crawlera.com/",
  "html": "<!DOCTYPE html><!--[if IE 8]>....",
  "title": "Crawlera"
}
```

Add ‘png=1’ to request to add base64-encoded PNG screenshot to the result:

```
{
  "url": "http://crawlera.com/",
  "geometry": [0, 0, 640, 480],
  "requestedUrl": "http://crawlera.com/",
  "png": "iVBORw0KGgoAAAAN...",
  "title": "Crawlera"
}
```

Setting both ‘html=1’ and ‘png=1’ allows to get HTML and a screenshot at the same time - this guarantees that the screenshot matches the HTML.

By adding “iframes=1” information about iframes could be obtained:

```
{
  "geometry": [0, 0, 640, 480],
  "frameName": "",
  "title": "Scrapinghub | Autoscraping",
  "url": "http://scrapinghub.com/autoscraping.html",
  "childFrames": [
    {
```

1.2. Splash HTTP API
Note that iframes can be nested.

Pass both ‘html=1’ and ‘iframes=1’ to get HTML for all iframes as well as for the main page:

{  
  "geometry": [0, 0, 640, 480],  
  "frameName": "",  
  "html": "<!DOCTYPE html...",  
  "title": "Scrapinghub | Autoscraping",  
  "url": "http://scrapinghub.com/autoscraping.html",  
  "childFrames": [  
    {  
      "geometry": [235, 502, 497, 310],  
      "frameName": "<!--framePath //<!--frame0-->-->",  
      "requestedUrl": "http://www.youtube.com/embed/lSJvVqDLOOs?version=3&rel=1&fs=1&showsearch=0&showinfo=1&iv_load_policy=1&wmode=transparent",  
      "childFrames": []  
    }  
  ],  
  "requestedUrl": "http://scrapinghub.com/autoscraping.html"  
}

Unlike ‘html=1’, ‘png=1’ does not affect data in childFrames.

When executing JavaScript code (see Executing custom Javascript code within page context) add the parameter ‘script=1’ to the request to include the code output in the result:

{  
  "url": "http://crawlera.com/",  
  "geometry": [0, 0, 640, 480],  
  "requestedUrl": "http://crawlera.com/",  
  "title": "Crawlera",  
  "script": "result of script..."  
}

The JavaScript code supports the console.log() function to log messages. Add ‘console=1’ to the request to include the console output in the result:

{  
  "url": "http://crawlera.com/",  
  "geometry": [0, 0, 640, 480],  
  "requestedUrl": "http://crawlera.com/",  
  "title": "Crawlera",  
  "script": "result of script...",  
  "console": ["first log message", "second log message", ...]  
}
Curl examples:

# full information

# HTML and meta information of page itself and all its iframes

# only meta information (like page/iframes titles and urls)

# render html and 320x240 thumbnail at once; do not return info about iframes

# Render page and execute simple Javascript function, display the js output
`curl -X POST -H 'content-type: application/javascript' \`
    -d 'function getAd(x){ return x; } getAd("abc");' \`

# Render page and execute simple Javascript function, display the js output and the console output
`curl -X POST -H 'content-type: application/javascript' \`
    -d 'function getAd(x){ return x; }; console.log("some log"); console.log("another log"); getAd("abc");' \`

### 1.2.5 execute

**Warning:** This endpoint is experimental. API could change in future releases.

Execute a custom rendering script and return a result.

`render.html`, `render.png`, `render.har` and `render.json` endpoints cover many common use cases, but sometimes they are not enough. This endpoint allows to write custom **Splash Scripts**.

Arguments:

- `lua_source` [string][required] Browser automation script. See [Splash Scripts Tutorial](#) for more info.
- `timeout` [float][optional] Same as ‘timeout’ argument for `render.html`.
- `allowed_domains` [string][optional] Same as ‘allowed_domains’ argument for `render.html`.
- `proxy` [string][optional] Same as ‘proxy’ argument for `render.html`.
- `filters` [string][optional] Same as ‘filters’ argument for `render.html`.

### 1.2.6 Executing custom Javascript code within page context

**Note:** See also: [executing JavaScript in Splash scripts](#)

Splash supports executing JavaScript code within the context of the page. The JavaScript code is executed after the page finished loading (including any delay defined by ‘wait’) but before the page is rendered. This allow to use the javascript code to modify the page being rendered.

To execute JavaScript code use `js_source` parameter. It should contain JavaScript code to be executed.

Note that browsers and proxies limit the amount of data can be sent using GET, so it is a good idea to use `content-type: application/json POST request.`
Curl example:

```
# Render page and modify its title dynamically
curl -X POST -H 'content-type: application/json' \
   -d '{"js_source": "document.title="My Title";", "url": "http://example.com"}' \
   'http://localhost:8050/render.html'
```

Another way to do it is to use a POST request with the content-type set to ‘application/javascript’. The body of the request should contain the code to be executed.

Curl example:

```
# Render page and modify its title dynamically
curl -X POST -H 'content-type: application/javascript' \
   -d 'document.title="My Title";' \
```

To get the result of a javascript function executed within page context use render.json endpoint with `script = 1` parameter.

In Splash-as-a-proxy mode use `X-Splash-js-source` header instead of a POST request.

**Javascript Profiles**

Splash supports “javascript profiles” that allows to preload javascript files. Javascript files defined in a profile are executed after the page is loaded and before any javascript code defined in the request.

The preloaded files can be used in the user’s POST’ed code.

To enable javascript profiles support, run splash server with the `--js-profiles-path=<path to a folder with js profiles>` option:

```
python -m splash.server --js-profiles-path=/etc/splash/js-profiles
```

**Note:** See also: Splash Versions.

Then create a directory with the name of the profile and place inside it the javascript files to load (note they must be utf-8 encoded). The files are loaded in the order they appear in the filesystem. Directory example:

```
/etc/splash/js-profiles/
   mywebsite/
      lib1.js
```

To apply this javascript profile add the parameter `js=mywebsite` to the request:

```
curl -X POST -H 'content-type: application/javascript' \
   -d 'myfunc("Hello");' \
```

Note that this example assumes that myfunc is a javascript function defined in lib1.js.

**Javascript Security**

If Splash is started with `--js-cross-domain-access` option

```
python -m splash.server --js-cross-domain-access
```
then javascript code is allowed to access the content of iframes loaded from a security origin different to the original page (browsers usually disallow that). This feature is useful for scraping, e.g. to extract the html of a iframe page. An example of its usage:

```bash
```

The javascript function `getContents` will look for a iframe with the id `external` and extract its html contents.

Note that allowing cross origin javascript calls is a potential security issue, since it is possible that secret information (i.e cookies) is exposed when this support is enabled; also, some websites don’t load when cross-domain security is disabled, so this feature is OFF by default.

### 1.2.7 Request Filters

Splash supports filtering requests based on Adblock Plus rules. You can use filters from EasyList to remove ads and tracking codes (and thus speedup page loading), and/or write filters manually to block some of the requests (e.g. to prevent rendering of images, mp3 files, custom fonts, etc.)

To activate request filtering support start splash with `--filters-path` option:

```bash
python -m splash.server --filters-path=/etc/splash/filters
```

**Note:** See also: *Splash Versions*.

The folder `--filters-path` points to should contain `.txt` files with filter rules in Adblock Plus format. You may download `easylist.txt` from EasyList and put it there, or create `.txt` files with your own rules.

For example, let’s create a filter that will prevent custom fonts in `.ttf` and `.woff` formats from loading (due to qt bugs they may cause splash to segfault on Mac OS X):

```bash
! put this to a /etc/splash/filters/nofonts.txt file
! comments start with an exclamation mark

.ttff
.woff
```

To use this filter in a request add `filters=nofonts` parameter to the query:

```bash
```

You can apply several filters; separate them by comma:

```bash
```

If `default.txt` file is present in `--filters-path` folder it is used by default when `filters` argument is not specified. Pass `filters=none` if you don’t want default filters to be applied.

To learn about Adblock Plus filter syntax check these links:

Splash doesn’t support full Adblock Plus filters syntax, there are some limitations:

- element hiding rules are not supported; filters can prevent network request from happening, but they can’t hide parts of an already loaded page;
Splash supports “proxy profiles” that allows to set proxy handling rules per-request using `proxy` parameter.

To enable proxy profiles support, run splash server with `--proxy-profiles-path=<path to a folder with proxy profiles>` option:

```
python -m splash.server --proxy-profiles-path=/etc/splash/proxy-profiles
```

Note: If you run Splash using Docker, check `Folders Sharing`.

Then create an INI file with “proxy profile” config inside the specified folder, e.g. `/etc/splash/proxy-profiles/mywebsite.ini`. Example contents of this file:

```
[proxy]
host=proxy.crawlera.com
port=8010

[rules]
whitelist=.*/mywebsite\.com.*

blacklist=.*/\js.*
.*\.css.*
.*\.png
```

whitelist and blacklist are newline-separated lists of regexes. If URL matches one of whitelist patterns and matches none of blacklist patterns, proxy specified in [proxy] section is used; no proxy is used otherwise.

Then, to apply proxy rules according to this profile, add `proxy=mywebsite` parameter to request:

```
```
If `default.ini` profile is present, it will be used when `proxy` argument is not specified. If you have `default.ini` profile but don’t want to apply it pass `none` as `proxy` value.

### 1.2.9 Splash as a Proxy

Splash supports working as HTTP proxy. In this mode all the HTTP requests received will be proxied and the response will be rendered based in the following HTTP headers:

- **X-Splash-render** [string][required] The render mode to use, valid modes are: html, png and json. These modes have the same behavior as the endpoints: `render.html`, `render.png` and `render.json` respectively.
- **X-Splash-js-source** [string] Allow to execute custom javascript code in page context. See *Executing custom Javascript code within page context*.
- **X-Splash-js** [string] Same as `js` argument for `render.html`. See *Javascript Profiles*.
- **X-Splash-timeout** [string] Same as `timeout` argument for `render.html`.
- **X-Splash-wait** [string] Same as `wait` argument for `render.html`.
- **X-Splash-proxy** [string] Same as `proxy` argument for `render.html`.
- **X-Splash-filters** [string] Same as `filters` argument for `render.html`.
- **X-Splash-allowed-domains** [string] Same as `allowed_domains` argument for `render.html`.
- **X-Splash-viewports** [string] Same as `viewports` argument for `render.html`.
- **X-Splash-images** [string] Same as `images` argument for `render.html`.
- **X-Splash-width** [string] Same as `width` argument for `render.png`.
- **X-Splash-height** [string] Same as `height` argument for `render.png`.
- **X-Splash-render-all** [string] Same as `render_all` argument for `render.png`.
- **X-Splash-scale-method** [string] Same as `scale_method` argument for `render.png`.
- **X-Splash-html** [string] Same as `html` argument for `render.json`.
- **X-Splash-png** [string] Same as `png` argument for `render.json`.
- **X-Splash-iframes** [string] Same as `iframes` argument for `render.json`.
- **X-Splash-script** [string] Same as `script` argument for `render.json`.
- **X-Splash-console** [string] Same as `console` argument for `render.json`.
- **X-Splash-history** [string] Same as `history` argument for `render.json`.
- **X-Splash-har** [string] Same as `har` argument for `render.json`.

**Note:** Proxying of HTTPS requests is not supported.

Curl examples:

```bash
# Display json stats
curl -x localhost:8051 -H 'X-Splash-render: json' \   http://www.domain.com

# Get the html page and screenshot
curl -x localhost:8051 \   -H "X-Splash-render: json" \   -H "X-Splash-html: 1"
```
# Splash Scripts Tutorial

**Warning:** Scripting support is an experimental feature for early adopters; API could change in future releases.

## 1.3.1 Intro

Splash can execute custom rendering scripts written in Lua programming language. This allows to use Splash as a browser automation tool similar to PhantomJS.

To execute a script and get the result back send it to `execute` endpoint in a `lua_source` argument.

**Note:** Most likely you’ll be able to follow Splash scripting examples even without knowing Lua. Nevertheless, the language worths learning - with Lua you can, for example, write Redis, Nginx, Apache, World of Warcraft scripts, create mobile apps using Moai or Corona SDK or use state of the arts Deep Learning framework Torch7. It is easy to get started and there are good online resources available like Learn Lua in 15 minutes tutorial and Programming in Lua book.

Let’s start with a basic example:

```lua
function main(splash)
  splash:go("http://example.com")
  splash:wait(0.5)
  local title = splash:evaljs("document.title")
  return {title=title}
end
```

If we submit this script to `execute` endpoint in a `lua_source` argument, Splash will go to example.com website, wait until it loads, then wait 0.5s more, then get page title (by evaluating a JavaScript snippet in page context), and then return the result as a JSON encoded object.
1.3.2 Entry Point: the “main” Function

The script must provide “main” function; this function is called by Splash. The result of this function is returned as an HTTP response. Script could contain other helper functions and statements, but ‘main’ is required.

In the first example ‘main’ function returned a Lua table (an associative array similar to JavaScript Object or Python dict). Such results are returned as JSON. This will return {"hello":"world!"} string as an HTTP response:

```
function main(splash)
  return {hello="world!"}
end
```

Script can also return a string:

```
function main(splash)
  return 'hello'
end
```

Strings are returned as-is (unlike tables they are not encoded to JSON). Let’s check it with curl:

```
$ curl 'http://127.0.0.1:8050/execute?lua_source=function+main%28splash%29+return+%27hello%27+end'
```

“main” function receives an object that allows to control the “browser tab”. All Splash features are exposed using this object. By a convention, this argument is called “splash”, but you are not required to follow this convention:

```
function main(please)
  please:go("http://example.com")
  please:wait(0.5)
  return "ok"
end
```

1.3.3 Where Are My Callbacks?

Here is a part of the first example:

```
splash:go("http://example.com")
splash:wait(0.5)
local title = splash:evaljs("document.title")
```

The code looks like a standard procedural code; there are no callbacks or fancy control flow structures. It doesn’t mean Splash works in a synchronous way; under the hood it is still async. When you call `splash.wait(0.5)`, Splash switches from the script to other tasks, and comes back after 0.5s.

It is possible to use loops, conditional statements, functions as usual in Splash scripts; this enables a more straightforward code.

Let’s check an example PhantomJS script:

```
var users = ["PhantomJS", "ariyahidayat", /*...*/];

function followers(user, callback) {
  var page = require("webpage").create();
  page.open('http://mobile.twitter.com/' + user, function (status) {
```
if (status === 'fail') {
    console.log(user + ': ?');
} else {
    var data = page.evaluate(function () {
        return document.querySelector('div.profile td.stat.stat-last div.statnum').innerText;
    });
    console.log(user + ': ' + data);
}
page.close();
callback.apply();
}

function process() {
    if (users.length > 0) {
        var user = users[0];
        users.splice(0, 1);
        followers(user, process);
    } else {
        phantom.exit();
    }
}
process();

The code is arguably tricky: process function implements a loop by creating a chain of callbacks; followers function doesn’t return a value (it would be more complex to implement) - the result is logged to the console instead.

A similar Splash script:

users = {'PhantomJS', 'ariyahidayat'}

function followers(splash, user)
    local ok, msg = splash:go('http://mobile.twitter.com/' .. user)
    if not ok then
        return "?"
    end
    return splash:evaljs([[
        document.querySelector('div.profile td.stat.stat-last div.statnum').innerText;
    ]]);
end

function process(splash, users)
    local result = {}
    for idx, user in ipairs(users) do
        result[user] = followers(splash, user)
    end
    return result
end

function main(splash)
    local users = process(splash, users)
    return {users=users}
end

Observations:

- some Lua knowledge is helpful to be productive in Splash Scripts: ipairs, [[multi-line strings]] or string concatenation via .. could be unfamiliar;
- in Splash variant followers function can return a result (a number of twitter followers); also, it doesn’t need a “callback” argument;
• instead of a `page.open` callback which receives “status” argument there is a “blocking” `splash:go` call which returns “ok” flag;

• error handling is different: in case of an HTTP 4xx or 5xx error PhantomJS doesn’t return an error code to `page.open` callback - example script will try to get the followers nevertheless because “status” won’t be “fail”; in Splash this error will be detected and “?” will be returned;

• `process` function can use a standard Lua `for` loop without a need to create a recursive callback chain;

• instead of console messages we’ve got a JSON HTTP API;

• apparently, PhantomJS allows to create multiple `page` objects and run several `page.open` requests in parallel (?). Splash only provides a single “browser tab” to a script via its `splash` parameter of `main` function (but you’re free to send multiple concurrent requests with Lua scripts to Splash).

There are great PhantomJS wrappers like CasperJS and NightmareJS which (among other things) bring a sync-looking syntax to PhantomJS scripts by providing custom control flow mini-languages. However, they all have their own gotchas and edge cases (loops? moving code to helper functions? error handling?). Splash scripts are standard Lua code.

**Note:** PhantomJS itself and its wrappers are great, they deserve lots of respect; please don’t take this writeup as an attack on them. These tools are much more mature and feature complete than Splash. Splash tries to look at the problem from a different angle, but for each unique Splash feature there are ten unique PhantomJS features.

### 1.3.4 Living Without Callbacks

**Note:** For the curious, Splash uses Lua coroutines under the hood.

In Splash scripts it is not explicit which calls are async and which calls are blocking. It is a common criticism of coroutines/greenlets; check e.g. this article for a good description of the problem. However, we feel that in Splash scripts negative effects are not quite there: scripts are meant to be small, shared state is minimized, and an API is designed to execute a single command at time, so in most cases the control flow is linear.

If you want to be safe then think of all `splash` methods as of async; consider that after you call `splash:foo()` a webpage being rendered can change. Often that’s the point of calling a method, e.g. `splash:wait(time)` or `splash:go(url)` only make sense because webpage changes after calling them, but still - keep it in mind.

There are async methods like `splash:go`, `splash:wait`, `splash:wait_for_resume`, etc.; most splash methods are currently not async, but thinking of them as of async will allow your scripts to work if we ever change that.

### 1.3.5 Calling Splash Methods

Unlike many languages, in Lua methods are usually separated from an object using a colon `:`; to call “foo” method of “splash” object use `splash:foo()` syntax. See [http://www.lua.org/pil/16.html](http://www.lua.org/pil/16.html) for more details.

There are two main ways to call Lua methods in Splash scripts: using positional and named arguments. To call a method using positional arguments use parentheses `splash:foo(val1, val2)`, to call it with named arguments use curly braces: `splash:foo(name1=val1, name2=val2):

```lua
-- Examples of positional arguments:
splash:go("http://example.com")
splash:wait(0.5, false)
local title = splash:evaljs("document.title")
```
-- The same using keyword arguments:
splash:go(url="http://example.com")
splash:wait(time=0.5, cancel_on_redirect=false)
local title = splash:evaljs(source="document.title")

-- Mixed arguments example:
splash:wait(0.5, cancel_on_redirect=false)

For the convenience all splash methods are designed to support both styles of calling. But note that generally this convention is not followed in Lua. There are no “real” named arguments in Lua, and most Lua functions (including the ones from the standard library) choose to support only one style of calling. Check http://www.lua.org/pil/5.3.html for more info.

1.3.6 Error Handling

There are two ways to report errors in Lua: raise an exception and return an error flag. See http://www.lua.org/pil/8.3.html.

Splash uses the following convention:

1. for developer errors (e.g. incorrect function arguments) exception is raised;
2. for errors outside developer control (e.g. a non-responding remote website) status flag is returned: functions that can fail return ok, reason pairs which developer can either handle or ignore.

If main results in an unhandled exception then Splash returns HTTP 400 response with an error message.

It is possible to raise an exception manually using Lua error function:

error("A message to be returned in a HTTP 400 response")

To handle Lua exceptions (and prevent Splash from returning HTTP 400 response) use Lua pcall; see http://www.lua.org/pil/8.4.html.

To convert “status flag” errors to exceptions Lua assert function can be used. For example, if you expect a website to work and don’t want to handle errors manually, then assert allows to stop processing and return HTTP 400 if the assumption is wrong:

local ok, msg = splash:go("http://example.com")
if not ok then
    -- handle error somehow, e.g.
    error(msg)
end

-- a shortcut for the code above: use assert
assert(splash:go("http://example.com"))

1.3.7 Sandbox

By default Splash scripts are executed in a restricted environment: not all standard Lua modules and functions are available, Lua require is restricted, and there are resource limits (quite loose though).

To disable the sandbox start Splash with --disable-lua-sandbox option:

$ python -m splash.server --disable-lua-sandbox
1.3.8 Custom Lua Modules

Splash provides a way to use custom Lua modules (stored on server) from scripts passed via HTTP API. This allows to

1. reuse code without sending it over network again and again;
2. use third-party Lua modules;
3. implement features which need unsafe code and expose them safely in a sandbox.

Note: To learn about Lua modules check e.g. http://lua-users.org/wiki/ModulesTutorial. Please prefer “the new way” of writing modules because it plays better with a sandbox. A good Lua modules style guide can be found here: http://hisham.hm/2014/01/02/how-to-write-lua-modules-in-a-post-module-world/

Setting Up

To use custom Lua modules, do the following steps:

1. setup the path for Lua modules and add your modules there;
2. tell Splash which modules are enabled in a sandbox;
3. use Lua require function from a script to load a module.

To setup the path for Lua modules start Splash with --lua-package-path option. --lua-package-path value should be a semicolon-separated list of places where Lua looks for modules. Each entry should have a ? in it that’s replaced with the module name.

Example:

$ python -m splash.server --lua-package-path "/etc/splash/lua_modules/?.lua;/home/myuser/splash-modules/?.lua"

Note: If you use Splash installed using Docker see Folders Sharing for more info on how to setup paths.

Note: For the curious: --lua-package-path value is added to Lua package.path.

When you use a Lua sandbox (default) Lua require function is restricted when used in scripts: it only allows to load modules from a whitelist. This whitelist is empty by default, i.e. by default you can require nothing. To make your modules available for scripts start Splash with --lua-sandbox-allowed-modules option. It should contain a semicolon-separated list of Lua module names allowed in a sandbox:

$ python -m splash.server --lua-sandbox-allowed-modules "foo;bar" --lua-package-path "/etc/splash/lua_modules/?.lua"

After that it becomes possible to load these modules from Lua scripts using require:

```lua
local foo = require("foo")
function main(splash)
  return {result=foo.myfunc()}
end
```

Writing Modules

A basic module could look like the following:
-- mymodule.lua
local mymodule = {

    function mymodule:hello(name)
        return "Hello, " .. name
    end

    return mymodule

} -- mymodule.lua

Usage in a script:
local mymodule = require("mymodule")

function main(splash)
    return mymodule.hello("world!")
end

Many real-world modules will likely want to use splash object. There are several ways to write such modules. The simplest way is to use functions that accept splash as an argument:

-- utils.lua
local utils = {

    function utils:wait_for(splash, condition)
        while not condition() do
            splash:wait(0.05)
        end
    end

    return utils

} -- utils.lua

Usage:
local utils = require("utils")

function main(splash)
    splash:go(splash.args.url)
    -- wait until <h1> element is loaded
    utils:wait_for(splash, function()
        return splash:evaljs("document.querySelector('h1') != null")
    end)
    return splash:html()
end

Another way to write such module is to add a method to splash object. This can be done by adding a method to its Splash class - the approach is called “open classes” in Ruby or “monkey-patching” in Python.

-- wait_for.lua

    local Splash = require("splash")

    function Splash:wait_for(condition)
        while not condition() do
            self:wait(0.05)
        end
    end
Usage:

```lua
require("wait_for")

function main(splash)
    splash:go(splash.args.url)

    -- wait until <h1> element is loaded
    splash:wait_for(function()
        return splash:evaljs("document.querySelector('h1') != null")
    end)

    return splash:html()
end
```

Which style to prefer is up to the developer. Functions are more explicit and composable, monkey patching enables a more compact code. Either way, `require` is explicit.

As seen in a previous example, sandbox restrictions for standard Lua modules and functions are not applied in custom Lua modules, i.e. you can use all the Lua powers. This makes it possible to import third-party Lua modules and implement advanced features, but requires developer to be careful. For example, let’s use `os` module:

```lua
-- evil.lua
local os = require("os")
local evil = {}

function evil.sleep()
    -- Don’t do this! It blocks the event loop and has a startup cost.
    -- splash:wait is there for a reason.
    os.execute("sleep 2")
end

function evil.touch(filename)
    -- another bad idea
    os.execute("touch " .. filename)
end

-- todo: rm -rf /

return evil
```

### 1.3.9 Timeouts

By default Splash aborts script execution after the timeout (30s by default). To override the timeout value use `timeout` argument of the `/execute` endpoint.

Note that the maximum allowed `timeout` value is limited by the maximum timeout setting, which is by default 60 seconds. In other words, by default you can’t pass `?timeout=300` to run a long script - an error will be returned. It is quite typical for scripts to work longer than 60s, so if you use Splash scripts it is recommended to explicitly set the maximum possible timeout by starting Splash with `--max-timeout` command line option:

```
$ python -m splash.server --max-timeout 3600
```
Note: See *Passing Custom Options* if you use Docker to run Splash.

## 1.4 Splash Scripts Reference

**Warning:** Scripting support is an experimental feature for early adopters; API could change in future releases.

splash object is passed to main function; via this object a script can control the browser. Think of it as of an API to a single browser tab.

### 1.4.1 splash:go

Go to an URL. This is similar to entering an URL in a browser address bar, pressing Enter and waiting until page loads.

**Signature:** \( \text{ok}, \text{reason} = \text{splash:go}(\text{url}, \text{baseurl}=\text{nil}, \text{headers}=\text{nil}) \)

**Parameters:**
- \text{url} - URL to load;
- \text{baseurl} - base URL to use, optional. When \text{baseurl} argument is passed the page is still loaded from \text{url}, but it is rendered as if it was loaded from \text{baseurl}; relative resource paths will be relative to \text{baseurl}, and the browser will think \text{baseurl} is in address bar;
- \text{headers} - a Lua table with HTTP headers to add/replace in the initial request.

**Returns:** \( \text{ok}, \text{reason} \) pair. If \text{ok} is nil then error happened during page load; \text{reason} provides an information about error type.

**Async:** yes, unless the navigation is locked.

Three types of errors are reported (\text{ok} can be \text{nil} in 3 cases):

1. There is nothing to render. This can happen if a host doesn’t exist, server dropped connection, etc. In this case \text{reason} is "error".
2. Server returned a response with 4xx or 5xx HTTP status code. \text{reason} is "http<code>" in this case, i.e. for HTTP 404 Not Found \text{reason} is "http404".
3. Navigation is locked (see splash:lock_navigation); \text{reason} is "navigation_locked".

**Error handling example:**

```lua
local ok, reason = splash:go("http://example.com")
if not ok then
    if reason:sub(0,4) == ’http’ then
        -- handle HTTP errors
    else
        -- handle other errors
    end
end
-- process the page

-- assert can be used as a shortcut for error handling
assert(splash:go("http://example.com"))
```
Errors (ok==nil) are only reported when “main” webpage request failed. If a request to a related resource failed then no error is reported by splash:go. To detect and handle such errors (e.g. broken image/js/css links, ajax requests failed to load) use splash:har.

splash:go follows all HTTP redirects before returning the result, but it doesn’t follow HTML <meta http-equiv="refresh" ...> redirects or redirects initiated by JavaScript code. To give the webpage time to follow those redirects use splash:wait.

headers argument allows to add or replace default HTTP headers for the initial request. To set custom headers for all further requests (including requests to related resources) use splash:set_custom_headers or splash:on_request.

Custom headers example:

```lua
local ok, reason = splash:go("http://example.com", headers={
    ["Custom-Header"] = "Header Value",
})
```

User-Agent header is special: once used, it is kept for further requests. This is an implementation detail and it could change in future releases; to set User-Agent header it is recommended to use splash:set_user_agent method.

### 1.4.2 splash:wait

Wait for time seconds. When script is waiting WebKit continues processing the webpage.

**Signature:**

```lua
ok, reason = splash:wait(time, cancel_on_redirect=false, cancel_on_error=true)
```

**Parameters:**

- `time` - time to wait, in seconds;
- `cancel_on_redirect` - if true (not a default) and a redirect happened while waiting, then splash:wait stops earlier and returns nil, "redirect". Redirect could be initiated by <meta http-equiv="refresh" ...> HTML tags or by JavaScript code.
- `cancel_on_error` - if true (default) and an error which prevents page from being rendered happened while waiting (e.g. an internal WebKit error or a network error like a redirect to a non-resolvable host) then splash:wait stops earlier and returns nil, "error".

**Returns:** `ok`, `reason` pair. If `ok` is nil then the timer was stopped prematurely, and `reason` contains a string with a reason. Possible reasons are "error" and "redirect".

**Async:** yes.

**Usage example:**

```lua
-- go to example.com, wait 0.5s, return rendered html, ignore all errors.
function main(splash)
    splash:go("http://example.com")
    splash:wait(0.5)
    return {html=splash:html()}
end
```

By default wait timer continues to tick when redirect happens. `cancel_on_redirect` option can be used to restart the timer after each redirect. For example, here is a function that waits for a given time after each page load in case of redirects:

```lua
function wait_restarting_on_redirects(splash, time, max_redirects)
    local redirects_remaining = max_redirects
    while redirects_remaining do
        local ok, reason = self:wait(time=time, cancel_on_redirect=true)
```

---

**1.4. Splash Scripts Reference**

---
if reason ~= ‘redirect’ then
    return ok, reason
end
redirects_remaining = redirects_remaining - 1
end
return nil, "too_many_redirects"

1.4.3 splash:jsfunc

Convert JavaScript function to a Lua callable.

Signature: lua_func = splash:jsfunc(func)

Parameters:
  • func - a string which defines a JavaScript function.

Returns: a function that can be called from Lua to execute JavaScript code in page context.

Async: no.

Example:

function main(splash)
    local get_div_count = splash:jsfunc([[function ()
        var body = document.body;
        var divs = body.getElementsByTagName(‘div’);
        return divs.length;
    ]])

    splash:go(splash.args.url)
    return get_div_count()
end

Note how Lua `[[ ]]` string syntax is helpful here.

JavaScript functions may accept arguments:

local vec_len = splash:jsfunc([[function(x, y) {
    return Math.sqrt(x*x + y*y)
}]])
return {res=vec_len(5, 4)}

Global JavaScript functions can be wrapped directly:

local pow = splash:jsfunc("Math.pow")
local twenty_five = pow(5, 2)  -- 5^2 is 25
local thousand = pow(10, 3)  -- 10^3 is 1000

Lua strings, numbers, booleans and tables can be passed as arguments; they are converted to JS strings/numbers/booleans/objects. Currently it is not possible to pass other Lua objects. For example, it is not possible to pass a wrapped JavaScript function or a regular Lua function as an argument to another wrapped JavaScript function.

Lua → JavaScript conversion rules:
Function result is converted from JavaScript to Lua data type. Only simple JS objects are supported. For example, returning a function or a JQuery selector from a wrapped function won’t work. JavaScript → Lua conversion rules:

<table>
<thead>
<tr>
<th>JavaScript</th>
<th>Lua</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>string</td>
</tr>
<tr>
<td>number</td>
<td>number</td>
</tr>
<tr>
<td>boolean</td>
<td>boolean</td>
</tr>
<tr>
<td>Object</td>
<td>table</td>
</tr>
<tr>
<td>Array</td>
<td>table</td>
</tr>
<tr>
<td>undefined</td>
<td>nil</td>
</tr>
<tr>
<td>null</td>
<td>&quot;&quot; (an empty string)</td>
</tr>
<tr>
<td>Date</td>
<td>string: date’s ISO8601 representation, e.g. 1958-05-21T10:12:00Z</td>
</tr>
<tr>
<td>RegExp</td>
<td>table {_jstype='RegExp', caseSensitive=true/false, pattern='my-regexp'}</td>
</tr>
<tr>
<td>function</td>
<td>an empty table {} (don’t rely on it)</td>
</tr>
</tbody>
</table>

Function arguments and return values are passed by value. For example, if you modify an argument from inside a JavaScript function then the caller Lua code won’t see the changes, and if you return a global JS object and modify it in Lua then object won’t be changed in webpage context.

Note: The rule of thumb: if an argument or a return value can be serialized via JSON, then it is fine.

If a JavaScript function throws an error, it is re-thrown as a Lua error. To handle errors it is better to use JavaScript try/catch because some of the information about the error can be lost in JavaScript → Lua conversion.

See also: `splash:runjs`, `splash:evaljs`, `splash:wait_for_resume`, `splash:autoload`.

### 1.4.4 splash:evaljs

Execute a JavaScript snippet in page context and return the result of the last statement.

**Signature:** `result = splash:evaljs(snippet)`

**Parameters:**
- `snippet` - a string with JavaScript source code to execute.

**Returns:** the result of the last statement in `snippet`, converted from JavaScript to Lua data types. In case of syntax errors or JavaScript exceptions an error is raised.

**Async:** no.

JavaScript → Lua conversion rules are the same as for `splash:jsfunc`.

`splash:evaljs` is useful for evaluation of short JavaScript snippets without defining a wrapper function. Example:

```lua
local title = splash:evaljs("document.title")
```

Don’t use `splash:evaljs` when the result is not needed - it is inefficient and could lead to problems; use `splash:runjs` instead. For example, the following innocent-looking code (using jQuery) may fail:
splash:evaljs("$(console.log('foo'));")

A gotcha is that to allow chaining jQuery `$` function returns a huge object, `splash:evaljs` tries to serialize it and convert to Lua. It is a waste of resources, and it could trigger internal protection measures; `splash:runjs` doesn’t have this problem.

If the code you’re evaluating needs arguments it is better to use `splash:jsfunc` instead of `splash:evaljs` and string formatting. Compare:

```
function main(splash)
    local font_size = splash:jsfunc([[
        function(sel) {
            var el = document.querySelector(sel);
            return getComputedStyle(el)["font-size"];  
        }
    ]])

    local font_size2 = function(sel)
        -- FIXME: escaping of 'sel' parameter!
        local js = string.format([[  
            var el = document.querySelector("%s");
            getComputedStyle(el)["font-size"]
        ]], sel)
        return splash:evaljs(js)
    end

    -- ...
end
```

See also: `splash:runjs`, `splash:jsfunc`, `splash:wait_for_resume`, `splash:autoload`.

### 1.4.5 `splash:runjs`

Run JavaScript code in page context.

**Signature:** `ok, error = splash:runjs(snippet)`

**Parameters:**

- `snippet` - a string with JavaScript source code to execute.

**Returns:** `ok, error` pair. When the execution is successful `ok` is True. In case of JavaScript errors `ok` is `nil`, and `error` contains the error string.

**Async:** no.

Example:

```
assert(splash:runjs("document.title = 'hello';"))
```

Note that JavaScript functions defined using `function foo(){}` syntax won’t be added to the global scope:

```
assert(splash:runjs("function foo(){return 'bar'}"))
local res = splash:evaljs("foo()") -- this raises an error
```

It is an implementation detail: the code passed to `splash:runjs` is executed in a closure. To define functions use global variables, e.g.:
assert(splash:runjs("foo = function (){return 'bar'}"))
local res = splash:evaljs("foo()") -- this returns 'bar'

If the code needs arguments it is better to use splash:jsfunc. Compare:

```lua
function main(splash)
    -- Lua function to scroll window to (x, y) position.
    function scroll_to(x, y)
        local js = string.format(
            "window.scrollTo(%s, %s);",
            tonumber(x),
            tonumber(y)
        )
        assert(splash:runjs(js))
    end
    -- a simpler version using splash:jsfunc
    local scroll_to2 = splash:jsfunc("window.scrollTo")
    -- ...
end
```

See also: splash:runjs, splash:jsfunc, splash:autoload, splash:wait_for_resume.

**1.4.6 splash:wait_for_resume**

Run asynchronous JavaScript code in page context. The Lua script will yield until the JavaScript code tells it to resume.

**Signature:** result, error = splash:wait_for_resume(snippet, timeout)

**Parameters:**

- snippet - a string with a JavaScript source code to execute. This code must include a function called main. The first argument to main is an object that has the properties `resume` and `error`. `resume` is a function which can be used to resume Lua execution. It takes an optional argument which will be returned to Lua in the `result.value` return value. `error` is a function which can be called with a required string value that is returned in the `error` return value.
- timeout - a number which determines (in seconds) how long to allow JavaScript to execute before forceably returning control to Lua. Defaults to zero, which disables the timeout.

**Returns:** result, error pair. When the execution is successful result is a table. If the value returned by JavaScript is not undefined, then the result table will contain a key `value` that has the value passed to splash.resume(...). The result table also contains any additional key/value pairs set by splash.set(...). In case of timeout or JavaScript errors result is nil and error contains an error message string.

**Async:** yes.

**Examples:**

The first, trivial example shows how to transfer control of execution from Lua to JavaScript and then back to Lua. This command will tell JavaScript to sleep for 3 seconds and then return to Lua. Note that this is an async operation: the Lua event loop and the JavaScript event loop continue to run during this 3 second pause, but Lua will not continue executing the current function until JavaScript calls splash.resume().
function main(splash)

    local result, error = splash:wait_for_resume(
        function main(splash) {
            setTimeout(function () {
                splash.resume();
                }, 3000);
            }
    })

    -- result is {}
    -- error is nil

end

result is set to an empty table to indicate that nothing was returned from splash.resume. You can use assert(splash:wait_for_resume(...)) even when JavaScript does not return a value because the empty table signifies success to assert().

Note: Your JavaScript code must contain a main() function. You will get an error if you do not include it. The first argument to this function can have any name you choose, of course. We will call it splash by convention in this documentation.

The next example shows how to return a value from JavaScript to Lua. You can return booleans, numbers, strings, arrays, or objects.

function main(splash)

    local result, error = splash:wait_for_resume(
        function main(splash) {
            setTimeout(function () {
                splash.resume([1, 2, 'red', 'blue']);
                }, 3000);
            }
    })

    -- result is {value=[1, 2, 'red', 'blue']}
    -- error is nil

end

Note: As with splash:evaljs, be wary of returning objects that are too large, such as the $ object in jQuery, which will consume a lot of time and memory to convert to a Lua result.

You can also set additional key/value pairs in JavaScript with the splash.set(key, value) function. Key/value pairs will be included in the result table returned to Lua. The following example demonstrates this.

function main(splash)

    local result, error = splash:wait_for_resume(
        function main(splash) {
            setTimeout(function () {
                splash.set("foo", "bar");
                splash.resume("ok");
                }, 3000);
            }
    })

end
The next example shows an incorrect usage of `splash:wait_for_resume()`: the JavaScript code does not contain a `main()` function. `result` is `nil` because `splash.resume()` is never called, and `error` contains an error message explaining the mistake.

```lua
function main(splash)
  local result, error = splash:wait_for_resume({
    console.log('hello!');
  })
  -- result is nil
  -- error is "error: wait_for_resume(): no main() function defined"
end
```

The next example shows error handling. If `splash.error(...)` is called instead of `splash.resume()`, then `result` will be `nil` and `error` will contain the string passed to `splash.error(...).
```
function main(splash)
  local result, error = splash:wait_for_resume({
    function main(splash)
      setTimeout(function () {
        splash.error("Goodbye, cruel world!");
      }, 3000);
    },
  })
  -- result is nil
  -- error is "error: Goodbye, cruel world!"
end
```

Your JavaScript code must either call `splash.resume()` or `splash.error()` exactly one time. Subsequent calls to either function have no effect, as shown in the next example.
```
function main(splash)
  local result, error = splash:wait_for_resume({
    function main(splash)
      setTimeout(function () {
        splash.resume("ok");
        splash.resume("still ok");
        splash.error("not ok");
      }, 3000);
    },
  })
  -- result is {value="ok"}
  -- error is nil
end
```

The next example shows the effect of the `timeout` argument. We have set the `timeout` argument to
1 second, but our JavaScript code will not call `splash.resume()` for 3 seconds, which guarantees that `splash:wait_for_resume()` will time out.

When it times out, `result` will be nil, `error` will contain a string explaining the timeout, and Lua will continue executing. Calling `splash.resume()` or `splash.error()` after a timeout has no effect.

```lua
function main(splash)
    local result, error = splash:wait_for_resume([], 1)
    -- result is nil
    -- error is "error: One shot callback timed out while waiting for resume() or error()."
end
```

**Note:** The timeout must be >= 0. If the timeout is 0, then `splash:wait_for_resume()` will never timeout (although Splash’s HTTP timeout still applies).

Note that your JavaScript code is not forcefully canceled by a timeout: it may continue to run until Splash shuts down the entire browser context.

See also: `splash:runjs`, `splash:jsfunc`, `splash:evaljs`.

### 1.4.7 `splash:autoload`

Set JavaScript to load automatically on each page load.

**Signature:** `ok, reason = splash:autoload(source_or_url, source=nil, url=nil)`

**Parameters:**
- `source_or_url` - either a string with JavaScript source code or an URL to load the JavaScript code from;
- `source` - a string with JavaScript source code;
- `url` - an URL to load JavaScript source code from.

**Returns:** `ok, reason` pair. If `ok` is nil, error happened and `reason` contains an error description.

**Async:** yes, but only when an URL of a remote resource is passed.

`splash:autoload` allows to execute JavaScript code at each page load. `splash:autoload` doesn’t doesn’t execute the passed JavaScript code itself. To execute some code once, after page is loaded use `splash:runjs` or `splash:jsfunc`.

`splash:autoload` can be used to preload utility JavaScript libraries or replace JavaScript objects before a webpage has a chance to do it.

**Example:**

```lua
function main(splash)
    splash:autoload([[
        function get_document_title()
            return document.title;
        }
    ]])
end
```
assert(splash:go(splash.args.url))
return splash:evaljs("get_document_title()")
end

For the convenience, when a first splash:autoload argument starts with "http://" or "https://" a script from the passed URL is loaded. Example 2 - make sure a remote library is available:

function main(splash)
  assert(splash:autoload("https://code.jquery.com/jquery-2.1.3.min.js"))
  assert(splash:go(splash.args.url))
  return splash:evaljs("$.fn.jquery") -- return jQuery version
end

To disable URL auto-detection use 'source' and 'url' arguments:

splash:autoload(url="https://code.jquery.com/jquery-2.1.3.min.js")
splash:autoload(source="window.foo = 'bar';")

It is a good practice not to rely on auto-detection when the argument is not a constant.

If splash:autoload is called multiple times then all its scripts are executed on page load, in order they were added.

See also: splash:evaljs, splash:runjs, splash:jsfunc, splash:wait_for_resume.

1.4.8 splash:http_get

Send an HTTP request and return a response without loading the result to the browser window.

Signature: response = splash:http_get(url, headers=nil, follow_redirects=true)

Parameters:

• url - URL to load;
• headers - a Lua table with HTTP headers to add/replace in the initial request;
• follow_redirects - whether to follow HTTP redirects.

Returns: a Lua table with the response in HAR response format.

Async: yes.

Example:

local reply = splash:http_get("http://example.com")
-- reply.content.text contains raw HTML data
-- reply.status contains HTTP status code, as a number
-- see HAR docs for more info

In addition to all HAR fields the response contains “ok” flag which is true for successful responses and false when error happened:

local reply = splash:http_get("some-bad-url")
-- reply.ok == false

This method doesn’t change the current page contents and URL. To load a webpage to the browser use splash:go.

1.4.9 splash:set_content

Set the content of the current page and wait until the page loads.
Signature: \( \text{ok, reason} = \text{splash}:\text{set\_content}\{\text{data, mime\_type="text/html; charset=utf-8", baseurl=""}\} \)

Parameters:
- data - new page content;
- mime\_type - MIME type of the content;
- baseurl - external objects referenced in the content are located relative to baseurl.

Returns: \( \text{ok, reason} \) pair. If \( \text{ok} \) is nil then error happened during page load; \( \text{reason} \) provides an information about error type.

Async: yes.

Example:

```lua
function main(splash)
  assert(splash:set_content("<html><body><h1>hello</h1></body></html>"))
  return splash:png()
end
```

### 1.4.10 splash:html

Return a HTML snapshot of a current page (as a string).

Signature: \( \text{html} = \text{splash}:\text{html}() \)

Returns: contents of a current page (as a string).

Async: no.

Example:

```lua
-- A simplistic implementation of render.html endpoint
function main(splash)
  splash:set_result_content_type("text/html; charset=utf-8")
  assert(splash:go(splash.args.url))
  return splash:html()
end
```

Nothing prevents us from taking multiple HTML snapshots. For example, let’s visit first 10 pages on a website, and for each page store initial HTML snapshot and an HTML snapshot after waiting 0.5s:

```lua
-- Given an url, this function returns a table with
-- two HTML snapshots: HTML right after page is loaded,
-- and HTML after waiting 0.5s.
function page_info(splash, url)
  local ok, msg = splash:go(url)
  if not ok then
    return {ok=false, reason=msg}
  end
  local res = {before=splash:html()}
  assert(splash:wait(0.5)) -- this shouldn’t fail, so we wrap it in assert
  res.after = splash:html() -- the same as res["after"] = splash:html()
  res.ok = true
  return res
end

-- visit first 10 http://example.com/pages/<num> pages,
-- return their html snapshots
```
function main(splash)
    local result = {}
    for i=1,10 do
        local url = "http://example.com/pages/" .. page_num
        result[i] = page_info(splash, url)
    end
    return result
end

1.4.11 splash:png

Return a width x height screenshot of a current page in PNG format.

Signature:     png = splash:png{width=nil, height=nil, render_all=false, scale_method='raster'}

Parameters:

- width - optional, width of a screenshot in pixels;
- height - optional, height of a screenshot in pixels;
- render_all - optional, if true render the whole webpage;
- scale_method - optional, method to use when resizing the image, ‘raster’ or ‘vector’

Returns: PNG screenshot data.

Async: no.

Without arguments splash:png() will take a snapshot of the current viewport.

width parameter sets the width of the resulting image. If the viewport has a different width, the image is scaled up or down to match the specified one. For example, if the viewport is 1024px wide then splash:png(width=100) will return a screenshot of the whole viewport, but the image will be downscaled to 100px width.

height parameter sets the height of the resulting image. If the viewport has a different height, the image is trimmed or extended vertically to match the specified one without resizing the content. The region created by such extension is transparent.

To set the viewport size use splash:set_viewport_size, splash:set_viewport_full or render_all argument. render_all=true is equivalent to running splash:set_viewport_full() just before the rendering and restoring the viewport size afterwards.

scale_method parameter must be either ‘raster’ or ‘vector’. When scale_method=’raster’, the image is resized per-pixel. When scale_method=’vector’, the image is resized per-element during rendering. Vector scaling is more performant and produces sharper images, however it may cause rendering artifacts, so use it with caution.

If the result of splash:png() is returned directly as a result of “main” function, the screenshot is returned as binary data:

-- A simplistic implementation of render.png endpoint
function main(splash)
    splash:set_result_content_type("image/png")
    assert(splash:go(splash.args.url))
    return splash:png{
        width=splash.args.width,
        height=splash.args.height
    }
end
If the result of `splash:png()` is returned as a table value, it is encoded to base64 to make it possible to embed in JSON and build a data:uri on a client (magic!):

```lua
function main(splash)
    assert(splash:go(splash.args.url))
    return {png=splash:png()}
end
```

If your script returns the result of `splash:png()` in a top-level "png" key (as we’ve done in a previous example) then Splash UI will display it as an image.

### 1.4.12 splash:har

**Signature:** `har = splash:har()`

**Returns:** information about pages loaded, events happened, network requests sent and responses received in HAR format.

**Async:** no.

If your script returns the result of `splash:har()` in a top-level "har" key then Splash UI will give you a nice diagram with network information (similar to “Network” tabs in Firefox or Chrome developer tools):

```lua
function main(splash)
    assert(splash:go(splash.args.url))
    return {har=splash:har()}
end
```

### 1.4.13 splash:history

**Signature:** `entries = splash:history()`

**Returns:** information about requests/responses for the pages loaded, in HAR entries format.

**Async:** no.

`splash:history` doesn’t return information about related resources like images, scripts, stylesheets or AJAX requests. If you need this information use `splash:har`.

Let’s get a JSON array with HTTP headers of the response we’re displaying:

```lua
function main(splash)
    assert(splash:go(splash.args.url))
    local entries = splash:history()
    -- #entries means "entries length"; arrays in Lua start from 1
    local last_entry = entries[#entries]
    return {
        headers = last_entry.response.headers
    }
end
```

### 1.4.14 splash:url

**Signature:** `url = splash:url()`

**Returns:** the current URL.

**Async:** no.
1.4.15 splash:get_cookies

**Signature:** `cookies = splash:get_cookies()`

**Returns:** CookieJar contents - an array with all cookies available for the script. The result is returned in HAR cookies format.

**Async:** no.

Example result:

```lua
[
  {
    "name": "TestCookie",
    "value": "Cookie Value",
    "path": "/",
    "domain": "www.example.com",
    "expires": "2016-07-24T19:20:30+02:00",
    "httpOnly": false,
    "secure": false,
  }
]
```

1.4.16 splash:add_cookie

Add a cookie.

**Signature:** `cookies = splash:add_cookie{name, value, path=nil, domain=nil, expires=nil, httpOnly=nil, secure=nil}`

**Async:** no.

Example:

```lua
function main(splash)
  splash:add_cookie("sessionid", "237465ghgfsd", "/", domain="http://example.com")
  splash:go("http://example.com/")
  return splash:html()
end
```

1.4.17 splash:init_cookies

Replace all current cookies with the passed cookies.

**Signature:** `splash:init_cookies(cookies)`

**Parameters:**

- cookies - a Lua table with all cookies to set, in the same format as `splash:get_cookies` returns.

**Returns:** nil.

**Async:** no.

Example 1 - save and restore cookies:

```lua
local cookies = splash:get_cookies()
-- ... do something ...
splash:init_cookies(cookies) -- restore cookies
```
Example 2 - initialize cookies manually:

```lua
splash:init_cookies({
    {name="baz", value="egg"},
    {name="spam", value="egg", domain="example.com"},
    {name="foo",
     value="bar",
     path="/",
     domain="localhost",
     expires="2016-07-24T19:20:30+02:00",
     secure=true,
     httpOnly=true,
    }
})
```

```lua
-- do something
assert(splash:go("http://example.com"))
```

### 1.4.18 splash:clear_cookies

Clear all cookies.

**Signature:** `n_removed = splash:clear_cookies()`

**Returns:** a number of cookies deleted.

**Async:** no.

To delete only specific cookies use `splash:delete_cookies`.

### 1.4.19 splash:delete_cookies

Delete matching cookies.

**Signature:** `n_removed = splash:delete_cookies{name=nil, url=nil}`

**Parameters:**
- `name` - a string, optional. All cookies with this name will be deleted.
- `url` - a string, optional. Only cookies that should be sent to this url will be deleted.

**Returns:** a number of cookies deleted.

**Async:** no.

This function does nothing when both `name` and `url` are nil. To remove all cookies use `splash:clear_cookies` method.

### 1.4.20 splash:lock_navigation

Lock navigation.

**Signature:** `splash:lock_navigation()`

**Async:** no.

After calling this method the navigation away from the current page is no longer permitted - the page is locked to the current URL.
1.4.21 splash:unlock_navigation

Unlock navigation.

Signature: splash:unlock_navigation()

Async: no.

After calling this method the navigation away from the page becomes permitted. Note that the pending navigation requests suppressed by splash:lock_navigation won’t be reissued.

1.4.22 splash:set_result_content_type

Set Content-Type of a result returned to a client.

Signature: splash:set_result_content_type(content_type)

Parameters:

• content_type - a string with Content-Type header value.

Returns: nil.

Async: no.

If a table is returned by “main” function then splash:set_result_content_type has no effect: Content-Type of the result is set to application/json.

This function does not set Content-Type header for requests initiated by splash:go; this function is for setting Content-Type header of a result.

Example:

```lua
function main(splash)
    splash:set_result_content_type("text/xml")
    return 
        [[
            <note>
                <to>Tove</to>
                <from>Jani</from>
                <heading>Reminder</heading>
                <body>Don’t forget me this weekend!</body>
            </note>
        ]] 
end
```

1.4.23 splash:set_images_enabled

Enable/disable images.

Signature: splash:set_images_enabled(enabled)

Parameters:

• enabled - true to enable images, false to disable them.

Returns: nil.

Async: no.
By default, images are enabled. Disabling of the images can save a lot of network traffic (usually around ~50%) and make rendering faster. Note that this option can affect the JavaScript code inside page: disabling of the images may change sizes and positions of DOM elements, and scripts may read and use them.

Splash uses in-memory cache; cached images will be displayed even when images are disabled. So if you load a page, then disable images, then load a new page, then likely first page will display all images and second page will display some images (the ones common with the first page). Splash cache is shared between scripts executed in the same process, so you can see some images even if they are disabled at the beginning of the script.

Example:

```lua
function main(splash)
  splash:set_images_enabled(false)
  assert(splash:go("http://example.com"))
  return {png=splash:png()}
end
```

1.4.24 splash:get_viewport_size

Get the browser viewport size.

**Signature:** width, height = splash:get_viewport_size()

**Returns:** two numbers: width and height of the viewport in pixels.

**Async:** no.

1.4.25 splash:set_viewport_size

Set the browser viewport size.

**Signature:** splash:set_viewport_size(width, height)

**Parameters:**

- width - integer, requested viewport width in pixels;
- height - integer, requested viewport height in pixels.

**Returns:** nil.

**Async:** no.

This will change the size of the visible area and subsequent rendering commands, e.g., `splash:png`, will produce an image with the specified size.

`splash:png` uses the viewport size.

Example:

```lua
function main(splash)
  splash:set_viewport_size(1980, 1020)
  assert(splash:go("http://example.com"))
  return {png=splash:png()}
end
```

**Note:** This will relayout all document elements and affect geometry variables, such as `window.innerWidth` and `window.innerHeight`. However `window.onresize` event callback will only be invoked during the next asynchronous operation and `splash:png` is notably synchronous, so if you have resized a page and want it to react accordingly before taking the screenshot, use `splash:wait`. 
1.4.26 splash:set_viewport_full

Resize browser viewport to fit the whole page.

**Signature:** `width, height = splash:set_viewport_full()`

**Returns:** two numbers: width and height the viewport is set to, in pixels.

**Async:** no.

`splash:set_viewport_full` should be called only after page is loaded, and some time passed after that (use `splash:wait`). This is an unfortunate restriction, but it seems that this is the only way to make automatic resizing work reliably.

See `splash:set_viewport_size` for a note about interaction with JS.

`splash:png` uses the viewport size.

Example:

```lua
function main(splash)
    assert(splash:go("http://example.com"))
    assert(splash:wait(0.5))
    splash:set_viewport_full()
    return {png=splash:png()}
end
```

1.4.27 splash:set_user_agent

Overwrite the User-Agent header for all further requests.

**Signature:** `splash:set_user_agent(value)`

**Parameters:**

- value - string, a value of User-Agent HTTP header.

**Returns:** nil.

**Async:** no.

1.4.28 splash:set_custom_headers

Set custom HTTP headers to send with each request.

**Signature:** `splash:set_custom_headers(headers)`

**Parameters:**

- headers - a Lua table with HTTP headers.

**Returns:** nil.

**Async:** no.

**Note:** Named arguments are not supported for this function.

Headers are merged with WebKit default headers, overwriting WebKit values in case of conflicts.

When `headers` argument of `splash:go` is used headers set with `splash:set_custom_headers` are not applied to the initial request: values are not merged, `headers` argument of `splash:go` has higher priority.
Example:

```lua
splash:set_custom_headers({
    "Header-1" = "Value 1",
    "Header-2" = "Value 2",
})
```

See also: `splash:on_request`.

### 1.4.29 splash:get_perf_stats

Return performance-related statistics.

**Signature:** `stats = splash:get_perf_stats()`

**Returns:** a table that can be useful for performance analysis.

**Async:** no.

As of now, this table contains:

- `walltime` - (float) number of seconds since epoch, analog of `os.clock`
- `cputime` - (float) number of cpu seconds consumed by splash process
- `maxrss` - (int) high water mark number of bytes of RAM consumed by splash process

### 1.4.30 splash:on_request

Register a function to be called before each HTTP request.

**Signature:** `splash:on_request(callback)`

**Returns:** nil.

**Async:** no.

**Note:** `splash:on_request` method doesn’t support named arguments.

`splash:on_request` callback receives a single `request` argument. `request` contains the following fields:

- `url` - requested URL;
- `method` - HTTP method name in upper case, e.g. “GET”;
- `info` - a table with request data in HAR request format (`url` and `method` values are duplicated here).

These fields are for information only; changing them doesn’t change the request to be sent. To change or drop the request before sending use one of the `request` methods:

- `request:abort()` - drop the request;
- `request:set_url(url)` - change request URL to a specified value;
- `request:set_proxy{host, port, username=nil, password=nil}` - set an HTTP proxy server to use for this request. Omit `username` and `password` arguments if a proxy doesn’t need auth.
- `request:set_header(name, value)` - set an HTTP header for this request. See also: `splash:set_custom_headers`.

A callback passed to `splash:on_request` can’t call Splash async methods like `splash:wait` or `splash:go`.

Example 1 - log all URLs requested:
function main(splash)
    local urls = {}
    splash:on_request(function(request)
        urls[#urls+1] = request.url
    end)
    assert(splash:go(splash.args.url))
    return urls
end

Example 2 - to log full request data use request.info attribute; don’t store request objects directly:

function main(splash)
    local entries = {}
    splash:on_request(function(request)
        entries[#entries+1] = request.info
    end)
    assert(splash:go(splash.args.url))
    return entries
end

Example 3 - drop all requests to resources containing ".css" in their URLs:

splash:on_request(function(request)
    if string.find(request.url, ".css") ~= nil then
        request.abort()
    end
end)

Example 4 - replace a resource:

splash:on_request(function(request)
    if request.url == "http://example.com/script.js" then
        request:set_url("http://mydomain.com/myscript.js")
    end
end)

Example 5 - set a custom proxy server, with credentials passed in an HTTP request to Splash:

splash:on_request(function(request)
    request:set_proxy{
        host = "0.0.0.0",
        port = 8990,
        username = splash.args.username,
        password = splash.args.password,
    }
end)

1.4.31 splash.args

splash.args is a table with incoming parameters. It contains merged values from the original URL string (GET arguments) and values sent using application/json POST request.

1.5 Splash and IPython (Jupyter)

Splash provides a custom IPython (Jupyter) kernel for Lua. Together with IPython (Jupyter) notebook frontend it forms an interactive web-based development environment for Splash Scripts with syntax highlighting, smart code
completion, context-aware help, inline images support and a real live WebKit browser window with Web Inspector enabled, controllable from a notebook.

### 1.5.1 Installation

To install Splash-Jupyter using Docker, run:

```
$ docker pull scrapinghub/splash-jupyter
```

Then start the container:

```
$ docker run -p 8888:8888 -it scrapinghub/splash-jupyter
```

**Note:** Without `-it` flags you won’t be able to stop the container using Ctrl-C.

If you’re on Linux, Jupyter server with Splash kernel enabled will be available at `http://0.0.0.0:8888`.

If you use `boot2docker`, run `$ boot2docker ip` to get the ip address, the visit `http://<ip-returned-by-boot2docker>:8888`.

By default, notebooks are stored in a Docker container; they are destroyed when you restart an image. To persist notebooks you can mount a local folder to `/notebooks`. For example, let’s use current folder to store the notebooks:

```
$ docker run -v '/bin/pwd'/notebooks:/notebooks -p 8888:8888 -it scrapinghub/splash-jupyter
```

Live Webkit window with web inspector is not available when Splash-Jupyter is executed from Docker. You can still use e.g. `splash:png` command to inspect what’s going on.

Currently to enable live Webkit window you must install Splash in a “manual way” - see **Ubuntu 12.04 (manual way)**.

1. Install IPython/Jupyter with notebook feature. Splash kernel requires IPython 3.x:

```
$ pip install 'ipython[notebook] >= 3.0.0, < 4.0'
```

2. Let IPython know about Splash kernel by running the following command:

```
$ python -m splash.kernel install
```

To run IPython with Splash notebook, first start IPython notebook and then create a new Splash notebook using “New” button.

### 1.5.2 From Notebook to HTTP API

After you finished developing the script using an IPython Notebook, you may want to convert it to a form suitable for submitting to Splash HTTP API (see **execute**).

To do that, copy-paste (or download using “File -> Download as -> .lua”) all relevant code, then put it inside function `main(splash)`:

```lua
function main(splash)
    -- Script code goes here,
    -- including all helper functions.
    return {...} -- return the result
end
```

To make the script more generic you can use `splash.args` instead of hardcoded constants (e.g. for page urls). Also, consider submitting several requests with different arguments instead of running a loop in a script if you need to visit and process several pages - it is an easy way to parallelize the work.
There are some gotchas:

1. When you run an IPython cell and then run another IPython cell there is a delay between runs; the effect is similar to inserting `splash:wait` calls at the beginning of each cell.

2. Regardless of `sandbox` settings, scripts in IPython notebook are **not** sandboxed. Usually it is not a problem, but some functions may be unavailable in HTTP API if sandbox is enabled.

1.6 Splash Development

1.6.1 Contributing

Splash is free & open source. Development happens at github: [https://github.com/scrapinghub/splash](https://github.com/scrapinghub/splash)

1.6.2 Functional Tests

Run with:

```
py.test --doctest-modules splash
```

To speedup test running install `pytest-xdist` Python package and run Splash tests in parallel:

```
py.test --doctest-modules -n4 splash
```

1.6.3 Stress tests

There are some stress tests that spawn its own splash server and a mock server to run tests against.

To run the stress tests:

```
python -m splash.tests.stress
```

Typical output:

```
$ python -m splash.tests.stress
Total requests: 1000
Concurrency : 50
Log file    : /tmp/splash-stress-48H91h.log

............................................................ ...

Received/Expected (per status code or error):
  200: 500/500
  504: 200/200
  502: 300/300
```

1.7 Changes

1.7.1 1.5 (2015-03-03)

In this release we introduce Splash-Jupyter - a web-based IDE for Splash Lua scripts with syntax highlighting, auto-completion and a connected live browser window. It is implemented as a kernel for Jupyter (IPython).

Docker images for Splash 1.5 are optimized - download size is much smaller than in previous releases.
Other changes:

- `splash:go()` returned incorrect result after an unsuccessful `splash:go()` call - this is fixed;
- Lua `main` function can now return multiple results;
- there are testing improvements and internal cleanups.

### 1.7.2 1.4 (2015-02-10)

This release provides faster and more robust screenshot rendering, many improvements in Splash scripting engine and other improvements like better cookie handling.

From version 1.4 Splash requires Pillow (built with PNG support) to work.

There are backwards-incompatible changes in Splash scripts:

- `splash:set_viewport()` is split into `splash:set_viewport_size()` and `splash:set_viewport_full()`;
- old `splash:runjs()` method is renamed to `splash:evaljs()`;
- new `splash:runjs` method just runs JavaScript code without returning the result of the last JS statement.

To upgrade check all `splash:runjs()` usages: if the returned result is used then replace `splash:runjs()` with `splash:evaljs()`. The `viewport=full` argument is deprecated; use `render_all=1`.

New scripting features:

- it is now possible to write custom Lua plugins stored server-side;
- a restricted version of Lua `require` is enabled in sandbox;
- `splash:autoload()` method for setting JS to load on each request;
- `splash:wait_for_resume()` method for interacting with async JS code;
- `splash:lock_navigation()` and `splash:unlock_navigation()` methods;
- `splash:set_viewport()` is split into `splash:set_viewport_size()` and `splash:set_viewport_full()`;
- `splash:get_viewport_size()` method;
- `splash:http_get()` method for sending HTTP GET requests without loading result to the browser;
- `splash:set_content()` method for setting page content from a string;
- `splash:get_cookies()`, `splash:add_cookie()`, `splash:clear_cookies()`, `splash:delete_cookies()` and `splash:init_cookies()` methods for working with cookies;
- `splash:set_user_agent()` method for setting User-Agent header;
- `splash:set_custom_headers()` method for setting other HTTP headers;
- `splash:url()` method for getting current URL;
- `splash:go()` now accepts `headers` argument;
- `splash:evaljs()` method, which is a `splash:runjs()` from Splash v1.3.1 with improved error handling (it raises an error in case of JavaScript exceptions);
- `splash:runjs()` method no longer returns the result of last computation;
- `splash:runjs()` method handles JavaScript errors by returning `ok, error` pair;

Other improvements:
• –max-timeout option can be passed to Splash at startup to increase or decrease maximum allowed timeout value;
• cookies are no longer shared between requests;
• PNG rendering becomes more efficient: less CPU is spent on compression. The downside is that the returned PNG images become 10-15% larger;
• there is an option (scale_method=vector) to resize images while painting to avoid pixel-based resize step - it can make taking a screenshot much faster on image-light webpages (up to several times faster);
• when ‘height’ is set and image is downscaled the rendering is more efficient because Splash now avoids rendering unnecessary parts;
• /debug endpoint tracks more objects;
• testing setup improvements;
• application/json POST requests handle invalid JSON better;
• undocumented splash:go_and_wait() and splash:_wait_restart_on_redirects() methods are removed (they are moved to tests);
• Lua sandbox is cleaned up;
• long log messages from Lua are truncated in logs;
• more detailed error info is logged;
• example script in Splash UI is simplified;
• stress tests now include PNG rendering benchmark.

Bug fixes:
• default viewport size and window geometry are now set to 1024x768; this fixes PNG screenshots with viewport=full;
• PNG rendering is fixed for huge viewports;
• splash:go() argument validation is improved;
• timer is properly deleted when an exception is raised in an errback;
• redirects handling for baseurl requests is fixed;
• reply is deleted only once when baseurl is used.

1.7.3 1.3.1 (2014-12-13)
This release fixes packaging issues with Splash 1.3.

1.7.4 1.3 (2014-12-04)
This release introduces an experimental scripting support.

Other changes:
• manhole is disabled by default in Debian package;
• more objects are tracked in /debug endpoint;
• “history” in render.json now includes “queryString” keys; it makes the output compatible with HAR entry format;
• logging improvements;
• improved timer cancellation.

1.7.5 1.2.1 (2014-10-16)

• Dockerfile base image is downgraded to Ubuntu 12.04 to fix random crashes;
• Debian/buildbot config is fixed to make Splash UI available when deployed from deb;
• Qt / PyQt / sip / WebKit / Twisted version numbers are logged at startup.

1.7.6 1.2 (2014-10-14)

• All Splash rendering endpoints now accept `Content-Type: application/json` POST requests with JSON-encoded rendering options as an alternative to using GET parameters;
• `headers` parameter allows to set HTTP headers (including user-agent) for all endpoints - previously it was possible only in proxy mode;
• `js_source` parameter allows to execute JS in page context without `application/javascript` POST requests;
• testing suite is switched to pytest, test running can now be parallelized;
• viewport size changes are logged;
• `/debug` endpoint provides leak info for more classes;
• Content-Type header parsing is less strict;
• documentation improvements;
• various internal code cleanups.

1.7.7 1.1 (2014-10-10)

• An UI is added - it allows to quickly check Splash features.
• Splash can now return requests/responses information in HAR format. See `render.har` endpoint and `har` argument of render.json endpoint. A simpler `history` argument is also available. With HAR support it is possible to get timings for various events, HTTP status code of the responses, HTTP headers, redirect chains, etc.
• Processing of related resources is stopped earlier and more robustly in case of timeouts.
• `wait` parameter changed its meaning: waiting now restarts after each redirect.
• Dockerfile is improved: image is updated to Ubuntu 14.04; logs are shown immediately; it becomes possible to pass additional options to Splash and customize proxy/js/filter profiles; adblock filters are supported in Docker; versions of Python dependencies are pinned; Splash is started directly (without supervisord).
• Splash now tries to start Xvfb automatically - no need for xvfb-run. This feature requires `xvfbwrapper` Python package to be installed.
• Debian package improvements: Xvfb viewport matches default Splash viewport, it is possible to change Splash option using `SPLASH_OPTS` environment variable.
• Documentation is improved: finally, there are some install instructions.
• Logging: verbosity level of several logging events are changed; data-uris are truncated in logs.
• Various cleanups and testing improvements.
1.7.8 1.0 (2014-07-28)

Initial release.
